RSB{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

### RSB, shift or rotate by value variant

Applies when $S == 0 \&\& !(\text{imm3} == 000 \&\& \text{imm2} == 00 \&\& \text{stype} == 11)$.

```assembly
RSB{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

### RSBS, rotate right with extend variant

Applies when $S == 1 \&\& \text{imm3} == 000 \&\& \text{imm2} == 00 \&\& \text{stype} == 11$.

```assembly
RSBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

### RSBS, shift or rotate by value variant

Applies when $S == 1 \&\& !(\text{imm3} == 000 \&\& \text{imm2} == 00 \&\& \text{stype} == 11)$.

```assembly
RSBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

### Decode for all variants of this encoding

```c
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

### Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
  - For the RSBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

- `<Rn>` For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        else
            R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.168   RSB, RSBS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**A1**

```
 31 28|27 26 25 24|23 22 21 20|19 16|15 12|11 8 |7 6 5 4 |3 1 0
 00 0|0 0 0 0|0 1 1 S| Rn Rd Rs 0 stype |1 Rm

Flag setting variant

Applies when S == 1.

```

RSBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

**Not flag setting variant**

Applies when S == 0.

```
RSB{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

```
<
See Standard assembler syntax fields on page F1-7228.
```

```
<q
See Standard assembler syntax fields on page F1-7228.
```

```
<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.
```

```
<Rn>
Is the first general-purpose source register, encoded in the "Rn" field.
```

```
<Rm>
Is the second general-purpose source register, encoded in the "Rm" field.
```

```
<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>stype</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>
```

```
<Rs>
Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
```
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.169   RSC, RSCS (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

\[
\begin{array}{cccccccccccc}
\hline
1=111 & 0 & 0 & 0 & 1 & 1 & 1 & S & Rn & Rd & | & | & imm12 \\
\end{array}
\]

**RSC variant**

Applies when S == 0.

RSC{<c>}{<q>} {<Rd>,} <Rn>, #<const>

**RSCS variant**

Applies when S == 1.

RSCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>

**Decode for all variants of this encoding**

\[
d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \quad \text{imm32} = \text{A32ExpandImm}(\text{imm12});
\]

**Assembler symbols**

- See Standard assembler syntax fields on page F1-7228.
- See Standard assembler syntax fields on page F1-7228.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
  - For the RSCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
<const> An immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

**Operation**

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(NOT(R[n]), imm32, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.170   RSC, RSCS (register)

Reverse Subtract with Carry (register) subtracts a register value and the value of NOT (Carry flag) from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for \texttt{<Rd>} identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR\textunderscore_<current\_mode>.
  - The PE checks SPSR\textunderscore_<current\_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\textbf{Assembler symbols}

\begin{verbatim}<c>\end{verbatim} See Standard assembler syntax fields on page F1-7228.
<q>See Standard assembler syntax fields on page F1-7228.</q>

<r>
Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the RSCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

<r>
Is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

<r>
Is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

**Operation**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.171  RSC, RSCS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value and the value of NOT (Carry flag) from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

```
| 31  | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

    PSTATE.GE<3:2> = if sum  >= 0 then '11' else '00';

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.175  SB

Speculation Barrier is a barrier that controls speculation.

The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

Assembler symbols

<q> See Standard assembler syntax fields on page F1-7228.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    SpeculationBarrier();
F5.1.176   SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

•   The SBC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

•   The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
  —   The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  —   The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  —   The instruction is UNDEFINED in Hyp mode.
  —   The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 \| n == 15 \| m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the SBCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_.current_mode.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
  if d == 15 then  // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.<N,Z,C,V> = nzcv;
**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F5.1.178 SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### A1

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

#### Decode for all variants of this encoding

```plaintext
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

#### Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.179 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

\]
\[
\text{if msbit > 31 then UNPREDICTABLE;}
\]

CONSTRAINED UNPREDICTABLE behavior

If msbit > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
The value in the destination register is UNKNOWN.

Notes for all encodings
For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols
• \(<c>\) See Standard assembler syntax fields on page F1-7228.
• \(<q>\) See Standard assembler syntax fields on page F1-7228.
• \(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.
• \(<Rn>\) Is the general-purpose source register, encoded in the "Rn" field.
• \(<lsb>\) For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
  For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
• \(<width>\) Is the width of the field, in the range 1 to 32-\(<lsb>\), encoded in the "widthm1" field as \(<width>-1.

Operation for all encodings
if ConditionPassed() then
  EncodingSpecificOperations();
  R[d] = SignExtend(R[n]<msbit:lsbit>, 32);

Operational information
If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:
• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.180  SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

A1

\[
\begin{array}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
\hline

\]

CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Overflow

If the signed integer division \(0x80000000 / 0xFFFFFFFF\) is performed, the pseudocode produces the intermediate integer result \(+2^{31}\), that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to \(<Rd>\) must be the bottom 32 bits of the binary representation of \(+2^{31}\). So the result of the division is \(0x80000000\).

Operation for all encodings

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    integer result;
    if SInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(SInt(R[n])) / Real(SInt(R[m])));
    R[d] = result<31:0>;
```
F5.1.181 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the PSTATE.GE flags.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
    sum  = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
    R[d]<15:0> = diff<16:1>;
    R[d]<31:16> = sum<16:1>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.189   SHSAX

Signed Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer subtraction and one signed 16-bit addition, halves the results, and writes the results to the destination register.

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.192   SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see Secure Monitor Call (SMC) exception on page G1-8969.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in User mode.

If the values of HCR.TSC and SCR.SCD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32 this exception is taken to Monitor mode. When EL3 is using AArch64, it is the SCR_EL3.SMD bit, rather than the SCR.SCD bit, that can change the effect of executing an SMC instruction.

If the value of HCR.TSC is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of SCR.SCD. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-9017.

If the value of HCR.TSC is 0 and the value of SCR.SCD is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

Assembler symbols

\(<c>\)  
See *Standard assembler syntax fields* on page F1-7228.

\(<q>\)  
See *Standard assembler syntax fields* on page F1-7228.

\(<\text{imm}4>\)  
Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but Arm does not recommend this.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();

    AArch32.CheckForSMCUndefOrTrap();

    if !ELUsingAArch32(EL3) then
        if SCR_EL3.SMD == '1' then
            // SMC disabled.
            UNDEFINED;
        else
            if SCR.SCD == '1' then
                // SMC disabled
                if CurrentSecurityState() == SS_Secure then
                    // Executes either as a NOP or UNALLOCATED.
                    c = ConstrainUnpredictable(Unpredictable_SMD);
                    assert c IN {Constraint_NOP, Constraint_UNDEF};
                    if c == Constraint_NOP then EndOfInstruction();
                    UNDEFINED;
                else
                    AArch32.CheckForSMCUndefOrTrap();
                endif
            else
                if !ELUsingAArch32(EL3) then
                    AArch64.CallSecureMonitor(Zeros(16));
                else
                    AArch32.TakeSMCException();
                endif
            endif
        endif
    endif
endif
```

**CONSTRAINED UNPREDICTABLE behavior**

If SCR.SCD == '1' && CurrentSecurityState() == SS_Secure, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
F5.1.193  **SMLABB, SMLABT, SMLATB, SMLATT**

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets $PSTATE.Q$ to 1. It is not possible for overflow to occur during the multiplication.

F5.1.194 SMLAD, SMLADX

Signed Multiply Accumulate Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets PSTATE.Q to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications.

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.196  SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and
accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom
or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit
product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected
if it occurs. Instead, the result wraps around modulo 2^64.

F5.1.198  SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets PSTATE.Q to 1. No overflow can occur during the multiplication.

F5.1.204  SMUAD, SMUADX

Signed Dual Multiply Add performs two signed 16 x 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets PSTATE.Q to 1 if the addition overflows. The multiplications cannot overflow.

| 1 1 1 1 1 0 1 1 0 0 0 | Rn | RdLo | RdHi | 0 0 0 0 | Rm |

T1 variant

SMULL{<c>}{<q}> <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```plaintext
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```
CONSTRANDED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<\> See Standard assembler syntax fields on page F1-7228.
<\> See Standard assembler syntax fields on page F1-7228.
<RdLo> Is the general-purpose destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi> Is the general-purpose destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   result = SInt(R[n]) * SInt(R[m]);
   R[dHi] = result<63:32>;
   R[dLo] = result<31:0>;
   if setflags then
      PSTATE.N = result<63>;
      PSTATE.Z = IsZeroBit(result<63:0>);
      // PSTATE.C, PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.207 SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.208   SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from
the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This
produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

F5.1.209  **SRS, SRSDA, SRSDB, SRSIA, SRSIB**

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see *Memory accesses* on page F1-7233.

SRS is **UNDEFINED** in Hyp mode.

SRS is **CONSTRAINED UNPREDICTABLE** if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that Table G1-5 on page G1-8912 does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

**A1**

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == M32_Hyp, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == M32_Monitor && (!HaveEL(EL3) || CurrentSecurityState() != SS_Secure), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
If BadMode(mode), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction stores to the stack of the mode in which it is executed.
- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.
F5.1.210  SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

\end{itemize}
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    sum = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
    R[d]<15:0> = sum<15:0>;
    R[d]<31:16> = diff<15:0>;
    PSTATE.GE<1:0> = if sum >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if diff >= 0 then '11' else '00';

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.213 SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.

- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.216   STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the DBGDTRRXint System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see Memory accesses on page F1-7233.

In an implementation that includes EL2, the permitted STC access to DBGDTRRXint can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general Non-secure System register accesses to debug registers on page G1-9027.

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

if \( n == 15 \) \&\& (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**
If \( n == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in *Using R15 by instruction* on page K1-11563.

**Notes for all encodings**
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

<><
See *Standard assembler syntax fields* on page F1-7228.

<q>
See *Standard assembler syntax fields* on page F1-7228.

<Rn>
For the offset or unindexed variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the offset, post-indexed or pre-indexed variant: is the general-purpose base register, encoded in the "Rn" field.

<option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register read from DBGDTRXint.
    MemA[address,4] = AArch32.SysRegRead(cp, ThisInstr());
    if wback then R[n] = offset_addr;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

**CONSTRAINED UNPREDICTABLE behavior**

If \( d == t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The store instruction executes but the value stored is **UNKNOWN**.

If \( d == n \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs the store to an **UNKNOWN** address.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:
  - 0  If the operation updates memory.
  - 1  If the operation fails to update memory.
- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns **TRUE**, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns **FALSE** and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  address = R[n];
  if AArch32.ExclusiveMonitorsPass(address, 4) then
    Mem0[address, 4] = R[t];
    R[d] = ZeroExtend('0', 32);
```

else
    R[d] = ZeroExtend('1', 32);

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.220  STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to
the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was
performed.

The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page E2-7186.
For more information about support for shared memory see Synchronization and semaphores on page E2-7211. For
information about memory accesses see Memory accesses on page F1-7233.

n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15 by instruction on page K1-11563.

if \( \text{registers}<13> = '1' \) then UNPREDICTABLE;
if \( \text{registers}<15> = '1' \) then UNPREDICTABLE;

CONstrained UNPRedictable behavior

If \( \text{BitCount}(\text{registers}) < 1 \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as \texttt{NOP}.
• The instruction operates as an \texttt{STM} with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If $\text{BitCount}(\text{registers}) = 1$, then one of the following behaviors must occur:
• The instruction is \texttt{UNDEFINED}.
• The instruction executes as \texttt{NOP}.
• The instruction executes as described, with no change to its behavior and no additional side effects.
• The instruction operates as an \texttt{STM} with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If $\text{wback} \&\& \text{registers}<n> == '1'$, then one of the following behaviors must occur:
• The instruction is \texttt{UNDEFINED}.
• The instruction executes as \texttt{NOP}.
• The store instruction executes but the value stored for the base register is \texttt{UNKNOWN}.

If $\text{registers}<13> == '1'$, then one of the following behaviors must occur:
• The instruction is \texttt{UNDEFINED}.
• The instruction executes as \texttt{NOP}.
• The store instruction performs all of the stores using the specified addressing mode but the value of R13 is \texttt{UNKNOWN}.

If $\text{registers}<15> == '1'$, then one of the following behaviors must occur:
• The instruction is \texttt{UNDEFINED}.
• The instruction executes as \texttt{NOP}.
• The store instruction performs all of the stores using the specified addressing mode but the value of R15 is \texttt{UNKNOWN}.

If $n == 15 \&\& \text{wback}$, then one of the following behaviors must occur:
• The instruction is \texttt{UNDEFINED}.
• The instruction executes as \texttt{NOP}.
• The instruction executes without writeback of the base address.
• The instruction executes with writeback to the PC. The instruction is handled as described in \textit{Using R15 by instruction on page K1-11563}.

Notes for all encodings
For more information about the \texttt{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see Appendix K1 \textit{Architectural Constraints on UNPREDICTABLE Behaviors}.

Assembler symbols

\texttt{IA} is an optional suffix for the Increment After form.

$<>$ See \textit{Standard assembler syntax fields} on page F1-7228.

$q$ See \textit{Standard assembler syntax fields} on page F1-7228.
<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS[address,4] = bits(32) UNKNOWN; // Only possible for encodings T1 and A1
            else
                MemS[address,4] = R[i];
                address = address + 4;
        if registers<i> == '1' then // Only possible for encoding A1
            MemS[address,4] = PCStoreValue();
        if wback then R[n] = R[n] + 4*BitCount(registers);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.225   STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC.

n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);  
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<amode>` is one of:
  - **DA**: Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
  - **ED**: Empty Descending. For this instruction, a synonym for DA.
  - **DB**: Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
  - **FD**: Full Descending. For this instruction, a synonym for DB.
  - **IA**: Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
  - **EA**: Empty Ascending. For this instruction, a synonym for IA.
Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as \( P = 1, U = 1 \).

Full Ascending. For this instruction, a synonym for \( \text{IB} \).

See *Standard assembler syntax fields* on page F1-7228.

Yesterday

See *Standard assembler syntax fields* on page F1-7228.

Is the general-purpose base register, encoded in the "Rn" field.

See *Standard assembler syntax fields* on page F1-7228.

Is a list of one or more registers, separated by commas and surrounded by \{ and \}. It specifies the set of registers to be stored by the \( \text{STM} \) instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F1-7234.

**Operation**

\[
\text{if } \text{ConditionPassed()} \text{ then}\n\quad \text{EncodingSpecificOperations();}\n\quad \text{if } \text{PSTATE.EL} = \text{EL2} \text{ then}\n\quad \quad \text{UNDEFINED;}\n\quad \text{elsif } \text{PSTATE.M} \in \{\text{M32_User, M32_System}\} \text{ then}\n\quad \quad \text{UNPREDICTABLE;}\n\quad \text{else}\n\quad \quad \text{length} = 4 \times \text{BitCount}(\text{registers});\n\quad \quad \text{address} = \text{if increment then} \ R[n] \text{ else} \ R[n]-\text{length};\n\quad \quad \text{if wordhigher then address = address + 4;}\n\quad \quad \text{for } i = 0 \text{ to 14}\n\quad \quad \quad \text{if registers} < i > = '1' \text{ then} \ // \text{Store User mode register}\n\quad \quad \quad \quad \text{MemS}[\text{address}, 4] = R\text{mode}[i, M32_\text{User}];\n\quad \quad \quad \quad \text{address} = \text{address} + 4;\n\quad \quad \quad \text{if registers} < 15 > = '1' \text{ then}\n\quad \quad \quad \quad \text{MemS}[\text{address}, 4] = \text{PCStoreValue();}\n\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{PSTATE.M} \in \{\text{M32_User, M32_System}\} \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an \( \text{STM} \) with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.226  STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC. For details of related system instructions see STM (User registers).

A1

A1 variant

            if registers<15> == '1' then
                MemS[address,4] = PCStoreValue();
            if wback then R[n] = R[n] + 4*BitCount(registers);
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.229 STR (immediate)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

This instruction is used by the alias PUSH (single register). See Alias conditions on page F5-7988 for details of when each alias is preferred.

</tr>
</tbody>
</table>

Assembler symbols

<
See *Standard assembler syntax fields* on page F1-7228.

<q>
See *Standard assembler syntax fields* on page F1-7228.

<Rt>
For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
For encoding T1, T2, T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn>
For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.
For encoding T1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field.

+/-
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

+ Specifies the offset is added to the base register.

<imm>
For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.
For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.
For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```c
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,4] = if t == 15 then PCStoreValue() else R[t];
        if wback then R[n] = offset_addr;
    else
        if ConditionPassed() then
            EncodingSpecificOperations();
            offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
            address = if index then offset_addr else R[n];
            MemU[address,4] = R[t];
            if wback then R[n] = offset_addr;
```

Alias of variant is preferred when

PUSH (single register) A1 (pre-indexed)
P == '1' & U == '0' & W == '1' & Rn == '1101' & imm12 == '000000000100'
PUSH (single register) T4 (pre-indexed)
Rn == '1101' & P == '1' & U == '0' & W == '1' & imm8 == '00000100'
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.230  STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see Memory accesses on page F1-7233.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If \( \text{wback} \&\& n = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- \( <c> \) See Standard assembler syntax fields on page F1-7228.
- \( <q> \) See Standard assembler syntax fields on page F1-7228.
- \( <Rt> \) Is the general-purpose register to be transferred, encoded in the "Rt" field.
- \( <Rn> \) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.
  For encoding T1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field.
- \( +/\- \) Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - \(- \) when \( U = 0 \)
  - \( + \) when \( U = 1 \)
- \(+ \) Specifies the offset is added to the base register.
For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

**Operation for all encodings**

```plaintext
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
  else
    if ConditionPassed() then
      EncodingSpecificOperations();
      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
      address = if index then offset_addr else R[n];
      MemU[address,1] = R[t]<7:0>;
      if wback then R[n] = offset_addr;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.232 STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see Memory accesses on page F1-7233.

A1

|31| 28|27|26|25|24|23|22|21|20|19|16|15|12|11| 7| 6| 5| 4| 3| 0 |
|  | !|=1111| 0| 1| 1| P| U| 1| W| 0| Rn| Rt| imm5| stype| 0| Rm |

**Offset variant**

Applies when \( P = 1 \) \&\& \( W = 0 \).

\[
\text{STRB}\{<c>\}{<q>}\ <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}] 
\]

**Post-indexed variant**

Applies when \( P = 0 \) \&\& \( W = 0 \).

\[
\text{STRB}\{<c>\}{<q>}\ <Rt>, [<Rn>], {+/-}<Rm>{, <shift>} 
\]

**Pre-indexed variant**

Applies when \( P = 1 \) \&\& \( W = 1 \).

\[
\text{STRB}\{<c>\}{<q>}\ <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}! 
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{if } P &= '0' \ &\& W = '1' \text{ then SEE "STRBT";} \\
\text{t} &= \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm); \\
\text{index} &= (P = '1'); \quad \text{add} = (U = '1'); \quad \text{wback} = (P = '0') \ || \ (W = '1'); \\
(shift_t, shift_n) &= \text{DecodeImmShift(stype, imm5)}; \\
\text{if } t &= 15 \ || \ m = 15 \text{ then UNPREDICTABLE;} \\
\text{if } \text{wback} \ &\& (n = 15 \ || \ n = t) \text{ then UNPREDICTABLE;}
\end{align*}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( t = 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to \( R15 \) is UNKNOWN.

If \( \text{wback} \ &\& n = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If \( \text{wback} \ &\& n = 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The instruction executes without writeback of the base address.
• The instruction uses the addressing mode described in the equivalent immediate offset instruction.

**T1**

<table>

_T2 variant_

STRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1

STRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>, LSL #<imm>]}

**Decode for this encoding**

if Rn == '1111' then UNDEFINED;
\[
t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm);
\]

index = TRUE;  add = TRUE;  wback = FALSE;

(shift_t, shift_n) = (SRType_LSL, UInt(imm2));

if t == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

**CONSTRAINED UNPREDICTABLE behavior**

If t == 15, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 _Architectural Constraints on UNPREDICTABLE Behaviors_.

**Assembler symbols**

See _Standard assembler syntax fields_ on page F1-7228.

See Standard assembler syntax fields on page F1-7228.

<\( \text{Rt} \)>

Is the general-purpose register to be transferred, encoded in the "Rt" field.

<\( \text{Rn} \)>

For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

\( +/- \)

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
- when \( U = 1 \)

<\( \text{Rm} \)>

Is the general-purpose index register, encoded in the "Rm" field.

<\( \text{shift} \)>

The shift to apply to the value read from <\( \text{Rm} \)>. If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F1-7231.

<\( \text{imm} \)>

If present, the size of the left shift to apply to the value from <\( \text{Rm} \)>, in the range 1-3. <\( \text{imm} \) is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.233  STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see Memory accesses on page F1-7233.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

```
| 31 28 27 26 25 24 | 23 22 21 20 | 19 16 | 15 | 12 | 11 | 0 |
```

\[ l=1111 \ 0 \ 1 \ 0 \ U \ 1 \ 1 \ 0 \ \text{Rn} \ \text{Rt} \ \text{imm12} \]

**A1 variant**

\[ \text{STRBT}\{<c>\}{<q>} \ <Rt>, \ [<Rn>] \ \{, \ #{+/-}<imm>\} \]

**Decode for this encoding**

\[ t = \text{UInt}(Rt); \ n = \text{UInt}(Rn); \ \text{postindex} = \text{TRUE}; \ \text{add} = (U == '1'); \]
\[ \text{register_form} = \text{FALSE}; \ \text{imm32} = \text{ZeroExtend}(<\text{imm12}, 32); \]
\[ \text{if } t == 15 || n == 15 || n == t \ \text{then UNPREDICTABLE;} \]

**CONSTRAINED UNPREDICTABLE behavior**

If \( t == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If \( n == t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If \( n == 15 \), then one of the following behaviors must occur:

- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

• The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15 by instruction on page K1-11563.

- The instruction uses immediate offset addressing with the base register as PC, without writeback.
A2

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 |

t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

**CONSTRAINED UNPREDICTABLE behavior**

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F1-7228.*
- `<q>` See *Standard assembler syntax fields on page F1-7228.*
- `<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
  - For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
- `+-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  - when U = 1
  - For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
    - when U = 0
    - when U = 1
- `<Rm>` Is the general-purpose index register, encoded in the "Rm" field.
- `<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register on page F1-7231.*
- `+` Specifies the offset is added to the base register.
- `<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
  - For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UNPREDICTABLE; // Hyp mode
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,1] = R[t]<7:0>;
    if postindex then R[n] = offset_addr;

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as STRB (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.234 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

A1

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

Offset variant
Applies when \( P == 1 && W == 0 \).

\[ \text{STRD} \{<c>\}{<q>} <Rt>, <Rt2>, [<Rn> {, #{+/-}<imm>}] \]

Post-indexed variant
Applies when \( P == 0 && W == 0 \).

\[ \text{STRD} \{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>], #{+/-}<imm> \]

Pre-indexed variant
Applies when \( P == 1 && W == 1 \).

\[ \text{STRD} \{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]! \]

Decode for all variants of this encoding

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If \( t == 15 || t2 == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The instruction executes without writeback of the base address.
• The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If \( \text{Rt}<\#> = '1' \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes with the additional decode: \( t2 = t \).
• The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when \( \text{Rt} == '1111' \).

If \( P == '0' \) \&\& \( W == '1' \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

Applies when \(P == 1 \&\& W == 0\).

\[\text{STRD}\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]\]

**Post-indexed variant**

Applies when \(P == 0 \&\& W == 0\).

\[\text{STRD}\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm}\]

**Pre-indexed variant**

Applies when \(P == 1 \&\& W == 1\).

\[\text{STRD}\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!\]

**Decode for all variants of this encoding**

\[
\text{if } Rt<0> == '1' \text{ then UNPREDICTABLE;}
\text{t} = \text{UInt}(Rt); \text{t2} = \text{t}+1; \text{n} = \text{UInt}(Rn); \text{m} = \text{UInt}(Rm);
\text{index} = (P == '1'); \text{add} = (U == '1'); \text{wback} = (P == '0') || (W == '1');
\text{if } P == '0' \&\& W == '1' \text{ then UNPREDICTABLE;}
\text{if } t2 == 15 || m == 15 \text{ then UNPREDICTABLE;}
\text{if wback \&\& (n == 15 || n == t || n == t2) then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \(t == 15 \&\& t2 == 15\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If \(\text{wback} \&\& (n == t \&\& n == t2)\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If \(\text{wback} \&\& n == 15\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The instruction executes without writeback of the base address.
• The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If $Rt<0> = '1'$, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes with the additional decode: $t<0> = '0'$.
• The instruction executes with the additional decode: $t2 = t$.
• The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

If $P == '0'$ \&\& $W == '1'$, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes with the additional decode: $P = '1'; W = '0'$.
• The instruction executes with the additional decode: $P = '1'; W = '1'$.
• The instruction executes with the additional decode: $P = '0'; W = '0'$.

Notes for all encodings
For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F1-7228.
\(<q>\) See Standard assembler syntax fields on page F1-7228.
\(<Rt>\) Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.
\(<Rt2>\) Is the second general-purpose register to be transferred. This register must be $R(t+1)$.

\(<Rn>\) Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

\(+/-\) Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when $U = 0$
+ when $U = 1$

\(<Rm>\) Is the general-purpose index register, encoded in the "Rm" field.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        bits(64) data;
    if BigEndian(AccType_ATOMIC) then
data<63:32> = R[t];
data<31:0> = R[t2];
else
  data<31:0> = R[t];
data<63:32> = R[t2];
  MemA[address,8] = data;
else
  MemA[address,4] = R[t];
  MemA[address+4,4] = R[t2];
  if wback then R[n] = offset_addr;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.236 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, stores a word from a register to the calculated address if the PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see Synchronization and semaphores on page E2-7211. For information about memory accesses see Memory accesses on page F1-7233.

A1

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```
CONSTRAINED UNPREDICTABLE behavior

If \( d == t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \texttt{NOP}.
- The store instruction executes but the value stored is UNKNOWN.

If \( d == n \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \texttt{NOP}.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<Rd>\) Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

\begin{align*}
0 & \quad \text{If the operation updates memory.} \\
1 & \quad \text{If the operation fails to update memory.}
\end{align*}

\(<Rt>\) Is the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Rn>\) Is the general-purpose base register, encoded in the "Rn" field.

\(<\text{imm}>\) For encoding A1: the immediate offset added to the value of \(<Rn>\) to calculate the address. \(<\text{imm}>\) can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of \(<Rn>\) to calculate the address. \(<\text{imm}>\) can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<Rd>\) is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns \texttt{TRUE}, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns \texttt{FALSE} and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address, 4) then
        MemA[address, 4] = R[t];
        R[d] = ZeroExtend('0', 32);
    else
        R[d] = ZeroExtend('1', 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.237   STREXB

Store Register Exclusive Byte derives an address from a base register value, stores a byte from a register to the
derived address if the executing PE has exclusive access to the memory at that address, and returns a status value
of 0 if the store was successful, or of 1 if no store was performed.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\)
See Standard assembler syntax fields on page F1-7228.

\(<q>\)
See Standard assembler syntax fields on page F1-7228.

\(<Rt>\)
For encoding A1 and A2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Rn>\)
Is the general-purpose base register, encoded in the "Rn" field.

\(+/-\)
For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

\(<Rm>\)
Is the general-purpose index register, encoded in the "Rm" field.

\(<\text{shift}>\)
The shift to apply to the value read from \(<Rm>\). If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F1-7231.

\(+\)
Specifies the offset is added to the base register.

\(<\text{imm}>\)
For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  if PSTATE.EL == EL2 then UNPREDICTABLE; // Hyp mode
  offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  bits(32) data;
  if t == 15 then // Only possible for encodings A1 and A2
    data = PCStoreValue();
  else
    data = R[t];
  MemU_unpriv[address,4] = data;
  if postindex then R[n] = offset_addr;

CONSTRANGED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as STR (immediate).

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.244    SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and
writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias
This instruction is an alias of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

A2

```
| 31 28 27 26 25 24 23 22 21 20 19 18 17 16 15 12 11 |   |   |
| 1=1111 | 0 0 1 0 0 1 0 0 1 1 1 1 | Rd | imm12 |
|         cond |
```

A2 variant

SUB\{<c>\}{<q>} <Rd>, PC, #<const>

is equivalent to

ADR\{<c>\}{<q>} <Rd>, <label>

and is the preferred disassembly when imm12 == '000000000000'.

T2

```
| 15 14 13 12 | 11 10 9 8 7 6 5 4 3 2 1 0 | 15 14 | 12 11 | 8 7 |   |   |
| 1 1 1 1 0 | 1 1 0 1 0 1 0 1 1 1 1 0 | imm3 | Rd | imm8 |
```

T2 variant

SUB\{<c>\}{<q>} <Rd>, PC, #imm12

is equivalent to

ADR\{<c>\}{<q>} <Rd>, <label>

and is the preferred disassembly when i:imm3:imm8 == '000000000000'.

Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page F1-7228.
- \(<q>\) See Standard assembler syntax fields on page F1-7228.
- \(<Rd>\) For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is
  used, the instruction is a branch to the address calculated by the operation. This is an interworking
  branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the
  PC on page E1-7133.
  For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.
- \(<label>\) For encoding A2: the label of an instruction or literal data item whose address is to be loaded into
  \(<Rd>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the
  ADR instruction to this label.
  If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.
If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in Modified immediate constants in A32 instructions on page F1-7244.

For encoding T2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the A1ign(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> An immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

Operation for all encodings

The description of ADR gives the operational pseudocode for this instruction.
F5.1.245 SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see ERET.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly SUBS PC, LR and related instructions (A32) on page K1-11576 and SUBS PC, LR and related instructions (T32) on page K1-11575.

Assembler symbols

<>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<r> Is the general-purpose source and destination register, encoded in the "Rdn" field.

<imm8> For encoding T2: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
For encoding T5: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
If <Rn> is the LR, and zero is used, see ERET.

If omitted, this register is the same as <r>. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation.
- This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is
the LR.
For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus immediate). If the PC is used, see ADR.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus immediate).

<iimm3> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<iimm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.

In the T32 instruction set, MOVS{<c>}{<q>} PC, LR is a pseudo-instruction for SUB{<c>}{<q>} PC, LR, #0.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.246  SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the
destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the
result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However,
when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on
  the AArch32 general-purpose registers and the PC on page E1-7133.

- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm
deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from
    AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Applies when $S == 0$.

```
SUB{<c>}{<q>}{<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding
```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.
F5.1.248  SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the
destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the
result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the
destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on
  the AArch32 general-purpose registers and the PC on page E1-7133.
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm
  deprecates use of this instruction. However, in this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  — The PE checks SPSR_ <current_mode> for an illegal return event. See Illegal return events from
    AArch32 state on page G1-8952.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

SP, Is the stack pointer.

<imm7> Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.
<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used:
- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is the LR.
For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.
For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    \( (result, nzcv) = \text{AddWithCarry}(R[13], \text{NOT}(\text{imm32}), '1') \);
    if d == 15 then  // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
F5.1.249   SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to
the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the
result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the
destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on
  the AArch32 general-purpose registers and the PC on page E1-7133.
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm
deprecates use of this instruction. However, in this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  — The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from
    AArch32 state on page G1-8952.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Assembler symbols

<<> See Standard assembler syntax fields on page F1-7228.
<q> See Standard assembler syntax fields on page F1-7228.
<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:
- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_{<current_mode>}. For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.
<Rm>       For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
       For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift>    Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
    LSL     when stype = 00
    LSR     when stype = 01
    ASR     when stype = 10
    ROR     when stype = 11

<amount>   For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
       For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[13], NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
### F5.1.250 SVC

Supervisor Call causes a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page G1-8968.

--- **Note** ---

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when the value of HCR.TGE is 1* on page G1-8945.

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see *Use of the HSR* on page G5-9265. The immediate field in the HSR:

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the imm8 field.
  - For the A32 instruction, is the least-significant 16 bits the imm24 field.
- If the SVC is conditional, is UNKNOWN.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<imm>
For encoding A1: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckForSVCTrap(imm32<15:0>);
    AArch32.CallSupervisor(imm32<15:0>);
F5.1.251   SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

$<c>$ See Standard assembler syntax fields on page F1-7228.

$<q>$ See Standard assembler syntax fields on page F1-7228.

$<Rd>$ Is the general-purpose destination register, encoded in the "Rd" field.

$<Rn>$ Is the first general-purpose source register, encoded in the "Rn" field.

$<Rm>$ Is the second general-purpose source register, encoded in the "Rm" field.

$<amount>$ Is the rotate amount, encoded in the "rotate" field. It can have the following values:

(omitted) when rotate = 00
8       when rotate = 01
16      when rotate = 10
24      when rotate = 11

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<15:0>, 32);

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.254 SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

F5.1.257   TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

T1

\[
\begin{array}{cccccccccccccccccccc}
0 & 1 & 5 & 1 & 4 & 13 & 12 & 11 & 10 & 9 & 8 & 7 & 6 & 5 & 4 & 3 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 0 & 1 & Rn & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & H & Rm
\end{array}
\]

**Byte variant**

Applies when \( H = 0 \).

\[ \text{TBB} \{\text{<c>}}\{\text{<q>}} \ [\text{<Rn>}, \text{<Rm>}} ] \] // Outside or last in IT block

**Halfword variant**

Applies when \( H = 1 \).

\[ \text{TBH} \{\text{<c>}}\{\text{<q>}} \ [\text{<Rn>}, \text{<Rm>}, \text{LSL} \#1] \] // Outside or last in IT block

**Decode for all variants of this encoding**

\[
n = \text{UInt}(\text{Rn}); \quad m = \text{UInt}(\text{Rm}); \quad \text{is_tbh} = (H == '1');
\]

if \( m = 15 \) then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

\(<\text{c}>\) See Standard assembler syntax fields on page F1-7228.

\(<\text{q}>\) See Standard assembler syntax fields on page F1-7228.

\(<\text{Rn}>\) Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.

