- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
- The Security state is indicated by the value of \(\text{SCR_EL3.NS}\) if \(\text{FEAT_RME}\) is not implemented, or \(\text{SCR_EL3.NSE, NS}\) if \(\text{FEAT_RME}\) is implemented.
- The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \(\text{SCR_EL3.EEL2}==1\), then:

- A PE with \(\text{SCR_EL3.EEL2}==1\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR_EL3.EEL2}==0\).
- A PE with \(\text{SCR_EL3.EEL2}==0\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR_EL3.EEL2}==1\).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granularity:
  - If \(\text{TTL}==01\) and BaseADDR\([29:12]\) is not equal to \(0000000000000000\).
  - If \(\text{TTL}==10\) and BaseADDR\([20:12]\) is not equal to \(000000000\).
- For the 16K translation granularity:
  - If \(\text{TTL}==10\) and BaseADDR\([24:14]\) is not equal to \(0000000000\).
- For the 64K translation granularity:
  - If \(\text{TTL}==01\) and BaseADDR\([41:16]\) is not equal to \(00000000000000000000000000\).
--- If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

### Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAALEI1IS, TLBI RVAALEI1ISNXS are **UNDEFINED**.

### Attributes

TLBI RVAALEI1IS, TLBI RVAALEI1ISNXS is a 64-bit System instruction.

### Field descriptions

<table>

**Bits [63:48]**

- Reserved, RES0.

**TG, bits [47:46]**

- Translation granule size.
  - 0b00: Reserved.
  - 0b01: 4K translation granule.
  - 0b10: 16K translation granule.
  - 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

**SCALE, bits [45:44]**

The exponent element of the calculation that is used to produce the upper range.

**NUM, bits [43:39]**

The base element of the calculation that is used to produce the upper range.

**TTL, bits [38:37]**

- TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
  - 0b00: The entries in the range can be using any level for the translation table entries.
  - 0b01: All entries to invalidate are Level 1 translation table entries.
    - If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
  - 0b10: All entries to invalidate are Level 2 translation table entries.
  - 0b11: All entries to invalidate are Level 3 translation table entries.
BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAALE1IS, TLBI RVAALE1ISNXS instruction

The A64 System Instruction Class

C5.5 A64 System instructions for TLB maintenance

TLBI RVAALE1ISNXS{, <Xt>}

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b1001</td>
<td>0b0010</td>
<td>0b111</td>
</tr>
</tbody>
</table>
The TLBI RVAALE1OS and TLBI RVAALE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq VA < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1)} \times \text{Translation Granite Size})\].
- When EL2 is implemented and enabled in the current Security state:
  - If \(\text{HCR EL2.E2H, TGE}\) is not \(\{1, 1\}\), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(\text{HCR EL2.E2H, TGE}\) is \(\{1, 1\}\), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
- The Security state is indicated by the value of \(\text{SCR EL3.NS}\) if \(\text{FEAT RME}\) is not implemented, or \(\text{SCR EL3.NSE, NS}\) if \(\text{FEAT RME}\) is implemented.
- The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \(\text{SCR EL3.EEL2}==1\), then:

- A PE with \(\text{SCR EL3.EEL2}==1\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR EL3.EEL2}==0\).
- A PE with \(\text{SCR EL3.EEL2}==0\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR EL3.EEL2}==1\).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If \(\text{TTL}==01\) and BaseADDR\[29:12\] is not equal to 00000000000000000000000000.
  - If \(\text{TTL}==10\) and BaseADDR\[20:12\] is not equal to 0000000000.
- For the 16K translation granule:
  - If \(\text{TTL}==10\) and BaseADDR\[24:14\] is not equal to 00000000000.
- For the 64K translation granule:
  - If \(\text{TTL}==01\) and BaseADDR\[41:16\] is not equal to 0000000000000000000000000000000000.
If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAALE1OS, TLBI RVAALE1OSNXS are UNDEFINED.

**Attributes**

TLBI RVAALE1OS, TLBI RVAALE1OSNXS is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>

</tr>
<tr>
<td>[36:32]</td>
<td>BaseADDR</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**TG, bits [47:46]**

Translation granule size.

- **0b00**  Reserved.
- **0b01**  4K translation granule.
- **0b10**  16K translation granule.
- **0b11**  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

**SCALE, bits [45:44]**

The exponent element of the calculation that is used to produce the upper range.

**NUM, bits [43:39]**

The base element of the calculation that is used to produce the upper range.

**TTL, bits [38:37]**

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- **0b00**  The entries in the range can be using any level for the translation table entries.
- **0b01**  All entries to invalidate are Level 1 translation table entries.
  
  **IF FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.**
- **0b10**  All entries to invalidate are Level 2 translation table entries.
All entries to invalidate are Level 3 translation table entries.

**BaseADDR, bits [36:0]**

*When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:*

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

*Otherwise:*

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.35 TLBI RVAE1, TLBI RVAE1NXS, TLB Range Invalidate by VA, EL1

The TLBI RVAE1 and TLBI RVAE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula: \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1)} \times \text{Translation\_Granule\_Size}) \].
- When EL2 is implemented and enabled in the current Security state:
  - If \text{HCR\_EL2.}{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \text{HCR\_EL2.}{E2H, TGE} is \{1, 1\}, the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE1, TLBI RVAE1NXS are UNDEFINED.

**Attributes**

TLBI RVAE1, TLBI RVAE1NXS is a 64-bit System instruction.

C5.5.36 TLBI RVAE1IS, TLBI RVAE1ISNXS, TLB Range Invalidate by VA, EL1, Inner Shareable

The TLBI RVAE1IS and TLBI RVAE1ISNXS characteristics are:

**Purpose**

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula 
  \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \cdot 2^{5 \cdot \text{SCALE} + 1} \cdot \text{Translation Granule Size}) \].
- When EL2 is implemented and enabled in the current Security state:
  - If \( \text{HCR_EL2.\{E2H, TGE\}} \) is not \( \{1, 1\} \), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \( \text{HCR_EL2.\{E2H, TGE\}} \) is \( \{1, 1\} \), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( \text{SCR_EL3.NS} \) if \( \text{FEAT_RME} \) is not implemented, or \( \text{SCR_EL3.\{NSE, NS\}} \) if \( \text{FEAT_RME} \) is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- **Note** ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \( \text{SCR_EL3.EEL2}==1 \), then:

- A PE with \( \text{SCR_EL3.EEL2}==1 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( \text{SCR_EL3.EEL2}==0 \).
- A PE with \( \text{SCR_EL3.EEL2}==0 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( \text{SCR_EL3.EEL2}==1 \).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
For the 64K translation granule:
- If TTL == 01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
- If TTL == 10 and BaseADDR[28:16] is not equal to 0000000000000.

Configurations
This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE1IS, TLBI RVAE1ISNXS are UNDEFINED.

ASID, bits [63:48]
ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]
Translation granule size.
0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.
The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
0b00  The entries in the range can be using any level for the translation table entries.
0b01  All entries to invalidate are Level 1 translation table entries.
      If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10  All entries to invalidate are Level 2 translation table entries.
All entries to invalidate are Level 3 translation table entries.

**BaseADDR, bits [36:0]**

*When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:*

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16]
for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as \texttt{0b0000}.
When using a 16KB translation granule, BaseADDR[15:14] is treated as \texttt{0b00}.

*Otherwise:*

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

TLBI RVAE1SNXS{,<X>}
C5.5.37 TLBI RVAE1OS, TLBI RVAE1OSNXS, TLB Range Invalidate by VA, EL1, Outer Shareable

The TLBI RVAE1OS and TLBI RVAE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{5 \times \text{SCALE} + 1} \times \text{Translation_Granule_Size})]\).
- When EL2 is implemented and enabled in the current Security state:
  - If \(HCR_{EL2}.\{E2H, TGE\} \neq \{1, 1\}\), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(HCR_{EL2}.\{E2H, TGE\} = \{1, 1\}\), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \(SCR_{EL3}.\{NS, NSE, NS\}\) if \(FEAT_RME\) is not implemented, or \(SCR_{EL3}.\{NSE, NS\}\) if \(FEAT_RME\) is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

--- **Note** ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \(SCR_{EL3}.\{EEL2\}==1\), then:

- A PE with \(SCR_{EL3}.\{EEL2\}==1\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(SCR_{EL3}.\{EEL2\}==0\).
- A PE with \(SCR_{EL3}.\{EEL2\}==0\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(SCR_{EL3}.\{EEL2\}==1\).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

---

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If \(TTL==01\) and \(\text{BaseADDR}[29:12]\) is not equal to \(0000000000000000\).
  - If \(TTL==10\) and \(\text{BaseADDR}[20:12]\) is not equal to \(000000000\).
- For the 16K translation granule:
  - If \(TTL==10\) and \(\text{BaseADDR}[24:14]\) is not equal to \(0000000000\).
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

For the 64K translation granule:
  — If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  — If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000000.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAE1OS, TLBI RVAE1OSNXS are UNDEFINED.

Attributes

TLBI RVAE1OS, TLBI RVAE1OSNXS is a 64-bit System instruction.

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00  The entries in the range can be using any level for the translation table entries.
0b01  All entries to invalidate are Level 1 translation table entries.

If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b10 All entries to invalidate are Level 2 translation table entries.
0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When \textit{FEAT\_LPA2} is implemented and TCR\_EL1.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE1OS, TLBI RVAE1OSNXS instruction

C5.5.38 TLBI RVAE2, TLBI RVAE2NXS, TLB Range Invalidate by VA, EL2

The TLBI RVAE2 and TLBI RVAE2NXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula
  \[
  \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1) \times \text{Translation_Granule_Size}})
  \]
  using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE2, TLBI RVAE2NXS are UNDEFINED.

Attributes

TLBI RVAE2, TLBI RVAE2NXS is a 64-bit System instruction.

C5.5.39   TLBI RVAE2IS, TLBI RVAE2ISNXS, TLB Range Invalidate by VA, EL2, Inner Shareable

The TLBI RVAE2IS and TLBI RVAE2ISNXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula
  \[ \text{BaseADDR} \leq \text{VA} \leq \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5\times\text{SCALE} + 1)} \times \text{Translation Granule Size}) \]
  using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE2IS, TLBI RVAE2ISNXS are UNDEFINED.