\(<\text{Rm}>\) For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

**Operation**

if \( \text{ConditionPassed()} \) then

\[
\begin{align*}
\text{EncodingSpecificOperations();} \\
\text{integer halfwords;} \\
\text{if is_tbh then} \\
\quad \text{halfwords} = \text{UInt(MemU}[R[n]+\text{LSL}(R[m],1)], 2)); \\
\text{else}
\end{align*}
\]
halfwords = UInt(MemU[R[n]+R[m], 1]);
BranchWritePC(PC + 2*halfwords, BranchType_INDIR);
TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.260   TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

- \(<q>\) See Standard assembler syntax fields on page F1-7228.
- \(<Rn>\) Is the first general-purpose source register, encoded in the "Rn" field.
- \(<Rm>\) Is the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{type}>\) Is the type of shift to be applied to the second source register, encoded in the "sttype" field. It can have the following values:
  - LSL when \(\text{stype} = 00\)
  - LSR when \(\text{stype} = 01\)
  - ASR when \(\text{stype} = 10\)
  - ROR when \(\text{stype} = 11\)
- \(<Rs>\) Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

\[
\begin{align*}
  \text{if } \text{ConditionPassed()} \text{ then} \\
  \text{EncodingSpecificOperations();} \\
  \text{shift}_n &= \text{UInt}(R[s]<7:0>); \\
  (\text{shifted, carry}) &= \text{Shift}_C(R[n], \text{shift}_t, \text{shift}_n, \text{PSTATE.C}); \\
  \text{result} &= R[n] \text{ EOR shifted;} \\
  \text{PSTATE.N} &= \text{result}<31>; \\
  \text{PSTATE.Z} &= \text{IsZeroBit(result)}; \\
  \text{PSTATE.C} &= \text{carry}; \\
  // \text{PSTATE.V} \text{ unchanged}
\end{align*}
\]
Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.261   TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If FEAT_TRF is not implemented, this instruction executes as a NOP.

A1

(FEAT_TRF)

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

cond

A1 variant

TSB{<c>}{<q>} CSYNC

Decode for this encoding

if !HaveSelfHostedTrace() then EndOfInstruction(); // Instruction executes as NOP
if cond != '1110' then UNPREDICTABLE;              // TSB must be encoded with AL condition

CONSTRANDED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes unconditionally.
• The instruction executes conditionally.

T1

(FEAT_TRF)

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

T1 variant

TSB{<c>}{<q>} CSYNC

Decode for this encoding

if !HaveSelfHostedTrace() then EndOfInstruction(); // Instruction executes as NOP
if InITBlock() then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes unconditionally.
• The instruction executes conditionally.

Assembler symbols

<\> See Standard assembler syntax fields on page F1-7228.

<\&> See Standard assembler syntax fields on page F1-7228.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    TraceSynchronizationBarrier();
F5.1.262   TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>stype</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.264 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| 31  | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

    PSTATE.GE<3:2> = if sum  >= 0x10000 then '11' else '00';

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.268   UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

A1

| 31 28|27 26 25 24|23 22 21 20| 16|15 | 12|11 |  7 6 5 4 |  3 0 |

**CONSTRAINED UNPREDICTABLE behavior**

If \(msbit > 31\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<\_c\_> See Standard assembler syntax fields on page F1-7228.

<\_q\_> See Standard assembler syntax fields on page F1-7228.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<lsb> For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.

For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.269   UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED. However:

- With the T32 instruction set, Arm deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

A1

T2 variant

UDF{<c>}.W {#}<imm> // <imm> can be represented in T1
UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

\[
\text{imm32} = \text{ZeroExtend}(\text{imm4}:\text{imm12}, 32);
\]

// imm32 is for assembly and disassembly only, and is ignored by hardware.
Assembler symbols

<
> For encoding A1: see Standard assembler syntax fields on page F1-7228. < must be AL or omitted.
For encoding T1 and T2: see Standard assembler syntax fields on page F1-7228. Arm deprecates using any < value other than AL.

<
> See Standard assembler syntax fields on page F1-7228.

<imm>
For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the"imm12:imm4" field. The PE ignores the value of this constant.
For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.
For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
F5.1.270   UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See Divide instructions on page F2-7267 for more information about this instruction.

- `<q>`  See *Standard assembler syntax fields on page F1-7228*.
- `<Rd>`  Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>`  Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`  Is the second general-purpose source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<15:0>) - UInt(R[m]<15:0>);
```
diff2 = UInt(R[n]<31:16>) - UInt(R[m]<31:16>);
R[d]<15:0> = diff1<16:1>;
R[d]<31:16> = diff2<16:1>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.276   UHSUB8

Unsigned Halving Subtract 8 performs four unsigned 8-bit integer subtractions, halves the results, and writes the results to the destination register.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.288 USAT

Unsigned Saturate saturates an optionally-shifted signed value to a selected unsigned range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

A1

Arithmetic shift right variant

Applies when sh == 1.

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Logical shift left variant

Applies when sh == 0.

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

if sh == '1' && (imm3:imm2) == '00000' then SEE “USAT16”;

T1

Arithmetic shift right variant

Applies when sh == 1 && !(imm3 == 000 && imm2 == 00).

Logical shift left variant

Applies when sh == 0.

Decode for all variants of this encoding

if sh == '1' && (imm3:imm2) == '00000' then SEE “USAT16”;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<imm>
Is the bit position for saturation, in the range 0 to 31, encoded in the "sat_imm" field.

<Rn>
Is the general-purpose source register, encoded in the "Rn" field.

<amount>
For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();

  PSTATE.GE<3:2> = if diff >= 0 then '11' else '00';

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the general-purpose source register, encoded in the "Rm" field.

<amount> Is the rotate amount, encoded in the "rotate" field. It can have the following values:

- (omitted) when rotate = 00
- 8 when rotate = 01
- 16 when rotate = 10
- 24 when rotate = 11

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<7:0>, 32);

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.297  UXTB16

Unsigned Extend Byte 16 extracts two 8-bit values from a register, zero-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

F5.1.299    WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any
PE in the multiprocessor system. For more information, see Wait For Event and Send Event on page G1-8988.

As described in Wait For Event and Send Event on page G1-8988, the execution of a WFE instruction that would
otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-9004.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on
  page G1-9032.

F5.2 Encoding and use of banked register transfer instructions

Software executing at EL1 or higher can use the MRS (banked register) and MSR (banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- Register arguments in the banked register transfer instructions.
- Usage restrictions on the banked register transfer instructions on page F5-8161.
- Encoding the register argument in the banked register transfer instructions on page F5-8162.
- Pseudocode support for the banked register transfer instructions on page F5-8163.

For descriptions of the instructions see MRS (Banked register) on page F5-7736 and MSR (Banked register) on page F5-7740.

F5.2.1 Register arguments in the banked register transfer instructions

Figure F5-1 shows the banked general-purpose registers and Special-purpose registers:

Software using an MRS (banked register) or MSR (banked register) instruction specifies one of these registers using a name shown in Figure F5-1, or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12 Each of these registers has two banked copies, _usr and _fiq, for example R8_usr and R8_fiq.
SP  There is a banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.

LR  There is a banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.

SPSR  There is a banked copy of SPSR for every mode except System mode and User mode.

ELR_hyp  Except for the operations provided by MRS (banked register) and MSR (banked register), ELR_hyp is accessible only from Hyp mode. It is not banked.

F5.2.2  Usage restrictions on the banked register transfer instructions

MRS (banked register) and MSR (banked register) instructions are CONSTRAINED UNPREDICTABLE if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a banked register that is not implemented, or that either:
  - Is not accessible from the current Privilege level and Security state.
  - Can be accessed from the current mode by using a different instruction.

MSR (banked register) and MRS (banked register) on page K1-11582 describes the permitted CONSTRAINED UNPREDICTABLE behavior.

An MRS (banked register) instruction or an MSR (banked register) instruction executed:

- At Non-secure EL1 cannot access any Hyp mode banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp banked registers.

This means that the banked registers that MRS (banked register) and MSR (banked register) instructions cannot access are:

From Monitor mode
- The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

From Hyp mode
- The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

**Note**

MRS (banked register) and MSR (banked register) instructions can access the current mode register ELR_hyp.

From FIQ mode
- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

From System mode
- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

From Supervisor mode, Abort mode, Undefined mode, and IRQ mode
- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.
If EL3 is using AArch64, all MRS (banked register) and MSR (banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3.

For more information, see:

- **Encoding the register argument in the banked register transfer instructions**.
- **Pseudocode support for the banked register transfer instructions on page F5-8163**.
- **MRS (Banked register) on page F5-7736**.
- **MSR (Banked register) on page F5-7740**.

--- **Note**

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

### F5.2.3 Encoding the register argument in the banked register transfer instructions

The MRS (banked register) and MSR (banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a banked copy of the SPSR, and Table F5-1 on page F5-8162 shows how the SYSm field defines the required register argument. In this table, CONST.

<table>
<thead>
<tr>
<th>SYSm&lt;2:0&gt;</th>
<th>SYSm&lt;4:3&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>0b01</td>

</table>

**F5.2.4 Pseudocode support for the banked register transfer instructions**

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRAccessValid()` check the validity of MRS (banked register) and MSR (banked register) accesses. That is, they filter the accesses that are CONSTRAINED UNPREDICTABLE either because:

- They attempt to access a register that Usage restrictions on the banked register transfer instructions on page F5-8161 shows is not accessible.
- They use an SYSm<4:0> encoding that Encoding the register argument in the banked register transfer instructions on page F5-8162 shows as CONSTRAINED UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and `SPSRAccessValid()` applies to accesses to the SPSRs.
Chapter F6
T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- Alphabetical list of Advanced SIMD and floating-point instructions on page F6-8166.

Note

Some headings in this chapter use the term floating-point register. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.
F6.1 Alphabetical list of Advanced SIMD and floating-point instructions

This section lists every Advanced SIMD and floating-point instruction in the T32 and A32 instruction sets. For details of the format used see Format of instruction descriptions on page F1-7224.

This section is formatted so that each instruction description starts on a new page.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    \(Q[d>>1] = AESMixColumns(Q[m>>1])\);

Operational information

If CPSR.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F6.1.5 FLDM\*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM\*X loads multiple SIMD\&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Arm deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

#### A1

\[
\begin{array}{c|cccccccc|c|}
\text{cond} & 1 & 1 & 0 & P & U & D & W & 1 & \text{imm8}{<7:1>} & 1 \\
\hline
\text{Decrement Before variant} & \text{Applies when } P == 1 && U == 0 && W == 1. \\
\text{FLDMDBX}{<c>}{<q>} <Rn>!, <dreglist> & \\
\text{Increment After variant} & \text{Applies when } P == 0 && U == 1. \\
\text{FLDMIAX}{<c>}{<q>} <Rn>{!}, <dreglist> & \\
\end{array}
\]

#### Decode for all variants of this encoding

if \( P == '0' && U == '0' \) then SEE "Related encodings";
if \( P == '1' && U == '0' \) then SEE "VLDR";
if \( P == U && U == '1' \) then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);

if regs == 0 || (d+regs) > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

#### CONSTRAINED UNPREDICTABLE behavior

If \( \text{regs} == 0 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If \( \text{regs} > 16 \) || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

- \( \text{singleRegs} = \text{FALSE}; \text{add} = (U = '1'); \text{wback} = (W = '1'); \)
- \( d = \text{UInt}(0:D); n = \text{UInt}(Rn); \text{imm32} = \text{ZeroExtend}(\text{imm8}'00', 32); \)
- \( \text{regs} = \text{UInt}(\text{imm8}) \text{ DIV 2}; \)

// If UInt(imm8) is odd, see "FLDM*X".

- if \( n = 15 \land (\text{wback} \land \text{CurrentInstrSet()} \neq \text{InstrSet_A32}) \) then UNPREDICTABLE;
- if \( \text{regs} = 0 \lor (\text{regs} > 16 \land (d+\text{regs}) > 32 \) then UNPREDICTABLE;
- if \( \text{imm8<0>} = '1' \land (d+\text{regs}) > 16 \) then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{regs} = 0 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \text{NOP}.
- The instruction operates as a \text{VLDM} with the same addressing mode but loads no registers.

If \( \text{regs} > 16 \lor (d+\text{regs}) > 16 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \text{NOP}.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Related encodings: See Advanced SIMD and floating-point 64-bit move on page F3-7324 for the T32 instruction set, or Advanced SIMD and floating-point 64-bit move on page F4-7410 for the A32 instruction set.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F1-7228.
See *Standard assembler syntax fields* on page F1-7228.

**Rn**

Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.

! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

**dreglist**

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.6 FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

Arm deprecates use of FSTMDBX and FSTMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, HCPTL, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D\:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M\:Vm" field as <Qm>*2.
### Operation for all encodings

```c
if ConditionPassed() then
    bits(128) result;
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    x = Q[d>>1]; y = Q[m>>1];
    t = y<31:0> : x<127:32>;
    for e = 0 to 3
        elt = Elem[t, e, 32];
        elt = ROR(elt, 7) EOR ROR(elt, 18) EOR LSR(elt, 3);
        Elem[result, e, 32] = elt + Elem[x, e, 32];
    Q[d>>1] = result;
```

### Operational information

If CPSR.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.
See Standard assembler syntax fields on page F1-7228.

Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- **S8** when $U = 0$, size = 00
- **S16** when $U = 0$, size = 01
- **S32** when $U = 0$, size = 10
- **U8** when $U = 1$, size = 00
- **U16** when $U = 1$, size = 01
- **U32** when $U = 1$, size = 10

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $<Qd>*2$.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for $r = 0$ to regs-1
        for $e = 0$ to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = absdiff<2*esize-1:0>;
            else
                Elem[D[d+r],e,esize] = absdiff<esize-1:0>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.22   VABS

Vector Absolute takes the absolute value of each element in a vector, and places the results in a second vector. The floating-point version only clears the sign bit.

Depending on settings in the CPACR, NSACR, HCPtr, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

\(<Qm>\) Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(<Dn>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\(<Dm>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

\[
\begin{align*}
\text{if } ConditionPassed() \text{ then } \\
\text{EncodingSpecificOperations(); CheckAdvSIMDEnabled();} \\
\text{for } r = 0 \text{ to regs-1} \\
\text{for } e = 0 \text{ to elements-1} \\
\text{op1} = \text{FPAbs}(\text{Elem}[D[n+r],e,esize]); \text{ op2} = \text{FPAbs}(\text{Elem}[D[m+r],e,esize]); \\
\text{boolean test\_passed;}
\end{align*}
\]
if or_equal then
    test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());
else
    test_passed = FPCompareGT(op1, op2, StandardFPSCRValue());
Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
F6.1.26  VACLT

Vector Absolute Compare Less Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VACGT instruction. This means that:

- The encodings in this description are named to match the encodings of VACGT.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VACGT gives the operational pseudocode for this instruction.

**A1**

\end{array}$$

**64-bit SIMD vector variant**

Applies when $Q == 0$.

VACLT{$<c>$}{$<q>$}{$<dt>$} {$<Dd>$}, {$<Dm>$}, {$<Dn>$}

is equivalent to

VACGT{$<c>$}{$<q>$}{$<dt>$} {$<Dd>$}, {$<Dm>$}, {$<Dn>$}

and is never the preferred disassembly.
128-bit SIMD vector variant

Applies when \( Q == 1 \).

\[
\text{VACLT}\{<c>\}{<q>}.\{\text{dt}\} \{<Qd>\}, \{<Qn>\}, \{<Qm>\}
\]
is equivalent to

\[
\text{VACGT}\{<c>\}{<q>}.\text{dt} \{<Qd>\}, \{<Qm>\}, \{<Qn>\}
\]
and is never the preferred disassembly.

Assembler symbols

\(<Dm>\)
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

\(<Dn>\)
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\(<Qm>\)
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<Qm>\times 2\).

\(<Qn>\)
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<Qn>\times 2\).

\(<c>\)
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(<q>\)
See Standard assembler syntax fields on page F1-7228.

\(<\text{dt}>\)
Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

\[\begin{array}{ll}
\text{F32} & \text{when } sz = 0 \\
\text{F16} & \text{when } sz = 1
\end{array}\]

\(<Qd>\)
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<Qd>\times 2\).

\(<Dd>\)
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation for all encodings

The description of VACGE gives the operational pseudocode for this instruction.

Operational information

The description of VACGE gives the operational pseudocode for this instruction.
F6.1.27 VADD (floating-point)

Vector Add (floating-point) adds corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPT, and FPX registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

      Elem[D[d+\(r\)],e,esize] = Elem[D[n+r],e,esize] + Elem[D[m+r],e,esize];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see VRADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

Assembler symbols

<c>

For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.
See Standard assembler syntax fields on page F1-7228.

Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

- I16  when size = 00
- I32  when size = 01
- I64  when size = 10

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F6.1.30 VADDL

Vector Add Long adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

ID081822 Non-Confidential
<dt> Is the data type for the elements of the second operand vector, encoded in the "U:size" field. It can have the following values:
- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- U8 when U = 1, size = 00
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10

<d> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <d>*2.

<D> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<M> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        integer op1;
        if is_vaddw then
            op1 = Int(Elem[Q[n>>1],e,2*esize], unsigned);
        else
            op1 = Int(Elem[D[n],e,esize], unsigned);
        result = op1 + Int(Elem[M[e,esize],unsigned];
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.31   VADDW

Vector Add Wide adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.32  **VAND (immediate)**

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VBIC (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VBIC (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VBIC (immediate) gives the operational pseudocode for this instruction.

**64-bit SIMD vector variant**

Applies when \( Q == 0 \).

VAND{\(<c>\)\}{\(<q>\)}.I16 {\(<Dd>\),} <Dd>, #\(<imm>\)

is equivalent to

VBIC{\(<c>\)\}{\(<q>\)}.I16 <Dd>, #~\(<imm>\)

and is never the preferred disassembly.

**128-bit SIMD vector variant**

Applies when \( Q == 1 \).

VAND{\(<c>\)\}{\(<q>\)}.I16 {\(<Qd>\),} <Qd>, #\(<imm>\)

is equivalent to

VBIC{\(<c>\)\}{\(<q>\)}.I16 <Qd>, #~\(<imm>\)

and is never the preferred disassembly.

**64-bit SIMD vector variant**

Applies when \( Q == 0 \).

VAND{\(<c>\)\}{\(<q>\)}.I32 {\(<Dd>\),} <Dd>, #\(<imm>\)

is equivalent to

VBIC{\(<c>\)\}{\(<q>\)}.I32 <Dd>, #~\(<imm>\)

and is never the preferred disassembly.
**128-bit SIMD vector variant**

Applies when \( Q = 1 \).

\[
\text{VAND}\{<c>\}{<q>}.I32 \{<Qd>,\} <Qd>, \#<imm>
\]

is equivalent to

\[
\text{VBIC}\{<c>\}{<q>}.I32 <Qd>, \#<imm>
\]

and is never the preferred disassembly.

**T1**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 0 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

128-bit SIMD vector variant

Applies when Q == 1.

VAND{<c>}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;

\[ d = \text{UInt}(D:Vd); \quad n = \text{UInt}(N:Vn); \quad m = \text{UInt}(M:Vm); \quad \text{regs} = \text{if Q == '0' then 1 else 2}; \]

Assembler symbols

<...> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

See Standard assembler syntax fields on page F1-7228.

An optional data type. It is ignored by assemblers, and does not affect the encoding.

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.34   VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instruction VAND (immediate). The pseudo-instruction is never the preferred disassembly.

            when VBitOps_VBIT  D[d+r] = (D[n+r] AND D[m+r]) OR (D[d+r] AND NOT(D[m+r]));
            when VBitOps_VBSL  D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]));

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.37  VBIT

Vector Bitwise Insert if True inserts each bit from the first source register into the destination register if the corresponding bit of the second source register is 1, otherwise leaves the bit in the destination register unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Operational information
If CPSR.DIT is 1 and this instruction passes its condition execution check:
• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.39 VCADD

Vector Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.41   VCEQ (register)

Vector Compare Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-8996*.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.43 VCGE (register)

Vector Compare Greater Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers, unsigned integers, or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instruction VCLE (register). The pseudo-instruction is never the preferred disassembly.

            bits(esize) zero = FPZero('0', esize);
            test_passed = FPCompareGT(Elem[D[m+r],e,esize], zero, StandardFPSCRValue());
         else
            test_passed = (SInt(Elem[D[m+r],e,esize]) > 0);
         Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.45  **VCGT (register)**

Vector Compare Greater Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers, unsigned integers, or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

This instruction is used by the pseudo-instruction VCLT (register). The pseudo-instruction is never the preferred disassembly.

### A1

64-bit SIMD vector variant

Applies when Q == 0.

\[ \text{VCGT}(\{c\}\{q\}.<dt> \{<Dd>, }<Dn>, <Dm]\]

**Operational information**

The description of VCGE (register) gives the operational pseudocode for this instruction.
F6.1.48 VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

         Elem[D[d+r],e,esize] = CountLeadingSignBits(Elem[D[m+r],e,esize])<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.
F6.1.49  VCLT (immediate #0)

Vector Compare Less Than Zero takes each element in a vector, and compares it with zero. If it is less than zero, 
the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector 
elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPtr registers, and the Security state and PE mode in which 
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For 
more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

CONSTRANGED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<=> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> Is the data type for the elements of the operands, encoded in the "F:size" field. It can have the following values:
S8 when F = 0, size = 00
S16 when F = 0, size = 01
S32 when F = 0, size = 10
F16 when F = 1, size = 01
F32 when F = 1, size = 10

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.

<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      boolean test_passed;
      if floating_point then
        bits(esize) zero = FPZero('0', esize);
        test_passed = FPCompareGT(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());

        test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
        Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.50  VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a
second vector. If the first is less than the second, the corresponding element in the destination vector is set to all
ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VCGT (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGT (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGT (register) gives the operational pseudocode for this instruction.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Vector Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.53 VCMLA (by element)

Vector Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<Sd>\) Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

\(<Sm>\) Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(<Dm>\) Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    bits(4) nzcv;
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0', 16) else S[m]<15:0>;
            nzcv = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR[]);
        when 32
            bits(32) op32 = if with_zero then FPZero('0', 32) else S[m];
            nzcv = FPCompare(S[d], op32, quiet_nan_exc, FPSCR[]);
        when 64
            bits(64) op64 = if with_zero then FPZero('0', 64) else D[m];
            nzcv = FPCompare(D[d], op64, quiet_nan_exc, FPSCR[]);
    FPSCR<31:28> = nzcv; // FPSCR.<N,Z,C,V> set to nzcv
```

**Operational information**

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the FPSCR condition flags to N=0, Z=0, C=1, and V=1.
F6.1.55  VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point
register and zero. It writes the result to the FPSCR flags. These are normally transferred to the PSTATE.{N, Z, C,
V} Condition flags by a subsequent VMRS instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of
NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

<

See *Standard assembler syntax fields* on page F1-7228.

<

See *Standard assembler syntax fields* on page F1-7228.

<

Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<

Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

<

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<

Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
  bits(4) nzcv;
  case esize of
    when 16
      bits(16) op16 = if with_zero then FPZero('0', 16) else S[m]<15:0>;
      nzcv = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR[]);
    when 32
      bits(32) op32 = if with_zero then FPZero('0', 32) else S[m];
      nzcv = FPCompare(S[d], op32, quiet_nan_exc, FPSCR[]);
    when 64
      bits(64) op64 = if with_zero then FPZero('0', 64) else D[m];
      nzcv = FPCompare(D[d], op64, quiet_nan_exc, FPSCR[]);
  FPSCR<31:28> = nzcv; // FPSCR.<N,Z,C,V> set to nzcv

**Operational information**

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the FPSCR condition flags to N=0, Z=0, C=1, and V=1.
F6.1.56  VCNT

Vector Count Set Bits counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[r],e,esize] = BitCount(Elem[D[r],e,esize]<esize-1:0>);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.57 VCVT (from single-precision to BFloat16, Advanced SIMD)

Vector Convert from single-precision to BFloat16 converts each 32-bit element in a vector from single-precision floating-point to BFloat16 format, and writes the result into a second vector. The result vector elements are half the width of the source vector elements.

Unlike the BFloat16 multiplication instructions, this instruction uses the Round to Nearest rounding mode, and can generate a floating-point exception that causes cumulative exception bits in the FPSCR to be set.

F6.1.60 VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.62 VCVT (integer to floating-point, floating-point)

Convert integer to floating-point converts a 32-bit integer to floating-point using the rounding mode specified by the FPSCR, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPtr, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.63 VCVT (between floating-point and fixed-point, Advanced SIMD)

Vector Convert between floating-point and fixed-point converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

  regs = if Q == '0' then 1 else 2;

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt1> Is the data type for the elements of the destination vector, encoded in the "op:U" field. It can have the following values:

F16 when op = 00, U = x
S16 when op = 01, U = 0
U16 when op = 01, U = 1
F32 when op = 10, U = x
S32 when op = 11, U = 0
U32 when op = 11, U = 1

<dt2> Is the data type for the elements of the source vector, encoded in the "op:U" field. It can have the following values:

S16 when op = 00, U = 0
U16 when op = 00, U = 1
F16 when op = 01, U = x
S32 when op = 10, U = 0
U32 when op = 10, U = 1
F32 when op = 11, U = x

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<fbits> The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- \((64 - \text{<fbits>})\) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see VCVT (between floating-point and integer, Advanced SIMD).

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m-r],e,esize];
            if to_fixed then
                result = FPtoFixed(op1, frac_bits, unsigned, StandardFPSCRValue(),
                    FPRounding_ZERO, esize);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(),
                    FPRounding_TIEEVEN, esize);
            Elem[D[d+r],e,esize] = result;
```

F6.1.64   VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPRTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.65 VCVTA (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest with Ties to Away converts each element in a vector from floating-point to integer using the Round to Nearest with Ties to Away rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.68  VCVTB (BFLOAT16)

Converts the single-precision value in a single-precision register to BFLOAT16 format and writes the result into the bottom half of a single precision register, preserving the top 16 bits of the destination register.

Unlike the BFLOAT16 multiplication instructions, this instruction honors all the control bits in the FPSCR that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the FPSCR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPSCR.

F6.1.71 VCVTN (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest converts each element in a vector from floating-point to integer using the Round to Nearest rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.75 VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the FPSCR and places the result in a second register.

VCVTR (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.76   VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

• Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.

• Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.

• Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

• Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. F6.1.77 VCVTT (BFloat16)

Converts the single-precision value in a single-precision register to BFloat16 format and writes the result in the top half of a single-precision register, preserving the bottom 16 bits of the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the FPSCR that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the FPSCR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPSCR.

            D[d] = FPDiv(D[n], D[m], FPSCR[]);
```
F6.1.79   VDOT (vector)

BFLOAT16 floating-point (BF16) dot product (vector). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Within each pair, the elements in the first source vector are multiplied by the corresponding elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element in the destination vector which aligns with the pair of BF16 values in the first source vector. The instruction does not update the FPSCR exception status.

F6.1.80 VDOT (by element)

BFloat16 floating-point indexed dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the indexed pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element in the destination vector which aligns with the pair of BFloat16 values in the first source vector. The instruction does not update the FPSCR exception status.

  D[d+r] = result;
F6.1.81 VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

\]
\[
\text{for } e = 0 \text{ to } \text{elements-1}
\]
\[
\text{Elem}[D[d+r],e,\text{size}] = \text{scalar};
\]

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.82 VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Assembler symbols**

<q> For encoding A1: see [Standard assembler syntax fields on page F1-7228](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F1-7228](#).

<q> See [Standard assembler syntax fields on page F1-7228](#).

<size> The data size. It must be one of:
- 8   Encoded as imm4<0> = '1'. imm4<3:1> encodes the index[x] of the scalar.
- 16  Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.
- 32  Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.83   VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

128-bit SIMD vector variant

Applies when Q == 1.

VEOR{<c>}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[n+r] EOR D[m+r];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.84  VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows the operation of VEXT doubleword operation for imm = 3.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instruction VEXT (multibyte elements). The pseudo-instruction is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

VEXT{<c>}{<q>}.8 {<Qd>,} <Qn>, <Qm>, #<imm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1');  position = 8 * UInt(imm4);
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<imm> For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the "imm4" field.
For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the "imm4" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
if quadword_operation then
    Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
else
    D[d] = (D[m]:D[n])<position+63:position>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.85  VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This instruction is a pseudo-instruction of the VEXT (byte elements) instruction. This means that:

- The encodings in this description are named to match the encodings of VEXT (byte elements).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

**64-bit SIMD vector variant**

Applies when Q == 0.

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Dd>,\} <Dn>, <Qm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Dd>,\} <Dn>, <Qm>, \#<\text{imm}*(size/8)>
\]

and is never the preferred disassembly.

**128-bit SIMD vector variant**

Applies when Q == 1.

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Qd>,\} <Qn>, <Qm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Qd>,\} <Qn>, <Qm>, \#<\text{imm}*(size/8)>
\]

and is never the preferred disassembly.

**T1**

\[
|15| 14| 13| 12| 11| 10| 9| 8| 7| 6| 5| 4| 3| 0|
\]

64-bit SIMD vector variant

Applies when Q == 0.

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Dd>,\} <Dn>, <Qm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Dd>,\} <Dn>, <Qm>, \#<\text{imm}*(size/8)>
\]

and is never the preferred disassembly.
128-bit SIMD vector variant

Applies when Q == 1.

\texttt{VEXT\{c\}\{q\}\{size\} \{Qd\}, \{Qn\}, \{Qm\}, \#imm}\n
is equivalent to

\texttt{VEXT\{c\}\{q\}\{size\}8 \{Qd\}, \{Qn\}, \{Qm\}, \#imm*(size/8)}

and is never the preferred disassembly.

Assembler symbols

\(<c>\) For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<\text{size}>\) For the 64-bit SIMD vector variant: is the size of the operation, and can be one of 16 or 32.

For the 128-bit SIMD vector variant: is the size of the operation, and can be one of 16, 32 or 64.

\(<\text{Qd}>\) Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<\text{Qd}>*2\).

\(<\text{Qn}>\) Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<\text{Qn}>*2\).

\(<\text{Qm}>\) Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<\text{Qm}>*2\).

\(<\text{Dd}>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(<\text{Dn}>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\(<\text{Dm}>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

\(<\text{imm}>\) For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to (128/<\text{size}>)-1.

For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to (64/<\text{size}>)-1.

Operation for all encodings

The description of \texttt{VEXT (byte elements)} gives the operational pseudocode for this instruction.
VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

VFMA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
advsimd = TRUE; op1_neg = (op == '1');
integer esize;
integer elements;
case sz of
when '0' esize = 32; elements = 2;
when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
regs = if Q == '0' then 1 else 2;

A2

VFMA{<c>}{<q>}.F16 <Sd>, <Sn>, <Sm>

Half-precision scalar variant

Applies when size == 01.

VFMA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Single-precision scalar variant

Applies when size == 10.
Double-precision scalar variant
Applies when size == 11.

VFMA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '03' && cond != '11110' then UNPREDICTABLE;
advsimd = FALSE; op1_neg = (op == '1');
integer esize;
integer d;
integer n;
integer m;
case size of
    when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

CONSTRAINED UNPREDICTABLE behavior
If size == '01' && cond != '11110', then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

64-bit SIMD vector variant
Applies when Q == 0.

VFMA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant
Applies when Q == 1.

VFMA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' ||Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && !InITBlock() then UNPREDICTABLE;
advsimd = TRUE; op1_neg = (op == '1');
integer esize;
integer elements;
case sz of
    when '0' esize = 32; elements = 2;
        when '1' esize = 16; elements = 4;
    d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    regs = if Q == '0' then 1 else 2;
**CONSTRAINED UNPREDICTABLE behavior**

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**T2**

<table>

</tbody>
</table>

**Half-precision scalar variant**

Applies when `size == 01`.

`VFMA{<c>}{<q>}.F16 <Sd>, <Sn>, <Sm>`

**Single-precision scalar variant**

Applies when `size == 10`.

`VFMA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>`

**Double-precision scalar variant**

Applies when `size == 11`.

`VFMA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>`

**Decode for all variants of this encoding**

```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
advsimd = FALSE; op1_neg = (op == '1');
integer esize;
integer d;
integer n;
integer m;
case size of
    when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

**CONSTRAINED UNPREDICTABLE behavior**

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

```

F6.1.87   VFMAB, VFMAT (BFloat16, vector)

The BFloat16 floating-point widening multiply-add long instruction widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first and second source vectors from BFloat16 to single-precision format. The instruction then multiplies and adds these values to the overlapping single-precision elements of the destination vector.

Unlike other BFloat16 multiplication instructions, this performs a fused multiply-add, without intermediate rounding that uses the Round to Nearest rounding mode and can generate a floating-point exception that causes cumulative exception bits in the FPSCR to be set.

Q[d>>1] = result;
F6.1.89   VFMAL (vector)

Vector Floating-point Multiply-Add Long to accumulator (vector). This instruction multiplies corresponding values in the vectors in the two source SIMD&FP registers, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

In Armv8.2 and Armv8.3, this is an an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note
ID_ISAR6.FHM indicates whether this instruction is supported.

```
F6.1.92 VFMSL (vector)

Vector Floating-point Multiply-Subtract Long from accumulator (vector). This instruction negates the values in the vector of one SIMD&FP register, multiplies these with the corresponding values in another vector, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and Floating-point support on page G1-8996.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_ISAR6.FHM indicates whether this instruction is supported.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    case esize of
        when 16
            op16 = if op1_neg then FPNeg(S[n]<15:0>) else S[n]<15:0>;
            S[d] = Zeros(16) : FPMulAdd(FPNeg(S[d]<15:0>), op16, S[m]<15:0>, FPSCR[]);
        when 32
            op32 = if op1_neg then FPNeg(S[n]) else S[n];
            S[d] = FPMulAdd(FPNeg(S[d]), op32, S[m], FPSCR[]);
        when 64
            op64 = if op1_neg then FPNeg(D[n]) else D[n];
            D[d] = FPMulAdd(FPNeg(D[d]), op64, D[m], FPSCR[]);
```
F6.1.95 VFNMS

Vector Fused Negate Multiply Subtract multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, HCPTT, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

    S[d] = S[m]<15:0> : S[d]<15:0>;

F6.1.99 VJCVT

Javascript Convert to signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in FPSCR, the exception results in either a flag being set or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page E1-7148.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\) For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<size>\) Is the data size, encoded in the "size" field. It can have the following values:

8 when size = 00
16 when size = 01
32 when size = 10

\(<list>\) Is a list containing the single 64-bit name of the SIMD&FP register holding the element.

The list must be \{ \(<Dd>\)[\{\<index>\}] \}.

The register \(<Dd>\) is encoded in the "D:Vd" field.

The permitted values and encoding of \(<index>\) depend on \(<size>\):

\(<size> == \&<index>\) is in the range 0 to 7, encoded in the "index_align<3:1>" field.
**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];  iswrite = FALSE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  Elem[D[d],index] = MemU[address,ebytes];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + ebytes;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.101   VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

```
[31 30 29 28 27 26 25 24 23 22 21 20 | 19 16 15 | 12 11 10 9 8 7 6 5 4 3 2 1 0 |
  1 1 1 1 0 1 0 0 1 1 0 | D | 1 | 0 | Rn | Vd | 1 1 0 0 | size | T | a | Rm |
```

\text{if } n &= \text{15} || \text{d+regs} > 32 \text{ then UNPREDICTABLE;}
\end{align*}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( d+\text{regs} > 32 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLDI (single element to all lanes) on page K1-11577.

**Assembler symbols**

- \(<c>\)
  - For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
  - For encoding T1: see Standard assembler syntax fields on page F1-7228.

- \(<q>\)
  - See Standard assembler syntax fields on page F1-7228.

- \(<\text{size}>\)
  - Is the data size, encoded in the "size" field. It can have the following values:
    - 8 when \( \text{size} = \ '00' \)
    - 16 when \( \text{size} = \ '01' \)
    - 32 when \( \text{size} = \ '10' \)
  - The encoding \( \text{size} = \ '11' \) is reserved.

- \(<\text{list}>\)
  - Is a list containing the 64-bit names of the SIMD&FP registers.
  - The list must be one of:
    - \{ <Dd>{} \} Encoded in the "T" field as 0.
{ <Dd>[], <Dd+1>[] } Encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "a" field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<align> == 16<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.
<align> == 32<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

**Operation for all encodings**

```c
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = FALSE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  constant integer esize = 8 * ebytes;
  bits(esize) element = MemU[address, ebytes];
  bits(64) replicated_element = Replicate(element, 64 DIV esize);
  for r = 0 to regs-1
    D[d+r] = replicated_element;
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + ebytes;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.102  **VLD1** (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. **CONSTRAINED UNPREDICTABLE behavior**

If \( d+regs > 32 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- One or more of the SIMD and floating-point registers are **UNKNOWN**. If the instruction specifies writeback, the base register becomes **UNKNOWN**. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*, and particularly *VLDI (multiple single elements)* on page K1-11577.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-7350 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-7434 for the A32 instruction set.

**Assembler symbols**

- `<c>`
  For encoding A1, A2, A3 and A4: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.
  For encoding T1, T2, T3 and T4: see *Standard assembler syntax fields* on page F1-7228.

- `<q>`
  See *Standard assembler syntax fields* on page F1-7228.

- `<size>`
  Is the data size, encoded in the "size" field. It can have the following values:
  
  8 when size = 00  
  16 when size = 01  
  32 when size = 10  
  64 when size = 11  

- `<list>`
  Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

{ <Dd> } Single register. Selects the A1 and T1 encodings of the instruction.
{ <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

- 64  64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
- 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as 0<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if ebytes != 8 then
                data = MemU[address, ebytes];
            else
                - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
                data|31:0| = if BigEndian(AccType_NORMAL) then MemU[address+4,4] else MemU[address,4];
                data|63:32| = if BigEndian(AccType_NORMAL) then MemU[address,4] else MemU[address+4,4];
                Elem[D[d+r],e] = data;
                address = address + ebytes;
            if wback then
                if register_index then
                    R[n] = R[n] + R[m];
                else
                    R[n] = R[n] + 8*regs;
            
**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.103  VLD2 (single 2-element structure to one lane)

Load single 2-element structure to one lane of two registers loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*, and particularly *VLD2 (single 2-element structure to one lane)* on page K1-11577.

**Assembler symbols**

\(<c>\) For encoding A1, A2 and A3: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields* on page F1-7228.

\(<q>\) See *Standard assembler syntax fields* on page F1-7228.

\(<\text{size}>\) Is the data size, encoded in the "size" field. It can have the following values:

- \(8\) when \( \text{size} = 00\)
- \(16\) when \( \text{size} = 01\)
- \(32\) when \( \text{size} = 10\)

\(<\text{list}>\) Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.

The list must be one of:

- \{ \langle Dd\rangle[\langle index\rangle], \langle Dd\rangle[\langle index\rangle+1] \} Single-spaced registers, encoded as "spacing" = 0.
- \{ \langle Dd\rangle[\langle index\rangle], \langle Dd\rangle[\langle index\rangle+2] \} Double-spaced registers, encoded as "spacing" = 1. Not permitted when \( \text{size} = 8\).

The encoding of "spacing" depends on \(<\text{size}>\).

\(<\text{size}> = 16"spacing" is encoded in the "index_{align}<1>" field.
<size> == 32"spacing" is encoded in the "index_align<2>" field.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
<size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and the encoding depends on <size>:
<size> == 8Encoded in the "index_align<0>" field as 0.
<size> == 16Encoded in the "index_align<0>" field as 0.
<size> == 32Encoded in the "index_align<1:0>" field as 0b0.
Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 8<align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 16<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 32<align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b1.
: is the preferred separator before the <align> value, but the alignment can be specified as 0<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.104 VLD2 (single 2-element structure to all lanes)

Load single 2-element structure and replicate to all lanes of two registers loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

Offset variant
Applies when \( Rm = 1111 \).

\[
\text{VLD2}{{<c>}}{<q>}.<\text{size}> <\text{list}>, [<\text{Rn}>{:<\text{align}>}]
\]

Post-indexed variant
Applies when \( Rm = 1101 \).

\[
\text{VLD2}{{<c>}}{<q>}.<\text{size}> <\text{list}>, [<\text{Rn}>{:<\text{align}>}]!
\]

Post-indexed variant
Applies when \( Rm != 11x1 \).

\[
\text{VLD2}{{<c>}}{<q>}.<\text{size}> <\text{list}>, [<\text{Rn}>{:<\text{align}>}],<\text{Rm}>
\]

\end{align*}
\]

CONSTRANDED UNPREDICTABLE behavior

If \( d2 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD2 (single 2-element structure to all lanes) on page K1-11578.

Assembler symbols

- For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
- For encoding T1: see Standard assembler syntax fields on page F1-7228.
- See Standard assembler syntax fields on page F1-7228.
- Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10
  - The encoding size = 11 is reserved.
- Is a list containing the 64-bit names of two SIMD&FP registers.
The list must be one of:
{ <Dd>[], <Dd+1>[] } Single-spaced registers, encoded in the "T" field as 0.
{ <Dd>[], <Dd+2>[] } Double-spaced registers, encoded in the "T" field as 1.
The register <Dd> is encoded in the "D:Vd" field.

<Rn>  Is the general-purpose base register, encoded in the "Rn" field.

<align>  Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 8<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.
<size> == 16<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
<size> == 32<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
:  is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>  Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    constant integer esize = 8 * ebytes;
    bits(esize) element1 = MemU[address, ebytes];
    bits(esize) element2 = MemU[address+ebytes, ebytes];
    D[d] = Replicate(element1, 64 DIV esize);
    D[d2] = Replicate(element2, 64 DIV esize);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
    
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.105  **VLD2 (multiple 2-element structures)**

Load multiple 2-element structures to two or four registers loads multiple 2-element structures from memory into two or four registers, with de-interleaving. For more information, see Element and structure load/store instructions on page F2-7278. Every element of each register is loaded. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

**CONSTRAINED UNPREDICTABLE behavior**

If \(d_2+\text{pairs} > 32\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD2 (multiple 2-element structures) on page K1-11577.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-7350 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-7434 for the A32 instruction set.

**Assembler symbols**

- `<c>` For encoding A1 and A2: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.
  
  For encoding T1 and T2: see *Standard assembler syntax fields* on page F1-7228.

- `<q>` See *Standard assembler syntax fields* on page F1-7228.

- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10

  The encoding size = 11 is reserved.

- `<list>` Is a list containing the 64-bit names of the SIMD&FP registers.

  The list must be one of:

  - \{<Dd>, <Dd+1>\} Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1000.
  - \{<Dd>, <Dd+2>\} Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1001.
  - \{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>\} Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

  The register <Dd> is encoded in the "D:Vd" field.

- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

- `<align>` Is the optional alignment.

  Whenever `<align>` is omitted, the standard alignment is used, see *Unaligned data access on page E2-7193*, and is encoded in the "align" field as 0b00.

  Whenever `<align>` is present, the permitted values are:

  - 64 64-bit alignment, encoded in the "align" field as 0b01.
  - 128 128-bit alignment, encoded in the "align" field as 0b10.
  - 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if `<list>` contains four registers.

  : is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode on page F1-7249*. 
<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode* on page F1-7249.

**Operation for all encodings**

```plaintext
if ConditionPassed() then

VLD3\{<c>\}\{<q>\}.<size>\ <list>, [\{<Rn>\}]
\]

**Post-indexed variant**

Applies when \( Rm \neq 11x1 \).

\[
VLD3\{<c>\}\{<q>\}.<size>\ <list>, [\{<Rn>\}], \langle Rm \rangle
\]

**Decode for all variants of this encoding**

if size == '11' then SEE "VLD3 (single 3-element structure to all lanes)"";
if index_align<1:0> != '00' then UNDEFINED;
  ebytes = 4;  index = UInt(index_align<3>);
in1 = if index_align<2> == '0' then 1 else 2;
d = UInt(D:Vd);  \( d2 = d + inc \);  \( d3 = d2 + inc \);  \( n = UInt(Rn) \);  \( m = UInt(Rm) \);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If \( d3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \textit{NOP}.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD3 (single 3-element structure to one lane) on page K1-11578.

**Assembler symbols**

\(<c>\) For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<size>\) Is the data size, encoded in the "size" field. It can have the following values:

- \( 8 \) when size = 00
- \( 16 \) when size = 01
- \( 32 \) when size = 10

\(<list>\) Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.

The list must be one of:

\{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as "spacing" = 0.

\{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when \(<size> == 8\).
The encoding of "spacing" depends on `<size>`:
- `<size> == 8"spacing" is encoded in the "index_align<0>" field.
- `<size> == 16"spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.
- `<size> == 32"spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register `<Dd>` is encoded in the "D:Vd" field.

The permitted values and encoding of `<index>` depend on `<size>`:
- `<size> == 8`<index>` is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- `<size> == 16`<index>` is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- `<size> == 32`<index>` is 0 or 1, encoded in the "index_align<3>" field.

`<Rn>`
- Is the general-purpose base register, encoded in the "Rn" field.

`<Rm>`
- Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F1-7249.*

Alignment

Standard alignment rules apply, see *Alignment support on page B2-189.*

**Operation for all encodings**

if `ConditionPassed()` then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n];
  Elem[D[d], index] = MemU[address,ebytes];
  Elem[D[d2], index] = MemU[address+ebytes,ebytes];
  Elem[D[d3], index] = MemU[address+2*ebytes,ebytes];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 3*ebytes;
  endif
endif

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.107  VLD3 (single 3-element structure to all lanes)

Load single 3-element structure and replicate to all lanes of three registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

\end{align*}
\]

CONstrained unPredictable behavior

If \( d3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONstrained unPredICtable behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly \( \text{VLD3 (single 3-element structure to all lanes)} \) on page K1-11578.

Assembler symbols

\(<c>\)  For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(<q>\)  See Standard assembler syntax fields on page F1-7228.

\(<\text{size}>\)  Is the data size, encoded in the "size" field. It can have the following values:

\[
\begin{align*}
8 & \text{ when size} = 00 \\
16 & \text{ when size} = 01 \\
32 & \text{ when size} = 10 \\
\end{align*}
\]

The encoding size = 11 is reserved.

\(<\text{list}>\)  Is a list containing the 64-bit names of three SIMD&FP registers.

The list must be one of:

\[
\{ <\text{Dd}>[], <\text{Dd+1}>[], <\text{Dd+2}>[] \} \text{Single-spaced registers, encoded in the "T" field as 0.}
\]
{ <Dd>[], <Dd+2>[], <Dd+4>[] } Double-spaced registers, encoded in the "T" field as 1.
The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F1-7249.*

Alignment

Standard alignment rules apply, see *Alignment support on page B2-189.*

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n];
  constant integer esize = ebytes * 8;
  bits(esize) element1 = MemU[address, ebytes];
  bits(esize) element2 = MemU[address+ebytes, ebytes];
  bits(esize) element3 = MemU[address+2*ebytes, ebytes];

  D[d] = Replicate(element1, 64 DIV esize);
  D[d2] = Replicate(element2, 64 DIV esize);
  D[d3] = Replicate(element3, 64 DIV esize);
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 3*ebytes;

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.108 VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see Element and structure load/store instructions on page F2-7278. Every element of each register is loaded. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPRR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

```

CONSTRANDED UNPREDICTABLE behavior

If \( d3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD3 (multiple 3-element structures) on page K1-11578.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.
Assembler symbols

&lt;c&gt; For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
   For encoding T1: see Standard assembler syntax fields on page F1-7228.

&lt;q&gt; See Standard assembler syntax fields on page F1-7228.

&lt;size&gt; Is the data size, encoded in the "size" field. It can have the following values:
   8 when size = 00
   16 when size = 01
   32 when size = 10
   The encoding size = 11 is reserved.

&lt;list&gt; Is a list containing the 64-bit names of the SIMD&FP registers.
   The list must be one of:
   { <Dd>, <Dd+1>, <Dd+2> }Single-spaced registers, encoded in the "itype" field as 0b0100.
   { <Dd>, <Dd+2>, <Dd+4> }Double-spaced registers, encoded in the "itype" field as 0b0101.
   The register &lt;Dd&gt; is encoded in the "D:Vd" field.

&lt;Rn&gt; Is the general-purpose base register, encoded in the "Rn" field.

&lt;align&gt; Is the optional alignment.
   Whenever &lt;align&gt; is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "align" field as 0000.
   Whenever &lt;align&gt; is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01.
   : is the preferred separator before the &lt;align&gt; value, but the alignment can be specified as @&lt;align&gt;, see The Advanced SIMD addressing mode on page F1-7249.

&lt;Rm&gt; Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about &lt;Rn&gt;, !, and &lt;Rm&gt;, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        address = address + 3*ebytes;
        if wback then
            if register_index then
                R[n] = R[n] + R[m];
            else
                R[n] = R[n] + 24;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.109 VLD4 (single 4-element structure to one lane)

Load single 4-element structure to one lane of four registers loads one 4-element structure from memory into corresponding elements of four registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD4 (single 4-element structure to one lane) on page K1-11578.

Assembler symbols
<<
For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<size>
Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10

<List>
Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.
The list must be one of:
{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Single-spaced registers, encoded as "spacing" = 0.
{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when size == 8.
The encoding of "spacing" depends on <size>:
- <size> == 16: "spacing" is encoded in the "index_align<1>" field.
- <size> == 32: "spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:
- <size> == 8: <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16: <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32: <index> is 0 or 1, encoded in the "index_align<3>" field.

<rn> is the general-purpose base register, encoded in the "Rn" field.
<align> is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and the encoding depends on <size>:
- <size> == 8: <align> is encoded in the "index_align<0>" field as 0.
- <size> == 16: <align> is encoded in the "index_align<0>" field as 0b00.
- <size> == 32: <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 0b0.

Whenever <align> is present, the permitted values and encoding depend on <size>:
- <size> == 8: <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16: <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32: <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

<rm> is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address, ebytes];
    Elem[D[d2], index] = MemU[address+ebytes, ebytes];
    Elem[D[d3], index] = MemU[address+2*ebytes, ebytes];
    Elem[D[d4], index] = MemU[address+3*ebytes, ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.110  VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

\]

CONSTRANDED UNPREDICTABLE behavior
If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings
For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD4 (single 4-element structure to all lanes) on page K1-11579.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<size>
Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 1x

<List>
Is a list containing the 64-bit names of four SIMD&FP registers.
The list must be one of:

- { <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[]} Single-spaced registers, encoded in the "T" field as 0.
- { <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[]} Double-spaced registers, encoded in the "T" field as 1.
The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
- <size> == 16<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
- <size> == 32<align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VLD4 (multiple 4-element structures) on page K1-11578.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.
Assembler symbols

<\>  For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.
   For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

<\>
   See *Standard assembler syntax fields on page F1-7228*.

<size>
   Is the data size, encoded in the "size" field. It can have the following values:
   8    when size = 00
   16   when size = 01
   32   when size = 10
   The encoding size = 11 is reserved.

/list
   Is a list containing the 64-bit names of the SIMD&FP registers.
   The list must be one of:
   \{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3>\} Single-spaced registers, encoded in the "itype" field as 0b0000.
   \{ <Dd>, <Dd+2>, <Dd+4>, <Dd+6>\} Double-spaced registers, encoded in the "itype" field as 0b0001.
   The register <Dd> is encoded in the "D:Vd" field.

<Rn>
   Is the general-purpose base register, encoded in the "Rn" field.

<align>
   Is the optional alignment.
   Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access on page E2-7193*, and is encoded in the "align" field as 0000.
   Whenever <align> is present, the permitted values are:
   64   64-bit alignment, encoded in the "align" field as 0b01.
   128  128-bit alignment, encoded in the "align" field as 0b10.
   256  256-bit alignment, encoded in the "align" field as 0b11.
   ; is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode on page F1-7249*.

<Rm>
   Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
   For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F1-7249*.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   address = R[n]; iswrite = FALSE;
   - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
   for e = 0 to elements-1
      Elem[D[d], e] = MemU[address,ebytes];
      Elem[D[d+2], e] = MemU[address+ebytes,ebytes];
      Elem[D[d+4], e] = MemU[address+2*ebytes,ebytes];
      Elem[D[d+6], e] = MemU[address+3*ebytes,ebytes];
      address = address + 4*ebytes;
   if wback then
      if register_index then
         R[n] = R[n] + R[m];
      else
         R[n] = R[n] + 32;
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.112   VLDM, VLDMDB, VLMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

 Depending on settings in the CPACR, NSACR, and HCPTF registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the alias VPOP. See Alias conditions on page F6-8479 for details of when each alias is preferred.

</tr>
</thead>
</table>

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
- `!` Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
- `<sreglist>` Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
- `<dreglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n].imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.113   VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

VLDR{<c>}{<q>}{.64} <Dd>, <label>
VLDR{<c>}{<q>}{.64} <Dd>, [PC, #{+/−}<imm>]

**Decode for all variants of this encoding**

if size == '00' || (size == '01' & & !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
esize = 8 << UInt(size); add = (U == '1');
imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
integer d;
case size of
  when '01' d = UInt(Vd:D);
  when '10' d = UInt(Vd:D);
  when '11' d = UInt(D:Vd);
n = UInt(Rn);

**CONSTRAINED UNPREDICTABLE behavior**

If size == '01' & & InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

<
| See Standard assembler syntax fields on page F1-7228.

<q>

.64

Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<0d>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

.32

Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<label> The label of the literal data item to be loaded.

For the single-precision scalar or double-precision scalar variants: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

For the half-precision scalar variant: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 2 in the range -510 to 510.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.
If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm> For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.
For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
  base = if n == 15 then Align(PC,4) else R[n];
  address = if add then (base + imm32) else (base - imm32);
  case esize of
    when 16
      S[d] = Zeros(16) : MemA[address,2];
    when 32
      S[d] = MemA[address,4];
    when 64
      word1 = MemA[address,4]; word2 = MemA[address+4,4];
      // Combine the word-aligned words in the correct order for current endianness.
      D[d] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.115 **VMAX (floating-point)**

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

<> See Standard assembler syntax fields on page F1-7228.

<dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
   F32 when sz = 0
   F16 when sz = 1

<q> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <q>d.*2.
<q> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <q>n.*2.
<q> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <q>m.*2.
<q> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<q> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<q> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Floating-point maximum and minimum
• max(+0.0, -0.0) = +0.0
• If any input is a NaN, the corresponding result element is the default NaN.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();  CheckAdvSIMDEnabled();
for r = 0 to regs-1
   for e = 0 to elements-1
      op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
      if maximum then
         Elem[D[d+r],e,esize] = FMax(op1, op2, StandardFPSCRValue());
else
    Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
F6.1.116 VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

         Elem[D[d+r],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.117 VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

else
    Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRVValue());
F6.1.119 **VMIN (integer)**

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

Assembler symbols

<q> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.
<dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
S8 when U = 0, size = 00
S16 when U = 0, size = 01
S32 when U = 0, size = 10
U8 when U = 1, size = 00
U16 when U = 1, size = 01
U32 when U = 1, size = 10

<Dd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Dd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();  CheckAdvSIMDEnabled();
   for r = 0 to regs-1
      for e = 0 to elements-1
         op1 = Int(Elem[D[n+r],e,esize], unsigned);
         op2 = Int(Elem[D[m+r],e,esize], unsigned);
         result = if maximum then Max(op1,op2) else Min(op1,op2);
         Elem[D[d+r],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.120 \textbf{VMINNM}

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point \texttt{VMIN}.

This instruction is not conditional.

<dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
I8 when size = 00
I16 when size = 01
I32 when size = 10

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[<Dd>,<Dn>,<Dm>],e,esize,unsigned) * Int(Elem[<Dd>,<Dn>,<Dm>],e,esize,unsigned);
            addend = if add then product else -product;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.123  VMLA (by scalar)

Vector Multiply Accumulate multiplies elements of a vector by a scalar, and adds the products to corresponding elements of the destination vector.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, and HCPTTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:

- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16 or U16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32 or U32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[ DIN[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[ DIN[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else
                FPNeg(FPMul(op1,op2,StandardFPSCRValue()));
                Elem[D[d+r],e,esize] = FPA dd(Elem[Din[d+r],e,esize], fp_addend, StandardFPSCRValue());
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then
                    Elem[Q[0][d>1],e,2*esize] = Elem[ Qin[d>1],e,2*esize] + addend;
                else
                    Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.131 VMMLA

BFLOAT16 floating-point matrix multiply-accumulate. This instruction multiplies the 2x4 matrix of B16 values in the first 128-bit source vector by the 4x2 B16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction does not update the FPSCR exception status.

Note

Arm expects that the VMMLA instruction will deliver a peak B16 multiply throughput that is at least as high as can be achieved using two VDOT instructions, with a goal that it should have significantly higher throughput.

F6.1.132   VMOV (between two general-purpose registers and a doubleword floating-point register)

Copy two general-purpose registers to or from a SIMD&FP register copies two words from two general-purpose
registers into a doubleword register in the Advanced SIMD and floating-point register file, or from a doubleword
register in the Advanced SIMD and floating-point register file to two general-purpose registers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode
in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp
mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Notes for all encodings**

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

**Assembler symbols**

- `<c>` For encoding A1, A3, A4 and A5: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
  
  For encoding A2, T1, T2, T3, T4 and T5: see Standard assembler syntax fields on page F1-7228.

- `<q>` See Standard assembler syntax fields on page F1-7228.

- `<dt>` The data type, encoded in the "cmode" field. It can have the following values:
  
  I32 when cmode = 110x
  
  I8 when cmode = 1110
  
  F32 when cmode = 1111

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

- `<imm>` For encoding A1, A3, A4, A5, T1, T3, T4 and T5: is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of `<imm>`, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F1-7245.
  
  For encoding A2 and T2: is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "imm4H:imm4L". For details of the range of constants available and the encoding of `<imm>`, see Modified immediate constants in T32 and A32 floating-point instructions on page F1-7246.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
  if single_register then
    S[d] = imm32;
  else
for r = 0 to regs-1
  D[d+r] = imm64;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.135  VMOV (register)

Copy between FP registers copies the contents of one FP register to another.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Assembler symbols

<\>  See Standard assembler syntax fields on page F1-7228.
<\>  See Standard assembler syntax fields on page F1-7228.
<\d>  Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<\m>  Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<\D>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<\M>  Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = S[m];
    else
        for r = 0 to regs-1
            D[d+r] = D[m+r];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
   — The values of the data supplied in any of its registers.
   — The values of the NZCV flags.
F6.1.136  VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another

This instruction is an alias of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The description of VORR (register) gives the operational pseudocode for this instruction.

### A1

| [31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 12|11 10 9 8|7 6 5 4 3|0 1 0 0 0 D 1 0 0 0 1 N Q M 1 | Vm |

and is the preferred disassembly when N:Vn == M:Vm.

**128-bit SIMD vector variant**

Applies when Q == 1.

\[
\text{V MOV}\{<c>\}{<q>\}{.<dt>} <Qd>, <Qm>
\]
is equivalent to

\[ \text{VORR}\{\langle c\rangle\{\langle q\rangle\{.\langle dt\rangle\}\langle Qd\rangle, \langle Qm\rangle, \langle Qm\rangle} \]

and is the preferred disassembly when \(N:Vn = M:Vm\).

**Assembler symbols**

\(\langle c\rangle\)  
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(\langle q\rangle\)  
See Standard assembler syntax fields on page F1-7228.

\(\langle dt\rangle\)  
An optional data type. \(\langle dt\rangle\) must not be F64, but it is otherwise ignored.

\(\langle Qd\rangle\)  
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(\langle Qd\rangle*2\).

\(\langle Qm\rangle\)  
Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as \(\langle Qm\rangle*2\).

\(\langle Dd\rangle\)  
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(\langle Dm\rangle\)  
Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.137  VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, HCPTCR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

T1

```
T1 variant

VMOV{<c>}{<q>}{.<size>} <Dd[x]>, <Rt>
```

**Decode for this encoding**

```java
boolean advsimd;
integer esize;
integer index;
case opc1:opc2 of
  when '1xxx'  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
  when '0xx1'  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
  when '0x00'  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
  when '0x10'  UNDEFINED;
```
d = UInt(D:Vd);  t = UInt(Rt);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings
For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<cf> See Standard assembler syntax fields on page F1-7228.
<cf><cf> See Standard assembler syntax fields on page F1-7228.
<cf><cf> The data size. It must be one of:
\begin{enumerate}
\item 8 Encoded as \texttt{opc1<1> = 1}. [x] is encoded in \texttt{opc1<0>}, \texttt{opc2}.
\item 16 Encoded as \texttt{opc1<1> = 0}, \texttt{opc2<0> = 1}. [x] is encoded in \texttt{opc1<0>}, \texttt{opc2<1>}.
\item 32 Encoded as \texttt{opc1<1> = 0}, \texttt{opc2 = 0b00}. [x] is encoded in \texttt{opc1<0>}.
\item omitted Equivalent to 32.
\end{enumerate}
<cf><cf><cf> The scalar. The register \texttt{<Dd>} is encoded in D:Vd. For details of how [x] is encoded, see the description of \texttt{<size>}.
<cf><cf> The source general-purpose register.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    Elem[D[d],index,esize] = R[t]<esize-1:0>;

Operational information
If CPSR.DIT is 1 and this instruction passes its condition execution check:
\begin{itemize}
\item The execution time of this instruction is independent of:
    \begin{itemize}
    \item The values of the data supplied in any of its registers.
    \item The values of the NZCV flags.
    \end{itemize}
\item The response of this instruction to asynchronous exceptions does not vary based on:
    \begin{itemize}
    \item The values of the data supplied in any of its registers.
    \item The values of the NZCV flags.
    \end{itemize}
\end{itemize}
F6.1.138 VMOV (between general-purpose register and single-precision)

Copy a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in a 32-bit SIMD&FP register to a general-purpose register, or the value held in a general-purpose register to a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

\]

if \( t = 15 \) then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<rt>  Is the general-purpose register that <sn> will be transferred to or from, encoded in the "Rt" field.

<sn>  Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Vn:N" field.

<->  See Standard assembler syntax fields on page F1-7228.

<q>  See Standard assembler syntax fields on page F1-7228.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

•  The execution time of this instruction is independent of:
    —  The values of the data supplied in any of its registers.
    —  The values of the NZCV flags.

•  The response of this instruction to asynchronous exceptions does not vary based on:
    —  The values of the data supplied in any of its registers.
    —  The values of the NZCV flags.
F6.1.139 VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, HCPTLR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 _Architectural Constraints on UNPREDICTABLE Behaviors_.

### Assembler symbols

- \(<c>\) See _Standard assembler syntax fields on page F1-7228_.
- \(<q>\) See _Standard assembler syntax fields on page F1-7228_.
- \(<dt>\) The data type. It must be one of:
  - \(S8\) Encoded as \(U = 0, \text{opc1}<1> = 1, [x] \) is encoded in \(\text{opc1}<0>, \text{opc2}\).
  - \(S16\) Encoded as \(U = 0, \text{opc1}<1> = 0, \text{opc2}<0> = 1, [x] \) is encoded in \(\text{opc1}<0>, \text{opc2}<1>\).
  - \(U8\) Encoded as \(U = 1, \text{opc1}<1> = 1, [x] \) is encoded in \(\text{opc1}<0>, \text{opc2}\).
  - \(U16\) Encoded as \(U = 1, \text{opc1}<1> = 0, \text{opc2}<0> = 1, [x] \) is encoded in \(\text{opc1}<0>, \text{opc2}<1>\).
  - \(32\) Encoded as \(U = 0, \text{opc1}<1> = 0, \text{opc2} = 0b00, [x] \) is encoded in \(\text{opc1}<0>\).
  - \(\text{omitted}\) Equivalent to \(32\).
- \(<Rt>\) The destination general-purpose register.
- \(<Dn[x]>\) The scalar. For details of how \([x]\) is encoded see the description of \(<dt>\).

### Operation for all encodings

if \( \text{ConditionPassed()} \) then

\[
\text{EncodingSpecificOperations();} \quad \text{CheckAdvSIMDorVFPEnabled(TRUE, advsimd)};
\]

if unsigned then

\[
R[t] = \text{ZeroExtend(Elem[D[n],index,esize], 32)};
\]

else

\[
R[t] = \text{SignExtend(Elem[D[n],index,esize], 32)};
\]

### Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F6.1.140 VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, HCPTTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-8996*.

A1

```

\]

\[
\text{if to}_{\text{arm}}\text{_registers} \&\& \text{ t } == \text{ t2 } \text{ then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{to}_{\text{arm}}\text{_registers} \&\& \text{ t } == \text{ t2} \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If \( \text{m} == 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

```
| 15 14 13 12 11 10 9 8 7 6 5 4 3 0 15 12 11 10 9 8 7 6 5 4 3 0 |
|-----------------------|-----------------|-----------------|-----------------|
|                         | 1 1 1 0 1 1 0 0 0 | 1 0 op          |
|                         | Rt2 Rt 1 0 1 0 0 0 | M 1 Vm          |
```
From general-purpose registers variant

Applies when op == 0.

VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>

To general-purpose registers variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>

Decode for all variants of this encoding

to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If m == 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VMOV (between two general-purpose registers and two single-precision registers) on page K1-11579.

Assembler symbols

<Rt2> Is the second general-purpose register that <Sm1> will be transferred to or from, encoded in the "Rt2" field.

<Rt> Is the first general-purpose register that <Sm> will be transferred to or from, encoded in the "Rt" field.

<Sm1> Is the 32-bit name of the second SIMD&FP register to be transferred. This is the next SIMD&FP register after <Sm>.

<Sm> Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Vm:M" field.

<> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
if to_arm_registers then
    R[t] = S[m];
    R[t2] = S[m+1];
else
    S[m] = R[t];
    S[m+1] = R[t2];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.141 VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

- **U16** when \( U = 1 \), \( \text{imm3H} = 010 \)
- **U32** when \( U = 1 \), \( \text{imm3H} = 100 \)

<Qd>Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<Qd>*2.\n
<Dm>Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```java
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.142   VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instructions VRSHRN (zero) and VSHRN (zero). The pseudo-instruction is never the preferred disassembly.

\end{array}
\]

T1 variant

VMOVX{<q>}.F16 <Sd>, <Sm>

Decode for this encoding

if InITBlock() then UNPREDICTABLE;
if !HaveFP16Ext() then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
d = UInt(Vd:D); m = UInt(Vm:M);

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<q> See Standard assembler syntax fields on page F1-7228.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    S[d] = Zeros(16) : S[m]<31:16>;
F6.1.144 VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the FPSCR, a form of the instruction transfers the FPSCR. {N, Z, C, V} condition flags to the APSR. {N, Z, C, V} condition flags.

Depending on settings in the CPACR, NSACR, HCPR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

When these settings permit the execution of Advanced SIMD and floating-point instructions, if the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when HCR.TID0 is set to 1, any VMRS access to FPSID from a Non-secure EL1 mode that would be permitted if HCR.TID0 was set to 0 generates a Hyp Trap exception. For more information, see ID group 0, Primary device identification registers on page G1-9019.

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

\]

### CONSTRAINED UNPREDICTABLE behavior

If \( \neg(\text{reg} \in \{'000x', '0101', '011x', '1000'\}) \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the APSR\_{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

### Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page F1-7228.
- \(<q>\) See Standard assembler syntax fields on page F1-7228.
- \(<\text{Rt}>\) Is the general-purpose destination register, encoded in the "Rt" field. Is one of:
  - R0-R14 General-purpose register.
  - APSR\_nzc\_v Permited only when \(<\text{spec_reg}>\) is FPSCR. Encoded as 0b1111. The instruction transfers the FPSCR\_\{N, Z, C, V\} condition flags to the APSR\_\{N, Z, C, V\} condition flags.
- \(<\text{spec_reg}>\) Is the source Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values:
  - FPSID when reg = 0000
  - FPSCR when reg = 0001
  - MVFR2 when reg = 0101
  - MVFR1 when reg = 0110
  - MVFR0 when reg = 0111
  - FPEXC when reg = 1000

The following encodings are UNPREDICTABLE:

- reg = 001x.
- reg = 0100.
- reg = 1001.
- reg = 101x.
- reg = 11xx.