**Attributes**

TLBI RVAE2IS, TLBI RVAE2ISNXS is a 64-bit System instruction.
### Field descriptions

#### ASID, bits [63:48]

- **When HCR_EL2.E2H == 1:**
  - ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
  - Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
  - If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

- **Otherwise:**
  - Reserved, RES0.

#### TG, bits [47:46]

Translation granule size.
- 0b00  Reserved.
- 0b01  4K translation granule.
- 0b10  16K translation granule.
- 0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

#### SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

#### NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

#### TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00  The entries in the range can be using any level for the translation table entries.
- 0b01  All entries to invalidate are Level 1 translation table entries. If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10  All entries to invalidate are Level 2 translation table entries.
- 0b11  All entries to invalidate are Level 3 translation table entries.

#### BaseADDR, bits [36:0]

- **When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:**
  - The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
  - When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.40 TLBI RVAE2OS, TLBI RVAE2OSNXS, TLB Range Invalidate by VA, EL2, Outer Shareable

The TLBI RVAE2OS and TLBI RVAE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula
  \[\text{BaseADDR} \leq \text{VA} \leq \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(\text{SCALE} + 1)} \times \text{Translation Granule Size})\]
  using the EL2 or EL2&0 translation regime, as determined by the current value of the \text{HCR_EL2.E2H} bit, for the Security state.
- If \text{HCR_EL2.E2H} == 0, the entry is from any level of the translation table walk.
- If \text{HCR_EL2.E2H} == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of \text{SCR_EL3.NS} if \text{FEAT_RME} is not implemented, or \text{SCR_EL3.[NSE, NS]} if \text{FEAT_RME} is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \text{TTL==01} and \text{BaseADDR[29:12]} is not equal to 0000000000000000.
  - If \text{TTL==10} and \text{BaseADDR[20:12]} is not equal to 00000000.
- For the 16K translation granule:
  - If \text{TTL==10} and \text{BaseADDR[24:14]} is not equal to 00000000.
- For the 64K translation granule:
  - If \text{TTL==01} and \text{BaseADDR[41:16]} is not equal to 00000000000000000000000.
  - If \text{TTL==10} and \text{BaseADDR[28:16]} is not equal to 000000000000.

If \text{FEAT_XS} is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when \text{FEAT_TLBIRANGE} is implemented and \text{FEAT_TLBIOS} is implemented. Otherwise, direct accesses to TLBI RVAE2OS, TLBI RVAE2OSNXS are UNDEFINED.

Attributes

TLBI RVAE2OS, TLBI RVAE2OSNXS is a 64-bit System instruction.

C5.5.41 TLBI RVAE3, TLBI RVAE3NXS, TLB Range Invalidate by VA, EL3

The TLBI RVAE3 and TLBI RVAE3NXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1) \times \text{Translation Granule Size}}) \].

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE3, TLBI RVAE3NXS are UNDEFINED.

C5.5.43 TLBI RVAE3OS, TLBI RVAE3OSNXS, TLB Range Invalidate by VA, EL3, Outer Shareable

The TLBI RVAE3OS and TLBI RVAE3OSNXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1) \times \text{Translation_Granule_Size}})$.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If $\text{TTL}==01$ and $\text{BaseADDR}[29:12]$ is not equal to 00000000000000000000000000000000.
  - If $\text{TTL}==10$ and $\text{BaseADDR}[20:12]$ is not equal to 0000000000000000000000000000000000.
- For the 16K translation granule:
  - If $\text{TTL}==10$ and $\text{BaseADDR}[24:14]$ is not equal to 000000000000000000000000000000000000000000000.
- For the 64K translation granule:
  - If $\text{TTL}==01$ and $\text{BaseADDR}[41:16]$ is not equal to 0000000000000000000000000000000000000000000000000000000000000000.
  - If $\text{TTL}==10$ and $\text{BaseADDR}[28:16]$ is not equal to 0000000000000000000000000000000000000000000000000000000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAE3OS, TLBI RVAE3OSNXS are UNDEFINED.

**Attributes**

TLBI RVAE3OS, TLBI RVAE3OSNXS is a 64-bit System instruction.

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL3.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
- When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
- When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.
- When using a 4KB translation granule, this field is BaseADDR[48:12].
- When using a 16KB translation granule, this field is BaseADDR[50:14].
- When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.44 TLBI RVALE1, TLBI RVALE1NXS, TLB Range Invalidate by VA, Last level, EL1

The TLBI RVALE1 and TLBI RVALE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{5 \cdot \text{SCALE} + 1}) \times \text{Translation_Granule_Size}]\).
- When EL2 is implemented and enabled in the current Security state:
  - If \(\text{HCR\_EL2}.\{\text{E2H, TGE}\} = \{0, 1\}\), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(\text{HCR\_EL2}.\{\text{E2H, TGE}\} = \{1, 1\}\), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \(\text{SCR\_EL3}.\text{NS}\) if \(\text{FEAT\_RME}\) is not implemented, or \(\text{SCR\_EL3}.\{\text{NSE, NS}\}\) if \(\text{FEAT\_RME}\) is implemented.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \(\text{TTL} = 01\) and \(\text{BaseADDR}[29:12]\) is not equal to 0000000000000000.
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[20:12]\) is not equal to 00000000.
- For the 16K translation granule:
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[24:14]\) is not equal to 0000000000.
- For the 64K translation granule:
  - If \(\text{TTL} = 01\) and \(\text{BaseADDR}[41:16]\) is not equal to 0000000000000000.
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[28:16]\) is not equal to 0000000000.

For more information about the architectural requirements for this System instruction, see Invalidating TLB entries from stage 2 translations on page D8-5211.

If \(\text{FEAT\_XS}\) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when \(\text{FEAT\_TLBIRANGE}\) is implemented. Otherwise, direct accesses to TLBI RVALE1, TLBI RVALE1NXS are UNDEFINED.
Attributes

TLBI RVALE1, TLBI RVALE1NXS is a 64-bit System instruction.

Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

- 0b00: Reserved.
- 0b01: 4K translation granule.
- 0b10: 16K translation granule.
- 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries.
  If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

  endif
TLBI RVALE1IS, TLBI RVALE1ISNXS, TLB Range Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI RVALE1IS and TLBI RVALE1ISNXS characteristics are:

**Purpose**

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula: \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{5 \times \text{SCALE} + 1} \times \text{Translation_Granule_Size}) \].
- When EL2 is implemented and enabled in the current Security state:
  - If \( \text{HCR}_\text{EL2}.\{\text{E2H}, \text{TGE}\} \) is not \( \{1, 1\} \), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \( \text{HCR}_\text{EL2}.\{\text{E2H}, \text{TGE}\} \) is \( \{1, 1\} \), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( \text{SCR}_\text{EL3}.\text{NS} \) if \( \text{FEAT}_\text{RME} \) is not implemented, or \( \text{SCR}_\text{EL3}.\{\text{NSE}, \text{NS}\} \) if \( \text{FEAT}_\text{RME} \) is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \( \text{SCR}_\text{EL3}.\text{EEL2}==1 \), then:

- A PE with \( \text{SCR}_\text{EL3}.\text{EEL2}==1 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( \text{SCR}_\text{EL3}.\text{EEL2}==0 \).
- A PE with \( \text{SCR}_\text{EL3}.\text{EEL2}==0 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( \text{SCR}_\text{EL3}.\text{EEL2}==1 \).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

---

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If \( \text{TTL}==01 \) and \( \text{BaseADDR}[29:12] \) is not equal to 000000000000000000000000.
  - If \( \text{TTL}==10 \) and \( \text{BaseADDR}[20:12] \) is not equal to 0000000000.
- For the 16K translation granule:
  - If \( \text{TTL}==10 \) and \( \text{BaseADDR}[24:14] \) is not equal to 00000000000.
- For the 64K translation granule:
  - If \( \text{TTL}==01 \) and \( \text{BaseADDR}[41:16] \) is not equal to 00000000000000000000000000.
If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE1IS, TLBI RVALE1ISNXS are UNDEFINED.

Attributes

TLBI RVALE1IS, TLBI RVALE1ISNXS is a 64-bit System instruction.

Field descriptions

C5.5.46 TLBI RVALE1OS, TLBI RVALE1OSNXS, TLB Range Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI RVALE1OS and TLBI RVALE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula \(\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5\times\text{SCALE} +1}) \times \text{Translation Granule Size})\).
- When EL2 is implemented and enabled in the current Security state:
  - If \(\text{HCR_EL2.E2H, TGE}\) is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(\text{HCR_EL2.E2H, TGE}\) is \{1, 1\}, the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \(\text{SCR_EL3.NS}\) if \(\text{FEAT_RME}\) is not implemented, or \(\text{SCR_EL3.NSE, NS}\) if \(\text{FEAT_RME}\) is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \(\text{SCR_EL3.EEL2}==1\), then:

- A PE with \(\text{SCR_EL3.EEL2}==1\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR_EL3.EEL2}==0\).
- A PE with \(\text{SCR_EL3.EEL2}==0\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR_EL3.EEL2}==1\).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

---

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \(\text{TTL}==01\) and \(\text{BaseADDR}[29:12]\) is not equal to 0000000000000000.
  - If \(\text{TTL}==10\) and \(\text{BaseADDR}[20:12]\) is not equal to 0000000000.
- For the 16K translation granule:
  - If \(\text{TTL}==10\) and \(\text{BaseADDR}[24:14]\) is not equal to 00000000000.
- For the 64K translation granule:
  - If \(\text{TTL}==01\) and \(\text{BaseADDR}[41:16]\) is not equal to 00000000000000000000000000.
If \( \text{TTL} = 10 \) and \( \text{BaseADDR}[28:16] \) is not equal to \( 0000000000000000 \).

If \text{FEAT\_XS} is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when \text{FEAT\_TLMIRANGE} is implemented and \text{FEAT\_TLMIBIOS} is implemented. Otherwise, direct accesses to TLBI RVALE1OS, TLBI RVALE1OSNXS are UNDEFINED.

**Attributes**

TLBI RVALE1OS, TLBI RVALE1OSNXS is a 64-bit System instruction.