### Operation for all encodings

\[
\text{if } \text{ConditionPassed()} \text{ then} \\
\text{EncodingSpecificOperations();} \\
\text{if } \text{reg} == '0001' \text{ then} \quad \text{// FPSCR} \\
\text{CheckVFPEnabled(TRUE);} \\
\text{if } t == 15 \text{ then}
\]
else
  R[t] = FPSCR;
elsif PSTATE.EI == EI0 then
  UNDEFINED;                        // Non-FPSCR registers accessible only at PL1 or above
else
  CheckVFPEnabled(FALSE);           // Non-FPSCR registers are not affected by FPEXC.EN
  AArch32.CheckAdvSIMDOrFPRegisterTraps(reg);
  case reg of
  when '0000'  R[t] = FPSID;
  when '0101'  R[t] = MVFR2;
  when '0110'  R[t] = MVFR1;
  when '0111'  R[t] = MVFR0;
  when '1000'  R[t] = FPEXC;
  otherwise  Unreachable();   // Dealt with above or in encoding-specific pseudocode
F6.1.145 VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

When these settings permit the execution of Advanced SIMD and floating-point instructions:

- If the specified floating-point System register is FPSID or FPEXC, the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the FPSID and the instruction is executed in a mode other than User mode, the instruction is ignored.

CheckVFPEnable(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN

case reg of
  when '0000' // VMSR access to FPSID is ignored
    when '1000' FPEXC = R[t];
  otherwise    Unreachable(); // Dealt with above or in encoding-specific pseudocode
F6.1.146 VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Assembler symbols**

\[<c>\] For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding A2, T1 and T2: see Standard assembler syntax fields on page F1-7228.

\[<q>\] See Standard assembler syntax fields on page F1-7228.

\[<dt>\] Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

\[F32 \quad \text{when } sz = 0\]
F16 when sz = 1

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

Operation for all encodings

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
— The values of the NZCV flags.
F6.1.148   VMUL (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, and HCPtr registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.150 VMULL (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see Advanced SIMD scalars on page F1-7254.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

if size == '10' then esize = 32;  elements = 2;  m = UInt(Vm);  index = UInt(M);
```
Notes for all encodings

Related encodings: See *Advanced SIMD data-processing* on page F3-7314 for the T32 instruction set, or *Advanced SIMD data-processing* on page F4-7422 for the A32 instruction set.

Assembler symbols

- `<c>`: For encoding A1: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.
  
  For encoding T1: see *Standard assembler syntax fields* on page F1-7228.

- `<q>`: See *Standard assembler syntax fields* on page F1-7228.

- `<dt>`: Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:
  
  - S16 when U = 0, size = 01
  - S32 when U = 0, size = 10
  - U16 when U = 1, size = 01
  - U32 when U = 1, size = 10

- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.

- `<Dn>`: Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

- `<Dm>`: Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when `<dt>` is S16 or U16, otherwise the "Vm" field.

- `<index>`: Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when `<dt>` is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = (op1val<op2val)<2*esize-1:0>;
                else
                    Elem[D[d+r],e,esize] = (op1val<op2val)<esize-1:0>;
            
        
    
```

F6-8585
F6.1.151 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings
Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

- `<c>`
  For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
  For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

- `<q>`
  See Standard assembler syntax fields on page F1-7228.

- `<qd>`
  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.`
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F1-7245.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

### Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.152 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                if floating_point then
                    Elem[D[d+r],e,esize] = FPNeg(Elem[D[m+r],e,esize]);
                else
                    result = -SInt(Elem[D[m+r],e,esize]);
                    Elem[D[d+r],e,esize] = result<esize-1:0>;
                else
                    case esize of
                        when 16 S[d] = Zeros(16) : FPNeg(S[m]<15:0>);
                        when 32 S[d] = FPNeg(S[m]);
                        when 64 D[d] = FPNeg(D[m]);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.154 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Note

Arm recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.157 VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (immediate) gives the operational pseudocode for this instruction.

A1

\[
VORN\{<c>\}{<q>}.I16 \{<Dd>,\} <Dd>, #<imm>
\]

\[
VORR\{<c>\}{<q>}.I16 <Dd>, #~<imm>
\]

is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

\[
VORN\{<c>\}{<q>}.I32 \{<Qd>,\} <Qd>, #<imm>
\]

\[
VORR\{<c>\}{<q>}.I32 <Qd>, #~<imm>
\]

and is never the preferred disassembly.

A2

\[
VORN\{<c>\}{<q>}.I32 \{<Dd>,\} <Dd>, #<imm>
\]

\[
VORR\{<c>\}{<q>}.I32 <Dd>, #~<imm>
\]

and is never the preferred disassembly.
### 128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VORN}(<c>{<q>}.I32 \{<Qd>,} <Qd>, \#<imm>
\]

is equivalent to

\[
\text{VORR}(<c>{<q>}.I32 <Qd>, \#<imm>
\]

and is never the preferred disassembly.

is equivalent to

VORR{<c>}{<q>}.I32 <Qd>, #~<imm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: For encoding A1 and A2: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional. For encoding T1 and T2: see *Standard assembler syntax fields* on page F1-7228.

- `<q>`: See *Standard assembler syntax fields* on page F1-7228.

- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<imm>`: Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of `<imm>`, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F1-7245.

**Operation for all encodings**

The description of VORR (immediate) gives the operational pseudocode for this instruction.
F6.1.158 **VORN (register)**

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

**64-bit SIMD vector variant**

Applies when Q == 0.

\[
\text{VORN} \{<c>\} \{<q>\} \{.<dt>\} \{<Dd>\}, <Dn>, <Dm>
\]

**128-bit SIMD vector variant**

Applies when Q == 1.

\[
\text{VORN} \{<c>\} \{<q>\} \{.<dt>\} \{<Qd>,\} <Qn>, <Qm>
\]

**Decode for all variants of this encoding**

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;

\[
d = \text{UInt}(D:Vd); \
 n = \text{UInt}(N:Vn); \
 m = \text{UInt}(M:Vm); \
 \text{regs} = \text{if Q == '0' then 1 else 2};
\]

T1

**64-bit SIMD vector variant**

Applies when Q == 0.

\[
\text{VORN} \{<c>\} \{<q>\} \{.<dt>\} \{<Dd>\}, <Dn>, <Dm>
\]

**128-bit SIMD vector variant**

Applies when Q == 1.

\[
\text{VORN} \{<c>\} \{<q>\} \{.<dt>\} \{<Qd>,\} <Qn>, <Qm>
\]

**Decode for all variants of this encoding**

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;

\[
d = \text{UInt}(D:Vd); \
 n = \text{UInt}(N:Vn); \
 m = \text{UInt}(M:Vm); \
 \text{regs} = \text{if Q == '0' then 1 else 2};
\]
Assembler symbols

<&> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as &Qd>*2.

<qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as &Qn>*2.

<qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as &Qm>*2.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[n+r] OR NOT(D[m+r]);

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.159 VORR (immediate)

Vector Bitwise OR (immediate) performs a bitwise OR between a register value and an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instruction VORN (immediate). The pseudo-instruction is never the preferred disassembly.

    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.161  VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADAL doubleword operation for data type S16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.162  VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{sz} = '1' \) \&\& \( \text{InITBlock}() \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

\(<c>\) For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

\(<q>\) See *Standard assembler syntax fields on page F1-7228*.

\(<dt>\) Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:

- F32 when \( \text{sz} = 0 \)
- F16 when \( \text{sz} = 1 \)

\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(<Dn>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

\(<Dm>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;
    for e = 0 to h-1
        \( \text{Elem}[\text{dest}, e, \text{esize}] = \text{FPAdd}(\text{Elem}[\text{D}[\text{n}], 2*e, \text{esize}], \text{Elem}[\text{D}[\text{n}], 2*e+1, \text{esize}], \text{StandardFPSCRValue}()); \)
        \( \text{Elem}[\text{dest}, e+h, \text{esize}] = \text{FPAdd}(\text{Elem}[\text{D}[\text{m}], 2*e, \text{esize}], \text{Elem}[\text{D}[\text{m}], 2*e+1, \text{esize}], \text{StandardFPSCRValue}()); \)
    \( \text{D}[\text{d}] = \text{dest}; \)
```
### F6.1.163 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows the operation of VPADD doubleword operation for data type I16.

![Diagram of VPADD operation](image)

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

**A1**

```plaintext

```

**T1 variant**

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

**Decode for this encoding**

if size == '11' || Q == '1' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
I8 when size = 00
I16 when size = 01
I32 when size = 10

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;
    for e = 0 to h-1
        Elem[dest,e,esize] = Elem[D[n],2*e,esize] + Elem[D[n],2*e+1,esize];
        Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];
    D[d] = dest;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.164 VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADDL doubleword operation for data type S16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

### Assembler symbols

- `<>` For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
- `<>` For encoding T1: see Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<dt>` Is the data type for the elements of the vectors, encoded in the "op:size" field. It can have the following values:
  - S8 when op = 0, size = 00
  - S16 when op = 0, size = 01
  - S32 when op = 0, size = 10
  - U8 when op = 1, size = 00
  - U16 when op = 1, size = 01
  - U32 when op = 1, size = 10
  - The following encodings are reserved:
    - op = 0, size = 11.
    - op = 1, size = 11.
- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.
- `<Qm>` Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>*2.

### Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  h = elements DIV 2;
  for r = 0 to regs-1
    for e = 0 to h-1
      op1 = Elem[D[m+r],2*e,esize];  op2 = Elem[D[m+r],2*e+1,esize];
      result = Int(op1, unsigned) + Int(op2, unsigned);
      Elem[D[d+r],e,2*esize] = result<2*esize-1:0>;
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.165  **VPMAX (floating-point)**

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

        op1 = Elem[D[m],2*e,esize]; op2 = Elem[D[m],2*e+1,esize];
        Elem[dest,e+h,esize] = if maximum then FPMax(op1,op2,StandardFPSCRValue()) else FPMin(op1,op2,StandardFPSCRValue());
    D[d] = dest;
```
F6.1.168  **VPMIN (integer)**

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

**Assembler symbols**

- `<c>`  
  For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.
  For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

- `<q>`  
  See *Standard assembler syntax fields on page F1-7228*.

- `<dt>`  
  Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
  
  - S8  
    when U = 0, size = 00
  
  - S16  
    when U = 0, size = 01
  
  - S32  
    when U = 0, size = 10
U8 when U = 1, size = 00
U16 when U = 1, size = 01
U32 when U = 1, size = 10

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;
    for e = 0 to h-1
        op1 = Int(Elem[D[n],2*e,esize], unsigned);
        op2 = Int(Elem[D[n],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e,esize] = result<esize-1:0>;
    op1 = Int(Elem[D[m],2*e,esize], unsigned);
    op2 = Int(Elem[D[m],2*e+1,esize], unsigned);
    result = if maximum then Max(op1,op2) else Min(op1,op2);
    Elem[dest,e+h,esize] = result<esize-1:0>;
    D[d] = dest;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.169 VPOP

Pop SIMD&FP registers from stack loads multiple consecutive Advanced SIMD and floating-point register file registers from the stack.

This instruction is an alias of the VLDM, VLMDB, VLMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VLDM, VLMDB, VLMIA.
- The description of VLDM, VLMDB, VLMIA gives the operational pseudocode for this instruction.

A1

\[

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.
T2

Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<sreglist> is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Operation for all encodings

The description of VLDM, VLDMDB, VLDMIA gives the operational pseudocode for this instruction.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.170 VPUSH

Push SIMD&FP registers to stack stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack.

This instruction is an alias of the VSTM, VSTMDB, VSTMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VSTM, VSTMDB, VSTMIA.
- The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.

VPUSH{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.
### Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

### Assembler symbols

- `<c>` See [Standard assembler syntax fields on page F1-7228.](#)
- `<q>` See [Standard assembler syntax fields on page F1-7228.](#)
- `<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
- `<sreglist>` Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
- `<dreglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

### Operation for all encodings

The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.

### Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.171  **VQABS**

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

**Notes for all encodings**

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

**Assembler symbols**

- **<c>** For encoding A1 and A2: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
  
  For encoding T1 and T2: see Standard assembler syntax fields on page F1-7228.

- **<q>** See Standard assembler syntax fields on page F1-7228.

- **<dt>** Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

  - S16 when size = 01
S32 when size = 10

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.

<index>
Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

        if sat1 || sat2 then FPSCR.QC = '1';
F6.1.174  VQDMLSL

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see Advanced SIMD scalars on page F1-7254.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    integer op2;
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat) = SignedSatQ(2*op1*op2, 2*esize);
        Elem[Q[d>>1],e,2*esize] = product;
        if sat then FPSCR.QC = '1';
```
**F6.1.177 VQMOVN, VQMOVUN**

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instructions VQRSHRN (zero), VQRSHRUN (zero), VQSHRN (zero), and VQSHRUN (zero). The pseudo-instruction is never the preferred disassembly.

```

**Signed result variant**

Applies when $op == 1x$.

\[
\text{VQMOVN}\{<c>\}\{<q>\}.<dt> <Dd>, <Qm>
\]
Unsigned result variant

Applies when op == 01.

VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>  

Decode for all variants of this encoding

if op == '00' then SEE "VMOVN";
if size == '11' || Vm<0> == '1' then UNDEFINED;
src_unsigned = (op == '11');  dest_unsigned = (op<0> == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);

Assembler symbols

<c>  For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q>  See Standard assembler syntax fields on page F1-7228.

<dt>  For the signed result variant: is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:
S16  when op<0> = 0, size = 00
S32  when op<0> = 0, size = 01
S64  when op<0> = 0, size = 10
U16  when op<0> = 1, size = 00
U32  when op<0> = 1, size = 01
U64  when op<0> = 1, size = 10
The following encodings are reserved:
  •  op<0> = 0, size = 11.
  •  op<0> = 1, size = 11.

For the unsigned result variant: is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
S16  when size = 00
S32  when size = 01
S64  when size = 10
The encoding size = 11 is reserved.

<Dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm>  Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    operand = Int(Elem[Qm][m+1],e,2*esize], src_unsigned);
    boolean sat;
    (Elem[D:d][e,esize], sat) = SatQ(operand, esize, dest_unsigned);
    if sat then FPSCR.QC = '1';
F6.1.178  **VQNEG**

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector. If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

Assembler symbols

<>  For encoding A1 and A2: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1 and T2: see Standard assembler syntax fields on page F1-7228.
<q>  See Standard assembler syntax fields on page F1-7228.
<dt>  Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
S16  when size = 01
S32  when size = 10
<Qd>  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>  Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>  Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>  Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm[x]>  Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>"", and x is encoded in "M:Vm<3>". If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".
<Dm>  Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  round_const = 1 << (esize-1);
  integer op2;
  if scalar_form then op2 = SInt(Elem[D[m],index,esize]);

    for e = 0 to elements-1
      op1 = SInt(Elem[D[m+r],e,esize]);
      if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
      (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
Elem[D+d+r],e,esize = result;
if sat then FPSCR.QC = '1';
F6.1.182 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see VQSHL (register).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPRTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

### Assembler symbols

- `<c>` For encoding A1: see [Standard assembler syntax fields on page F1-7228](#). This encoding must be unconditional.
  
  For encoding T1: see [Standard assembler syntax fields on page F1-7228](#).

- `<q>` See [Standard assembler syntax fields on page F1-7228](#).

- `<dt>` Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:

  - S16 when op<0> = 0, size = 00
  - S32 when op<0> = 0, size = 01
  - S64 when op<0> = 0, size = 10
  - U16 when op<0> = 1, size = 00
U32 when op<0> = 1, size = 01
U64 when op<0> = 1, size = 10

The following encodings are reserved:
• op<0> = 0, size = 11.
• op<0> = 1, size = 11.

<d> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.
F6.1.184  \textbf{VQRSHRN, VQRSHRUN}

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see \texttt{VQSHL} (register).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, \texttt{FPSCR.QC}, is set if saturation occurs. For details see \texttt{Pseudocode description of saturation} on page \texttt{E1-7131}.

Depending on settings in the \texttt{CPACR}, \texttt{NSACR}, and \texttt{HCPTR} registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see \textit{Enabling Advanced SIMD and floating-point support} on page \texttt{G1-8996}.

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.
<t>
See *Standard assembler syntax fields* on page F1-7228.
</t>

<type>
Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>when U = 0</td>
</tr>
<tr>
<td>U</td>
<td>when U = 1</td>
</tr>
</tbody>
</table>
</type>

<size>
Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>when L = 0, imm6&lt;5:3&gt; = 001</td>
</tr>
<tr>
<td>16</td>
<td>when L = 0, imm6&lt;5:3&gt; = 01x</td>
</tr>
<tr>
<td>32</td>
<td>when L = 0, imm6&lt;5:3&gt; = 1xx</td>
</tr>
<tr>
<td>64</td>
<td>when L = 1, imm6&lt;5:3&gt; = xxx</td>
</tr>
</tbody>
</table>
</size>

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm>
Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r],e,esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```

F6.1.187 **VQSHL (register)**

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see **VQRSHL**.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

{<dt>}

Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:

S16  when op<0> = 0, size = 00
S32  when op<0> = 0, size = 01
S64  when op<0> = 0, size = 10
U16  when op<0> = 1, size = 00
U32 when op<0> = 1, size = 01
U64 when op<0> = 1, size = 10

The following encodings are reserved:
• op<0> = 0, size = 11.
• op<0> = 1, size = 11.

<Ωd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Ωm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Ωm>*2.

**Operation for all encodings**

The description of *VQMOVN, VQMOVUN* gives the operational pseudocode for this instruction.
F6.1.189  VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see VQRSHRN, VQRSHRUN.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-7131.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

F6.1.192 VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see VADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Notes for all encodings**

Related encodings: See Advanced SIMD data-processing on page F3-7314 for the T32 instruction set, or Advanced SIMD data-processing on page F4-7422 for the A32 instruction set.

**Assembler symbols**

For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.
<q>
See Standard assembler syntax fields on page F1-7228.
</q>

<dt>
Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

- I16 when size = 00
- I32 when size = 01
- I64 when size = 10

<dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<q>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
</q>

<q>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
</q>

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  round_const = 1 << (esize-1);
  for e = 0 to elements-1
    result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
    Elem[D[d],e,esize] = result<2*esize-1:esize>;

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.193 VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal square root estimate and step on page E1-7156.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<dt> Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
    U32 when F = 0, size = 10
    F16 when F = 1, size = 01
    F32 when F = 1, size = 10

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see Floating-point reciprocal estimate and step on page E1-7155.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        Elem[D[d+r],e,esize] = FPRecipEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = UnsignedRecipEstimate(Elem[D[m+r],e,esize]);
F6.1.194   VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-7155.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.197  VREV64

Vector Reverse in doublewords reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

The following figure shows the operation of VREV64 doubleword operations.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Assembler symbols

- `<c>`
  - For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.
  - For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

- `<q>`
  - See *Standard assembler syntax fields on page F1-7228*.

- `<dt>`
  - Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
    - 8 when $size = 00$
    - 16 when $size = 01$
    - 32 when $size = 10$
  - The encoding $size = 11$ is reserved.

- `<Qd>`
  - Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $<Qd>*2$.

- `<Qm>`
  - Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as $<Qm>*2$.

- `<Dd>`
  - Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>`
  - Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
Operation for all encodings

        element = element + 1;
        rev_element = rev_element - 1;
      D[d+r] = result;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.198   VRHADD

Vector Rounding Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The results of the halving operations are rounded. For truncated results, see VHADD.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

if InITBlock() then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<q> See Standard assembler syntax fields on page F1-7228.
<dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
    F16 when size = 01
    F32 when size = 10
<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.
<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.
<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[D[m+r],e,esize];
        result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
        Elem[D[d+r],e,esize] = result;
F6.1.209  VRINTX (floating-point)

Round floating-point to integer inexact rounds a floating-point value to an integral floating-point value of the same size, using the rounding mode specified in the FPSCR, and raises an Inexact exception when the result value is not numerically equal to the input value. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

  when 64
    D[d] = FPRoundInt(D[m], FPSCR[], rounding, exact);
F6.1.212   VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

    Elem[D[d+r], e, esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.213 VRSHR

Vector Rounding Shift Right takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see VSHR.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.214  VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another. This instruction is a pseudo-instruction of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

### 64-bit SIMD vector variant

Applies when \( Q = 0 \).

\[
\text{VRSHR}\{<c>\}{<q>}.<dt> <Dd>, <Dm>, #0
\]

is equivalent to

\[
\text{VORR}\{<c>\}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>
\]

and is never the preferred disassembly.

### 128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VRSHR}\{<c>\}{<q>}.<dt> <Qd>, <Qm>, #0
\]

is equivalent to

\[
\text{VORR}\{<c>\}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>
\]

and is never the preferred disassembly.

### T1

VRSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to
VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>` For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.
  
  For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

- `<q>` See *Standard assembler syntax fields on page F1-7228*.

- `<dt>` Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>]*2.

- `<Qm>` Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as `<Qm>]*2.

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>` Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.215  VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see VSHRN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

A1 variant

Applies when \text{imm6} \neq 000xxx.

\text{VRSHRN}\langle c\rangle\langle q\rangle.I\langle \text{size}\rangle \langle Dd\rangle, \langle Qm\rangle, \#\langle \text{imm}\rangle

Decode for this encoding

\begin{verbatim}

\end{verbatim}
when '1xxxx' esize = 32; elements = 2; shift_amount = 64 - UInt(imm6);
  d = UInt(D:Vd);  m = UInt(M:Vm);

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<> See Standard assembler syntax fields on page F1-7228.

<size> Is the data size for the elements of the vectors, encoded in the "imm6<5:3>" field. It can have the following values:
  16  when imm6<5:3> = 001
  32  when imm6<5:3> = 01x
  64  when imm6<5:3> = 1xx

<DD> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  round_const = 1 << (shift_amount-1);
  for e = 0 to elements-1
    result = LSR(ElemQin[m>>1],e,esize) + round_const, shift_amount);
    ElemD[d],e,esize] = result<esize-1:0>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.216 VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector.

This instruction is a pseudo-instruction of the VMOVN instruction. This means that:

- The encodings in this description are named to match the encodings of VMOVN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VMOVN gives the operational pseudocode for this instruction.

**A1**

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

**T1**

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional. For encoding T1: see Standard assembler syntax fields on page F1-7228.
- `<q>`: See Standard assembler syntax fields on page F1-7228.
- `<dt>`: Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
  - I16 when size = 00
  - I32 when size = 01
  - I64 when size = 10
  - The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of **VMOVN** gives the operational pseudocode for this instruction.
VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-7155.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**64-bit SIMD vector variant**

Applies when Q == 0.

VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>

**128-bit SIMD vector variant**

Applies when Q == 1.

VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>

**Decode for all variants of this encoding**

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && (!HaveFP16Ext() || F == '0')) || size IN {'00', '11'} then UNDEFINED;
floating_point = (F == '1');
integer esize;
integer elements;
\[ \text{case size of } \]
\[ \text{when '01' esize = 16; elements = 4;} \]
\[ \text{when '10' esize = 32; elements = 2;} \]
d = UInt(D:Vd); m = UInt(M:Vm); \[ \text{regs = if Q == '0' then 1 else 2;} \]

**64-bit SIMD vector variant**

Applies when Q == 0.

VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>

**128-bit SIMD vector variant**

Applies when Q == 1.

VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>
Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' || (HaveFP16Ext() || F == '0')) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
floating_point = (F == '1');
integer esize;
integer elements;
case size of
  when '01' esize = 16; elements = 4;
  when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<*> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
   For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.
<dt> Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
   U32 when F = 0, size = 10
   F16 when F = 1, size = 01
   F32 when F = 1, size = 10
<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see Floating-point reciprocal estimate and step on page E1-7155.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        Elem[D[d+r],e,esize] = FPRSqrtEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);

F6.1.218  VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-7155.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

            Elem[D+d+r],e,esize] = Elem[D+d+r],e,esize] + result;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.220  VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see VSUBHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

<qt> See Standard assembler syntax fields on page F1-7228.
<qt> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>.*2.
<qt> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>.*2.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  round_const = 1 << (esize-1);
  for e = 0 to elements-1
    result = (Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize]) + round_const;
    Elem[D[d],e,esize] = result<2*esize-1:esize>;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.221   VSDOT (by element)

Dot Product index form with signed integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note ---

ID_ISAR6.DP indicates whether this instruction is supported.

64-bit SIMD vector variant

Applies when Q == 0.

VSDOT{<q>}.S8 <Dd>, <Dn>, <Dm>[<index>]

128-bit SIMD vector variant

  when 64
    D[d] = if ConditionHolds(cond) then D[n] else D[m];
F6.1.224  VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
    For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
    8  when L = 0, imm6<5:3> = 001
    16 when L = 0, imm6<5:3> = 01x
    32 when L = 0, imm6<5:3> = 1xx
    64 when L = 1, imm6<5:3> = xxx

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.225 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of
the corresponding element of a second vector, and places the results in the destination vector. If the shift value is
positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see VRSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTER registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Assembler symbols**

\(<c>\) For encoding A1: see *Standard assembler syntax fields on page F1-7228*. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields on page F1-7228*.
\(<q>\) See *Standard assembler syntax fields on page F1-7228*.
\(<dt>\) Is the data type for the elements of the vectors, encoded in the "U:size" field. It can have the following values:
- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- S64 when U = 0, size = 11
- U8 when U = 1, size = 00
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10
- U64 when U = 1, size = 11

\(<Qd>\) Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<Qd>\)*2.
\(<Qm>\) Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<Qm>\)*2.
\(<Qn>\) Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<Qn>\)*2.
\(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
\(<Dm>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
\(<Dn>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      shift = SInt(Elem[D[n+r],e,esize]<7:0>);  
      if shift >= 0 then
        result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
      else
        result = Int(Elem[D[m+r],e,esize], unsigned) >> -shift;
      Elem[D[d+r],e,esize] = result<esize-1:0>;
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.226  VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.228 VSHR (zero)

Vector Shift Right copies the contents of one SIMD register to another

This instruction is a pseudo-instruction of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

A1

**64-bit SIMD vector variant**

Applies when Q == 0.

VSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

**128-bit SIMD vector variant**

Applies when Q == 1.

VSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

T1

**64-bit SIMD vector variant**

Applies when Q == 0.

VSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

**128-bit SIMD vector variant**

Applies when Q == 1.
VSHR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

**Assembler symbols**

<<c>> For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

<<q>> See Standard assembler syntax fields on page F1-7228.

<<dt>> Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

<<Qd>> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<<Qm>> Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as <Qm>*2.

<<Dd>> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<<Dm>> Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.229  **VSHRN**

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see VRSHRN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:

- I16 when size = 00
- I32 when size = 01
- I64 when size = 10

The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of VMOVN gives the operational pseudocode for this instruction.
F6.1.231 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTCR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

<>  For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
    For encoding T1: see Standard assembler syntax fields on page F1-7228.
<q>  See Standard assembler syntax fields on page F1-7228.
<size>  Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
    8  when L = 0, imm6<5:3> = 001
    16 when L = 0, imm6<5:3> = 01x
    32 when L = 0, imm6<5:3> = 1xx
    64 when L = 1, imm6<5:3> = xxx
<Qd>  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>  Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>  Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>  Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  mask = LSL(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
      Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.232 VSMMLA

The widening integer matrix multiply-accumulate instruction multiplies the 2x8 matrix of signed 8-bit integer values held in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator held in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an optional instruction. ID_ISAR6.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-7322 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-7430 for the A32 instruction set.

Assembler symbols

- `<c>`: For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
  
  For encoding T1: see Standard assembler syntax fields on page F1-7228.

- `<q>`: See Standard assembler syntax fields on page F1-7228.

- `<type>`: Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:
  
  - S when U = 0
  - U when U = 1

- `<size>`: Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
  
  - 8 when L = 0, imm6<5:3> = 001
  - 16 when L = 0, imm6<5:3> = 01x
  - 32 when L = 0, imm6<5:3> = 1xx
  - 64 when L = 1, imm6<5:3> = xxx

- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>"*2.

- `<Qm>`: Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>"*2.

- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>`: Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

- `<imm>`: Is an immediate value, in the range 1 to `<size>`, encoded in the "imm6" field as `<size> - <imm>".
Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
      Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
Vector Shift Right and Insert takes each element in the operand vector, right shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the right of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.
<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.
<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<img> Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <img>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  mask = LSR(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSR(Elem[D[m+r],e,esize], shift_amount);
      Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.236 VST1 (single element from one lane)

Store single element from one lane of one register stores one element to memory from one element of a register. For
details of the addressing mode, see *The Advanced SIMD addressing mode on page F1-7249.*

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which
the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information, see *Enabling Advanced SIMD and floating-point support on page G1-8996.*

if n == 15 then UNPREDICTABLE;

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

\(<c>\)

For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

\(<q>\)

See Standard assembler syntax fields on page F1-7228.

\(<size>\)

Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

\(<list>\)

Is a list containing the single 64-bit name of the SIMD&FP register holding the element.

The list must be \{<Dd>[<index>]\}.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

- <size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page F2-7193, and the encoding depends on <size>:
<size> == 8Encoded in the "index_align<0>" field as 0.
<size> == 16Encoded in the "index_align<1:0>" field as 0b00.
<size> == 32Encoded in the "index_align<2:0>" field as 0b000.
Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 16<align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
<size> == 32<align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b11.
: is the preferred separator before the <align> value, but the alignment can be specified as 0<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  MemU[address,ebytes] = Elem[D[d],index];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + ebytes;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.237  VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode, see *The Advanced SIMD addressing mode* on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

\end{align*}
\]

CONSTRANGED UNPREDICTABLE behavior
If \( d+\text{regs} > 32 \), then one of the following behaviors must occur:
\begin{itemize}
  \item The instruction is UNDEFINED.
  \item The instruction executes as NOP.
  \item The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.
\end{itemize}

Notes for all encodings
For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VST1 (multiple single elements) on page K1-11579.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.

Assembler symbols
\[
\begin{align*}
<\text{c}> & \quad \text{For encoding A1, A2, A3 and A4: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.} \\
& \quad \text{For encoding T1, T2, T3 and T4: see Standard assembler syntax fields on page F1-7228.} \\
<\text{q}> & \quad \text{See Standard assembler syntax fields on page F1-7228.}
\end{align*}
\]
<size> Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10
64 when size = 11

=list> Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:
{ <Dd> } Single register. Selects the A1 and T1 encodings of the instruction.
{ <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.
The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "align" field as 0000.
Whenever <align> is present, the permitted values are:
64 64-bit alignment, encoded in the "align" field as 0b01.
128 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
For more information about <Rn>, !, and <Rm>, see The Advanced SIMD addressing mode on page F1-7249.

    if register_index then
        R[n] = R[n] + R[m];
    else
        R[n] = R[n] + 8*regs;
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.238  VST2 (single 2-element structure from one lane)

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

Notes for all encodings
For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VST2 (single 2-element structure from one lane) on page K1-11580.

Assembler symbols

<<> For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<size> Is the data size, encoded in the "size" field. It can have the following values:

8 when size = 00
16 when size = 01
32 when size = 10

<list> Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.
The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>] } Single-spaced registers, encoded as "spacing" = 0.
{<Dd>[<index>], <Dd+2>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:
<size> == 16"spacing" is encoded in the "index_align<1>" field.
<size> == 32"spacing" is encoded in the "index_align<2>" field.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
<size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and the encoding depends on <size>:
<size> == 8Encoded in the "index_align<0>" field as 0.
<size> == 16Encoded in the "index_align<0>" field as 0.
<size> == 32Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 8<align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 16<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 32<align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.239 VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see Element and structure load/store instructions on page F2-7278. Every element of each register is saved. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*, and particularly VST2 (multiple 2-element structures) on page K1-11579.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.

**Assembler symbols**

<\c> For encoding A1 and A2: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields* on page F1-7228.

<\q> See *Standard assembler syntax fields* on page F1-7228.

<size> Is the data size, encoded in the "size" field. It can have the following values:

- 8 when \( size = 00 \)
- 16 when \( size = 01 \)
- 32 when \( size = 10 \)

The encoding \( size = 11 \) is reserved.

<\list> Is a list containing the 64-bit names of the SIMD\&FP registers.

The list must be one of:

- \{ \langle Dd\rangle, \langle Dd+1\rangle \} Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1000.
- \{ \langle Dd\rangle, \langle Dd+2\rangle \} Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1001.
- \{ \langle Dd\rangle, \langle Dd+1\rangle, \langle Dd+2\rangle, \langle Dd+3\rangle \} Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register \langle Dd\rangle is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access on page E2-7193*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

- 64 64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10.
256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as 0<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to pairs-1
        for e = 0 to elements-1
            MemU[address, ebytes] = Elem[D[d+r], e];
            MemU[address+ebytes, ebytes] = Elem[D[d2+r], e];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*pairs;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.240  VST3 (single 3-element structure from one lane)

Store single 3-element structure from one lane of three registers stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors*, and particularly VST3 (single 3-element structure from one lane) on page K1-11580.

**Assembler symbols**

- `<<>>` For encoding A1, A2 and A3: see *Standard assembler syntax fields* on page F1-7228. This encoding must be unconditional.
  
  For encoding T1, T2 and T3: see *Standard assembler syntax fields* on page F1-7228.

- `<<>>` See *Standard assembler syntax fields* on page F1-7228.

- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>when size = 00</td>
</tr>
<tr>
<td>16</td>
<td>when size = 01</td>
</tr>
<tr>
<td>32</td>
<td>when size = 10</td>
</tr>
</tbody>
</table>

- `<list>` Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.
  The list must be one of:
  
  `{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as "spacing" = 0.`
\{<Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>]\} Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:
- <size> == 8"spacing" is encoded in the "index_align<0>" field.
- <size> == 16"spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.
- <size> == 32"spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:
- <size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Alignment

Standard alignment rules apply, see Alignment support on page B2-189.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    MemU[address, ebytes] = Elem[D[d], index];

            R[n] = R[n] + 3*ebytes;
    else
        R[n] = R[n] + 3*ebytes;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.241  VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see Element and structure load/store instructions on page F2-7278. Every element of each register is saved. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

A1

\[
\begin{array}{ccccccccccccccccccc}
\text{it} & 31 & 30 & 29 & 28 & 27 & 26 & 25 & 24 & 23 & 22 & 21 & 20 & 19 & 16 & 15 & 12 & 11 & 8 & 7 & 6 & 5 & 4 & 3 & 0 \\
1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & D & 0 & 0 & Rn & Vd & 0 & 1 & 0 & x & size & align & Rm
\end{array}
\]

**Offset variant**

Applies when \( Rm = 1111 \).

\[
\text{VST3}\{<c>\}{<q>}.<size> <list>, [<Rn>{:<align}>}
\]

**Post-indexed variant**

Applies when \( Rm = 1101 \).

\[
\text{VST3}\{<c>\}{<q>}.<size> <list>, [<Rn>{:<align}>]}!
\]

**Post-indexed variant**

Applies when \( Rm \neq 11x1 \).

\[
\text{VST3}\{<c>\}{<q>}.<size> <list>, [<Rn>{:<align}>}], <Rm>
\]

**Decode for all variants of this encoding**

\[
\text{if size} = \text{'11' || align}<1> = '1' \text{ then UNDEFINED; integer inc; case itype of when '0100' inc = 1; when '0101' inc = 2; otherwise SEE "Related encodings"; alignment = if align}<0> = '0' \text{ then 1 else 8; ebytes = 1 << UInt(size); elements = 8 DIV ebytes; d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm); wback = (m != 15); register_index = (m != 15 && m != 13); if n == 15 || d3 > 31 then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( d3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.
### Offset variant

Applies when $Rm = 1111$.

$$VST3\{<c>\}{<q>}.<size>\ <list>,\ [<Rn}\{:<align}\]$$

### Post-indexed variant

Applies when $Rm = 1101$.

### Post-indexed variant

Applies when $Rm != 11x1$.

$$VST3\{<c>\}{<q>}.<size>\ <list>,\ [<Rn}\{:<align}\],\ <Rm>$$

#### Decode for all variants of this encoding

```plaintext
if size == '11' || align<1> == '1' then UNDEFINED;
integer inc;
case itype of
  when '0100'
    inc = 1;
  when '0101'
    inc = 2;
  otherwise
    SEE "Related encodings";
alignment = if align<0> == '0' then 1 else 8;
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If $d3 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly $VST3$ (multiple 3-element structures) on page K1-11580.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<size>
Is the data size, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Size Value</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>size = 00</td>
</tr>
<tr>
<td>16</td>
<td>size = 01</td>
</tr>
<tr>
<td>32</td>
<td>size = 10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

<list>
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

- \{ <Dd>, <Dd+1>, <Dd+2> \} Single-spaced registers, encoded in the "itype" field as 0b0100.
- \{ <Dd>, <Dd+2>, <Dd+4> \} Double-spaced registers, encoded in the "itype" field as 0b0101.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2], e];
        MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.242 VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VST4 (single 4-element structure from one lane) on page K1-11580.
Assembler symbols

<<c>>

For encoding A1, A2 and A3: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

<<p>>

See Standard assembler syntax fields on page F1-7228.

<<size>>

Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

<<list>>

Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of:

- \{<Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>]\} Single-spaced registers, encoded as "spacing" = 0.
- \{<Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>]\} Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

- <size> == 16"spacing" is encoded in the "index_align<1>" field.
- <size> == 32"spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

- <size> == 8<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn>>

Is the general-purpose base register, encoded in the "Rn" field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and the encoding depends on <size>:

- <size> == 8Encoded in the "index_align<0>" field as 0.
- <size> == 16Encoded in the "index_align<0>" field as 0.
- <size> == 32Encoded in the "index_align<1:0>" field as 00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16<align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32<align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>>

Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,         ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2],index];
    MemU[address+2*ebytes,ebytes] = Elem[D[d3],index];
    MemU[address+3*ebytes,ebytes] = Elem[D[d4],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.243 VST4 (multiple 4-element structures)

Store multiple 4-element structures from four registers to memory from four registers, with interleaving. For more information, see Element and structure load/store instructions on page F2-7278. Every element of each register is saved. For details of the addressing mode, see The Advanced SIMD addressing mode on page F1-7249.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

\[
\text{VST4}\{<c>\}{<q>}.<size> \text{ <list>}, \[<Rn>\{:<align>\}]!
\]

Post-indexed variant
Applies when \( Rm \neq 111x \).
\[
\text{VST4}\{<c>\}{<q>}.<size> \text{ <list>}, \[<Rn>\{:<align>\}], <Rm>
\]

Decode for all variants of this encoding
\[
\text{if size == '11' then UNDEFINED;}
\text{integer inc;}
\text{case itype of}
\quad \text{when '0000', inc = 1;}
\quad \text{when '0001', inc = 2;}
\quad \text{otherwise}
\quad \text{SEE "Related encodings";}
\text{alignment = if align == '00' then 1 else 4 << UInt(align);}
\text{ebytes = 1 << UInt(size); elements = 8 DIV ebytes;}
\text{d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);}
\text{wback = (m != 15); register_index = (m != 15 && m != 13);}
\text{if n == 15 || d4 > 31 then UNPREDICTABLE;}
\]

CONstrained UNPREDICTABLE behavior
If \( d4 > 31 \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings
For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly VST4 (multiple 4-element structures) on page K1-11580.

Related encodings: See Advanced SIMD element or structure load/store on page F3-7350 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-7434 for the A32 instruction set.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<size>
Is the data size, encoded in the "size" field. It can have the following values:
- 8 when size = 00
- 16 when size = 01
- 32 when size = 10
The encoding size = 11 is reserved.

<list>
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:
- \{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> \} Single-spaced registers, encoded in the "itype" field as 0b0000.
- \{ <Dd>, <Dd+2>, <Dd+4>, <Dd+6> \} Double-spaced registers, encoded in the "itype" field as 0b0001.
The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-7193, and is encoded in the "align" field as 0000.
Whenever <align> is present, the permitted values are:
- 64 64-bit alignment, encoded in the "align" field as 0b01.
- 128 128-bit alignment, encoded in the "align" field as 0b10.
- 256 256-bit alignment, encoded in the "align" field as 0b11.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F1-7249.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F1-7249.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Mem[address, ebytes] = Elem[D[d], e];
        Mem[address+ebytes, ebytes] = Elem[D[d2], e];
        Mem[address+2*ebytes, ebytes] = Elem[D[d3], e];
        Mem[address+3*ebytes, ebytes] = Elem[D[d4], e];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F6.1.244  VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, HCPR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the alias VPUSH. See Alias conditions on page F6-8845 for details of when each alias is preferred.

Assembler symbols

<-> See Standard assembler syntax fields on page F1-7228.
<#> See Standard assembler syntax fields on page F1-7228.
<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
<Rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, Arm deprecates use of the PC.
! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<reglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r]; address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian(AccType_ATOMIC) then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian(AccType_ATOMIC) then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### F6.1.245 VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

<dt>
  Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following
  values:
  I8  when size = 00
  I16 when size = 01
  I32 when size = 10
  I64 when size = 11

<Qd>
  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
  Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
  Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as
  <Qm>*2.

<Dd>
  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
  Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
  Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[r]+d, e, esize] = Elem[D[r]+n, e, esize] - Elem[D[r]+m, e, esize];

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.248  VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see VRSUBHN.

There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

Assembler symbols

<>  For encoding A1: see Standard assembler syntax fields on page F1-7228. This encoding must be unconditional.
   For encoding T1: see Standard assembler syntax fields on page F1-7228.
See *Standard assembler syntax fields* on page F1-7228.

Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

- **I16** when size = 00
- **I32** when size = 01
- **I64** when size = 10

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<Qn>\)*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<Qm>\)*2.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Vector Subtract Long subtracts the elements of one doubleword vector from the corresponding elements of another doubleword vector, and places the results in a quadword vector. Before subtracting, it sign-extends or zero-extends the elements of both operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.251 VSUDOT (by element)

Dot Product index form with signed and unsigned integers. This instruction performs the dot product of the four signed 8-bit integer values in each 32-bit element of the first source register with the four unsigned 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2, this is an OPTIONAL instruction. ID_ISAR6.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

\[\text{else}\]
\[D[d+r] = \text{Din}[m+r];\]
\[D[m+r] = \text{Din}[d+r];\]

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F6.1.253 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the CPACR, NSACR, and HCPtr registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

| 31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 12|11 10 9 8 7 6 5 4 3 0 |
| 1 1 1 0 1 1 1 | D | 1 1 | Vn | Vd | 1 0 | len | N | op | M | 0 | Vm |

VTBL variant

Applies when op == 0.

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

VTBX variant

Applies when op == 1.

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Decode for all variants of this encoding

is_vtbl = (op == '0'); length = UInt(len)+1;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

T1

| 15 14 13 12|11 10 9 8 7 6 5 4 3 0 | 15 12|11 10 9 8 7 6 5 4 3 0 |
| 1 1 1 1 1 1 1 | D | 1 1 | Vn | Vd | 1 0 | len | N | op | M | 0 | Vm |

VTBL variant

Applies when op == 0.

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>
VTBX variant
Applies when op == 1.

```
VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>
```

Decode for all variants of this encoding

```
is_vtbl = (op == '0');  length = UInt(len)+1;

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);

if n+length > 32 then UNPREDICTABLE;
```

CONSTRANDED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

\]

**Operational information**

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VTRN doubleword operations.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

This instruction is used by the pseudo-instructions VUZP (alias) and VZIP (alias). The pseudo-instruction is never the preferred disassembly.

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.255   VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-8996.

    — The values of the data supplied in any of its registers.
    — The values of the NZCV flags.
F6.1.256  VUDOT (by element)

Dot Product index form with unsigned integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note  ---
ID_ISAR6.DP indicates whether this instruction is supported.

**F6.1.257  VUDOT (vector)**

Dot Product vector form with unsigned integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of the corresponding 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- Note ---

ID_ISAR6.DP indicates whether this instruction is supported.

F6.1.258   VUMMLA

The widening integer matrix multiply-accumulate instruction multiplies the 2x8 matrix of unsigned 8-bit integer values held in the first source vector by the 8x2 matrix of unsigned 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator held in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an optional instruction. ID_ISAR6.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

F6.1.262  **VUZP**

Vector Unzip de-interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VUZP doubleword operation for data type 8.

**VUZP.8, doubleword**

<table>
<thead>
<tr>
<th>Register state before operation</th>
<th>Register state after operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dd A7 A6 A5 A4 A3 A2 A1 A0</td>
<td>Dm B7 B6 B5 B4 B3 B2 B1 B0</td>
</tr>
</tbody>
</table>

The following figure shows the operation of VUZP quadword operation for data type 32.

**VUZP.32, quadword**

<table>
<thead>
<tr>
<th>Register state before operation</th>
<th>Register state after operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qd A3 A2 A1 A0</td>
<td>Qm B3 B2 B1 B0</td>
</tr>
</tbody>
</table>

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-8996.

        for e = 0 to (64 DIV esize) - 1

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F6.1.263 VUZP (alias)

Vector Unzip de-interleaves the elements of two vectors

This instruction is a pseudo-instruction of the VTRN instruction. This means that:

- The encodings in this description are named to match the encodings of VTRN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VTRN gives the operational pseudocode for this instruction.

F6.1 Alphabetical list of Advanced SIMD and floating-point instructions
Part G
The AArch32 System Level Architecture
Chapter G1
The AArch32 System Level Programmers’ Model

This chapter gives a system level description of the programmers’ model for execution in AArch32 state. It contains the following sections:

- About the AArch32 System level programmers’ model on page G1-8898.
- Exception levels on page G1-8899.
- Exception terminology on page G1-8900.
- Execution state on page G1-8902.
- Instruction Set state on page G1-8904.
- Security state on page G1-8905.
- Security state, Exception levels, and AArch32 execution privilege on page G1-8908.
- Virtualization on page G1-8910.
- AArch32 state PE modes, and general-purpose and Special-purpose registers on page G1-8912.
- Process state, PSTATE on page G1-8921.
- Instruction set states on page G1-8927.
- Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.
- Routing of aborts taken to AArch32 state on page G1-8948.
- Exception return to an Exception level using AArch32 on page G1-8951.
- Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-8956.
- AArch32 state exception descriptions on page G1-8964.
- Reset into AArch32 state on page G1-8986.
- Mechanisms for entering a low-power state on page G1-8988.
- The AArch32 System register interface on page G1-8993.
- Advanced SIMD and floating-point support on page G1-8996.
- Configurable instruction enables and disables, and trap controls on page G1-9001.
G1.1 About the AArch32 System level programmers’ model

An application programmer has only a restricted view of the system. The System level programmers’ model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers’ model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers’ model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the Arm architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- Exception levels on page G1-8899.
- Exception terminology on page G1-8900.
- Execution state on page G1-8902.
- Instruction Set state on page G1-8904.
- Security state on page G1-8905.
- Virtualization on page G1-8910.

The rest of this chapter describes the system level programmers’ model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - Chapter G4 The AArch32 System Level Memory Model describes the general features of the Armv8 memory model, when executing in AArch32 state, that are not visible at the application level.
  - Note Chapter E2 The AArch32 Application Level Memory Model describes the application level view of the memory model.
  - Chapter G5 The AArch32 Virtual Memory System Architecture describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.

- The AArch32 System registers, see Chapter G8 AArch32 System Register Descriptions.
  - Note The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See, for example, ERET on page F5-7570.
G1.2 Exception levels

The architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

Effect of not implementing an Exception level on page D1-4633 provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within Security states. The Armv8-A security model on page G1-8905 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter G5 The AArch32 Virtual Memory System Architecture.

G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- **EL0** Applications.
- **EL1** OS kernel and associated functions that are typically described as privileged.
- **EL2** Hypervisor.
- **EL3** Secure monitor.
G1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

• Terminology for taking an exception.
• Terminology for returning from an exception.
• Exception levels.
• Definition of a precise exception.
• Definitions of synchronous and asynchronous exceptions on page G1-8901.

G1.3.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is taken from. The PE state immediately after taking the exception is the state that the exception is taken to.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state that the exception returns to.

G1.3.3 Exception levels

An Exception level, ELn, with a larger value of n than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of n than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

• Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
• Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

An exception is described as imprecise if it is not precise.

Other than the SError interrupt all exceptions that are taken to AArch32 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

The terms precise and imprecise can also apply to Debug entry state. See Imprecise entry to Debug state on page H2-10236.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

• The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
• The registers are not involved in the calculation of the memory address that is used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

Note

For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page E2-7165.
G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-8929.
G1.4 Execution state

The Execution states are:

- **AArch64**: The 64-bit Execution state.
- **AArch32**: The 32-bit Execution state.

*Execution state on page A1-39* gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

--- Note ---

- *Typical Exception level usage model on page G1-8899* shows which Exception levels different software layers might typically use.

- *Effect of not implementing an Exception level on page D1-4633* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-4684* describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in *AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-8917*.

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor,Abort, Undefined, IRQ, and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in *Security state on page G1-8905*.
- User mode. This mode always executes at EL0.

--- Note ---

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32 state.

---

For more information on modes, see *AArch32 state PE mode descriptions on page G1-8912*.

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2 and EL3.
Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the default mode for that exception.

In AArch32 state, a number of different modes can exist at the same Exception level. All modes at a particular Exception level have the same execution privilege, meaning they have the same access rights for accesses to memory and to System registers. However, the mapping of PE modes to Exception levels depends on the Security state, as described in Security state on page G1-8905. Security state, Exception levels, and AArch32 execution privilege on page G1-8908 gives more information about the PE modes, their associated execution privilege, and how this maps onto the Exception levels.
G1.5 Instruction Set state

In AArch32 state, the Instruction Set state determines the instruction set that the PE is executing. In an implementation that follows the Arm recommendations, the available Instruction Set states are:

- **T32 state** The PE is executing T32 instructions.
- **A32 state** The PE is executing A32 instructions.

--- Note ---

In previous versions of the Arm architecture:
- The T32 instruction set was called the Thumb instruction set.
- The A32 instruction set was called the ARM instruction set.

---

For more information, see Process state, PSTATE on page E1-7133.
G1.6 Security state

The architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see About VMSAv8-32 on page G5-9146.

G1.6.1 The Armv8-A security model

The principles of the Armv8-A security model are defined in Security state on page D1-4632.

The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and execution privilege.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same execution privilege.

In Secure state:
- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.

- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3.
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.

See Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64 on page G1-8941 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has the lowest possible execution privilege.

Hyp mode always executes in Non-secure state at EL2 and has higher execution privilege than all of:
- User mode.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode.
Limited use of Privilege level in AArch32 state on page G1-8909 describes how, in some contexts, the concept of Privilege levels can be used to represent the execution privilege hierarchy.

For more information about the modes, see About the AArch32 PE modes on page G1-8902.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

Figure G1-1 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

**Secure state**
- **EL0**: User mode.
- **EL3**: Any mode that is available in Secure state, other than User mode.

**Non-secure state**
- **EL0**: User mode.
- **EL1**: Any mode that is available in Non-secure state, other than Hyp mode and User mode.
- **EL2**: Hyp mode.

Execution at EL0 is described as unprivileged execution.

A mode associated with a particular Exception level, ELn, is described as an ELn mode.
The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

When EL3 is using AArch32, many AArch32 System registers accessible at PL1 are *banked* between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, System registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1-accessible System registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 System registers in an interprocessing environment, see *Mapping of the System registers between the Execution states* on page D1-4686.

For more information on the System registers, see *The AArch32 System register interface* on page G1-8993.

The *Secure Monitor Call (SMC)* instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see *Secure Monitor Call (SMC) exception* on page G1-8969 and *SMC* on page F5-7900.

Changing from Secure state to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the SCR.NS bit, when EL3 is using AArch32.
- By the SCR_EL3.NS bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to Non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while SCR.NS is 1.
- Using an MCR instruction that writes SCR.NS to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

Arm strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to Non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.
G1.7 Security state, Exception levels, and AArch32 execution privilege

The hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G1-1 on page G1-8908 shows this hierarchy for each Security state.

Table G1-1 Execution privilege and Exception levels, by Security state

<table>
<thead>
<tr>
<th>Execution privilege</th>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Typical use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>

</tr>
<tr>
<td>Lowest, Unprivileged</td>
<td>EL0</td>
<td>EL0</td>
<td>Secure or Non-secure application</td>
</tr>
</tbody>
</table>

a. EL3 is never implemented in Non-secure state.

b. If FEAT_SEL2 is implemented in AArch64 state, EL2 can be enabled in Secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current PE mode. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-8906 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-8915 shows this mapping when EL3 is using AArch64.

Table G1-2 on page G1-8908 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state if either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state if EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

Table G1-2 Mapping of AArch32 PE modes to Exception levels

<table>
<thead>
<tr>
<th>Exception level</th>
<th>PE modes in the given Security state, and EL3 Execution state</th>
<th>Secure state, EL3 using AArch32</th>
<th>Secure state, EL3 using AArch64a</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3</td>
<td>Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>

</tr>
<tr>
<td>EL0</td>
<td>User</td>
<td>User</td>
<td>User</td>
<td></td>
</tr>
</tbody>
</table>

a. If FEAT_SEL2 is implemented and enabled in AArch64 State, this column can be applied to EL2.

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.
G1.7.1  Limited use of Privilege level in AArch32 state

As described in The VMSAv8-32 translation regimes on page G5-9148, a translation regime maps a virtual address (VA) to the corresponding physical address (PA). The VMSAv8-64 translation regimes are defined by the Exception levels that use them. However, because the mapping between PE modes and Exception levels in Secure state depends on whether EL3 is using AArch32 or is using AArch64, as shown in Table G1-2 on page G1-8908, the VMSAv8-32 translation regimes cannot be described simply in terms of either the Exception levels or the PE modes that use them.

To provide a consistent description of address translation as seen from AArch32 state, the VMSAv8-32 translation regimes are described in terms of the Privilege levels originally defined in the Armv7 descriptions of AArch32 state. Table G1-3 on page G1-8909 shows how the PE modes map to these Privilege levels:

Table G1-3 Mapping of PE modes to AArch32 Privilege levels

<table>
<thead>
<tr>
<th>Privilege level</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL2</td>
<td>-</td>
<td>Hyp(^a)</td>
</tr>
<tr>
<td>PL1</td>
<td>Monitor(^b), System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>PL0</td>
<td>User</td>
<td>User</td>
</tr>
</tbody>
</table>

\(^a\) Implemented only in Non-secure state, and only if EL2 is using AArch32 state.

\(^b\) Implemented only in Secure state, and only if EL3 is using AArch32 state.

Comparing Table G1-3 on page G1-8909 with Table G1-2 on page G1-8908 shows that:

In Non-secure state

Each privilege level maps to the corresponding Exception level. For example, PL1 maps to EL1.

In Secure state

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

- **EL3 using AArch64**  Secure PL1 maps to Secure EL1. Monitor mode is not implemented.
- **EL3 using AArch32**  Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.
G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in Hyp mode when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the ERET instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an A-profile implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The architecture supports both of these models.

The hypervisor assigns a VMID to each virtual machine.

In AArch32 state, EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent translation regime for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the virtual address (VA) to an intermediate physical address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the physical address (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter G5 The AArch32 Virtual Memory System Architecture.

G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. EL2 configurable controls on page G1-9010, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.
Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See Virtual interrupts.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-8956.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information, see:
  - Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.
  - Routing debug exceptions to EL2 using AArch32 on page G1-8946.
  - Routing of aborts taken to AArch32 state on page G1-8948

- Provides mechanisms to trap PE operations to EL2. See EL2 configurable controls on page G1-9010.

When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

### Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table G1-4.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>External SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example G1-1 shows a usage model for virtual interrupts.

#### Example G1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information, see Virtual exceptions when an implementation includes EL2 on page G1-8956.
G1.9 AArch32 state PE modes, and general-purpose and Special-purpose registers

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- AArch32 state PE mode descriptions.
- AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-8917.
- Saved Program Status Registers (SPSRs) on page G1-8919.
- ELR_hyp on page G1-8920.

Note

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, which can be described as R15.

G1.9.1 AArch32 state PE mode descriptions

Table G1-5 on page G1-8912 shows the PE modes defined by the Arm architecture, for execution in AArch32 state. In this table:

- The PE mode column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-8917.
- The Encoding column gives the corresponding PSTATE.M field.
- The Exception level column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see Exception levels on page G1-8899.

^a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.
FEAT_SEL2 is not supported if EL2 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.

This section gives more information about each of the modes, when it is implemented.

User mode
Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:
- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.

System mode
System mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode
Supervisor mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing an SVC (Supervisor Call) instruction generates a Supervisor Call exception.
In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on reset.

Abort mode
Abort mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode
Undefined mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode
FIQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode
IRQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-8914.
IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode
Hyp mode is the Non-secure EL2 mode.
Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.
In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode when EL2 is using AArch32.

Executing an HVC (Hypervisor Call) instruction generates a Hypervisor Call exception. See Hypervisor Call (HVC) exception on page G1-8970.

For more information, see Hyp mode on page G1-8915.

Monitor mode

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the SCR.NS bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see PE mode for taking exceptions on page G1-8939.

When EL3 is using AArch32, software executing in Monitor mode:
• Has access to both the Secure and Non-secure copies of System registers.
• Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

Secure and Non-secure modes

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:
• If a PE is in Supervisor mode and Secure state, it is in Secure Supervisor mode.
• If a PE is in User mode and Non-secure state, it is in Non-secure User mode.

Note

As indicated in the appropriate Mode descriptions:
• Monitor mode is a Secure mode, meaning it is always in the Secure state.
• Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.

Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-8906 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 on page G1-8915 shows how the implemented modes change when EL3 is using AArch64.
Comparing Figure G1-1 on page G1-8906 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

**Non-secure state**

- If Non-secure EL1 is using AArch32, then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

**Secure state**

- The implementation of these modes depends on the Execution state that EL3 is using, as follows:
  - **EL3 using AArch64** If Secure EL1 is using AArch32, then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.
  - **EL3 using AArch32** In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-8906.

**Hyp mode**

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

---

**Note**

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the SCR_EL3.NS or SCR.NS bit set to 1.
This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see Figure G1-1 on page G1-8906.
- Hyp mode is accessible only in Non-secure state. In Secure state, an attempt by a CPS or an MSR instruction to change PSTATE.M to Hyp mode is an illegal change to PSTATE.M, as described in Illegal changes to PSTATE.M on page G1-8925.
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see ERET on page F5-7570.
- In Hyp mode, the CPACR has no effect on the execution of:
  - System register access instructions.
  - Advanced SIMD and floating-point instructions.
  - The HCPTR controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see SVC on page F5-8055.
- An exception return with restored PSTATE specifying Hyp mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-8952, if any of the following applies:
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - EL3 is using AArch32 and the value of SCR.NS is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - SRS. See SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-7936.
  - RFE. See RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-7830.
  - LDM (exception return) on page F5-7604.
  - LDM (User registers) on page F5-7606.
  - STM (User registers) on page F5-7976.
  - The SUBS PC, LR forms of the instructions described in SUB, SUBS (immediate) on page F5-8039.

  **Note**

  In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

  The exception return form of the instructions described in MOV, MOVS (register) on page F5-7719.

  In addition, deprecated forms of the A32 ADCS, ADDS, ANDS, BICS, EORS, MOVs, WNS, ORRS, RSBS, RCS, SBCS, and SUBS instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.

- The Load unprivileged and Store unprivileged instructions LDRT, LDRSH, LDRHT, LDRBT, STRT, STRHT, and STRBT, are CONSTRAINED UNPREDICTABLE if executed in Hyp mode.

To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the SCR_EL3.HCE bit to 1, if EL3 is using AArch64.
- By setting the SCR.HCE bit to 1, if EL3 is using AArch32.

If EL3 is implemented and using AArch32, and SCR.HCE is set to 0, the HVC instruction is UNPREDICTABLE in Hyp mode. The instruction is either UNDEFINED or executes as a NOP.
If EL3 is implemented and using AArch64, and SCR_EL3.HCE is set to 0, the HVC instruction is UNDEFINED in Hyp mode.

If EL3 is not implemented and HCR.HCD is set to 1, the HVC instruction is UNDEFINED in Hyp mode.

**Pseudocode description of mode operations**

The `BadMode()` function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The `BadMode()` function is defined in Chapter J1 *Armv8 Pseudocode*.

**G1.9.2 AArch32 general-purpose registers, the PC, and the Special-purpose registers**

The general-purpose registers, and the PC, in AArch32 state on page E1-7131 describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
  - The preferred name for R13 is SP (stack pointer).
  - The preferred name for R14 is LR (link register).
- The PC, which can be described as R15.

These registers are selected from a larger set of registers that includes banked copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those Exception levels are using AArch32. Figure G1-3 on page G1-8918 shows the full set of banked general-purpose registers, and the Special-purpose registers:

- The Program Status Registers CPSR and SPSR.
- ELR_hyp.

*Note*

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.
As described in PE mode for taking exceptions on page G1-8939, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the Special-purpose register ELR_hyp.
  - For the other privileged modes to which exceptions can be taken, a banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of PSTATE, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition, FIQ mode has banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see The general-purpose registers, and the PC, in AArch32 state on page E1-7131.

**AArch32 Special-purpose registers**

In AArch32 state, the Special-purpose registers are:

- The CPSR and its view as the APSR.
- The SPSR, including the banked copies SPSR_abt, SPSR_fiq, SPSR_hyp, SPSR_irq, SPSR_mon, SPSR_svc, and SPSR_und.
- The ELR_hyp.
Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, \( _R \), indexed by parameter \( n \). This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. \( _PC \) is the Program Counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

\( \text{LookUpRIndex()} \) looks up the index value, \( n \), for the specified register number and PE mode, using \( \text{RBankSelect()} \) to evaluates the result.

\( _R \) accesses the specified general-purpose register in the current PE mode, using \( \text{Rmode[]} \) to access the register, accessing \( _R \) if necessary. \( \text{SP} \) accesses the stack pointer, \( \text{LR} \) accesses the link register, and \( \text{PC} \) accesses the Program Counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than \( \text{PC} \), which has only a non-assignment form.

\( \text{BranchTo()} \) performs a branch to the specified address.

The \( _R, _PC, \text{LR}, \text{SP}, \text{LookUpRIndex()}, \text{RBankSelect()}, \text{Rmode[]}, \text{and BranchTo()} \) functions are defined in Chapter J1 Armv8 Pseudocode.

G1.9.3 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in Figure G1-3 on page G1-8918. For example, the SPSR for Monitor mode is called \( \text{SPSR\_mon} \).

--- Note ---

Exceptions cannot be taken to EL0.

---

When the PE takes an exception, PE state is saved from \( \text{PSTATE} \) in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Monitor mode, PE state is saved in \( \text{SPSR\_mon} \). For more information on \( \text{PSTATE} \), see Process state, \( \text{PSTATE} \) on page G1-8921.

--- Note ---

All \( \text{PSTATE} \) fields are saved, including those which have no direct read and write access.

---

Saving the \( \text{PSTATE} \) fields means the exception handler can:

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
  - \( \text{ERET} \).
  - \( \text{LDM} \).
  - The Exception return form of the instruction described in \( \text{MOV, MOVs (register)} \) on page F5-7719.
  - The Exception return form of the instruction described in \( \text{SUB, SUBS (immediate)} \) on page F5-8039.

For example, on returning from Monitor mode, PE state is restored to the state stored in \( \text{SPSR\_mon} \). If the exception return is made using the RFE instruction, the PE restores the PE state from an SPSR valued read from memory.

- Examine the value that \( \text{PSTATE} \) had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are \text{UNKNOWN} on a Warm reset. Any operation in a Non-secure EL1 or EL0 mode makes \( \text{SPSR\_hyp} \) unknown.

SPSR bits that are defined as \text{RES0} on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.

For more information on SPSR, see SPSR, Saved Program Status Register on page G8-9706.
Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The `SPSR[]` function accesses the current SPSR and is common to AArch32 and AArch64 operation.

The `SPSRWriteByInstr()` function is used by the MSR (register) and MSR (immediate) instructions to update the current SPSR.

The `SPSR[]` and `SPSRWriteByInstr()` functions are defined in Chapter J1 Armv8 Pseudocode.

G1.9.4 ELR_hyp

Hyp mode does not provide its own banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR_hyp, a 32-bit Special-purpose register implemented for this purpose.

ELR_hyp can be accessed explicitly only by executing:
• An MRS or MSR instruction that targets ELR_hyp, see:
   — `MRS (Banked register)` on page F5-7736.
   — `MSR (Banked register)` on page F5-7740.

The `ERET` instruction uses the value in ELR_hyp as the return address for the exception. For more information, see `ERET` on page F5-7570.

Software execution in any Non-secure EL1 or EL0 mode makes ELR_hyp UNKNOWN.
G1.10 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the `PSTATE` structure, of type `ProcState`. `ProcState` is defined in Chapter J1 *Armv8 Pseudocode*.

The PSTATE fields that are meaningful in AArch32 state are:

**The Condition flags**
- **N** Negative Condition flag.
- **Z** Zero Condition flag.
- **C** Carry Condition flag.
- **V** Overflow Condition flag.

*Process state, PSTATE on page E1-7133* gives more information about these.

**The overflow or saturation flag**
- **Q** See *Process state, PSTATE on page E1-7133*.

**The greater than or equal flags**
- **GE[3:0]** See *Process state, PSTATE on page E1-7133*.

**The PE state controls**
- **J, T** Instruction set state. See *Process state, PSTATE on page E1-7133*. J is RES0. On a Warm reset to AArch32 state, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to:
  - A PL1 mode using AArch32, T is set to SCTLR.TE.
  - EL2 using AArch32, T is set to HSCTLR.TE.
- **IT[7:0]** IT block state bits. See *Process state, PSTATE on page E1-7133*. On a Warm reset or taking an exception to AArch32 state, these bits are set to 0.
- **E** Endianness of data accesses. See *Process state, PSTATE on page E1-7133*. If an implementation provides both Big-endian and Little-endian support, then:
  - On a Warm reset to AArch32 state this bit is set to the IMPLEMENTATION DEFINED reset value of:
    - SCTLR.EE if the highest implemented Exception level is not EL2.
    - HSCTLR.EE if the highest implemented Exception level is EL2.
  - On taking an exception to:
    - A PL1 mode using AArch32, this bit is set to SCTLR.EE.
    - EL2 using AArch32, this bit is set to HSCTLR.EE
- **IL** Illegal Execution state bit. See *The Illegal Execution state exception on page G1-8954*. On a Warm reset or taking an exception to AArch32 state, this bit is set to 0.

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see *Accessing the PE state controls and the Execution state bit on page G1-8924*.

**The asynchronous exception mask bits**
- **A** SError interrupt mask bit.
- **I** IRQ interrupt mask bit.
- **F** FIQ interrupt mask bit.
For each bit, the values are:

0   Exception not masked.
1   Exception masked.

On a Warm reset to AArch32 state, these bits are set to 1.
On taking an exception to AArch32 state, one or more of these bits are set to 1.
For more information, see both:

• Asynchronous exception masking controls on page G1-8959.
• PE state on exception entry on page G1-8942.

The mode bits

M[4:0]   Current mode of the PE. Table G1-5 on page G1-8912 lists the permitted values of this field. All other values are reserved. Illegal changes to PSTATE.M on page G1-8925 describes the effect of setting M[4:0] to a reserved value.
M[4] is:

M[4], Execution state

The current Execution state:

0   AArch64 state.
1   AArch32 state.

Note

This is consistent with the use of M[4:0] in previous versions of the architecture.

On a Warm reset to AArch32 state, M[4:0] is set to:

• 0b10011, meaning Supervisor mode, if the highest implemented Exception level is not EL2.
• 0b11010, meaning Hyp mode, if the highest implemented Exception level is EL2.

On taking an exception to AArch32 state, M[4:0] is set to the target mode for the exception type.
For more information about the PE modes, see:

• AArch32 state PE mode descriptions on page G1-8912.
• PE state on exception entry on page G1-8942.

Access control bits, from Armv8.1

PAN    Privileged Access Never (PAN) state bit, see About the PAN bit on page G5-9195.

Timing control bits

DIT    Data Independent Timing (DIT) bit. For more information, see About the DIT bit on page E1-7139.
This bit is implemented only when FEAT_DIT is implemented.
On a Warm reset to AArch32 state, this bit is set to 0.

Speculation control bits

SSBS   Speculative Store Bypass Safe (SSBS) bit. For more information, see Speculative Store Bypass Safe (SSBS) on page E2-7179.
This bit is implemented only when FEAT_SSBS is implemented.
On a Warm reset to AArch32 state, this bit is set to an IMPLEMENTATION DEFINED value.

G1.10.1 Accessing PSTATE fields

The PSTATE fields can be accessed as described in the following subsections:

• The Current Program Status Register, CPSR on page G1-8923.
• Accessing the PE state controls and the Execution state bit on page G1-8924.
• The CPS instruction on page G1-8924.
• The SETEND instruction on page G1-8925.
• The SETPAN instruction on page G1-8925.

### The Current Program Status Register, CPSR

Some PSTATE fields can be accessed using the Special-purpose Current Program Status Register (CPSR). The CPSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

The CPSR bit assignments are:

<table>

  - The PSTATE endianness bit.
- **A, I, F, bits [8:6]**
  - The PSTATE asynchronous exception mask bits.
- **M[4:0], bits [4:0]**
  - The PSTATE mode bits.

The other PSTATE fields cannot be accessed by using the CPSR. For information on how to access them, see Accessing the PE state controls and the Execution state bit on page G1-8924.

The application level alias for the CPSR is the APSR. The APSR is a subset of the CPSR. See The Application Program Status Register, APSR on page E1-7135.

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.
The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to \texttt{PSTATE.M} can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next \textit{Context synchronization event} in the execution stream.
- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See \textit{Exception return to an Exception level using AArch32} on page G1-8951 for the definition of exception return instructions.

### Accessing the PE state controls and the Execution state bit

ThePE state controls are the \texttt{PSTATE.\{IL, IT[7:0], J, E, T\}} fields. Software can read or write these in an SPSR.

In the CPSR:

- The PE state controls, other than \texttt{PSTATE.E}, are RAZ when read by an \texttt{MRS} instruction.
- Writes to the PE state controls, other than \texttt{PSTATE.E}, by \texttt{MSR (register)} or \texttt{MSR (immediate)}, are ignored in all modes.

Instructions other than \texttt{MRS, MSR (register)}, or \texttt{MSR (immediate)} that access the PE state controls can read and write them in any mode.

Unlike the other \texttt{PSTATE} PE state controls, \texttt{PSTATE.E} can be read by an \texttt{MRS} instruction and might be written by \texttt{MSR (register)} or \texttt{MSR (immediate)}. However, Arm deprecates \texttt{PSTATE.E} having a different value from the equivalent System register EE bit, see \textit{Mixed-endian support} on page G4-9112.

#### Note

To determine the current endianness, software can use an \texttt{LDR} instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an \texttt{LDR} instruction to load a word whose four bytes are \texttt{0x01, 0x00, 0x00, 0x00} in ascending order of memory address loads the destination register with:

- \texttt{0x00000001} if the current endianness is little-endian.
- \texttt{0x01000000} if the current endianness is big-endian.

The \texttt{PSTATE.M[4]} bit is the Execution state bit. When read by an \texttt{MRS} instruction in AArch32 state, this bit always reads as 1. When written by an \texttt{MSR (register)} instruction or \texttt{MSR (immediate)} instruction, writing a value other than 1 is an illegal change to the \texttt{PSTATE.M} field. See \textit{Illegal changes to PSTATE.M} on page G1-8925.

### The CPS instruction

The A32 and T32 instruction sets both include an instruction to manipulate \texttt{PSTATE.\{A, I, F\}} and \texttt{PSTATE.M}:

\begin{verbatim}
CPSIE <iflags> {, #<mode>}
\end{verbatim}

Sets the specified \texttt{PSTATE.\{A, I, F\}} exception masks to 0, enabling the exception, and optionally changes to the specified mode.

\begin{verbatim}
CPSID <iflags> {, #<mode>}
\end{verbatim}

Sets the specified \texttt{PSTATE.\{A, I, F\}} exception masks to 1, disabling the exception, and optionally changes to the specified mode.

\begin{verbatim}
CPS #<mode>
\end{verbatim}

Changes to the specified mode without affecting the \texttt{PSTATE.\{A, I, F\}} exception masks.
The CPS instruction is unconditional. For more information, see CPS, CPSID, CPSIE on page F5-7535.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

SETEND BE  Sets PSTATE.E to 1, for big-endian operation.
SETEND LE  Sets PSTATE.E to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see SETEND on page F5-7882. Arm deprecates use of the SETEND instruction.

The SETPAN instruction

FEAT_PAN adds the SETPAN instruction to the A32 and T32 instruction sets, to manipulate PSTATE.PAN:

SETPAN #0  Sets PSTATE.PAN to 0, disabling Privileged access-never operation.
SETPAN #1  Sets PSTATE.PAN to 1, enabling Privileged access-never operation.

The SETPAN instruction is unconditional.

• SETPAN on page F5-7883.
• About the PAN bit on page G5-9195.

G1.10.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in Saved Program Status Registers (SPSRs) on page G1-8919.

G1.10.3 Illegal changes to PSTATE.M

In AArch32 PE modes other than User mode, MSR and CPS instructions can explicitly change PSTATE.M. The following changes to PSTATE.M by MSR or CPS instructions are illegal:

• A change to an encoding that Table G1-5 on page G1-8912 does not show.
• A change to a mode that is not implemented.
• A change to a mode that is not accessible from the context the MSR or CPS instruction is executed in, as follows:
  — A change to a mode that would cause entry to a higher Exception level.
  — When executing in Non-secure state, a change to Monitor mode.
  — When executing in Secure EL1, a change to Monitor mode when EL3 is using AArch64.
  — A change to Hyp mode from any other mode.
  — A change from Hyp mode to any other mode.
  — When the value of HCR.TGE is 1, attempting to change from Monitor mode to a Non-secure PL1 mode, see Trapping of general exceptions to Hyp mode on page K1-11582.

On executing an instruction that attempts an illegal change to PSTATE.M:

• PSTATE.M is unchanged, and the current mode remains unchanged.
• PSTATE.IL is set to 1.
• All other PSTATE fields are written to as normal.

Note

For the PSTATE fields that MSR and CPS instructions update, see the instruction descriptions:

• MSR (register) on page F5-7746.
• MSR (immediate) on page F5-7744.
• CPS, CPSID, CPSIE on page F5-7535.
When the value of `PSTATE.IL` is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception* on page G1-8954.

--- Note ---

The PE ignores writes to `PSTATE.M` when executing at PL0.

### G1.10.4 Pseudocode description of PSTATE operations

The `CPSRWriteByInstr()` function is used by the MSR (register) and MSR (immediate) instructions to update PSTATE.

The `SetPSTATEFromPSR()` function updates PSTATE from a CPSR or SPSR.

*Chapter J1 Armv8 Pseudocode* defines these functions.
G1.11 Instruction set states

The instruction set states are described in Chapter E2 The AArch32 Application Level Memory Model and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- Exceptions and instruction set state.
- Unimplemented instruction sets.

G1.11.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the SCTLR.TE bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of HSCTLR.TE.
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE. If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry, see Overview of exception entry on page G1-8936.

G1.11.2 Unimplemented instruction sets

The PSTATE.T bit defines the current instruction set state, see Process state, PSTATE on page E1-7133.

From the introduction of the Armv8 architecture, there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in Trivial implementation of the Jazelle extension.

Note

In previous versions of the Arm architecture, the PSTATE.{J, T} bits determined the Instruction set state. From the introduction of Armv8, PSTATE.J is RES0.

Trivial implementation of the Jazelle extension

The implementation of AArch32 state is required to include the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1, EL2, or EL3, if the Exception level is using AArch32:
  - The JMCR and JOSCR are RAZ/WI.
  - The JIDR is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
  - It is IMPLEMENTATION DEFINED whether the JMCR and JOSCR are RAZ/WI or UNDEFINED.
  - It is IMPLEMENTATION DEFINED whether JIDR is RAZ or UNDEFINED.
- The BXJ instruction behaves identically to the BX instruction in all circumstances.

Note

This is consistent with the JMCR.JE bit being RAZ, and means that the A32 and T32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.
Jazelle state, as defined in previous versions of the Arm architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly.

A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

--- Note ---

This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.
G1.12 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- Exception vectors and the exception base address.
- Exception prioritization for exceptions taken to AArch32 state on page G1-8932.
- Overview of exception entry on page G1-8936.
- PE mode for taking exceptions on page G1-8939.
- PE state on exception entry on page G1-8942.
- Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.
- Routing debug exceptions to EL2 using AArch32 on page G1-8946.

See also:

- Routing of aborts taken to AArch32 state on page G1-8948.
- Exception return to an Exception level using AArch32 on page G1-8951.
- Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-8956.
- AArch32 state exception descriptions on page G1-8964.

G1.12.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the exception vector for that exception. The vectors for the different types of exception form a vector table.

Note

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32.

When an exception is taken to an Exception level that is using AArch64, then the exception is taken as described in Chapter D1 The AArch64 System Level Programmers’ Model using the exception vectors described in Exception vectors on page D1-4640.

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an exception base address. These eight vectors form an AArch32 vector table.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.
Note

Exceptions cannot be taken to System mode.

For this vector table:
- When SCTLR.V == 0, the VBAR holds the exception base address.
- When SCTLR.V == 1, the exception base address is 0xFFFF0000.

Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.
  For this vector table, HVBAR holds the exception base address.

Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.
  For this vector table, MVBAR holds the exception base address.
- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.
  - When the Secure instance of SCTLR.V == 0, the Secure instance of VBAR holds the exception base address.
  - When the Secure instance of SCTLR.V == 1, the exception base address is 0xFFFF0000.
- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.
  - When the Non-secure instance of SCTLR.V == 0, the Non-secure instance of VBAR holds the exception base address.
  - When the Non-secure instance of SCTLR.V == 1, the exception base address is 0xFFFF0000.

The following subsections give more information:

- The vector tables and exception offsets.
- Pseudocode determination of the exception base address on page G1-8932.

The vector tables and exception offsets

Table G1-6 on page G1-8931 defines the AArch32 vector table entries. In this table:

- The Hyp column defines the vector table entries for exceptions taken to Hyp mode.
- The Monitor column defines the vector table entries for exceptions taken to Monitor mode.
- The Secure and Non-secure columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-7 on page G1-8931 shows the mode to which each of these exceptions is taken. Each of these modes is described as the default mode for taking the corresponding exception.

Note

Exceptions cannot be taken to System mode or User mode.
For more information about determining the mode to which an exception is taken, see *PE mode for taking exceptions on page G1-8939*.

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see *Offsets of AArch32 exceptions provided by EL2 on page G1-8932*.

a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table.
d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. From the introduction of Armv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
e. See *Use of offset 0x14 in the Hyp vector table on page G1-8932*.

For more information about use of the vector tables, see *Overview of exception entry on page G1-8936*. 
Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in Table G1-6 on page G1-8931:

**Hypervisor Call**  
If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see *Use of offset 0x14 in the Hyp vector table.*

**Hyp Trap**  
Shown explicitly in the Hyp mode vector table.

**Virtual Abort**  
Entered through the Data Abort vector in the Non-secure vector table.

**Virtual IRQ**  
Entered through the IRQ vector in the Non-secure vector table.

**Virtual FIQ**  
Entered through the FIQ vector in the Non-secure vector table.

---  
**Note**  
*Virtual exceptions when an implementation includes EL2 on page G1-8956* gives more information about the virtual exceptions.

---

**Use of offset 0x14 in the Hyp vector table**

The vector at offset 0x14 in the Hyp vector table is used for all exceptions that cause entry to Hyp mode from Non-secure EL0 and EL1, except for IRQ and FIQ exceptions.

---  
**Note**  
Virtual exceptions are never taken to Hyp mode.

---

**Pseudocode determination of the exception base address**

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address. The `ExcVectorBase()` function is defined in Chapter J1 *Armv8 Pseudocode.*

---  
**Note**  
The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information, see *Security state, Exception levels, and AArch32 execution privilege* on page G1-8908.

---

G1.12.2 Exception prioritization for exceptions taken to AArch32 state

The following sections describe the requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-8933.*
- *Architectural requirements for taking asynchronous exceptions on page G1-8935.*

See also:

- *AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248,* for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation.
- *Debug state entry and debug event prioritization on page H2-10235* for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.
Synchronous exception prioritization for exceptions taken to AArch32 state

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

Note

• An exception that is taken to an Exception level that is using AArch32 must have been taken from an Exception level that is using AArch32.
• The priority numbering in this list correlates with the equivalent AArch64 list in Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.

For an exception that is taken to an Exception level that is using AArch32, exceptions are prioritized as follows, where 1 is the highest priority.

1-5 These priority numbers are used by AArch64 exceptions or debug events.

6 PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:
• The CONstrained UNPREDICTABLE handling of a branch to an unaligned address, see Branching to an unaligned PC on page K1-11564.
• Exiting from Debug state to AArch32 specifying an unaligned PC value, see Exiting Debug state on page H2-10271.

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-8972.

7 Prefetch Abort exceptions. See Prefetch Abort exception on page G1-8971 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248.

8 Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
• Breakpoint exceptions on page G2-9054.
• Vector Catch exceptions on page G2-9093.

Note

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

9 Illegal Execution state exceptions. See The Illegal Execution state exception on page G1-8954.

10 Software Breakpoint Exceptions caused by the execution of a BKPT Exception generating instruction.

11 This priority number is used by AArch64 exceptions.

12 Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
• HSTR.Tn.
• HCR.TIDCP.

13 Undefined Instruction exceptions that occur as a result of one or more of the following:
• An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
• An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
• Debug state execution of an instruction encoding that is not accessible in Debug state.
• Non-debug state execution of an instruction encoding that is not accessible in Non-debug state.
• Execution of an HVC instruction when HVC instructions are disabled by SCR.HCE or HCR.HCD.
• Execution of an HLT instruction when HLT instructions are disabled by EDSCR.HDE or when halting is prohibited.
• When FEAT_FGT and FEAT_PMUv3 are implemented, executing an MSR or MSR instruction in AArch64 state, or an MCR or MRS instruction in AArch32 state, that accesses a register associated with an unimplemented event counter.
• In Debug state:
  — Execution of a DCPS1 instruction in Non-secure EL0 when HCR.TGE is 1.
  — Execution of a DCPS2 instruction in EL1 or EL0 when SCR.NS is 0 or when EL2 is disabled or not implemented in the current Security state.
  — Execution of a DCPS3 instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
  — When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
• Execution of an instruction that is UNDEFINED as a result of any of:
  — Being in an IT block when SCTLR.ITD is 1, or when HSCTLR.ITD is 1.
  — Executing a SETEND instruction when SCTLR.SED is 1, or when HSCTLR.SED is 1.
  — Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTLR.CP15BEN is 0, or when HSCTLR.CP15BEN is 0.

See Disabling or enabling PL0 and PL1 use of AArch32 optional functionality on page G1-9004 and Disabling or enabling EL2 use of AArch32 optional functionality on page G1-9013.
• Execution of an instruction that is UNDEFINED because at least one of FPSCR.\{Stride, Len\} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exceptions and exception traps on page E1-7148.

14 Exceptions taken to EL1, or taken to EL2 because the value of HCR.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 6-13.

15 Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
• HSTR.Tn.
• HCR.TIDCP.

16 Exceptions taken to EL2 because of configuration settings in the HCPTR.

17 Exceptions taken to EL2 because of one of the following configuration settings:
• Any setting in HCR, other than the TIDCP bit.
• Any setting in CNTHCTL.
• Any setting in HDCR.
• If EL1 is using AArch64 state, any of the fine-grained traps in HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGITR_EL2, HFGTR_EL2, HFGWTR_EL2.

18 Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 6-17.

19 Exceptions caused by the S\$C instruction being UNDEFINED because the value of SCR.SCD is 1.

20 Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, or S\$C.

21-22 These priority numbers are used by AArch64 exceptions.

23 Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in SDCR.

24 Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 6-23.
This priority number is used by AArch64 exceptions.

Trapped floating-point exceptions, if supported. See Floating-point exceptions and exception traps on page E1-7148.

These priority numbers are used by AArch64 exceptions and debug events.

Data Abort exceptions other than a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by priority 33. See Data Abort exception on page G1-8975 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as priority 33.

Watchpoint exceptions. See Watchpoint exceptions on page G2-9079.

Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk, see External aborts on page G4-9139. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as priority 31.

For priorities 31-33, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

Note

Exceptions generated by a translation table walk are reported and prioritized as either a Prefetch Abort exception, priority 7 in this list, or a Data Abort exception, priority 31 in this list. See also AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248.

Architectural requirements for taking asynchronous exceptions

The Arm architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before a Context synchronization event in the following list, is taken before the first instruction after the context synchronizing event, provided that the pending asynchronous event is not masked:

- Execution of an ISB instruction that does not fail its Condition code check.
- Exception entry.
- Exception return.
- Exit from Debug state.

Note

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.
- The ISR identifies any pending asynchronous exceptions.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

Note

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.
If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits
the interrupt to be taken, but does not require this to happen. If the interrupt is taken, then it must be taken before
the first Context synchronization event after the interrupt was changed to not pending.

**PSTATE** includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the
corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls
can modify the effect of these bits. For more information, see Asynchronous exception behavior for exceptions taken
from AArch32 state on page G1-8956.