**Field descriptions**

- **ASID**, bits [63:48]
  - ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
  - Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
  - If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

- **TG**, bits [47:46]
  - Translation granule size.
  - \( 0b00 \) Reserved.
  - \( 0b01 \) 4K translation granule.
  - \( 0b10 \) 16K translation granule.
  - \( 0b11 \) 64K translation granule.
  - The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

- **SCALE**, bits [45:44]
  - The exponent element of the calculation that is used to produce the upper range.

- **NUM**, bits [43:39]
  - The base element of the calculation that is used to produce the upper range.
TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- **0b00**: The entries in the range can be using any level for the translation table entries.
- **0b01**: All entries to invalidate are Level 1 translation table entries. If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- **0b10**: All entries to invalidate are Level 2 translation table entries.
- **0b11**: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

*When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:*

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

*Otherwise:*

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.47 TLBI RVALE2, TLBI RVALE2NXS, TLB Range Invalidate by VA, Last level, EL2

The TLBI RVALE2 and TLBI RVALE2NXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula \[ \text{BaseADDR} \leq VA \leq \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1)} \times \text{Translation Granule Size}) \] using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 00000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE2, TLBI RVALE2NXS are UNDEFINED.

**Attributes**

TLBI RVALE2, TLBI RVALE2NXS is a 64-bit System instruction.

ASID, bits [63:48]

When \texttt{HCR\_EL2.E2H} == 1:

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

Reserved, \texttt{RES0}.

TG, bits [47:46]

Translation granule size.

- \texttt{0b00}: Reserved.
- \texttt{0b01}: 4K translation granule.
- \texttt{0b10}: 16K translation granule.
- \texttt{0b11}: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- \texttt{0b00}: The entries in the range can be using any level for the translation table entries.
- \texttt{0b01}: All entries to invalidate are Level 1 translation table entries.
  
  \textbf{If \texttt{FEAT\_LPA2} is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as \texttt{0b00}.}

- \texttt{0b10}: All entries to invalidate are Level 2 translation table entries.
- \texttt{0b11}: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When \texttt{FEAT\_LPA2} is implemented and \texttt{TCR\_EL2.DS} == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as \texttt{0b0000}. 
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.48 TLBI RVALE2IS, TLBI RVALE2ISNXS, TLB Range Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI RVALE2IS and TLBI RVALE2ISNXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)] using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000000000.
  - If TTL==10 and BaseADDR[20: 12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 00000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE2IS, TLBI RVALE2ISNXS are UNDEFINED.

**Attributes**

TLBI RVALE2IS, TLBI RVALE2ISNXS is a 64-bit System instruction.
### Field descriptions

C5.5.49   TLBI RVALE2OS, TLBI RVALE2OSNXS, TLB Range Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI RVALE2OS and TLBI RVALE2OSNXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate any VA in the range determined by the formula
  \[ \text{BaseADDR} <= \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1) \times \text{Translation Granule Size}}) \]
  using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 00000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVALE2OS, TLBI RVALE2OSNXS are **UNDEFINED**.

**Attributes**

TLBI RVALE2OS, TLBI RVALE2OSNXS is a 64-bit System instruction.
Field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>ASID</td>
<td>63-48</td>
</tr>
<tr>
<td>TG</td>
<td>47-46</td>
</tr>
<tr>
<td>NUM</td>
<td>43-39</td>
</tr>
<tr>
<td>TTL</td>
<td>38-37</td>
</tr>
<tr>
<td>BaseADDR</td>
<td>36-0</td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

*When HCR_EL2.E2H == 1:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

*Otherwise:*

Reserved, RES0.

**TG, bits [47:46]**

Translation granule size.

- **0b00**: Reserved.
- **0b01**: 4K translation granule.
- **0b10**: 16K translation granule.
- **0b11**: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

**SCALE, bits [45:44]**

The exponent element of the calculation that is used to produce the upper range.

**NUM, bits [43:39]**

The base element of the calculation that is used to produce the upper range.

**TTL, bits [38:37]**

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- **0b00**: The entries in the range can be using any level for the translation table entries.
- **0b01**: All entries to invalidate are Level 1 translation table entries. 
  *If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.*
- **0b10**: All entries to invalidate are Level 2 translation table entries.
- **0b11**: All entries to invalidate are Level 3 translation table entries.

**BaseADDR, bits [36:0]**

*When FEAT_LPA2 is implemented and TCR_EL2.DS == 1:*

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.51 TLBI RVALE3IS, TLBI RVALE3ISNXS, TLB Range Invalidate by VA, Last level, EL3, Inner Shareable

The TLBI RVALE3IS and TLBI RVALE3ISNXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)*2^{5 \times \text{SCALE}} +1) \times \text{Translation\_Granule\_Size})\].

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \(\text{TTL}==01\) and \(\text{BaseADDR}[29:12]\) is not equal to 000000000000000000.
  - If \(\text{TTL}==10\) and \(\text{BaseADDR}[20:12]\) is not equal to 0000000000.
- For the 16K translation granule:
  - If \(\text{TTL}==10\) and \(\text{BaseADDR}[24:14]\) is not equal to 0000000000.
- For the 64K translation granule:
  - If \(\text{TTL}==01\) and \(\text{BaseADDR}[41:16]\) is not equal to 00000000000000000000000000.
  - If \(\text{TTL}==10\) and \(\text{BaseADDR}[28:16]\) is not equal to 000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

0b01  All entries to invalidate are Level 1 translation table entries.
      If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value
      is reserved and hardware should treat this field as 0b00.
0b10  All entries to invalidate are Level 2 translation table entries.
0b11  All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL3.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16]
for all translation granules.
   When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
   When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.
Otherwise:
The starting address for the range of the maintenance instruction.
   When using a 4KB translation granule, this field is BaseADDR[48:12].
   When using a 16KB translation granule, this field is BaseADDR[50:14].
   When using a 64KB translation granule, this field is BaseADDR[52:16].

**TLBI RVALE3OS, TLBI RVALE3OSNXS, TLB Range Invalidate by VA, Last level, EL3, Outer Shareable**

The TLBI RVALE3OS and TLBI RVALE3OSNXS characteristics are:

### Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} - 1) \times \text{Translation_Granule_Size}})\].

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

### Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVALE3OS, TLBI RVALE3OSNXS are **UNDEFINED**.

### Attributes

TLBI RVALE3OS, TLBI RVALE3OSNXS is a 64-bit System instruction.

### Field descriptions

**Bits [63:48]**

Reserved, RES0.
TG, bits [47:46]
Translation granule size.
- 0b00: Reserved.
- 0b01: 4K translation granule.
- 0b10: 16K translation granule.
- 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries.
  If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

*When FEAT_LPA2 is implemented and TCR_EL3.DS == 1:*

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

*Otherwise:*

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.53 TLBI VAAE1, TLBI VAAE1NXS, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 and TLBI VAAE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAAE1, TLBI VAAE1NXS is a 64-bit System instruction.

  - VA[55:12]
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

TTL, bits [47:44]

**When FEAT_TTL is implemented:**

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0b0x is encoded as:
  - 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0b0x is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

- **0b11xx** The entry comes from a 64KB translation granule. The level of walk for the leaf level 0b0x is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

endif
C5.5.54  TLBI VAAE1IS, TLBI VAAE1ISNXS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS and TLBI VAAE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If 
    
    HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If 
    
    HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of 

SCR_EL3.NS if FEAT_RME is not implemented, or

SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if 

SCR_EL3.EEL2==1, then:

- A PE with 
  
  SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with 
  
  SCR_EL3.EEL2==0.
- A PE with 
  
  SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with 
  
  SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

--- Note ---

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAAE1IS, TLBI VAAE1ISNXS is a 64-bit System instruction.
Field descriptions

Bits [63:48]
Reserved, RES0.

TTL, bits [47:44]

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

*Otherwise:*
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:
- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing TLBI VAAE1IS, TLBI VAAE1ISNXS instruction**

        end
    end
end
The TLBI VAAE1OS and TLBI VAAE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If \( HCR\_EL2.\{E2H, TGE\} \) is not \( \{1, 1\} \), the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If \( HCR\_EL2.\{E2H, TGE\} \) is \( \{1, 1\} \), the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( SCR\_EL3.NS \) if FEAT_RME is not implemented, or \( SCR\_EL3.\{NSE, NS\} \) if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \( SCR\_EL3.EEL2==1 \), then:

- A PE with \( SCR\_EL3.EEL2==1 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( SCR\_EL3.EEL2==0 \).
- A PE with \( SCR\_EL3.EEL2==0 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( SCR\_EL3.EEL2==1 \).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAAE1OS, TLBI VAAE1OSNXS are UNDEFINED.

**Attributes**

TLBI VAAE1OS, TLBI VAAE1OSNXS is a 64-bit System instruction.
Field descriptions

Bits [63:48]
Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b0: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b1: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b0: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b1: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.
- 0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b0: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b1: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are \texttt{RES0} and ignored when the instruction is executed, because \texttt{VA[15:12]} have no effect on the operation of the instruction.

**Executing TLBI VAAE1OS, TLBI VAAE1OSNXS instruction**

C5.5.56 TLBI VAALE1, TLBI VAALE1NXS, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALE1 and TLBI VAALE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAALE1, TLBI VAALE1NXS is a 64-bit System instruction.

**Field descriptions**

<table>

**Bits [63:48]**

Reserved, RES0.
TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAALE1, TLBI VAALE1NXS instruction

C5.5.57 TLBI VAALE1IS, TLBI VAALE1ISNXS, TLB Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI VAALE1IS and TLBI VAALE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- **Note** ---

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

--- **Note** ---

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAALE1IS, TLBI VAALE1ISNXS is a 64-bit System instruction.
Field descriptions

Bits [63:48]
Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx  No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx  The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
           0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
           0b01 : Level 1.
           0b10 : Level 2.
           0b11 : Level 3.

0b10xx  The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
           0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
           0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
           0b10 : Level 2.
           0b11 : Level 3.

0b11xx  The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
           0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
           0b01 : Level 1.
           0b10 : Level 2.
           0b11 : Level 3.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing TLBI VAALE1IS, TLBI VAALE1ISNXS instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

        TLBI_ExcludeXS, X[t, 64]);
The TLBI VAALE1OS and TLBI VAALE1OSNXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAALE1OS, TLBI VAALE1OSNXS are UNDEFINED.

Attributes

TLBI VAALE1OS, TLBI VAALE1OSNXS is a 64-bit System instruction.
Field descriptions

Bits [63:48]:
Reserved, RES0.

TTL, bits [47:44]:
When FEAT_TTL is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10: Level 2.
0b11: Level 3.

0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]:
Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:
• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

C5.5.59 TLBI VAE1, TLBI VAE1NXS, TLB Invalidate by VA, EL1

The TLBI VAE1 and TLBI VAE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If $HCR\_EL2\_{[E2H, TGE]}$ is not $\{1, 1\}$, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If $HCR\_EL2\_{[E2H, TGE]}$ is $\{1, 1\}$, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of $SCR\_EL3\_{[NS]}$ if FEAT_RME is not implemented, or $SCR\_EL3\_{[NSE, NS]}$ if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE1, TLBI VAE1NXS is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>ASID</th>
<th>TTL</th>
<th>VA[55:12]</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>48</td>
<td>47</td>
</tr>
<tr>
<td>46</td>
<td>44</td>
<td>33</td>
</tr>
<tr>
<td>32</td>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**  No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**  The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b10xx**  The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b11xx**  The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

*Otherwise:*

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing TLBI VAE1, TLBI VAE1NXS instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:
**TLBI VAE1({, <Xt>})**

The TLBI VAE1IS and TLBI VAE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE1IS, TLBI VAE1ISNXS is a 64-bit System instruction.
Field descriptions

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - **0b00**: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

*Otherwise:*

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.
The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing TLBI VAE1IS, TLBI VAE1ISNXS instruction**

C5.5.61 TLBI VAE1OS, TLBI VAE1OSNXS, TLB Invalidate by VA, EL1, Outer Shareable

The TLBI VAE1OS and TLBI VAE1OSNXS characteristics are:

**Purpose**

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE1OS, TLBI VAE1OSNXS are undefined.
Attributes

TLBI VAE1OS, TLBI VAE1OSNXS is a 64-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>ASID</th>
<th></th>
<th>TTL</th>
<th></th>
<th>VA[55:12]</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>48</td>
<td>47</td>
<td>44</td>
<td>32</td>
</tr>
<tr>
<td>31</td>
<td>0</td>
<td>30</td>
<td>29</td>
<td>28</td>
</tr>
</tbody>
</table>

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

<table>
<thead>
<tr>
<th>TTL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00xx</td>
<td>No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL&lt;1:0&gt; is RES0.</td>
</tr>
<tr>
<td>0b01xx</td>
<td>The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL&lt;3:2&gt; is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.</td>
</tr>
<tr>
<td>0b10xx</td>
<td>The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL&lt;3:2&gt; is 0b00. 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL&lt;3:2&gt; is 0b00. 0b10 : Level 2. 0b11 : Level 3.</td>
</tr>
<tr>
<td>0b11xx</td>
<td>The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL&lt;3:2&gt; is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.</td>
</tr>
</tbody>
</table>

Otherwise:

Reserved, RES0.
**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing TLBI VAE1OS, TLBI VAE1OSNXS instruction**

### C5.5.62 TLBI VAE2, TLBI VAE2NXS, TLB Invalidate by VA, EL2

The TLBI VAE2 and TLBI VAE2NXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE2, TLBI VAE2NXS is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>ASID, bits [63:48]</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.</td>
</tr>
<tr>
<td>Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.</td>
</tr>
<tr>
<td>If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.</td>
</tr>
</tbody>
</table>
TTL, bits [47:44]

When **FEAT_TTL** is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**   No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**   The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: If **FEAT_LPA2** is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b10xx**   The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: If **FEAT_LPA2** is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b11xx**   The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

C5.5.63 TLBI VAE2IS, TLBI VAE2ISNXS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS and TLBI VAE2ISNXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE2IS, TLBI VAE2ISNXS is a 64-bit System instruction.

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.
TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

C5.5.64 TLBI VAE2OS, TLBI VAE2OSNXS, TLB Invalidate by VA, EL2, Outer Shareable

The TLBI VAE2OS and TLBI VAE2OSNXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE2OS, TLBI VAE2OSNXS are UNDEFINED.

**Attributes**

TLBI VAE2OS, TLBI VAE2OSNXS is a 64-bit System instruction.