Taking an exception sets an exception-dependent subset of these mask bits.

**Note**

In some contexts, the **PSTATE.**{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on
exception entry, described in **PSTATE.**{A, I, F, M} values on exception entry on page G1-8943, can prevent an
exception handler being interrupted by an asynchronous exception.

**G1.12.3 Overview of exception entry**

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken
to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes
distinguish between the **EL2 mode** and the **non-EL2 modes**.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see PE mode for taking exceptions
   on page G1-8939.

2. A link value, indicating the [preferred return address](#) for the exception, is saved. This is a possible return
   address for the exception handler, and depends on:
   - The exception type.
   - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
   - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.
   Where the link value is saved depends on whether the exception is taken to the EL2 mode.
   For more information, see Link values saved on exception entry on page G1-8937.

3. The value of **PSTATE** is saved in the **SPSR** for the mode to which the exception must be taken. The value
   saved in **SPSR.IT[7:0]** is always correct for the preferred return address.

4. In an implementation that includes EL3, when EL3 is using AArch32:
   - If the exception is taken from Monitor mode, **SCR.NS** is cleared to 0.
   - Otherwise, taking the exception leaves **SCR.NS** unchanged.
   When EL3 is using AArch64, Monitor mode is not available.

5. **PSTATE** is updated with new context information for the exception handler. This includes:
   - Setting **PSTATE.M** to the PE mode to which the exception is taken.
   - Setting the appropriate **PSTATE** mask bits. This can disable the corresponding exceptions, preventing
     uncontrolled nesting of exception handlers.
   - Setting the instruction set state to the state required for exception entry.
   - Setting the endianness to the required value for exception entry.
   - Clearing the **PSTATE.IT[7:0]** bits to 0.
   For more information, see PE state on exception entry on page G1-8942.

6. The appropriate exception vector is loaded into the PC, see Exception vectors and the exception base address
   on page G1-8929.

7. Execution continues from the address held in the PC.
For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-7936 and CPS, CPSID, CPSIE on page F5-7535.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-8 on page G1-8937 gives an index to these descriptions:

### Table G1-8 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- **PE mode for taking exceptions** on page G1-8939.
- **PE state on exception entry** on page G1-8942.

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the preferred return address for the exception, as shown in Table G1-9 on page G1-8937:

### Table G1-9 Exception return addresses for exceptions taken to AArch32 state

<table>
<thead>
<tr>
<th>Exception</th>
<th>Preferred return address</th>
<th>Taken to a mode at</th>
</tr>
</thead>
<tbody>
<tr>

<td>Address of the instruction after the SVC instruction</td>
<td>Non-EL2&lt;sup&gt;a&lt;/sup&gt; or EL2&lt;sup&gt;c&lt;/sup&gt;</td>
</tr>
</tbody>
</table>
Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.

- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

**Exception taken to a non-EL2 mode**

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table G1-10 on page G1-8938 shows:

**Table G1-9 Exception return addresses for exceptions taken to AArch32 state (continued)**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Preferred return address</th>

Exception taken to an EL2 mode

The link value is saved in the ELR_hyp Special-purpose register.
The saved link value is the preferred return address for the exception, as shown in Table G1-9 on page G1-8937, with no offset.

G1.12.4 PE mode for taking exceptions

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:

- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.

- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

  **In an implementation that does not include EL2 or EL3**
  An exception is always taken to the default mode for that exception.

  **In an implementation that includes EL3**
  A Secure Monitor Call exception is always taken to EL3. This means:

  - If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
  - If EL3 is using AArch64, then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32 on page G1-8941*.

  IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

  When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode.

  Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Security state, Exception levels, and AArch32 execution privilege on page G1-8908*, this means it is taken to:

  - An EL3 mode other than Monitor mode if EL3 is using AArch32.
  - An EL1 mode if EL3 is using AArch64.

  If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.
In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

• If the exception is taken from Hyp mode, then it is taken to Hyp mode.
• Otherwise, the exception is either taken to Hyp mode, as described in Exceptions taken to Hyp mode, or taken to the default mode for the exception.

Note

• Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
• Hyp mode has no effect on the handling of exceptions taken from Secure state.

Table G1-7 on page G1-8931 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page G1-8957 describes the exception routing controls provided by EL2 and EL3.

Routing of aborts taken to AArch32 state on page G1-8948 gives more information about the modes to which memory aborts are taken.

The possible modes for taking each exception on page G1-8941 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

• That include neither EL2 nor EL3.
• That include EL2 but not EL3.
• That do not include EL2 but include EL3.
• That include both EL2 and EL3.

Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

• Any exception taken from Hyp mode that is not routed to EL3 by the controls described in Asynchronous exception routing controls on page G1-8957 is taken to Hyp mode.

• The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  — An abort that Routing of aborts taken to AArch32 state on page G1-8948 identifies as taken to Hyp mode.
  — A Hyp Trap exception, see EL2 configurable controls on page G1-9010.
  — A Hypervisor Call exception. This is generated by executing an HVC instruction in a Non-secure mode.
  — An SError interrupt exception, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in Asynchronous exception routing controls on page G1-8957.
  — A synchronous External abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.

Note

A synchronous External abort can be routed to Hyp mode only if it is not routed to EL3.

Note

A debug exception that is explicitly routed to Hyp mode, as described in Routing debug exceptions to EL2 using AArch32 on page G1-8946.

Note

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.
Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64

As described in The Armv8-A security model on page G1-8905, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- Execution of an SMC instruction from a privileged Exception level that is using AArch32
- Non-secure reads of the NSACR
- Secure EL1 operations when Secure EL1 is using AArch32 state

Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of \(0x13\), SMC instruction executed in AArch32 state.

Non-secure reads of the NSACR

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of \(0x00000C00\) in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

Secure EL1 operations when Secure EL1 is using AArch32 state

When Secure EL1 is using AArch32 and if FEAT_SEL2 is implemented and enabled or EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the SCR, NSACR, MVBAR, and SDCR.
  - Executing any of the \(\text{ATS12NSO}^{**}\) instructions.
  - Executing an \(\text{SRS}\) instruction that would use SP_mon, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-7936.
  - Executing an \(\text{MRS}\) (banked register) or \(\text{MSR}\) (banked register) instruction that would access SPSR_mon, SP_mon, or LR_mon, see MRS (Banked register) on page F5-7736 and MSR (Banked register) on page F5-7740.

- Any attempt to move into Hypervisor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal return events from AArch32 state on page G1-8952.

- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal return events from AArch32 state on page G1-8952.

Note

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

The possible modes for taking each exception

Each of the exception descriptions in AArch32 state exception descriptions on page G1-8964 includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- The PE mode to which the Undefined Instruction exception is taken on page G1-8965.
• The PE mode to which the Hyp Trap exception is taken on page G1-8967.
• The PE mode to which the Monitor Trap exception is taken on page G1-8967.
• The PE mode to which the Supervisor Call exception is taken on page G1-8968.
• The PE mode to which the Secure Monitor Call exception is taken on page G1-8970.
• The PE mode to which the Hypervisor Call exception is taken on page G1-8971.
• The PE mode to which the Prefetch Abort exception is taken on page G1-8973.
• The PE mode to which the Data Abort exception is taken on page G1-8976.
• The PE mode to which the Virtual SError interrupt exception is taken on page G1-8980.
• The PE mode to which the physical IRQ exception is taken on page G1-8981.
• The PE mode to which the Virtual IRQ exception is taken on page G1-8982.
• The PE mode to which the physical FIQ exception is taken on page G1-8983.
• The PE mode to which the Virtual FIQ exception is taken on page G1-8984.

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:
• HCR, rather than HCR_EL2, controls the routing of exceptions to EL2.
• SCR, rather than SCR_EL3, controls the routing of exceptions to EL3.

For more information about:
• Vector offsets, see Exception vectors and the exception base address on page G1-8929.
• The routing of synchronous External aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see Asynchronous exception routing controls on page G1-8957.

UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see Routing exceptions from Non-secure EL0 to EL2 on page G1-8944. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. The architecture does not constrain this UNPREDICTABLE behavior, but software that follows the Arm recommendations cannot get to this state. When following the Arm recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:
• An illegal exception return, see Illegal return events from AArch32 state on page G1-8952.
• An illegal PE mode change, see Illegal changes to PSTATE.M on page G1-8925.

G1.12.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as Table G1-8 on page G1-8937 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:
• Instruction set state on exception entry on page G1-8943.
• PSTATE.E value on exception entry on page G1-8943.
• PSTATE.{A, I, F, M} values on exception entry on page G1-8943.

Note

The descriptions in these sections assume that EL2 and EL3, which control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:
• If EL2 is using AArch64:
  — Controls shown as provided by the HSCTLR are provided by the SCTLR_EL2.
  — Controls shown as provided by the HCR are provided by the HCR_EL2.
• If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR_EL3.
Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, PSTATE.T is set to the required value, as determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. Table G1-11 on page G1-8943 shows this:

Table G1-11 PSTATE.T bit value on exception entry

<table>
<thead>
<tr>
<th>Mode to which exception is taken</th>
<th>HSCTLR.TE</th>
<th>SCTLR.TE</th>
<th>PSTATE.T</th>
<th>Exception handler state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Hyp mode</td>
<td>x</td>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>1</td>

</tr>
<tr>
<td>Hyp mode</td>
<td>0</td>
<td>x</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>x</td>
<td>T32</td>
</tr>
</tbody>
</table>

When an implementation includes EL3 and EL3 is using AArch32, SCTLR is banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a PE mode other than Hyp mode, the SCTLR.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the instruction set state in which an exception handler might execute depends on the Security state to which the exception is taken.

PSTATE.E value on exception entry

PSTATE.E controls the load and store endianness for data handling. Table G1-12 on page G1-8943 show the value to which this bit is set on exception entry:

Table G1-12 PSTATE.E value on exception entry

<table>
<thead>
<tr>
<th>Exception mode</th>
<th>HSCTLR.EE</th>
<th>SCTLR.EE</th>
<th>Endianness for data loads and stores</th>
<th>PSTATE.E</th>

<td>Big-endian</td>
<td>1</td>
</tr>
</tbody>
</table>

For more information, see the bit description in Saved Program Status Registers (SPSRs) on page G1-8919.

PSTATE.{A, I, F, M} values on exception entry

On exception entry, PSTATE.M is set to the value for the mode to which the exception is taken, as described in PE mode for taking exceptions on page G1-8939.

Table G1-13 on page G1-8944 shows the cases where PSTATE.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a PSTATE.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The PE mode exception is taken to column is the mode to which the exception is taken.
- The Non-secure column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The Secure column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
Exceptions taken to Non-secure state in an implementation that includes EL2.

Table G1-13 PSTATE.{A, I, F} values on exception entry

</tbody>
</table>

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-8956 describes how, in some situations, the PSTATE.{A, I, F} bits mask the taking of SError interrupts, IRQ interrupts, and FIQ interrupts.

G1.12.6 Routing exceptions from Non-secure EL0 to EL2

--- Note ---

The routing control described in this section permits a Non-secure state usage model where applications execute in User mode under a hypervisor, which executes in Hyp mode, without a Guest OS running at Non-secure EL1. This control applies when the PE is executing in Non-secure EL0 using AArch32 and EL2 is using AArch32 and the value of HCR.TGE is 1.

If the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2 if either:

- EL2 is using AArch32 and the value of HCR.TGE is 1.
  - In this case the exception is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. For more information, see Exception reporting when HCR.TGE routes an exception to EL2 using AArch32 on page G1-8945.

- EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.
  - In this case the exception is taken to EL2 using AArch64, see Exception entry on page D1-4641.

Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected by the value of HCR.TGE or HCR_EL2.TGE.

When the value of HCR.TGE is 1, meaning TGE routing from Non-secure EL0 using AArch32 to EL2 using AArch32 applies:

- The SCTLR.M bit is treated as 0 for all purposes other than a direct read of the SCTLR register.
- Each of the HCR.\{FMO, IMO, AMO\} bits is treated as 1 for all purposes other than a direct read of the HCR register.
• Each of the HDCR. {TDE, TDA, TDRA, TDOSA} bits is treated as 1 for all purposes other than a direct read of the HDCR register.

• An exception return to Non-secure EL1 is treated as an illegal exception return, see Illegal return events from AArch32 state on page G1-8952.

• All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

Exception reporting when HCR.TGE routes an exception to EL2 using AArch32

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of HCR.TGE is 1:

• Undefined Instruction exception, when the value of HCR.TGE is 1.

• Supervisor Call exception, when the value of HCR.TGE is 1.

• Abort exceptions, when the value of HCR.TGE is 1.

• Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1 on page G1-8946.

Undefined Instruction exception, when the value of HCR.TGE is 1

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value 0x00. For more information, see Use of the HSR on page G5-9265.

Supervisor Call exception, when the value of HCR.TGE is 1

When HCR.TGE is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

• If the SVC is unconditional, takes for the imm16 value in the HSR:
  — A zero-extended 8-bit immediate value for the T32 SVC instruction.

    Note
    The only T32 encoding for SVC is a 16-bit instruction encoding.

    — The bottom 16 bits of the immediate value for the A32 SVC instruction.

• If the SVC is conditional, the imm16 value in the HSR is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its Condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see Use of the HSR on page G5-9265.

    Note
    The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

Abort exceptions, when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or to EL3 using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

When SCR.EA is set to 1, External aborts and SError interrupts are routed to EL3, and this routing takes priority over the HCR.TGE routing. For more information, see Routing of aborts taken to AArch32 state on page G1-8948.
An SError interrupt that is routed to Hyp mode because the value of HCR.TGE is 1 is reported as a Data Abort exception routed to Hyp mode.

The HSR reports the exception either:
- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see Use of the HSR on page G5-9265.

**Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1**

PL1 configurable controls on page G1-9002 describes controls that, when the value of HCR.TGE is 0, can generate exceptions that are taken from Non-secure EL0 to EL1. When EL2 is using AArch32 and the value of HCR.TGE is 1, the exceptions generated by these controls are routed to Hyp mode. Table G1-14 shows how these exceptions are then reported in the HSR.

### Table G1-14 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables

**G1.12.7 Routing debug exceptions to EL2 using AArch32**

When the value of HDCR.TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see Chapter G2 AArch32 Self-hosted Debug.
- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See Watchpoint exceptions on page G2-9079.

When the value of HDCR.TDE is 1, each of the HDCR.\{TDRA, TDOSA, TDA\} bits is treated as 1 for all purposes other than reading the HDCR register.

---

**Note**

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See Breakpoint and Watchpoint debug events on page H2-10234.
• When HDCR.TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.

• Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.

When a Hyp Trap exception is generated because the value of HDCR.TDE is 1, The HSR reports the exception either:
• As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
• As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information, see Use of the HSR on page G5-9265.
G1.13 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

• To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.

• To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  — Using AArch32. In this case, this chapter describes how the abort is handled.
  — Using AArch64. In this case, Chapter D8 The AArch64 Virtual Memory System Architecture describes how the abort is handled.

For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

Memory aborts taken to Monitor mode

If an implementation includes EL3, when the value of SCR.EA is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes.

Memory aborts taken to Secure Abort mode

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

——— Note —————

The only memory aborts that can be routed to Monitor mode are External aborts.

———

Memory aborts taken to Hyp mode

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

• Alignment faults taken:
  — When the PE is in Hyp mode.
  — When the PE is in a Non-secure PL1 or EL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  — When the PE is in Non-secure User mode and HCR.TGE is set to 1. For more information, see Abort exceptions, when the value of HCR.TGE is 1 on page G1-8945.

• When the PE is using the Non-secure PL1&0 translation regime:
  — MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  — Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see Stage 2 fault on a stage 1 translation table walk on page G5-9246.

• When the PE is using the Non-secure EL2 translation regime, MMU faults from stage 1 translations.

——— Note —————

The Non-secure EL2 translation regime has only one stage of translation.

———

• External aborts, if SCR.EA is set to 0 and any of the following applies:
  — The PE was executing in Hyp mode when it took the exception.
The PE was executing in a Non-secure PL1 or EL0 mode when it took the exception, the abort is asynchronous, and HCR.AMO is set to 1. For more information, see *Asynchronous exception routing controls* on page G1-8957.

— The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and HCR.TGE is set to 1. For more information, see *Abort exceptions, when the value of HCR.TGE is 1* on page G1-8945.

— The Reliability, Availability, and Serviceability Extension is implemented, the PE was executing in a Non-secure PL1 or EL0 mode when it took the exception, the abort is synchronous, and the value of HCR2.TEA is 1.

— The abort occurred on a stage 2 translation table walk.

- Debug exceptions, if HDCR.TDE is set to 1. For more information, see *Routing debug exceptions to EL2 using AArch32* on page G1-8946.

### Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

- When the PE is in a Non-secure PL1 or EL0 mode, Alignment faults taken for any of the following reasons:
  — SCTLR.A is set to 1.
  — An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  — The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

**Note**

In an implementation that does not include EL2, this case results in a **CONSTRAINED UNPREDICTABLE** memory access, see *Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE* on page E2-7194 and *Loads and Stores to unaligned locations* on page K1-11564.

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of HCR.TGE is 0.

- When the PE is using the Non-secure PL1&0 translation regime, an MMU fault from a stage 1 translation.

- External aborts, if the PE was executing in a Non-secure PL1 or EL0 mode when it took the exception and both:
  — The value of SCR.EA is 0, meaning the abort is not taken to EL3.
  — The abort is not taken to EL2 for one of the reasons defined in *Memory aborts taken to Hyp mode*.

- Virtual Aborts, see *Virtual exceptions when an implementation includes EL2* on page G1-8956.

- When the value of HDCR.TDE is 0, Debug exceptions. For more information, see *Routing debug exceptions to EL2 using AArch32* on page G1-8946.

**Note**

If EL0 is using AArch32 and EL1 is using AArch64, then any of these memory aborts taken from User mode are taken to EL1, as described in *Chapter D8 The AArch64 Virtual Memory System Architecture*.
Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the SCTLRA bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information, see Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.
G1.14 Exception return to an Exception level using AArch32

In the Arm architecture, exception return to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The Arm architecture defines a preferred return address for each exception other than Reset, see Link values saved on exception entry on page G1-8937. The values of the SPSR.IT[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the PSTATE takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current SPSR at the time of the exception return.

If FEAT_MTE is implemented PSTATE.TCO is not updated on Exception return to AArch32 state.

Illegal return events from AArch32 state on page G1-8952 describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

G1.14.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- Return from an exception taken to a PE mode other than Hyp mode.
- Return from an exception taken to Hyp mode on page G1-8952.

Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the Arm AArch32 architecture provides the following exception return instructions:

- From privileged modes other than System mode, the ERET instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which ERET is executed. See ERET on page F5-7570.
- Data-processing instructions with the S bit set and the PC as a destination, see MOV, MOVS (register) on page F5-7719 and SUB, SUBS (immediate) on page F5-8039.

Note

The A32 instruction set includes other instructions that can be used for an exception return, but Arm deprecates any use of those instructions.
Typically:
— A return where no subtraction is required uses `SUBS` with an operand of 0, or the equivalent `MOVS` instruction.
— A return requiring subtraction uses `SUBS` with a nonzero operand.

• The `RFE` instruction, see `RFE, RFEDA, RFEDB, RFEIA, RFEIB` on page F5-7830. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the `RFE` instruction.

• In A32 state, a form of the `LDM` instruction in which the PC is one of the registers loaded, see `LDM (exception return)` on page F5-7604. If a subtraction is required, typically it is performed before saving the LR value to memory.

**Return from an exception taken to Hyp mode**

For an exception taken to Hyp mode, the Arm architecture provides the `ERET` instruction, see `ERET` on page F5-7570. An exception handler executing in Hyp mode must return using the `ERET` instruction.

Hyp mode is implemented only as part of EL2.

**G1.14.2 Alignment of exception returns**

The T bit of the value transferred to the `PSTATE` by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the T bit is as follows:

\[
\begin{align*}
T &= 0 & \text{The target instruction set state is A32 state. Bits}[1:0]\text{ of the address transferred to the PC are ignored by the hardware.} \\
T &= 1 & \begin{align*}
\text{The target instruction set state is T32 state:} \\
\bullet & \text{Bit}[0] \text{ of the address transferred to the PC is ignored by the hardware.} \\
\bullet & \text{Bit}[1] \text{ of the address transferred to the PC is part of the instruction address.}
\end{align*}
\end{align*}
\]

**Note**

In previous versions of the Arm architecture, the `PSTATE.{J, T}` bits determined the Instruction set state. From the introduction of Armv8, `PSTATE.J` is `RES0`.

Arm deprecates any dependence on the requirements that the hardware ignores bits of the address. Arm recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the `SPSR.T` bit. This means that if exception return instructions are used with the LR and `SPSR` values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

**G1.14.3 Illegal return events from AArch32 state**

Throughout this section:

**Return**

In AArch32 state, refers to any of:
• Execution of any exception return instruction.
• Execution of a `DRPS` instruction in Debug state.
• Exit from Debug state.

If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:
• Zero.
• The value of bit[1] of the return address for the exception or debug return.
The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.

--- Note ---
This means software must support both alternatives.

**Saved process state value**
In AArch32 state, refers to any of:
- The value held in the SPSR for any exception return other than an exception return made by executing an RFE instruction.
- The value read from memory that is to be restored to PSTATE by the execution of an RFE instruction.
- The value held in the SPSR for the execution of a DRPS instruction in Debug state.
- The value held in the DSPSR for a Debug state exit.

**Link address**
In AArch32 state, refers to any of:
- The address held in the link register for any exception return other than an exception return made by executing an ERET, LDM, or RFE instruction.
- The address held in ELR_hyp for any exception return made by executing an ERET instruction.
- The address read from memory that is to be restored to the PC by the execution of an LDM or RFE instruction.
- The address held in the DLR for Debug state exit.

**Configured from reset**
Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:
- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the mode being returned to is not implemented. For example:
  - A return to Hyp mode when EL2 is not implemented.
  - A return to Monitor mode, when EL3 is either not implemented or using AArch64 state.
- A return to EL2 when:
  - EL3 is implemented and using AArch64, and the values of SCR_EL3.{NS, EEL2} 0.
  - EL3 is implemented and using AArch32, and the value of the SCR.NS bit is 0.
- A return to Non-secure EL1 when:
  - EL2 is implemented and using AArch64, and the value of the HCR_EL2.TGE bit is 1.
  - EL2 is implemented and using AArch32, and the value of the HCR.TGE bit is 1.
- A return where the value of the saved process state M[4:0] field is not a valid AArch32 PE mode for the implementation. Table G1-5 on page G1-8912 shows the valid M[4:0] values for AArch32 PE modes.

In these cases:
- PSTATE.IL is set to 1, to indicate an illegal return.
- PSTATE.M is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see *Software Step exceptions* on page D2-4742.
The following PSTATE bits are restored from the saved process state value:
- The Q Overflow or saturation flag.
- The GE Greater than or Equal flags.
- The E Endianness mapping bit.
- The A, I, F exception mask bits.
- The DIT Data Independent Timing bit.

The PSTATE.{IT, T} bits are each either:
- Set to 0.
- Copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PC is restored from the link address, unless the illegal return is the execution of a DRPS instruction in Debug state.

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

G1.14.4 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the meaning that is defined in Illegal return events from AArch32 state on page G1-8952.

If the IL bit in the saved process state value is 1, then it is copied to PSTATE meaning that PSTATE.IL is set to 1. In this case, the PSTATE.{IT, T} bits are each either:
- Set to 0.
- Copied from the SPSR, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the PSTATE.IL bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

G1.14.5 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the PSTATE.IL bit can be set to 1 by one of the following:
- An illegal return, as described in Illegal return events from AArch32 state on page G1-8952.
- An illegal change to PSTATE.M, as described in Illegal changes to PSTATE.M on page G1-8925.
- A legal return that sets PSTATE.IL to 1, as described in Legal returns that set PSTATE.IL to 1.

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the HSR provides additional syndrome information for the exception, see Use of the HSR on page G5-9265.

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.
This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state.

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the PSTATE.IL bit is 1 and this is copied to the SPSR.IL bit for the PE mode to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

Note
This means that it is not possible for software to observe the value of PSTATE.IL.

Pseudocode description of exception return

The AArch32.ExceptionReturn() function transfers the return address to the PC and restores PSTATE to its saved value.

This function uses the function SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.

Chapter J1 Armv8 Pseudocode includes the definitions of these functions.
G1.15  Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An SError interrupt is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the default PE modes for taking these exceptions.

However, the PSTATE.{A, I, F} bits mask the asynchronous exceptions, meaning that when the value of one of these PSTATE bits is 1, the corresponding exception is not taken.

If a masked asynchronous exception remains signaled, then the exception remains pending unless the value of the PSTATE bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see Asynchronous exception routing controls on page G1-8957.
- Masking of these exceptions in Non-secure state, see Asynchronous exception masking controls on page G1-8959.

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the HCR when EL2 is using AArch32, and by the HCR_EL2 when EL2 is using AArch64.
- The EL3 controls are provided by the SCR when EL3 is using AArch32, and by the SCR_EL3 when EL3 is using AArch64.

Therefore, most references to the HCR or SCR in this section are to entries in Table K17-1 on page K17-11836, which disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-8961.

G1.15.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, which correspond to the physical asynchronous exceptions:

- Virtual SError, which corresponds to a physical external SError interrupt.
- Virtual IRQ, which corresponds to a physical IRQ.
- Virtual FIQ, which corresponds to a physical FIQ.

When the value of HCR.TGE is 0 and the value of an HCR.{AMO, IMO, FMO} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, HCR.{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual SError is taken to Non-secure Abort mode.
• A Virtual IRQ is taken to Non-secure IRQ mode.
• A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-15 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

### Table G1-15 HCR bits controlling asynchronous exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Routing the physical exception to EL2</th>
<th>Generating the virtual exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>HCR.AMO</td>
<td>HCR.VA</td>
</tr>
<tr>
<td>IRQ</td>
<td>HCR.IMO</td>
<td>HCR.VI</td>
</tr>
<tr>
<td>FIQ</td>
<td>HCR.FMO</td>
<td>HCR.VF</td>
</tr>
</tbody>
</table>

The HCR.{VA, VI, VF} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.{AMO, IMO, FMO} is 1.

Similarly, if the implementation also includes EL3, the HCR.{AMO, IMO, FMO} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.{EA, IRQ, FIQ} bit. For more information, see Asynchronous exception routing controls.

When the value of an HCR.{AMO, IMO, FMO} control bit is 1, the corresponding mask bit in PSTATE:
• Does not mask the physical exception.
• Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

--- Note ---
This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See WFE wake-up events on page G1-8990 and Wait For Interrupt on page G1-8991 for information about how virtual exceptions affect wake up from power-saving states.

--- Note ---
A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

### Effects of the HCR.{AMO, IMO, FMO} bits

As described in this section, the HCR.{AMO, IMO, FMO} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:
• As mentioned in this section, affect the routing of the exceptions. See Asynchronous exception routing controls.
• Affect the masking of the exceptions. See Asynchronous exception masking controls on page G1-8959.

### G1.15.2 Asynchronous exception routing controls

--- Note ---
This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-8961.
In an implementation that includes EL3 the following bits in the SCR control the routing of asynchronous exceptions:

**SCR.EA**  
When the value of this bit is 1, any SError interrupt is taken to EL3.

--- **Note** ---
Although this section describes the asynchronous exception routing controls, SCR.EA also controls the routing of synchronous External aborts, see *Routing of aborts taken to AArch32 state* on page G1-8948.

**SCR.FIQ**  
When the value of this bit is 1, any FIQ exception is taken to EL3.

**SCR.IRQ**  
When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the SCR.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode. Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the HCR route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the SCR.{EA, FIQ, IRQ} controls, to be taken to EL3.

**HCR.AMO**  
When the value of this bit is 1, an SError interrupt exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of SCR.EA is 0. When the value of SCR.EA is 1, the value of the AMO bit is ignored.

**HCR.FMO**  
When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.FIQ is 0. When the value of SCR.FIQ is 1, the value of the FMO bit is ignored.

**HCR.IMO**  
When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.IRQ is 0. When the value of SCR.IRQ is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the HCR.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode. Only software executing in Hyp mode, or Secure software executing at EL3 with SCR.NS set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The HCR.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in *Asynchronous exception masking controls* on page G1-8959.

The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

--- **Note** ---
When the PE is in Hyp mode:
- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-8956.
### G1.15.3 Asynchronous exception masking controls

**Note**

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see *Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-8961.*

The PSTATE.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:
- PSTATE.A can mask SError interrupt exceptions.
- PSTATE.I can mask IRQ exceptions.
- PSTATE.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the SCR.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the PSTATE.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the PSTATE.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:
- Asynchronous exception masking in an implementation that includes EL2 but not EL3.
- Asynchronous exception masking in an implementation that includes EL3 but not EL2.
- Asynchronous exception masking in an implementation that includes both EL2 and EL3.
- Summary of the asynchronous exception masking controls on page G1-8960.

#### Asynchronous exception masking in an implementation that includes EL2 but not EL3

The HCR.{AMO, IMO, FMO} bits modify the effect of the PSTATE.{A, I, F} bits. When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding PSTATE.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

#### Asynchronous exception masking in an implementation that includes EL3 but not EL2

The SCR.{AW, FW} bits modify the effect of the PSTATE.{A, F} bits. When the value of one of the SCR.{AW, FW} bits is 0, the corresponding PSTATE bit is ignored when both of the follow apply:
- The corresponding exception is taken from Non-secure state.
- The value of the corresponding SCR.{EA, IRQ, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

**Note**

Whenever the value of PSTATE.I is 1, IRQ exceptions are masked and cannot be taken.

#### Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding PSTATE.{A, I, F} bit is ignored when both of the following apply:
- The exception is taken from Non-secure state.
- Either:
  - The corresponding SCR.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.
In addition, when the value of an SCR.{AW, FW} bit is 0, the value of the corresponding PSTATE.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding SCR.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding HCR.{AMO, FMO} mask override bit is set to 0.

### Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the PSTATE.{A, I, F} bits. For an implementation that does not include all of the Exception levels:

**If the implementation includes only EL1 and EL0**

The PSTATE bits cannot be masked. The behavior is as shown in the Secure row of the tables.

**If the implementation includes EL2 but not EL3**

The behavior is as shown in the Non-secure table rows when the control bits in the SCR are both 0.

**If the implementation includes EL3 but not EL2**

The behavior is as shown in the table rows where the control bit in the HCR is 0.

Table G1-16 shows the controls of the masking of SError interrupt exceptions by PSTATE.A.

G1.15.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

Asynchronous exception routing controls on page G1-8957 and Asynchronous exception masking controls on page G1-8959 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- Summary of physical interrupt routing.
- Summary of physical interrupt masking on page G1-8962.

Summary of physical interrupt routing

The Table G1-19 on page G1-8962 shows the routing of physical FIQ, IRQ and SError interrupts when the highest Exception level is using AArch32.

In this table:

- SCR: This is the *Effective value* of a field in SCR.
- HCR: This is the *Effective value* of a field in HCR.
- FIQ IRQ EA: The *Effective value* of the field that handles the asynchronous exception type in SCR.
- FMO IMO AMO: The *Effective value* of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.
- FIQ IRQ Abt: The exception is taken to the FIQ mode, the IRQ mode or the Abort mode according to the type of asynchronous exception.
- Hyp: The exception is taken to AArch32 Hyp mode.
- Mon: The exception is taken to AArch32 Monitor mode.
n/a This field does not exist, or the Exception level is not accessible in this configuration.

### Summary of physical interrupt masking

Table G1-20 on page G1-8962 shows the masking of physical FIQ, IRQ and SError interrupts when the highest Exception level is using AArch32.

In this table:

- **SCR**: This is the *Effective value* of a field in SCR.
- **HCR**: This is the *Effective value* of a field in HCR.
- **FIQ IRQ EA**: The *Effective value* of the field that handles the asynchronous exception type in SCR.
- **FMO IMO AMO**: The *Effective value* of the mask override field for the asynchronous exception type in HCR.
- **FW AW**: For FIQ interrupts, the SCR.FW field, and for SError interrupts, the SCR.AW field. For IRQ interrupts, there is no equivalent field, so the *Effective value* is 0 and rows where this cell is 1 should be ignored.
- **A**: When the interrupt is asserted, it is taken regardless of the value of the PSTATE mask bit.
- **B**: When the interrupt is asserted, it is subject to the corresponding PSTATE mask bit. If the value of the mask is 1, the interrupt is not taken. If the value of the mask is 0, the interrupt is taken.
- **n/a**: This field does not exist, or the Exception level is not accessible in this configuration.

G1.15.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch32 state, an interrupt cannot be taken during a sequence of memory accesses caused by a single load or store instruction, except that when FEAT_LSMAOC is implemented and the value of the applicable LSMAOE field is 0, an interrupt can be taken between two memory accesses made by a single AArch32 Load Multiple (LDM) or Store Multiple (STM) instruction.

The applicable LSMAOE field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the LDM or STM instruction is executed.

When the value of the LSMAOE bit is 0 and an interrupt is taken between two memory accesses made by a single AArch32 LDM or STM instruction, then:

- For a load, any register being loaded by the instruction other than a register used in the generation of the address by the instruction or the PC, can contain an UNKNOWN value. Any register used in the generation of the address is restored to its initial value and the LR is set on the interrupt to a value consistent with returning to the instruction.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

Armv8.2 deprecates software relying on interrupts not being taken during the sequence of memory accesses caused by a single load or store instruction.

G1.16 AArch32 state exception descriptions

Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- Undefined Instruction exception.
- Monitor Trap exception on page G1-8966.
- Hyp Trap exception on page G1-8967.
- Supervisor Call (SVC) exception on page G1-8968.
- Secure Monitor Call (SMC) exception on page G1-8969.
- Hypervisor Call (HVC) exception on page G1-8970.
- Prefetch Abort exception on page G1-8971.
- Data Abort exception on page G1-8975.
- Virtual SError interrupt exception on page G1-8979.
- IRQ exception on page G1-8980.
- Virtual IRQ exception on page G1-8982.
- FIQ exception on page G1-8982.
- Virtual FIQ exception on page G1-8984.

Additional pseudocode functions for exception handling on page G1-8984 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

G1.16.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, HCPTR, and DBGDSCRext.
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
  - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See Floating-point exceptions and exception traps on page E1-7148.
  - Execution of certain floating-point instructions when one or both of the FPSCR. {Stride, Len} fields in nonzero, in an implementation in which those fields are RW. The description of FPEXC specifies the instructions to which this applies.
- An instruction that is UNDEFINED.

Note

The Undefined Instruction exception is taken using offset 0x04 in the Hyp, Secure, or Non-secure vector table. In the Monitor vector table this offset is used for the Monitor Trap exception. See Monitor Trap exception on page G1-8966 and The vector tables and exception offsets on page G1-8930.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Undefined Instruction exception is taken on page G1-8965.

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- Lazy context switching of System registers.
The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the SPSR and LR_und values generated by the exception entry, as follows:
  - If SPSR.T is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

--- Note

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

The PE mode to which the Undefined Instruction exception is taken

Figure G1-4 shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken, when the exception is taken to an Exception level that is using AArch32.

---

Figure G1-4 The PE mode an Undefined Instruction exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-8942.
Pseudocode description of taking the Undefined Instruction exception

The AArch32.UndefinedFault() pseudocode procedure determines whether the Undefined Instruction exception is taken to AArch32 state. If it is taken to AArch32 state, the AArch32.TakeUndefInstrException() pseudocode procedure describes how the PE takes the exception.

An Undefined Instruction exception is taken to an Exception level using AArch64 if either:

- It is generated in User mode when EL1 is using AArch64.
- It is generated in User mode when EL2 is enabled in the current Security state and is using AArch64 and the value of HCR_EL2.TGE is 1.

Conditional execution of undefined instructions

The conditional execution rules described in Conditional execution on page F1-7229 apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception:
  - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.
  - The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

Note

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.

G1.16.2 Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.

Note

The Monitor Trap exception is taken using offset 0x04 in the Monitor vector table. In the other vector tables, this offset is used for the Undefined Instruction exception. See Undefined Instruction exception on page G1-8964 and The vector tables and exception offsets on page G1-8930.
A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a `WFI` or `WFE` instruction that would otherwise cause suspension of execution when:

- In the case of the `WFI` instruction, the value of the `SCR.TWI` bit is 1.
- In the case of the `WFE` instruction, the value of the `SCR.TWE` bit is 1.

**Note**

Since a `WFE` or `WFI` can complete at any time, even without a Wakeup event, the traps on `WFE` or `WFI` are not guaranteed to be taken, even if the `WFE` or `WFI` is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the `SPSR` and `LR_mon` values generated by the exception entry, as follows:

- If `SPSR.T` is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
- If `SPSR.T` is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see *Exception return to an Exception level using AArch32* on page G1-8951.

**The PE mode to which the Monitor Trap exception is taken**

When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of `0x04` from the Monitor exception base address.

**Pseudocode description of taking the Monitor Trap exception**

The `AArch32.TakeMonitorTrapException()` pseudocode procedure describes how the PE takes the exception.

### G1.16.3 Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor.

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the `HCR`, `HCPTR`, `HDCR`, or `HSTR`. For more information, see *EL2 configurable controls* on page G1-9010.

Traps to Hyp mode never apply in Secure state, regardless of the value of the `SCR.NS` bit.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an `ERET` instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

**Note**

The `SPSR` and `ELR_hyp` values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying `ELR_hyp`, and possibly updating `SPSR_hyp`.

When the PE enters the handler for a Hyp Trap exception, the `HSR` holds syndrome information for the exception. For more information, see *Use of the HSR* on page G5-9265.

**The PE mode to which the Hyp Trap exception is taken**

A Hyp Trap exception is taken to Hyp mode, using a vector offset of `0x14` from the Hyp exception base address.
Pseudocode description of taking the Hyp Trap exception

The `AArch32.TakeHypTrapException()` pseudocode procedure describes how the PE takes the exception.

### G1.16.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see SVC on page F5-8055.

--- Note ---

In an implementation that includes EL2, when EL2 is using AArch32:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information, see SVC on page F5-8055.

- When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-8945.

By default, a Supervisor Call exception that is taken to AArch32 state is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Supervisor Call exception is taken.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR_svc values generated by the exception entry, in an exception return instruction without subtraction.

- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

### The PE mode to which the Supervisor Call exception is taken

Figure G1-5 on page G1-8969 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken, when the exception is taken to an Exception level that is using AArch32.
Figure G1-5 The PE mode the Supervisor Call exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-8942.

Pseudocode description of taking the Supervisor Call exception

The AArch32.CallSupervisor() pseudocode procedure determines whether the Supervisor Call exception is taken to AArch32 state. If it is taken to AArch32 state, the AArch32.TakeSVCException() pseudocode procedure describes how the PE takes the exception.

An Supervisor Call exception is taken to an Exception level using AArch64 if either:

• It is generated by executing an SVC instruction in User mode when EL1 is using AArch64.
• It is generated by executing an SVC instruction in Non-secure User mode when EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

G1.16.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see SMC on page F5-7900.

Note

• In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when HCR.TSC 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information, see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-9017.
• The Operation pseudocode in the description of the AArch32 SMC instruction, in SMC on page F5-7900, identifies cases where execution of the instruction generates an exception that is taken to EL3 using AArch64.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. For an exception taken to AArch32 state, this return is performed using the SPSR and LR_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

Note
For an exception taken to AArch32 state, the exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then asynchronous exceptions might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:
• The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.
• The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

The PE mode to which the Secure Monitor Call exception is taken
The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset 0x08 from the Monitor exception base address.

Note
• An SMC instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see The PE mode to which the Hyp Trap exception is taken on page G1-8967.
• If EL3 is using AArch64 then Security behavior in Exception levels using AArch32 when EL2 or EL3 are using AArch64 on page G1-8941 describes the effect of executing an SMC instruction at an Exception level that is using EL1.

Pseudocode description of taking the Secure Monitor Call exception
The AArch32.TakeSMCException() pseudocode procedure describes how the PE takes the exception when the exception is taken to an Exception level that is using AArch32.

G1.16.6 Hypervisor Call (HVC) exception
The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see HVC on page F5-7576.

Note
• Execution of HVC instructions is disabled when the value of SCR.HCE is 0. Descriptions of HVC instruction execution elsewhere in this section assume the Effective value of SCR.HCE is 1.
• When EL2 is using AArch64 an HVC instruction executed in a Non-secure EL1 mode generates an exception that is taken to EL2 using AArch64.
The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information, see Use of the HSR on page G5-9265.

**The PE mode to which the Hypervisor Call exception is taken**

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

![Figure G1-6 The PE mode the Hypervisor Call exception is taken to in AArch32 state](image)

**Pseudocode description of taking the Hypervisor Call exception**

The `AArch32.CallHypervisor()` pseudocode procedure determines whether the valid execution of an HVC instruction in AArch32 state generates an exception that is taken to EL2 using AArch64, or generates a Hypervisor Call exception taken to Hyp mode. The `AArch32.TakeHVCException()` pseudocode procedure describes how the PE takes a Hypervisor Call exception.

**G1.16.7 Prefetch Abort exception**

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

  **Note**

  Asynchronous External aborts on instruction fetches are reported as SError interrupts using the Data Abort exception, see Data Abort exception on page G1-8975.

  A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

  For more information about memory aborts see VMSAv8-32 memory aborts on page G5-9238.

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see Chapter G2 AArch32 Self-hosted Debug.

  **Note**

  If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

  - Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.

  - Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.
By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Prefetch Abort exception is taken to an Exception level that is using AArch32, see *The PE mode to which the Prefetch Abort exception is taken* on page G1-8973.
- About cases where the Prefetch Abort generates an exception that is taken to an Exception level that is using AArch64, see *Pseudocode description of taking the Prefetch Abort exception* on page G1-8975.