**Field descriptions**

```
<table>
<thead>
<tr>
<th>ASID</th>
<th>TTL</th>
<th>VA[55:12]</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>48</td>
<td>47</td>
</tr>
<tr>

<td>43</td>
<td>32</td>
</tr>
<tr>
<td>31</td>
<td>30</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

*When HCR_EL2.E2H == 1:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.
Otherwise:
Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10: Level 2.
0b11: Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]
Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

<td>[31:0]</td>
<td>VA[55:12]</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
0b11: Level 3.

0b11xx  The entry comes from a 64KB translation granule. The level of walk for the leaf level
0xxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:
• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

C5.5.67 TLBI VAE3OS, TLBI VAE3OSNXS, TLB Invalidate by VA, EL3, Outer Shareable

The TLBI VAE3OS and TLBI VAE3OSNXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE3OS, TLBI VAE3OSNXS are UNDEFINED.

**Attributes**

TLBI VAE3OS, TLBI VAE3OSNXS is a 64-bit System instruction.

**Field descriptions**

![Field descriptions diagram]

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx  The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

C5.5.68 TLBI VALE1, TLBI VALE1NXS, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 and TLBI VALE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE1, TLBI VALE1NXS is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA[55:12]</td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0xx is encoded as:
  - 0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0xx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- **0b11xx** The entry comes from a 64KB translation granule. The level of walk for the leaf level 0xx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

*Otherwise:*

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

C5.5.69 TLBI VALE1IS, TLBI VALE1ISNXS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS and TLBI VALE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If \( HCR_{EL2}.\{E2H, TGE\} \) is not \( \{1,1\} \), the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If \( HCR_{EL2}.\{E2H, TGE\} \) is \( \{1,1\} \), the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( SCR_{EL3}.NS \) if \( FEAT\_RME \) is not implemented, or \( SCR_{EL3}.\{NSE, NS\} \) if \( FEAT\_RME \) is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \( SCR_{EL3}.EEL2==1 \), then:

- A PE with \( SCR_{EL3}.EEL2==1 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( SCR_{EL3}.EEL2==0 \).

- A PE with \( SCR_{EL3}.EEL2==0 \) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \( SCR_{EL3}.EEL2==1 \).

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If \( FEAT\_XS \) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE1IS, TLBI VALE1ISNXS is a 64-bit System instruction.
Field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>[63:48]</td>
<td>ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction. Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field. If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.</td>
</tr>
<tr>
<td>TTL</td>
<td>[47:44]</td>
<td>When FEAT_TTL is implemented: Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated. 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL&lt;1:0&gt; is RES0. 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL&lt;3:2&gt; is 0b00. 0b01: Level 1. 0b10: Level 2. 0b11: Level 3. 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00: Reserved. Treat as if TTL&lt;3:2&gt; is 0b00. 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL&lt;3:2&gt; is 0b00. 0b10: Level 2. 0b11: Level 3. 0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00: Reserved. Treat as if TTL&lt;3:2&gt; is 0b00. 0b01: Level 1. 0b10: Level 2. 0b11: Level 3. If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB. Otherwise: Reserved, RES0.</td>
</tr>
<tr>
<td>VA[55:12]</td>
<td>[43:0]</td>
<td>Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction. If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.</td>
</tr>
</tbody>
</table>
The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

### Executing TLBI VALE1IS, TLBI VALE1ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\text{TLBI VALE1IS, } \langle \text{Xt} \rangle
\]

C5.5.70 TLBI VALE1OS, TLBI VALE1OSNXS, TLB Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI VALE1OS and TLBI VALE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE1OS, TLBI VALE1OSNXS are UNDEFINED.

**Attributes**

TLBI VALE1OS, TLBI VALE1OSNXS is a 64-bit System instruction.
Field descriptions

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
   0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
   0b01: Level 1.
   0b10: Level 2.
   0b11: Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
   0b00: Reserved. Treat as if TTL<3:2> is 0b00.
   0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
   0b10: Level 2.
   0b11: Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
   0b00: Reserved. Treat as if TTL<3:2> is 0b00.
   0b01: Level 1.
   0b10: Level 2.
   0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.
The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

  endif
TLBI VALE2, TLBI VALE2NXS, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 and TLBI VALE2NXS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE2, TLBI VALE2NXS is a 64-bit System instruction.

**Field descriptions**

\[
\begin{array}{c|c|c}
|   & ASID & TTL | VA[55:12] \\
\hline
|   & 48 | 47 | 44 | 33 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
\end{array}
\]

ASID, bits [63:48]

*When HCR_EL2.E2H == 1:*

- ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
- Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
- If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

*Otherwise:*

- Reserved, RES0.
TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for
the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the
  entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level
  0bxx is encoded as:
    - **0b00**: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
    - **0b01**: Level 1.
    - **0b10**: Level 2.
    - **0b11**: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level
  0bxx is encoded as:
    - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
    - **0b01**: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
    - **0b10**: Level 2.
    - **0b11**: Level 3.
- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level
  0bxx is encoded as:
    - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
    - **0b01**: Level 1.
    - **0b10**: Level 2.
    - **0b11**: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.
TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx  No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx  The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
          0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
          0b01 : Level 1.
          0b10 : Level 2.
          0b11 : Level 3.

0b10xx  The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
          0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
          0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
          0b10 : Level 2.
          0b11 : Level 3.

0b11xx  The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
          0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
          0b01 : Level 1.
          0b10 : Level 2.
          0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE2IS, TLBI VALE2ISNXS instruction

C5.5.73  TLBI VALE2OS, TLBI VALE2OSNXS, TLB Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI VALE2OS and TLBI VALE2OSNXS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime, as determined by the current value of the HCR_EL2.E2H bit, for the Security state.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk that matches the specified ASID.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE2OS, TLBI VALE2OSNXS are UNDEFINED.

Attributes

TLBI VALE2OS, TLBI VALE2OSNXS is a 64-bit System instruction.

</tr>
</tbody>
</table>

ASID, bits [63:48]

When HCR_EL2.E2H == 1:

- ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
- Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
- If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Otherwise:

- Reserved, RES0.
TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for
the address being invalidated.

0b00xx  No information supplied as to the translation table level. Hardware must assume that the
entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx  The entry comes from a 4KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
    0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
    0b01 : Level 1.
    0b10 : Level 2.
    0b11 : Level 3.

0b10xx  The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
    0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
    0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
    0b10 : Level 2.
    0b11 : Level 3.

0b11xx  The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
    0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
    0b01 : Level 1.
    0b10 : Level 2.
    0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:

- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b11: Level 3.
0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
  0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  0b01: Level 1.
  0b10: Level 2.
  0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

Executing TLBI VALE3IS, TLBI VALE3ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

**TLBI VALE3IS{, <Xt>}**

  AArch64.TLBI_VA(SecurityStateAtEL(EL3), Regime_EL3, VMID[], Shareability_ISH, TLBILevel_Last,
  TLBI_ExcludeXS, X[t, 64]);
The TLBI VALE3OS and TLBI VALE3OSNXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE3OS, TLBI VALE3OSNXS are UNDEFINED.

**Attributes**

TLBI VALE3OS, TLBI VALE3OSNXS is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:48</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>47:44</td>
<td>TTL, indicates the level of the translation table walk</td>
</tr>
<tr>
<td>43:32</td>
<td>VA[55:12], the address being invalidated</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When FEAT_TTL is implemented:*

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

\- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
\- 0b01: Level 1.
\- 0b10: Level 2.
\- 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**
Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

C5.5.77 TLBI VMALLE1, TLBI VMALLE1NXS, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 and TLBI VMALLE1NXS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

• The entry is a stage 1 translation table entry, from any level of the translation table walk.

• When EL2 is implemented and enabled in the current Security state:
  — If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  — If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.

• When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1, TLBI VMALLE1NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

C5.5.78 TLBI VMALLE1IS, TLBI VMALLE1ISNXS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS and TLBI VMALLE1ISNXS characteristics are:

**Purpose**

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If $HCR_{EL2}\cdot E2H, TGE$ is not $\{1, 1\}$, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If $HCR_{EL2}\cdot E2H, TGE$ is $\{1, 1\}$, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
- The Security state is indicated by the value of $SCR_{EL3}\cdot NS$ if $FEAT_RME$ is not implemented, or $SCR_{EL3}\cdot NSE, NS$ if $FEAT_RME$ is implemented.
- The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- **Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if $SCR_{EL3}\cdot EEL2==1$, then:

- A PE with $SCR_{EL3}\cdot EEL2==1$ is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with $SCR_{EL3}\cdot EEL2==0$.
- A PE with $SCR_{EL3}\cdot EEL2==0$ is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with $SCR_{EL3}\cdot EEL2==1$.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

--- **Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

---

If $FEAT_XS$ is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

  endif

The TLBI VMALLE1OS and TLBI VMALLE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMD and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VMALLE1OS, TLBI VMALLE1OSNXS are **UNDEFINED**.

**Attributes**

TLBI VMALLE1OS, TLBI VMALLE1OSNXS is a 64-bit System instruction.

C5.5.80 TLBI VMALLS12E1, TLBI VMALLS12E1NXS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 and TLBI VMALLS12E1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - If SCR_EL3.{NSE, NS} is {0, 0}, then:
    - The entry would be required to translate an address using the Secure EL1&0 translation regime.
    - If FEAT_SEL2 is implemented and enabled, the entry would be used with the current VMID.
  - If SCR_EL3.{NSE, NS} is {0, 1}, then:
    - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
    - If Non-secure EL2 is implemented, the entry would be used with the current VMID.
  - If SCR_EL3.{NSE, NS} is {1, 1}, then:
    - The entry would be required to translate an address using the Realm EL1&0 translation regime.
    - The entry would be used with the current VMID.
- If FEAT_RME is not implemented, one of the following applies:
  - If SCR_EL3.NS is 0, then:
    - The entry would be required to translate an address using the Secure EL1&0 translation regime.
    - If FEAT_SEL2 is implemented and enabled, the entry would be used with the current VMID.
  - If SCR_EL3.NS is 1, then:
    - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
    - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete. The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.
Attributes

TLBI VMALLS12E1, TLBI VMALLS12E1NXS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLS12E1, TLBI VMALLS12E1NXS instruction

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONstrained UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.81 TLBI VMALLS12E1IS, TLBI VMALLS12E1ISNXS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable

The TLBI VMALLS12E1IS and TLBI VMALLS12E1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - If SCR_EL3.{NSE, NS} is {0, 0}, then:
    - The entry would be required to translate an address using the Secure EL1&0 translation regime.
    - If FEAT_SEL2 is implemented and enabled, the entry would be used with the current VMID.
  - If SCR_EL3.{NSE, NS} is {0, 1}, then:
    - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
    - If Non-secure EL2 is implemented, the entry would be used with the current VMID.
  - If SCR_EL3.{NSE, NS} is {1, 1}, then:
    - The entry would be required to translate an address using the Realm EL1&0 translation regime.
    - The entry would be used with the current VMID.
- If FEAT_RME is not implemented, one of the following applies:
  - If SCR_EL3.NS is 0, then:
    - The entry would be required to translate an address using the Secure EL1&0 translation regime.
    - If FEAT_SEL2 is implemented and enabled, the entry would be used with the current VMID.
  - If SCR_EL3.NS is 1, then:
    - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
    - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.
Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete. The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

C5.6 A64 System instructions for prediction restriction

This section lists the A64 System instructions for prediction restriction.
C5.6.1 CFP RCTX, Control Flow Prediction Restriction by Context

The CFP RCTX characteristics are:

**Purpose**

Control Flow Prediction Restriction by Context applies to all Control Flow Prediction Resources that predict execution based on information gathered within the target execution context or contexts. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

--- **Note** ---

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

--- **Configurations** ---

This instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to CFP RCTX are UNDEFINED.

--- **Attributes** ---

CFP RCTX is a 64-bit System instruction.

--- **Field descriptions** ---

Bits [63:49] reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

- 0b0 Applies to specified VMID for an EL0 or EL1 target execution context.
- 0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.
VMID, bits [47:32]
Only applies when bit[48] is 0 and the target execution context is either:
- EL1.
- EL0 when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0).
Otherwise this field is RES0.
When the instruction is executed at EL1, this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0), this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1), this field is ignored.
If EL2 is not implemented or not enabled for the target Security state, this field is RES0.
If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:28]
Reserved, RES0.

NSE, bit [27]
When FEAT_RME is implemented:
Together with the NS field, selects the Security state.
For a description of the values derived by evaluating NS and NSE together, see CFP_RCTX.NS.
Otherwise:
Reserved, RES0.

NS, bit [26]
When FEAT_RME is implemented:
Together with the NSE field, selects the Security state. Defined values are:

<table>
<thead>
<tr>
<th>NSE</th>
<th>NS</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b0</td>
<td>Secure.</td>
</tr>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>Non-secure.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b0</td>
<td>Root.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b1</td>
<td>Realm.</td>
</tr>
</tbody>
</table>

Some Effective values are determined by the current Security state:
- When executed in Secure state, the Effective value of NSE is 0.
- When executed in Non-secure state, the Effective value of {NSE, NS} is {0, 1}.
- When executed in Realm state, the Effective value of {NSE, NS} is {1, 1}.
An instruction with an EL field that has a value other than 0b11 (EL3) is treated as a NOP when executed at EL3 with CFP_RCTX.{NSE, NS} == {1, 0}.

Otherwise:
Security State. Defined values are:
- 0b0 Secure state.
- 0b1 Non-secure state.
When executed in Non-secure state, the Effective value of NS is 1.
EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>EL0</td>
</tr>
<tr>
<td>0b01</td>
<td>EL1</td>
</tr>
<tr>
<td>0b10</td>
<td>EL2</td>
</tr>
<tr>
<td>0b11</td>
<td>EL3</td>
</tr>
</tbody>
</table>

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Applies to specified ASID for an EL0 target execution context.</td>
</tr>
<tr>
<td>0b1</td>
<td>Applies to all ASIDs for an EL0 target execution context.</td>
</tr>
</tbody>
</table>

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

**Executing CFP RCTX instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

**CFP RCTX, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>

    AArch64.RestricPrediction(X[t, 64], RestrictType_ControlFlow);
  endif
endif
AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
elsif PSTATE_EL == EL2 then
  AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
elsif PSTATE_EL == EL3 then
  AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
C5.6.2 CPP RCTX, Cache Prefetch Prediction Restriction by Context

The CPP RCTX characteristics are:

**Purpose**

Cache Prefetch Prediction Restriction by Context applies to all Cache Allocation Resources that predict cache allocations based on information gathered within the target execution context or contexts.

The actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitively control cache prefetch predictions occurring after the instruction is complete and synchronized.

This instruction applies to all:
- Instruction caches.
- Data caches.
- TLB prefetching hardware used by the executing PE that applies to the supplied context or contexts.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

**Note**

This instruction does not require the invalidation of Cache Allocation Resources so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute.

This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

**Configurations**

This instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to CPP RCTX are UNDEFINED.

**Attributes**

CPP RCTX is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:49</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>48:32</td>
<td>VMID</td>
</tr>
<tr>
<td>31:23</td>
<td>NS EL RES0</td>
</tr>
<tr>
<td>22:0</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**Bits [63:49]**

Reserved, RES0.

**GVMID, bit [48]**

Execution of this instruction applies to all VMIDs or a specified VMID.

- **0b0**: Applies to specified VMID for an EL0 or EL1 target execution context.
- **0b1**: Applies to all VMIDs for an EL0 or EL1 target execution context.
For target execution contexts other than EL0 and EL1, this field is RES0.
If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.
If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

VMID, bits [47:32]
Only applies when bit[48] is 0 and the target execution context is either:
• EL1.
• EL0 when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0).
Otherwise this field is RES0.
When the instruction is executed at EL1, this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0), this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1), this field is ignored.
If EL2 is not implemented or not enabled for the target Security state, this field is RES0.
If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:28]
Reserved, RES0.

NSE, bit [27]
When FEAT_RME is implemented:
Together with the NS field, selects the Security state.
For a description of the values derived by evaluating NS and NSE together, see CPP_RCTX.NS.
Otherwise:
Reserved, RES0.

NS, bit [26]
When FEAT_RME is implemented:
Together with the NSE field, selects the Security state. Defined values are:

<table>
<thead>
<tr>
<th>NSE</th>
<th>NS</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b0</td>
<td>Secure.</td>
</tr>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>Non-secure.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b0</td>
<td>Root.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b1</td>
<td>Realm.</td>
</tr>
</tbody>
</table>

Some Effective values are determined by the current Security state:
• When executed in Secure state, the Effective value of NSE is 0.
• When executed in Non-secure state, the Effective value of {NSE, NS} is \{0, 1\}.
• When executed in Realm state, the Effective value of {NSE, NS} is \{1, 1\}.
An instruction with an EL field that has a value other than 0b11 (EL3) is treated as a NOP when executed at EL3 with CPP_RCTX.{NSE, NS} == \{1, 0\}.

Otherwise:
Security State. Defined values are:
0b0  Secure state.
0b1  Non-secure state.
When executed in Non-secure state, the Effective value of NS is 1.

**EL, bits [25:24]**
Exception Level. Indicates the Exception level of the target execution context.

0b00  EL0.
0b01  EL1.
0b10  EL2.
0b11  EL3.

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

**Bits [23:17]**
Reserved, RES0.

**GASID, bit [16]**
Execution of this instruction applies to all ASIDs or a specified ASID.

0b0  Applies to specified ASID for an EL0 target execution context.
0b1  Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.
If the instruction is executed at EL0, this field has an Effective value of 0.

**ASID, bits [15:0]**
Only applies for an EL0 target execution context and when bit[16] is 0. Otherwise, this field is RES0.
When the instruction is executed at EL0, this field is treated as the current ASID.
If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

**Executing CPP RCTX instruction**
Accesses to this instruction use the following encodings in the System instruction encoding space:

**CPP RCTX, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

  AArch64.SystemAccessTrap(EL2, 0x18);
else
  AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
elseif PSTATE.EL == EL2 then
  AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
elseif PSTATE.EL == EL3 then
  AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
C5.6.3 DVP RCTX, Data Value Prediction Restriction by Context

The DVP RCTX characteristics are:

**Purpose**

Data Value Prediction Restriction by Context applies to all Data Value Prediction Resources that predict execution based on information gathered within the target execution context or contexts. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

--- **Note** ---

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

---

**Configurations**

This instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to DVP RCTX are UNDEFINED.

**Attributes**

DVP RCTX is a 64-bit System instruction.

**Field descriptions**

```
       63    49  48  47  32
       RES0                            VMID

       31    28  27  26  25  24  23  17  16  15  0
       RES0  NS  EL  RES0              ASID
```

**Bits [63:49]**

Reserved, RES0.

**GVMID, bit [48]**

Execution of this instruction applies to all VMIDs or a specified VMID.

- 0b0 Applies to specified VMID for an EL0 or EL1 target execution context.
- 0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, then this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.
VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0 when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0).

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0), this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1), this field is ignored.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:28]

Reserved, RES0.

NSE, bit [27]

When FEAT_RME is implemented:

Together with the NS field, selects the Security state.

For a description of the values derived by evaluating NS and NSE together, see DVP_RCTX.NS.

Otherwise:

Reserved, RES0.

NS, bit [26]

When FEAT_RME is implemented:

Together with the NSE field, selects the Security state. Defined values are:

<table>
<thead>
<tr>
<th>NSE</th>
<th>NS</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b0</td>
<td>Secure.</td>
</tr>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>Non-secure.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b0</td>
<td>Root.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b1</td>
<td>Realm.</td>
</tr>
</tbody>
</table>

Some Effective values are determined by the current Security state:

- When executed in Secure state, the Effective value of NSE is 0.
- When executed in Non-secure state, the Effective value of {NSE, NS} is {0, 1}.
- When executed in Realm state, the Effective value of {NSE, NS} is {1, 1}.

An instruction with an EL field that has a value other than 0b11 (EL3) is treated as a NOP when executed at EL3 with DVP_RCTX.{NSE, NS} == {1, 0}.

Otherwise:

Security State. Defined values are:

- 0b0 Secure state.
- 0b1 Non-secure state.

When executed in Non-secure state, the Effective value of NS is 1.
EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

- 0b00: EL0.
- 0b01: EL1.
- 0b10: EL2.
- 0b11: EL3.

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

- 0b0: Applies to specified ASID for an EL0 target execution context.
- 0b1: Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0. Otherwise this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing DVP RCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

**DVP RCTX, <X>**

<table>

C5.7 A64 System instructions for the Branch Record Buffer Extension

This section lists the A64 System instructions for the Branch Record Buffer Extension.
C5.7.1 BRB IALL, Invalidate the Branch Record Buffer

The BRB IALL characteristics are:

**Purpose**

Invalidates all Branch records in the Branch Record Buffer.

**Configurations**

This instruction is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRB IALL are UNDEFINED.

**Attributes**

BRB IALL is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

**Executing BRB IALL instruction**

Rt should be encoded as 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b001</td>
<td>0b1111</td>
<td>0b0010</td>
<td>0b100</td>
</tr>
</tbody>
</table>

if PSTATE_EL == EL0 then
    UNDEFINED;
elsif PSTATE_EL == EL1 then
    if Halted() & HaveEL(EL3) & EDSCR.SDD == '1' & boolean IMPLEMENTATION_DEFINED EL3 trap priority when SDD == '1' & MDCR.EL3.SBRBE != '1' & SCR.EL3.NS == '0' then
        UNDEFINED;

    BRB_IALL();
elsif PSTATE.EL == EL3 then
    BRB_IALL();
C5.7.2 BRB INJ, Branch Record Injection into the Branch Record Buffer

The BRB INJ characteristics are:

**Purpose**

Injects the Branch Record held in BRBINJ_EL1, BRBSRCINJ_EL1, and BRBTGTINJ_EL1 into the Branch Record Buffer.

**Configurations**

This instruction is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRB INJ are UNDEFINED.

**Attributes**

BRB INJ is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

**Executing BRB INJ instruction**

Rt should be encoded as 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

### BRB INJ

Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

- *About the A64 base instructions on page C6-1166.*
- *Alphabetical list of A64 base instructions on page C6-1169.*
C6.1 About the A64 base instructions

Alphabetical list of A64 base instructions on page C6-1169 gives full descriptions of the A64 instructions that are in the following instruction groups:

- Branch, Exception generation, and System instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

A64 instruction set encoding on page C4-388 provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The rest of this section is general description of the base instructions. It contains the following subsections:

- Register size.
- Use of the PC.
- Use of the stack pointer on page C6-1167.
- Condition flags and related instructions on page C6-1167.

C6.1.1 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The Condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise ORR could be performed using a 64-bit ORR and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the ORR instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an ADD, SUB, ADDS, or SUBS instruction and the index register of a load/store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See Register names on page C1-230 and Register indexed addressing on page C1-234.

C6.1.2 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

For more details of instructions that can modify the PC, see Branches, Exception generating, and System instructions on page C3-248.
C6.1.3  **Use of the stack pointer**

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned. That is, it must be aligned to 16 bytes. Misalignment generates an SP alignment fault. See [SP alignment checking](#) on page D1-4668 for more information.

- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.

- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.1.4  **Condition flags and related instructions**

The A64 base instructions that use the Condition flags as an input are:

- Conditional branch. The conditional branch instruction is `B.cond`.

- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are `ADC`, `ADCS`, `SBC`, and `SBCS`, or an architectural alias for these instructions.

- Conditional select with increment, negate, or invert. This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are `CSINC`, `CSINV`, and `CSNEG`.

  These instructions also implement:
  - Conditional select or move. The Condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, `CSEL`.
  - Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the Condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include `CSET` and `CSETM`.

- Conditional compare. This instruction type sets the Condition flags to the result of a comparison if the original condition is true, otherwise it sets the Condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers. The conditional compare instructions are `CCMP` and `CMN`.

The A64 base instructions that update the Condition flags as an output are:

- Flag-setting data processing instructions, such as `ADCS`, `ADDS`, `ANDS`, `BICS`, `RMIF`, `SBCS`, `SETF8`, `SETF16`, and `SUBS`, and the aliases `CMN`, `CMP`, and `TST`.

- Conditional compare instructions such as `CMN`, `COMP`.

- The random number generation instructions MRS RNDR and MRS RNDRRS, see [Effect of random number generation instructions on Condition flags](#) on page C6-1168.

The A64 base instructions that manipulate the Condition flags are:

- The flag manipulation instruction `CFINV`, which inverts the value of the Carry flag.
• If `FEAT_FlagM2` is implemented, the base instructions `AXFLAG` and `XAFLAG`. These instructions convert between the Arm floating point comparison PSTATE condition flag format and an alternative format shown in Table C6-1.

Table C6-1 Relationship between ARM format and alternative format PSTATE condition flags

<table>
<thead>
<tr>
<th>Result</th>
<th>ARM format</th>
<th>Alternative format</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>N Z C V</td>
<td>N Z C V</td>
</tr>
<tr>
<td>Greater than</td>
<td>0 0 1 0</td>
<td>0 0 1 0</td>
</tr>
<tr>
<td>Less than</td>
<td>1 0 0 0</td>
<td>0 0 0 0</td>
</tr>
<tr>
<td>Equal</td>
<td>0 1 1 0</td>
<td>0 1 1 0</td>
</tr>
<tr>
<td>Unordered</td>
<td>0 0 1 1</td>
<td>0 1 0 0</td>
</tr>
</tbody>
</table>

The flags can be directly accessed for a read/write using the `NZCV, Condition Flags` on page C5-706.

The A64 base instructions also include conditional branch instructions that do not use the Condition flags as an input:

• Compare and branch if a register is zero or nonzero, `CBZ` and `CBNZ`.
• Test a single bit in a register and branch if the bit is zero or nonzero, `TBZ` and `TBNZ`.

Effect of random number generation instructions on Condition flags

If `FEAT_RNG` is implemented, then:

• When a valid random number is returned, the `PSTATE.NZCV` flags are set to 0b0000.
• If the random number hardware is not capable of returning a random number in a reasonable period of time, the `PSTATE.NZCV` flags are set to 0b0100, and the random number generation instructions return the value 0.

_____ Note _____

The definition of “reasonable period of time” is IMPLEMENTATION DEFINED. The expectation is that software might use this as an opportunity to reschedule or run a different routine, perhaps after a small number of retries have failed to return a valid value.
C6.2 Alphabetical list of A64 base instructions

This section lists every instruction in the base category of the A64 instruction set. For details of the format used, see Understanding the A64 instruction descriptions on page C2-240.
C6.2.1 ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

32-bit variant
Applies when \( sf = 0 \).
ADC \(<Wd>, <Wn>, <Wm>\)

64-bit variant
Applies when \( sf = 1 \).
ADC \(<Xd>, <Xn>, <Xm>\)

Decode for all variants of this encoding
\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf = '1' \text{ then } 64 \text{ else } 32;
\end{align*}
\]

Assembler symbols
\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
\(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
\(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation
\[
\begin{align*}
\text{bits(datasize)} \text{ result;} \\
\text{bits(datasize)} \text{ operand1} &= X[n, \text{datasize}]; \\
\text{bits(datasize)} \text{ operand2} &= X[m, \text{datasize}]; \\
(\text{result, -}) &= \text{AddWithCarry}(\text{operand1, operand2, PSTATE.C}); \\
X[d, \text{datasize}] &= \text{result};
\end{align*}
\]

Operational information
If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.2 ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

For 32-bit variant:
Applies when \( sf = 0 \).

\[
ADCS \ <Wd>, \ <Wn>, \ <Wm> 
\]

For 64-bit variant:
Applies when \( sf = 1 \).

\[
ADCS \ <Xd>, \ <Xn>, \ <Xm> 
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf = '1' \text{ then } 64 \text{ else } 32;
\end{align*}
\]

**Assembler symbols**

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\): Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\): Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\): Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\): Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

**Operation**

\[
\begin{align*}
\text{bits(datasize) result}; \\
\text{bits(datasize) operand1} &= X[n, \text{datasize}]; \\
\text{bits(datasize) operand2} &= X[m, \text{datasize}]; \\
\text{bits(4) nzcv}; \\
(\text{result, } nzcv) &= \text{AddWithCarry(operand1, operand2, PSTATE.C)}; \\
\text{PSTATE.<N,Z,C,V> } &= nzcv; \\
X[d, \text{datasize}] &= \text{result};
\end{align*}
\]
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.3 ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the \(<Rm>\) register can be a byte, halfword, word, or doubleword.

32-bit variant

Applies when \(sf == 0\).

\[
\text{ADD} \; <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

64-bit variant

Applies when \(sf == 1\).

\[
\text{ADD} \; <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{ExtendType } \text{extend_type} &= \text{DecodeRegExtend}(\text{option}); \\
\text{integer } \text{shift} &= \text{UInt}(\text{imm3}); \\
\text{if } \text{shift} > 4 \text{ then UNDEFINED; }
\end{align*}
\]

Assembler symbols

\(\text{<Wd|WSP>}\) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(\text{<Wn|WSP>}\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

\(\text{<Wm>}\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(\text{<Xd|SP>}\) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(\text{<Xn|SP>}\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

\(\text={<R>}\) Is a width specifier, encoded in the "option" field. It can have the following values:

\[
\begin{align*}
\text{W} & \quad \text{when option} = 00x \\
\text{W} & \quad \text{when option} = 010 \\
\text{X} & \quad \text{when option} = 111 \\
\text{W} & \quad \text{when option} = 10x \\
\text{W} & \quad \text{when option} = 110
\end{align*}
\]

\(\text{<m>}\) Is the number \([0-30]\) of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted
when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is
'010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UTX when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when
"imm3" is '000'. In all other cases <extend> is required and must be UTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in
the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL,
and is optional when <extend> is present but not LSL.

Operation

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[<datasize-1:0>] else X[n, datasize];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
(result, -) = AddWithCarry(operand1, operand2, '0');
if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 0:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.4 ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when \( sf == 0 \).

\[
\text{ADD} \ <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>} 
\]

64-bit variant
Applies when \( sf == 1 \).

\[
\text{ADD} \ <Xd|SP>, <Xn|SP>, #<imm>{, <shift>} 
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{bits} (\text{datasize}) \text{ imm};
\end{align*}
\]

\[
\begin{align*}
\text{case } \text{sh} \text{ of}
\end{align*}
\]

\[
\begin{align*}
\text{when } '0' \text{ imm} &= \text{ZeroExtend}(\text{imm12}, \text{datasize}); \\
\text{when } '1' \text{ imm} &= \text{ZeroExtend}(\text{imm12}:\text{Zeros}(12), \text{datasize});
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (to/from SP)</td>
<td>( sh == '0' &amp;&amp; imm12 == '000000000000' &amp;&amp; (Rd == '11111' &amp;&amp; Rn == '11111') )</td>
</tr>
</tbody>
</table>

Assembler symbols

| <Wd|WSP> | Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field. |
|------|---------------------------------------------------------------|
| <Wn|WSP> | Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.         |
| <Xd|SP>  | Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.     |
| <Xn|SP>  | Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.         |
| <imm> | Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field. |
<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the “sh” field. It can have the following values:

- LSL #0 when sh = 0
- LSL #12 when sh = 1

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[<datasize-1:0> else X[n, datasize];

(result, -) = AddWithCarry(operand1, imm, '0');

if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.5   ADD (shifted register)

Add (shifted register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

### 32-bit variant

Applies when sf == 0.

ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

### 64-bit variant

Applies when sf == 1.

ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

### Assembler symbols

- `<Wd>`  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`  Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`  Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>`  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`  Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`  Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>`  Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - The encoding shift = 11 is reserved.
- `<amount>`  For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

(result, -) = AddWithCarry(operand1, operand2, '0');
X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.6 ADDG

Add with Tag adds an immediate value scaled by the Tag granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

#### Integer

(FEAT_MTE)