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Prefetch Abort exceptions in AArch32 state see *Exception return to an Exception level using AArch32* on page G1-8951.

### Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

**If the exception is taken to EL1 using AArch32 or EL3 using AArch32**

- The IFSR indicates the cause of the exception:
  - If the value of TTBCR.EAE is 0, IFSR.FS takes the value \(0b00001\).
  - If the value of TTBCR.EAE is 1, IFSR.STATUS takes the value \(0b100001\).
- IFAR holds the value of the address that faulted, including the misaligned low order bit or bits.
- R14_abt holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

**If the exception is taken to EL2 using AArch32**

- HSR.EC takes the value \(0b100010\).
- HSR.IL is **UNKNOWN**.
- HSR.ISS is **RES0**.
- HIFAR and ELR_hyp each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the **CONSTRAINED UNPREDICTABLE** behavior of a branch to an unaligned PC value, as described in *Branching to an unaligned PC* on page K1-11564, then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in *Exiting Debug state* on page H2-10271, then it is **CONSTRAINED UNPREDICTABLE** whether bit[0] of the faulting address is forced to zero.
The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 on page G1-8974 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken, when the exception is taken to an Exception level that is using AArch32.

Note

In this figure, the Effective value of HCR2.TEA is 0 if The Reliability, Availability, and Serviceability Extension is not implemented.
Figure G1-7 The PE mode the Prefetch Abort exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-8942.
Pseudocode description of taking the Prefetch Abort exception

The AArch32.Abort() pseudocode function determines whether the Prefetch Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Prefetch Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the AArch32.TakePrefetchAbortException() pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  — The value of HCR_EL2.TGE is 1 and the exception is generated in Non-secure User mode.
  — The value of MDCR_EL2.TDE is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  — The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of SCR_EL3.EA is 1. and the exception is generated by an External abort in AArch32 state.

G1.16.8 Data Abort exception

In AArch32 state, a Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError interrupt. The SError interrupt might be caused by an External abort on a memory access, which can be any of:
  — A data read or write access.
  — An instruction fetch.
  — In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously.

As described in Asynchronous exception masking controls on page G1-8959, SError interrupts can be masked. When this happens, a generated SError interrupt is not taken until it is not masked.

- A watchpoint, see Watchpoint exceptions on page G2-9079.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Data Abort exception is taken to an Exception level that is using AArch32 see The PE mode to which the Data Abort exception is taken on page G1-8976.
- About memory aborts in AArch32 state see VMSAv8-32 memory aborts on page G5-9238.
- About cases where the Data Abort generates an exception that is taken to an Exception level that is using AArch64 see Pseudocode description of taking the Data Abort exception on page G1-8978.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError interrupt exception was taken. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  — SPSR_abt and LR_abt if returning from Abort mode.
— SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Data Abort exceptions in AArch32 state see Exception return to an Exception level using AArch32 on page G1-8951.

The PE mode to which the Data Abort exception is taken

Figure G1-8 on page G1-8977 shows the determination of the mode to which a Data Abort exception is taken when the exception is taken to an Exception level that is using AArch32.

Note

In this figure, the Effective value of HCR2.TEA is 0 if The Reliability, Availability, and Serviceability Extension is not implemented.
Figure G1-8 The PE mode the Data Abort exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-8942.
Pseudocode description of taking the Data Abort exception

The AArch32.Abort() pseudocode function determines whether the Data Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Data Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the AArch32.TakeDataAbortException() pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of HCR_EL2.TGE is 1 and the exception is generated in Non-secure User mode.
  - The value of MDCR_EL2.TDE is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of SCR_EL3.EA is 1. and the exception is generated by an External abort in AArch32 state.

Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the location, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - An Alignment fault is generated.
  - An MMU fault is generated.
  - A Watchpoint is generated.
  - An External abort is generated, if that External abort is taken synchronously.
- UNKNOWN for any location for which no exception and no debug event is generated.

If the access to a memory location generates an External abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the External abort. However, in general, Arm recommends that such locations are unchanged.

For External aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying base register writeback, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have CONSTRAINED UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct transfer to or from the Debug Communication Channel (DCC) register, using the LDC and STC instructions. For more information, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.
  
  If the instruction that accesses the DCC registers is an LDC or STC instruction, UNKNOWN values are left in the Data Transfer Register and DCC flow-control flags.
- By modifying PSTATE.
If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- **On entry to the Data Abort exception handler:**
  - The PC value is the Data Abort vector address, see Exception vectors and the exception base address on page G1-8929.
  - The LR_abt value is determined from the address of the aborted instruction. Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register file, UNKNOWN values are left in the registers that are affected.
- **PSTATE** bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREX®, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN. Therefore, Arm strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the Exclusives monitor state.

An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted. The error that caused the External abort might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

**The Arm abort model**

The abort model used by an Arm PE is described as a Base Restored Abort Model. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

**G1.16.9 Virtual SError interrupt exception**

The Virtual SError interrupt exception is implemented only as part of EL2 is enabled in the current Security state.

A Virtual SError interrupt exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of PSTATE.A is 0.
- Either:
  - EL2 is using AArch32 and the values of the HCR.{TGE, AMO, VA} bits are {0, 1, 1}.
  - EL2 is using AArch64 and the values of the HCR_EL2.{TGE, AMO, VA} bits are {0, 1, 1}.

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state, this return is performed using the SPSR and LR_abt values generated by the exception entry, using an exception return instruction without subtraction.
The PE mode to which the Virtual SError interrupt exception is taken

The Virtual SError interrupt exception is taken using a vector offset of 0x10 from the Non-secure exception base address.

The conditions for generating a Virtual SError interrupt exception in AArch32 state mean the exception is:

- Taken from a EL1 or EL0 mode.
- Taken to Abort mode if EL1 is using AArch32.
- Taken to EL1, when EL0 is using AArch32 and EL1 is using AArch64.

For more information, see Virtual exceptions when an implementation includes EL2 on page G1-8956.

Note

Because a Virtual SError interrupt exception taken to AArch32 state is always taken to Abort mode, on exception entry the preferred return address is always saved to LR_abt.

Pseudocode description of taking the Virtual SError interrupt exception

The AArch32.TakeVirtualSErrorException() pseudocode procedure describes how the PE takes the exception.

G1.16.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-8959, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the exception is taken to an Exception level using AArch32 see The PE mode to which the physical IRQ exception is taken on page G1-8981.
- About cases where the exception is taken to an Exception level using AArch64 see Pseudocode description of taking the physical IRQ exception on page G1-8981.

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_irq and LR_irq if returning from IRQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.
The PE mode to which the physical IRQ exception is taken

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken when the exception is taken to an Exception level that is using AArch32.

![Figure G1-9 The PE mode the IRQ exception is taken to in AArch32 state](image)

Pseudocode description of taking the physical IRQ exception

The `AArch32.TakePhysicalIRQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from User mode, EL2 is implemented in the current Security state and using AArch64, and the value of `HCR_EL2.TGE` is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from EL0 or EL1 mode, EL2 is implemented in the current Security state and using AArch64, and the value of `HCR_EL2.IMO` is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of `SCR_EL3.IRQ` is 1. The Exception is taken to EL3 using AArch64.
G1.16.11  Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual IRQ exception is generated in AArch32 state if all of the following apply:

• The PE is in a mode other than Hyp mode.
• The value of PSTATE.I is 0.
• Either:
  — EL2 is using AArch32 and the value of HCR.{TGE, IMO} is {0, 1}.
  — EL2 is using AArch64 and the value of HCR_EL2.{TGE, IMO} is {0, 1}.
• One of the following applies:
  — EL2 is using AArch32 and the value of HCR.VI is 1.
  — EL2 is using AArch64 and the value of HCR_EL2.VI is 1.
  — A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception uses a vector offset of 0x18.

The conditions for generating a Virtual IRQ exception in AArch32 state mean the exception is:

• Taken from an EL1 or EL0 mode.
• Taken to IRQ mode if EL1 is using AArch32.
• Taken to EL1 if EL0 is using AArch32 and EL1 is using AArch64.

For more information, see Virtual exceptions when an implementation includes EL2 on page G1-8956.

Pseudocode description of taking the Virtual IRQ exception

The AArch32.TakeVirtualIRQException() pseudocode procedure describes how the PE takes the exception.

G1.16.12  FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-8959, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to:

• EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
• EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

• About cases where the exception is taken to an Exception level using AArch32 see The PE mode to which the physical FIQ exception is taken on page G1-8983.
• About cases where the exception is taken to an Exception level using AArch64 see Pseudocode description of taking the FIQ exception on page G1-8984.
The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_fiq and LR_fiq if returning from FIQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

**The PE mode to which the physical FIQ exception is taken**

Figure G1-9 on page G1-8981 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken when the exception is taken to an Exception level that is using AArch32.

![FIQ exception diagram](image)

Figure G1-10 The PE mode the FIQ exception is taken to in AArch32 state
Pseudocode description of taking the FIQ exception

The `AArch32.TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from User mode, EL2 is implemented in the current Security state and using AArch64, and the value of `HCR_EL2.TGE` is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from an EL0 or EL1 mode, EL2 is implemented in the current Security state and using AArch64, and the value of `HCR_EL2.FMO` is 1. The Exception is taken to EL2 using AArch64.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of `SCR_EL3.FIQ` is 1. The Exception is taken to EL3 using AArch64.

G1.16.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual FIQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of `PSTATE.F` is 0.
- Either:
  - EL2 is using AArch32 and the value of `HCR.{TGE, FMO}` is {0, 1}.
  - EL2 is using AArch64 and the value of `HCR_EL2.{TGE, FMO}` is {0, 1}.
- One of the following applies:
  - EL2 is using AArch32 and the value of `HCR.VF` is 1.
  - EL2 is using AArch64 and the value of `HCR_EL2.VF` is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the `SPSR` and `LR_irq` values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is taken using a vector offset of 0x1C.

The conditions for generating a Virtual FIQ exception in AArch32 state mean the exception is:

- Taken from EL1 or EL0.
- Taken to FIQ mode if EL1 is using AArch32.
- Taken to EL1 if EL0 is using AArch32 and EL1 is using AArch64.

For more information, see Virtual exceptions when an implementation includes EL2 on page G1-8956.

Pseudocode description of taking the Virtual FIQ exception

The `AArch32.TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception.

G1.16.14 Additional pseudocode functions for exception handling

The `AArch32.EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes.
The `AArch32.EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The `AArch32.EnterMode()` pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The `AArch32.EnterMonitorMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMode()` functions are described in Chapter J1 *Armv8 Pseudocode*. 
G1.17 Reset into AArch32 state

Resets and power domains on page D1-4673 describes the Armv8 reset model, including the defined levels of reset. When reset is deasserted, the PE starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

• In Secure state, if the implementation includes EL3.
• With interrupts disabled:
  — In Hyp mode, if the highest implemented Exception level is EL2.
  — In Supervisor mode, otherwise.

--- Note ---

• This section describes the architectural requirements for a reset into AArch32 state. It takes no account of whether Arm licenses any particular combination of Exception levels and Execution state. For more information about the licensed combinations, see Exception levels on page D1-4632.

• The Execution state in which the highest implemented Execution level starts executing instructions on coming out of reset might be determined by a configuration input signal.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in PE state on reset into AArch32 state. For more information about behavior when resetting into an Exception level using AArch32, see:

• Behavior of caches at reset on page G4-9119.
• Enabling stages of address translation on page G5-9156.
• TLB behavior at reset on page G5-9217.
• Reset and debug on page H6-10348.

When reset is deasserted, if the PE resets into an Exception level that is using AArch32, it is IMPLEMENTATION DEFINED whether execution starts:

• From an IMPLEMENTATION DEFINED address.
• If reset is into EL3 or EL1, from the low or high reset vector address, as determined by the reset value of the SCTLR.V bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

--- Note ---

This option might be implemented for compatibility with earlier versions of the architecture.

Software might be able to identify the reset address:

• If reset is into EL3, by reading the reset value of MVBAR. That is, after coming out of reset, by reading MVBAR before the boot software has updated it. It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported.
• If reset is into EL2 or EL1, by reading RVBAR. RVBAR can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3.

If RVBAR is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for RVBAR is UNDEFINED.

The Arm architecture does not define any way of returning to a previous Execution state from a reset.

G1.17.1 PE state on reset into AArch32 state

Immediately after a reset, much of the PE state is architecturally UNKNOWN. However, some of the PE state is defined, see the individual register descriptions for more information. The state that is reset to known values is sufficient to permit predictable initial execution at the highest Exception level, such that this execution is then capable of initializing the remaining state of the system where necessary before use.
If the PE resets to AArch32 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- The global exclusive monitor and local exclusive monitor for the PE are **UNKNOWN**.
- If reset is into EL2 using AArch32, then reset is into Hyp mode and PSTATE.M resets to `0b1010`, otherwise reset is into Supervisor mode and PSTATE.M resets to `0b0011`.
- PSTATE.IL resets to 0.

### G1.17.2 Pseudocode descriptions of reset

The `AArch32.TakeReset()` pseudocode procedure describes how the PE behaves when reset is deasserted.

The `AArch32.ResetGeneralRegisters()` pseudocode function resets the general-purpose registers.

The `AArch32.ResetSIMDFPRegisters()` pseudocode function resets the SIMD and floating-point registers.

The `AArch32.ResetSpecialRegisters()` pseudocode function resets the Special-purpose registers, and the debug System registers DLR and DSPSR, which are used for handling Debug exceptions.

The `AArch32.ResetSystemRegisters()` pseudocode function resets all System registers in the `(coproc==0b111x)` encoding space to their reset state as defined in the register descriptions in Chapter G8 AArch32 System Register Descriptions.

--- Note ---

The `AArch32.ResetSystemRegisters()` function only resets the System registers. It has no effect on memory-mapped registers.

--- Note ---

The `ResetExternalDebugRegisters()` pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 External Debug Register Descriptions.
G1.18 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- Wait For Event and Send Event.
- Wait For Interrupt on page G1-8991.

G1.18.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. Example G1-2 describes how a spinlock implementation might use this mechanism to save energy.

Example G1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page E2-7211.
- If the PE obtains the lock, it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point, it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system, the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation, the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a WFE instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
  — The Event Register is not set.
  — There is not a pending WFE wake-up event.

For more information about the trap to EL2, see Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020.

The architecture does not define the exact nature of the low power state entered as a result of executing a WFE instruction, but the execution of a WFE instruction must not cause a loss of memory coherency or architectural state.
— Note ——-

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see WFE wake-up events on page G1-8990.
- The Event Register, see The Event Register.
- The Send Event instructions, see The Send Event instructions on page G1-8990.
- The Wait For Event instruction, see The Wait For Event instruction.

The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see Event streams on page G6-9295.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The execution in AArch32 state of a WFE instruction that would otherwise cause suspension of execution might be trapped, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-9004.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-9032.
The Wait For Event instruction, \( \text{WFE} \), is available at all privilege levels, see \( \text{WFE} \) on page F5-8154.

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

**WFE wake-up events**

The following events are \( \text{WFE} \) wake-up events:

- The execution of an \( \text{SEV} \) instruction on any PE in the system.
- The execution of an \( \text{SEVL} \) instruction on the PE.
- A physical IRQ interrupt, unless masked by the \( \text{PSTATE}.I \) bit.
- A physical FIQ interrupt, unless masked by the \( \text{PSTATE}.F \) bit.
- A physical SError interrupt, unless masked by the \( \text{PSTATE}.A \) bit.
- In Non-secure state in any mode other than Hyp mode:
  - When \( \text{HCR}.I \) is set to 1, a virtual IRQ interrupt, unless masked by the \( \text{PSTATE}.I \) bit.
  - When \( \text{HCR}.F \) is set to 1, a virtual FIQ interrupt, unless masked by the \( \text{PSTATE}.F \) bit.
  - When \( \text{HCR}.A \) is set to 1, a virtual SError interrupt, unless masked by the \( \text{PSTATE}.A \) bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed, see \( \text{Halting allowed and halting prohibited} \) on page H2-10233.
  See also \( \text{External Debug Request debug event} \) on page H3-10291.
- An event sent by the timer event stream, see \( \text{Event streams} \) on page D10-5239.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and \( \text{EDSCR}.\text{HDE} \) is set to 1, \( \text{EDSCR}.\text{INTdis} \) can mask interrupts, including masking them acting as WFE wake-up events. See the register description for more information.

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

——— \textbf{Note} ————

For more information about \( \text{PSTATE} \) masking, see \( \text{Asynchronous exception masking controls} \) on page G1-8959. If the configuration of the masking controls provided by EL2 and EL3 mean that a \( \text{PSTATE} \) mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the \( \text{PSTATE} \) mask bit.

——— \textbf{Note} ————

The Send Event instructions

The Send Event instructions are:

**SEV, Send Event**

This causes an event to be signaled to all PEs in the multiprocessor system.

**SEVL, Send Event Local**

This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the \( \text{SEV} \) instruction. Therefore, Arm recommends that software includes a \text{DSB} instruction before any \text{SEV} instruction.

——— \textbf{Note} ————

A \text{DSB} instruction ensures that no instruction, including any \text{SEV} instruction, that appears in program order after the \text{DSB} instruction, can execute until the \text{DSB} instruction has completed. For more information, see \( \text{Data Synchronization Barrier (DSB)} \) on page E2-7182.

——— \textbf{Note} ————

The \text{SEVL} instruction appears to execute in program order relative to any subsequent \text{WFE} instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.
Execution of the Send Event instruction sets the Event Register.
The Send Event instructions are available at all privilege levels.

**Pseudocode description of the Wait For Event mechanism**

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `IsEventRegisterSet()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

### G1.18.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, `WFI`, which is provided in the A32 and T32 instruction sets. For more information, see `WFI` on page F5-8156.

When a PE issues a `WFI` instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a `WFI` instruction that would otherwise cause suspension of execution might be trapped, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-9004.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-9032.

The execution of a `WFI` instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wake-up event.

**WFI wake-up events**

The PE can remain suspended in its WFI state until it is reset, or one of the following WFI wake-up events occurs:

- A physical IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
- A physical FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
- A physical SError interrupt, regardless of the value of the `PSTATE.A` bit.
- In Non-secure state in any mode other than Hyp mode:
  - When `HCR.IMO` is set to 1, a virtual IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
  - When `HCR.FMO` is set to 1, a virtual FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
  - When `HCR.AMO` is set to 1, a virtual SError interrupt, regardless of the value of the `PSTATE.A` bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed, see Halting allowed and halting prohibited on page H2-10233.

See also External Debug Request debug event on page H3-10291.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the `WFI` instruction completes.

WFI wake-up events cannot be masked by the mask bits in the `PSTATE`.

The architecture does not define the exact nature of the low power state, except that:

- The execution of a `WFI` instruction must not cause a loss of memory coherency.
• If the system is configured such that the WFI instruction can be completed, then the WFI instruction must not cause a loss of architectural state.

--- Note ---
In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wake-up events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

--- Note ---
• Because debug events are WFI wake-up events, Arm strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.

• In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.

• Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The Arm architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

Using WFI to indicate an idle state on bus interfaces
A common implementation practice is to complete any entry into powerdown routines with a WFI instruction. Typically, the WFI instruction:
1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If FEAT_DoubleLock is implemented and the value of DBGOSDLR.DLK, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

--- Note ---
When separate Core and Debug power domains are implemented, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see Power domains and debug on page H6-10335.

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode description of Wait For Interrupt
The WaitForInterrupt() pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
G1.19 The AArch32 System register interface

Most System registers are accessed using the instructions described in System register access instructions on page F2-7277. The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters \{coproc, opc1, CRn, CRm, opc2\}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions.
- To maintain compatibility with previous versions of the Arm architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

--- Note ---

See Background to the System register interface on page G1-8994 for more information.

The following sections give more information about the AArch32 System register interface:

- System registers in the coproc == 0b111x encoding space.
- Access to System registers.
- Access controls for Advanced SIMD and floating-point functionality.
- Background to the System register interface on page G1-8994.

G1.19.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
  - Debug features, see Debug registers on page G8-9831.
  - Trace features, see the Embedded Trace Macrocell Architecture Specification.
  - Identification registers for the Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-8927.
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information, see Chapter G8 AArch32 System Register Descriptions.

G1.19.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0 the register descriptions in Chapter G8 AArch32 System Register Descriptions indicate whether a register is accessible from EL0.

G1.19.3 Access controls for Advanced SIMD and floating-point functionality

The CPACR controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The \{cp10, cp11\} fields control access to all Advanced SIMD and floating-point functionality, and can:
  - Disable EL0 and PL1 access to this functionality.
  - Enable access to this functionality at PL1 only.
  - Enable access to this functionality at EL0 and PL1.
- The ASEDIS field controls access to Advanced SIMD instructions that are not also floating-point instructions.
Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

Note
The CPACR has no effect on accesses from Hyp mode.

If an implementation includes EL3, the NSACR determines whether Advanced SIMD and floating-point functionality can be accessed from Non-secure state:
- The \( \{cp10, cp11\} \) fields control Non-secure access to all Advanced SIMD and floating-point functionality.
- The NSASEDIS field controls Non-secure access to Advanced SIMD instructions that are not also floating-point instructions.

If an implementation includes EL2, the HCPTR provides additional controls on Non-secure accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the CPACR and NSACR settings, setting HCPTR bits to 1:
- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the HCPTR:
- The \( \{TCP10, TCP11\} \) fields control access to all Advanced SIMD and floating-point functionality.
- The TASE field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The TCPAC field traps Non-secure EL1 accesses to the CPACR to Hyp mode.

For more information, see General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-9021.

Note
Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. If these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE, see Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-11568.

For more information about Advanced SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-8996.

G1.19.4 Background to the System register interface

Note
This section is not part of the Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic coprocessor interface that gave access to 15 coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by Arm, while CP0 - CP7 were available for IMPLEMENTATION DEFINED coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see System register access instructions on page F2-7277.

In the Arm coprocessor model, a coprocessor included both:
- Primary and secondary coprocessor registers, which form part of the coprocessor interface.
- A number of internal registers.
When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the coproc parameter and taking a value between \( p0 \) for CP0 and \( p15 \) for CP15.
- The primary coprocessor register, specified by the \( CRn \) parameter and taking a value between \( c0 \) and \( c15 \).
- The secondary coprocessor register, specified by the \( CRn \) parameter and taking a value between \( c0 \) and \( c15 \).
- Up to two additional parameters, \( opc1 \) and \( opc2 \), taking values between 0 and 7.

Other instructions in the group described in System register access instructions on page F2-7277 take a subset of these parameters:

- In the Armv7 definitions, LDC and STC instructions take parameters \{coproc, CRd\}, where \( CRd \) is the primary coprocessor register.
- MCR and MRRC instructions take parameters \{coproc, opc1, CRn\}, where \( CRn \) is the primary coprocessor register.

To maintain backwards compatibility, the arguments to an MCR or MRC instruction remain \{coproc, opc1, CRn, CRm, opc2\}. Correspondingly, the encoding of the AArch64 System registers is described using the parameters \{op0, op1, CRn, CRm, op2\}. However:

- The naming of these parameters no longer has any particular significance.
- While the coproc field is a 4-bit field, \( op0 \) is a 2-bit field.

Of the coprocessors reserved for use by Arm, in earlier versions of the architecture:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. From the introduction of Armv8, these registers are described as being in the \( \text{coproc} = \text{0b1111} \) encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. From the introduction of Armv8, these registers are described as being in the \( \text{coproc} = \text{0b1110} \) encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
  - Generally from the introduction of Armv8 the architecture does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
  - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.\{cp10, cp11\}. In these cases, both fields must be set to the same value. For more information, see Access controls for Advanced SIMD and floating-point functionality on page G1-8993.

From the introduction of Armv8:

- The AArch32 System registers include registers that were described as Special registers in Armv7 and earlier versions of the architecture. This means that the System registers include registers that are outside the earlier coprocessor model.
- The Armv7 AArch32 instruction encodings for LDC, STC, MCR, MRC, MCRR, and MRRC instructions with coproc field values other than \{1010, 1011, 1110, 1111\} are available for reuse. Armv8.2 re-uses some encodings in this way.
G1.20 Advanced SIMD and floating-point support

Advanced SIMD and floating-point instructions on page E1-7140 introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, which can be viewed as:
  - Singleword registers S0 - S31.
  - Doubleword registers D0 - D31.
  - Quadword registers Q0 - Q15.
- The Floating-Point Status and Control Register (FPSCR).
- Floating-point exceptions and exception traps on page E1-7148

For more information about the System registers for the Advanced SIMD and floating-point operation, see Advanced SIMD and floating-point System registers on page G1-8998. Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

AArch32 implications of not including support for Advanced SIMD and floating-point summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:

- Enabling Advanced SIMD and floating-point support.
- Advanced SIMD and floating-point System registers on page G1-8998.
- Context switching when using Advanced SIMD and floating-point functionality on page G1-8999.

G1.20.1 AArch32 implications of not including support for Advanced SIMD and floating-point

The architecture generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. However, for implementations targeting specialized markets, Arm might produce or license implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- The CPACR.{ASEDIS, cp11, cp10} fields are RES0.
- The NSACR.{NSASEDIS, cp11, cp10} fields are RES0.
- The HCPTR.{TASE, TCP11, TCP10} fields are RES1.
- The FPEXC, FPSCR, FPSID, MVFR0, MVFR1, and MVFR2 registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.

G1.20.2 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in Configurable instruction enables and disables, and trap controls on page G1-9001, and this section:

- Summarizes those controls.
- Provides additional information in the following subsections:
  - FPEXC control of access to Advanced SIMD and floating-point functionality on page G1-8998.
  - EL0 access to Advanced SIMD and floating-point functionality on page G1-8998.

Note

This section shows the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.
The controls of access to Advanced SIMD and floating-point functionality are:

**General \{cp10, cp11\} or \{TCP10, TCP11\} controls**

This relates to the CPACR.\{cp10, cp11\}, NSACR.\{cp10, cp11\}, and HCPTR.\{TCP10, TCP11\} controls.

--- **Note** ---

*Background to the System register interface* on page G1-8994 explains the naming of these controls.

The \{cp10, cp11\} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- **CPACR.\{cp10, cp11\}** control access from PE modes other than Hyp mode. These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- **In an implementation that includes EL3, NSACR.\{cp10, cp11\}** control access from Non-secure state.
- **In an implementation that includes EL2, if NSACR.\{cp10, cp11\}** permit Non-secure accesses, or if EL3 is not implemented, HCPTR.\{TCP10, TCP11\} provide an additional control on those accesses.

In each case, the \{cp10, cp11\} controls must be programmed to the same value, otherwise operation is **CONSTRAINED UNPREDICTABLE**. The CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information, see *Handling of System register control fields for Advanced SIMD and floating-point operation* on page K1-11568.

For more information about these controls, see:

- Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-9006.
- General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-9021.
- Enabling Non-secure access to SIMD and floating-point functionality on page G1-9034.

**Control of accesses to the CPACR from Non-secure PL1 modes**

As stated in **General \{cp10, cp11\} or \{TCP10, TCP11\} controls**, the CPACR controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the CPACR from Non-secure PL1 modes can be trapped to EL2, see *Traps to Hyp mode of Non-secure EL1 accesses to the CPACR* on page G1-9023.

**Additional controls of Advanced SIMD functionality**

- If implemented as an RW field, CPACR.ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.
- **In an implementation that includes EL3, when CPACR.ASEDIS** permits use of the Advanced SIMD instructions or if the CPACR.ASEDIS control is not implemented, NSACR.NSASEDIS can make all Advanced SIMD instructions UNDEFINED in Non-secure state.
- **In an implementation that includes EL2, when the CPACR and NSACR** settings permit Non-secure use of the Advanced SIMD instructions, if HCPTR.TASE is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a Non-secure PL0 or PL1 mode.

For more information about these controls, see:

- Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-9007.
- Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-9022.
- Disabling Non-secure access to Advanced SIMD functionality on page G1-9034.
Pseudocode description of enabling SIMD and floating-point functionality on page G1-9035 provides links to the pseudocode descriptions of all of these controls.

**FPEXC control of access to Advanced SIMD and floating-point functionality**

In addition, FPEXC.EN is an enable bit for most Advanced SIMD and floating-point operations. When FPEXC.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the FPEXC or FPSID register.
- A VMRS from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register.

These instructions can be executed only at EL1 or higher.

--- Note ---

- When the FPSID is accessible, any write access to the FPSID is ignored.
- When FPEXC.EN is 0, these operations are treated as UNDEFINED:
  - A VMSR to the FPSCR.
  - A VMRS from the FPSCR.

---

See Enabling access to the SIMD and floating-point registers on page G1-9007 for more information about the scope of the FPEXC.EN control.

When executing at EL0, the PE behaves as if the value of FPEXC.EN is 1 if either:

- EL1 is using AArch64.
- EL2 is enabled in the current Security state and is using AArch64 and the value of HCR_EL2.TGE is 1.

--- Note ---

In Non-secure state, if the value of HCR_EL2.RW is 0 then it is permitted for the value of FPEXC32_EL2.EN to control whether Advanced SIMD and floating-point functionality is enabled. However, Arm deprecates using the value of FPEXC32_EL2.EN to determine behavior.

**EL0 access to Advanced SIMD and floating-point functionality**

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the FPSCR.
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in Advanced SIMD and floating-point System registers on page E1-7142.

**G1.20.3 Advanced SIMD and floating-point System registers**

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- Register map of the Advanced SIMD and floating-point System registers on page G1-8999.
- Accessing the Advanced SIMD and floating-point System registers on page G1-8999.
Register map of the Advanced SIMD and floating-point System registers

Table G1-21 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide.

<table>
<thead>
<tr>
<th>Name</th>
<th>Permitted access</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPEXC</td>
<td>RW</td>
</tr>
<tr>
<td>FPSCR</td>
<td>RW</td>
</tr>
<tr>
<td>FPSID</td>
<td>RW(^a)</td>
</tr>
<tr>
<td>MVFR0</td>
<td>RO</td>
</tr>
<tr>
<td>MVFR1</td>
<td>RO</td>
</tr>
<tr>
<td>MVFR2</td>
<td>RO</td>
</tr>
</tbody>
</table>

\(^a\) When FPSID is accessible, VMSR accesses to FPSID are ignored.

In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see Common System registers on page G5-9284.

Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- **VMRS on page F6-8565.**
- **VMSR on page F6-8568.**

For example:

- `VMRS <Rt>, FPSID` ; Read Floating-Point System ID Register
- `VMRS <Rt>, MVFR1` ; Read Media and VFP Feature Register 1
- `VMSR FPSCR, <Rt>` ; Write Floating-Point System Control Register

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see Enabling Advanced SIMD and floating-point support on page G1-8996.

Note

All hardware ID information can be accessed only from EL1 or higher. This means:

- **The FPSID is accessible only from EL1 or higher.**
  
  This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

- **The MVFR registers are accessible only from EL1 or higher.**
  
  Unprivileged software must issue a system call to determine what features are supported.

G1.20.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.
In the simplest lazy context switch implementation, the primary context switch software uses the CPACR. {cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see Enabling Advanced SIMD and floating-point support on page G1-8996. Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.
G1.21 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch32 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control:

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED. The exception generated by attempting to execute an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944. When the exception is taken to EL1, it is taken to Undefined mode.
- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
  - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
  - Otherwise, the exception is taken to Undefined mode.

Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are trapped.

Note

AArch32 trap controls are described in terms of Privilege levels, rather than Exception levels, because the PL1 traps apply at and are controlled from:

EL1 In Non-secure state, and in Secure state when EL3 is using AArch64.
EL3 In Secure state when EL3 is using AArch32.

For more information, see Security state, Exception levels, and AArch32 execution privilege on page G1-8908.

Trap controls are grouped as:

PL1, excluding Monitor mode

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944. For more information about these traps, see PL1 configurable controls on page G1-9002.

Hyp mode (PL2)

These traps apply only to execution in Non-secure state. This section only describes the traps that apply when EL2 is using AArch32.

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps, see EL2 configurable controls on page G1-9010. See also Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.

Monitor mode (Secure PL1)

This section describes only the traps that apply when EL3 is using AArch32.

Trapped instructions generate Monitor Trap exceptions, which are taken to Monitor mode.

For more information about these traps, see EL3 configurable controls on page G1-9030.
An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. Exception prioritization for exceptions taken to AArch32 state on page G1-8932 defines the prioritization of different exceptions on the same instruction.

Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the HSR.

--- Note ---

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, CPACR.TRCDIS is a trap control even though TRCDIS is a mnemonic for Trace Disable.

- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

- Configurable instruction controls on page D1-4665 describes controls provided by AArch64 state for enabling, disabling, and trapping instructions. Generally, where an AArch64 control applies to execution at lower Exception levels, it traps the equivalent functionality when that lower Exception level is using AArch32. See the AArch64 trap controls for more information.

This section is organized as follows:

- Register access instructions.
- PL1 configurable controls.
- EL2 configurable controls on page G1-9010.
- EL3 configurable controls on page G1-9030.
- Pseudocode description of configurable instruction enables, disables, and traps on page G1-9034.

G1.21.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

G1.21.2 PL1 configurable controls

In AArch32 state, each control is associated with a particular System register field that is accessible:

- When EL3 is using AArch64, or when an implementation does not include EL3, from EL1.
- When EL3 is using AArch32:
  - In Non-secure state, from EL1.
  - In Secure state, from EL3.

This means that the controls are described as PL1 controls, because PL1 is defined as being the Privilege level of software that is executing:

- At EL3, if the PE is executing in EL3 and EL3 is using AArch32.
- At EL1 under all other conditions.

Where there is an AArch64 control that is equivalent to an AArch32 PL1 control, the AArch64 control is an EL1 control.

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

--- Note ---

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.
Table G1-22 shows the AArch32 System registers that contain these controls.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.

Instructions that fail their Condition code check

See Conditional execution of undefined instructions on page G1-8966.

Trapping to PL1 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates an Undefined Instruction exception.

Traps to Undefined mode of EL0 execution of WFE and WFI instructions

SCTL.R.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to Undefined mode:

SCTL.R.nTWE

1  This control has no effect on the EL0 execution of WFE instructions.
0  Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTL.R.nTWI

1  This control has no effect on the EL0 execution of WFI instructions.
0  Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

•  Wait For Event and Send Event on page G1-8988.
•  Wait For Interrupt on page G1-8991.

Disabling or enabling PL0 and PL1 use of AArch32 optional functionality

Table G1-25 on page G1-9005 shows the optional AArch32 functionality that might have disable controls in the SCTL.R:

•  The SED control is implemented if the implementation supports mixed-endian operation at any Exception level.
•  Whether the ITD control is implemented is IMPLEMENTATION DEFINED.
•  Whether the CP15BEN control is implemented is IMPLEMENTATION DEFINED.
•  If a control is not implemented, then the associated functionality cannot be disabled.

When an instruction is disabled by one of these controls, it is UNDEFINED at PL0 and PL1. This means an attempt to execute the instruction at PL0 or PL1 generates an Undefined Instruction exception that is taken to Undefined mode, unless both of the following apply, in which case the attempted execution generates an exception that is taken to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944:

•  The instruction is executed at Non-secure EL0 using AArch32.
Either:
— EL2 is using AArch32 and the value of HCR.TGE is 1.
— EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

Table G1-25 PL1 controls for disabling and enabling PL0 and PL1 use of AArch32 optional functionality

<table>
<thead>
<tr>
<th>Optional AArch32 functionality</th>
<th>Instruction enable or disable in the SCTLR(^a)</th>
<th>Disabled instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED(^b)</td>
<td>SETEND instructions</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD(^c)</td>
<td>See the SCTLR.ITD description</td>
</tr>
<tr>
<td>Accesses to the CP15DMB, CP15DSB, and CP15ISB barrier instructions</td>
<td>CP15BEN(^d)</td>
<td>(\times) accesses to the CP15DMB, CP15DSB, and CP15ISB instructions</td>
</tr>
</tbody>
</table>

\(^a\) The controls that are implemented in SCTLR are also implemented in SCTLR_EL1, and apply when PL1 is using AArch64 and PL0 is using AArch32.
\(^b\) SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
\(^c\) IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
\(^d\) System register (\(\text{copyrc}==0b1111\)) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

Note

The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers

If implemented, the CPACR.TRCDIS control traps PL0 and PL1 System register accesses to the trace registers to Undefined mode, as follows:

1. PL0 and PL1 accesses to the System register interface to the trace unit are trapped to Undefined mode
2. This control has no effect on PL0 and PL1 accesses to the System register interface to the trace unit.

If the CPACR.TRCDIS control is not implemented, then the CPACR.TRCDIS field is RAZ/WI. This means the CPACR does not provide a trap to Undefined mode of PL1 and PL0 System register accesses to trace registers. See the register description for more information.

Note

• System register accesses to the trace unit use the (\(\text{coproc}==0b1110\)) encoding space.
• The ETMv4 architecture does not permit EL0 to access the trace registers. If the architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace System registers are UNDEFINED.
• The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page G1-9002.

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, CPACR.TRCDIS behaves as RAO/WI in Non-secure state. This behavior also applies if the CPACR.TRCDIS control is not implemented.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.
Enabling use of Advanced SIMD and floating-point functionality

Table G1-26 on page G1-9006 summarizes the controls of Advanced SIMD and floating-point functionality.

Table G1-26 Controls of use of Advanced SIMD and floating-point functionality

<table>
<thead>
<tr>
<th>Control</th>
<th>Type</th>
<th>Description, see</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPACR.{cp11, cp10}</td>
<td>E</td>
<td>Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-9006</td>
</tr>
<tr>
<td>FPEXC.EN</td>
<td>E</td>
<td>Enabling access to the SIMD and floating-point registers on page G1-9007</td>
</tr>
<tr>
<td>CPACR.ASEDIS</td>
<td>D</td>
<td>Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-9007</td>
</tr>
</tbody>
</table>

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED. Support for the CPACR.ASEDIS control is optional, and if the control is not implemented behavior is as if the control permits the execution of Advanced SIMD instructions at PL1 and PL0.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.

Enabling PL0 and PL1 accesses to the SIMD and floating-point registers

CPACR.{cp11, cp10} enable PL0 and PL1 accesses to the SIMD and floating-point registers.

When CPACR.cp10 is:

- **00**: PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **01**: PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **10**: Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE.
- **11**: This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The value of CPACR.cp11 is ignored. If CPACR.cp11 is programmed with a different value to CPACR.cp10 then CPACR.cp11 is UNKNOWN on a direct read of the CPACR.

Note

- Software must set CPACR.cp11 and CPACR.cp10 to the same value.

Table G1-27 on page G1-9006 shows the registers for which accesses are enabled.

Table G1-27 Register accesses enabled at PL0 and PL1 by CPACR.{cp11, cp10}

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL0 and PL1, or PL0 only(^a)</td>
<td>FPSR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers(^b)</td>
</tr>
</tbody>
</table>

\(^a\) Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

\(^b\) Permitted VMSR accesses to the FPSID are ignored, but for the purposes of the \(\{cp10, cp11\}\) controls the architecture defines a VMSR accesses to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.
If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, the functionality described in this section is disabled in Non-secure state, and CPACR.{cp11, cp10} are RAZ/WI in Non-secure state. See Enabling Non-secure access to SIMD and floating-point functionality on page G1-9034.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-8996.

**Enabling access to the SIMD and floating-point registers**

FPEXC.EN enables accesses to the SIMD and floating-point registers at all Exception levels, but does not control the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

When FPEXC.EN is:

- 1: Accesses to the registers shown in Table G1-28 on page G1-9007 are enabled at all Exception levels.
- 0: All accesses to the registers shown in Table G1-28 on page G1-9007 are UNDEFINED.

Table G1-28 on page G1-9007 shows the registers for which accesses are enabled, and for an exception taken to Hyp mode, how the exception is reported in HSR.

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
<th>Syndrome reporting in HSRa</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Exception levels</td>
<td>FPSCR, and any of the SIMD and floating-point registers Q0-Q15,</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td></td>
<td>including their views as D0-D31 registers or S0-S31 registers.</td>
<td></td>
</tr>
</tbody>
</table>

a. Only for exceptions that are taken to Hyp mode.

For more information, see Advanced SIMD and floating-point support on page G1-8996.

**Disabling PL0 and PL1 execution of Advanced SIMD instructions**

If implemented as an RW field, CPACR.ASEDIS can disable PL0 and PL1 execution of Advanced SIMD instructions, as follows:

- 1: Advanced SIMD instructions are UNDEFINED at PL0 and PL1.
- 0: Advanced SIMD instruction execution is enabled at PL0 and PL1.

The instructions that CPACR.ASEDIS disables are those described in Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-7153.

When the control is not implemented, meaning the CPACR.ASEDIS field is RAZ/WI, behavior is as if the control permits execution of Advanced SIMD instructions at PL0 and PL1.

If EL3 is implemented and is using AArch32, and NSACR.NSASEDIS is 1, CPACR.ASEDIS is RAO/WI in Non-secure state. This also applies when the CPACR.ASEDIS control is not implemented.

**Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers**

DBGDSCRext.UDCCdis traps EL0 accesses to the DCC registers to Undefined mode:

- 1: EL0 accesses to the DCC registers are trapped to Undefined mode
- 0: This control has no effect on EL0 accesses to the DCC registers.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.
Table G1-29 shows the registers for which accesses are trapped.

**Table G1-29 Register accesses trapped to Undefined mode when DBGDSCRext.UDCCdis is 1**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDASAR, DBGDAR</td>
</tr>
</tbody>
</table>

**Note**

All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRC accesses to DBGDASR and DBGDAR.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-8944.

**Traps to Undefined mode of EL0 accesses to the Generic Timer registers**

CNTKCTL.{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN} trap EL0 accesses to the Generic Timer registers to Undefined mode, as follows:

- CNTKCTL.PL0PTEN traps EL0 accesses to the physical timer registers.
- CNTKCTL.PL0VTEN traps EL0 accesses to the virtual timer registers.
- CNTKCTL.PL0PCTEN traps EL0 accesses to the frequency register and physical counter register.
- CNTKCTL.PL0VCTEN traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

Accesses to the frequency register, CNTFRQ, are only trapped if CNTKCTL.PL0PCTEN and CNTKCTL.PL0VCTEN are both 0.