```plaintext
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21</th>
<th>16</th>
<th>15 14 13</th>
<th>10 9</th>
<th>5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0</td>
<td>1 0 0 1 1 0</td>
<td>uimm6</td>
<td>(0)</td>
<td>uimm4</td>
<td>Xn</td>
<td>Xd</td>
<td></td>
</tr>
</tbody>
</table>
```

#### Encoding

ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>

#### Decode for this encoding

- if !HaveMTEExt() then UNDEFINED;
- integer d = UInt(Xd);
- integer n = UInt(Xn);
- bits(64) offset = LSL(ZeroExtend(uimm6, 64), LOG2_TAG_GRANULE);

#### Assembler symbols

- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<uimm6>` Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "uimm6" field.
- `<uimm4>` Is an unsigned immediate, in the range 0 to 15, encoded in the "uimm4" field.

#### Operation

```plaintext
bits(64) operand1 = if n == 31 then SP[] else X[n, 64];
bits(4) start_tag = AArch64.AllocationTagFromAddress(operand1);
bits(16) exclude = GCR_EL1.Exclude;
bits(64) result;
bits(4) rtag;
if AArch64.AllocationTagAccessTypeIsEnabled(AccType_NORMAL) then
    rtag = AArch64.ChooseNonExcludedTag(start_tag, uimm4, exclude);
else
    rtag = '0000';
(result, -) = AddWithCarry(operand1, offset, '0');
result = AArch64.AddressWithAllocationTag(result, AccType_NORMAL, rtag);
if d == 31 then
    SP[] = result;
else
    X[d, 64] = result;
```
C6.2.7 ADDS (extended register)

Add (extended register), setting flags, adds a register value and a sign or zero-extended register value, followed by
an optional left shift amount, and writes the result to the destination register. The argument that is extended from
the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register). See Alias conditions for details of when each alias is
preferred.

### 32-bit variant

Applies when \( sf == 0 \).

\[
\text{ADD} <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

### 64-bit variant

Applies when \( sf == 1 \).

\[
\text{ADD} <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
\]

#### Decode for all variants of this encoding

```
integer d = UInt(Rd);
ingen n = UInt(Rn);
ingen m = UInt(Rm);
datatype datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMN (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in the "option" field. It can have the following values:
  - \( w \) when option = 00x
W when option = 010
X when option = x11
W when option = 10x
W when option = 110

Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000
UXTH when option = 001
LSL|UXTW when option = 010
UXTX when option = 011
SXTB when option = 100
SXTH when option = 101
SXTW when option = 110
SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000
UXTH when option = 001
UXTW when option = 010
LSL|UXTX when option = 011
SXTB when option = 100
SXTH when option = 101
SXTW when option = 110
SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[<datasize-1:0>] else X[n, datasize];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

PSTATE.<N,Z,C,V> = nzcv;
X[d, datasize] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
**C6.2.8 ADDS (immediate)**

Add (immediate), setting flags, adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias **CMN (immediate)**. See **Alias conditions** for details of when each alias is preferred.

---

**32-bit variant**

Applies when $sf == 0$.

```
ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

**64-bit variant**

Applies when $sf == 1$.

```
ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

**Decode for all variants of this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

bits(datasize) result;
bins(datasize) operand1 = X[n, datasize];
bins(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bins(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');
PSTATE.<N,Z,C,V> = nzcv;
X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.10   ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

![Instruction Format](image)

**Encoding**

ADR <Xd>, <label>

**Decode for this encoding**

integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo, 64);

**Assembler symbols**

Xd: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

label: Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

**Operation**

bits(64) base = PC[];

X[d, 64] = base + imm;
C6.2.11 ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

```
[31 30 29 28|27 26 25 24|23 |    |    |    | 5 4 | 0 ]
   1 | immlo 1 0 0 0 0     immhi     Rd
op
```

**Encoding**

ADRP <Xd>, <label>

**Decode for this encoding**

integer d = UInt(Rd);
bits(64) imm;

\[
imm = \text{SignExtend}(immhi:immlo:Zeros(12), 64);
\]

**Assembler symbols**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<label> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

**Operation**

bits(64) base = PC[];
base<11:0> = Zeros(12);
X[d, 64] = base + imm;
C6.2.12 **AND (immediate)**

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

```
[31 30 29 28|27 26 25 24|23 22 21 | 16|15 | 10 9 | 5 4 | 0 ]
```

**32-bit variant**

Applies when sf == 0 && N == 0.

AND <Wd|WSP>, <Wn>, #<imm>

**64-bit variant**

Applies when sf == 1.

AND <Xd|SP>, <Xn>, #<imm>

**Decode for all variants of this encoding**

```java
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
b bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE, datasize);
```

**Assembler symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<imm>` For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

```java
bits(datasize) result;
bits(datasize) operand1 = X[n, datasize];
result = operand1 AND imm;
if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.13   **AND (shifted register)**

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

### 32-bit variant

Applies when `sf == 0`.

\[
\text{AND } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle\{, \langle shift \rangle \#<\text{amount}>\}
\]

Assembler symbols

<id>   Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<in>   Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<im>   Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<id>   Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn>   Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm>   Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- **LSL** when shift = 00
- **LSR** when shift = 01
- **ASR** when shift = 10
- **ROR** when shift = 11

For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```
bits(datasize) oper1 = X[n, datasize];
bisg(datasize) oper2 = ShiftReg(m, shift_type, shift_amount, datasize);
bisg(datasize) result;
result = oper1 AND oper2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.16   **ASR (register)**

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the **ASRV** instruction. This means that:

- The encodings in this description are named to match the encodings of **ASRV**.
- The description of **ASRV** gives the operational pseudocode for this instruction.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>16</th>

<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
```

32-bit variant

Applies when $sf == 0$.

`ASR <Wd>, <Wn>, <Wm>`

is equivalent to

`ASRV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1$.

`ASR <Xd>, <Xn>, <Xm>`

is equivalent to

`ASRV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

**Assembler symbols**

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

The description of **ASRV** gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.17  ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when sf == 0 \&\& N == 0 \&\& imms == 011111.

ASR <Wd>, <Wn>, #<shift>

is equivalent to

SBFM <Wd>, <Wn>, #<shift>, #31

and is always the preferred disassembly.

**64-bit variant**

Applies when sf == 1 \&\& N == 1 \&\& imms == 111111.

ASR <Xd>, <Xn>, #<shift>

is equivalent to

SBFM <Xd>, <Xn>, #<shift>, #63

and is always the preferred disassembly.

**Assembler symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <shift> For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.18 ASRV

Arithmetic Shift Right Variable shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ASR (register). The alias is always the preferred disassembly.

32-bit variant
Applies when \( sf = 0 \).
ASRV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when \( sf = 1 \).
ASRV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

\[

\text{bits(datasize)} & \text{ operand2} = X[m, \text{datasize}]; \\
\text{result} & = \text{ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);} \\
X[d, \text{datasize}] & = \text{result}; \\
\end{align*}
\]
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.19 AT

Address Translate. For more information, see op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>Encoding</th>
<th>AT &lt;at_op&gt;, &lt;Xt&gt; is equivalent to</th>
<th>SYS #&lt;op1&gt;, C7, &lt;Cm&gt;, #&lt;op2&gt;, &lt;Xt&gt; and is the preferred disassembly when SysOp(op1,'0111',CRm,op2) == Sys_AT.</th>
</tr>
</thead>
</table>

### Encoder

<at_op> Is an AT instruction name, as listed for the AT system instruction group, encoded in the "op1:CRm<0>:op2" field. It can have the following values:

- S1E1R when op1 = 000, CRm<0> = 0, op2 = 000
- S1E1W when op1 = 000, CRm<0> = 0, op2 = 001
- S1E0R when op1 = 000, CRm<0> = 0, op2 = 010
- S1E0W when op1 = 000, CRm<0> = 0, op2 = 011
- S1E2R when op1 = 100, CRm<0> = 0, op2 = 000
- S1E2W when op1 = 100, CRm<0> = 0, op2 = 001
- S12E1R when op1 = 100, CRm<0> = 0, op2 = 100
- S12E1W when op1 = 100, CRm<0> = 0, op2 = 101
- S12E0R when op1 = 100, CRm<0> = 0, op2 = 110
- S12E0W when op1 = 100, CRm<0> = 0, op2 = 111
- S1E3R when op1 = 110, CRm<0> = 0, op2 = 000
- S1E3W when op1 = 110, CRm<0> = 0, op2 = 001

When FEAT_PAN2 is implemented, the following values are also valid:

- S1E1RP when op1 = 000, CRm<0> = 1, op2 = 000
- S1E1WP when op1 = 000, CRm<0> = 1, op2 = 001

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
Operation

The description of SYS gives the operational pseudocode for this instruction.
AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

```

**AUTDA variant**

Applies when Z == 0.

AUTDA <Xd>, <Xn|SP>

**AUTDZA variant**

Applies when Z == 1 && Rn == 11111.

AUTDZA <Xd>

Decode for all variants of this encoding

```java
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UNDEFINED;

if Z == '0' then // AUTDA
    if n == 31 then source_is_sp = TRUE;
else // AUTDZA
    if n != 31 then UNDEFINED;
```

Assemble symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```java
if HavePACExt() then
    if source_is_sp then
        X[d, 64] = AuthDA(X[d, 64], SP[], FALSE);
    else
        X[d, 64] = AuthDA(X[d, 64], X[n, 64], FALSE);
```
C6.2.21 AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by `<Xd>`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by `<Xn|SP>` for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

  - The values of the NZCV flags.
C6.2.29   BFI

Bitfield Insert copies a bitfield of `<width>` bits from the least significant bits of the source register to bit position `<lsb>` of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when `<sf == 0 && N == 0>`.

BFI `<Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

BFM `<Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

### 64-bit variant

Applies when `<sf == 1 && N == 1>`.

BFI `<Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

BFM `<Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

### Assembler symbols

- `<Wd>`  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>`  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<lsb>`  For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- `<width>`  For the 32-bit variant: is the width of the bitfield, in the range 1 to 32.<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64.<lsb>.

### Operation

The description of BFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.30 BFM

Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL. See Alias conditions on page C6-1222 for details of when each alias is preferred.

32-bit variant

Applies when sf == 0 && N == 0.

BFM <Wd>, <Wn>, #<immr>, #<imms>

64-bit variant

Applies when sf == 1 && N == 1.

BFM <Xd>, <Xn>, #<immr>, #<imms>

Decode for all variants of this encoding

```c
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer r;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then UNDEFINED;
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then UNDEFINED;

r = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE, datasize);
```

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>BFC</td>
<td>Rn == '11111' &amp;&amp; UInt(imms) &lt; UInt(immr)</td>
</tr>
<tr>
<td>BFI</td>
<td>Rn != '11111' &amp;&amp; UInt(imms) &lt; UInt(immr)</td>
</tr>
<tr>
<td>BFXIL</td>
<td>UInt(imms) &gt;= UInt(immr)</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<immr>`: For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
- `<imms>`: For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

**Operation**

```
bits(datasize) dst = X[d, datasize];
bits(datasize) src = X[n, datasize];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, r) AND wmask);

// combine extension bits and result bits
X[d, datasize] = (dst AND NOT(tmask)) OR (bot AND tmask);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.31 BFXIL

Bitfield Extract and Insert Low copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when sf == 0 && N == 0.

BFXIL <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when UInt(imms) >= UInt(immr).

### 64-bit variant

Applies when sf == 1 && N == 1.

BFXIL <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when UInt(imms) >= UInt(immr).

### Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32.<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64.<lsb>.

### Operation

The description of BFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.32   BIC (shifted register)

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when \( sf == 0 \).

\[ \text{BIC } <\text{Wd}>, <\text{Wn}>, <\text{Wm}>{{, \text{<shift> #<amount>}}} \]

64-bit variant

Applies when \( sf == 1 \).

\[ \text{BIC } <\text{Xd}>, <\text{Xn}>, <\text{Xm}>{{, \text{<shift> #<amount>}}} \]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}\left(\text{Rd}\right); \\
\text{integer } n &= \text{UInt}\left(\text{Rn}\right); \\
\text{integer } m &= \text{UInt}\left(\text{Rm}\right); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then 64 else 32}; \\
&\text{if } sf == '0' \text{ & & imm6<5> == '1' then UNDEFINED;} \\
\text{ShiftType } \text{shift_type} &= \text{DecodeShift}(\text{shift}); \\
\text{integer } \text{shift_amount} &= \text{UInt}(\text{imm6}); \\
\end{align*}
\]

Assembler symbols

- \(<\text{Wd}>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Wn}>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<\text{Wm}>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{Xd}>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Xn}>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<\text{Xm}>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{<shift>}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - ROR when \( \text{shift} = 11 \)
- \(<\text{<amount>}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
**Operation**

```plaintext
bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 AND operand2;
X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.33 BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

<table>

<td></td>
</tr>
</tbody>
</table>
```

**Encoding**

BL <label>

**Decode for this encoding**

```
bits(64) offset = SignExtend(imm26:'00', 64);
```

**Assembler symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

**Operation**

```
X[30, 64] = PC[] + 4;

BranchTo(PC[] + offset, BranchType_DIRCALL, FALSE);
```
C6.2.35   BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9  | 5 4  | 0 ]
  1 1 0 1 0 1 1 1 0 0 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
  Z  op  A  M  Rn  Rm
```

**Encoding**

BLR <Xn>

**Decode for this encoding**

```python
integer n = UInt(Rn);
```

**Assembler symbols**

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

```python
bits(64) target = X[n, 64];
X[30, 64] = PC[] + 4;
// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL, FALSE);
```
C6.2.36   BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the
general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at
the authenticated address, setting register X30 to PC+4.

The modifier is:

• In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
• The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a
Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

Integer

(FEAT_PAuth)

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
|1 1 0 1 0 1 1 | Z 0 0 1 | 1 1 1 1 | 0 0 0 | 0 | 1 | M | Rn | Rm |
```

Key A, zero modifier variant

Applies when \( Z == 0 \land M == 0 \land Rm == 11111 \).

BLRAA <Xn>

Key A, register modifier variant

Applies when \( Z == 1 \land M == 0 \).

BLRAA <Xn>, <Xm|SP>

Key B, zero modifier variant

Applies when \( Z == 0 \land M == 1 \land Rm == 11111 \).

BLRABZ <Xn>

Key B, register modifier variant

Applies when \( Z == 1 \land M == 1 \).

BLRAB <Xn>, <Xm|SP>

Decode for all variants of this encoding

```python
define n = UInt(Rn);
define m = UInt(Rm);
define use_key_a = (M == '0');
define source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UNDEFINED;

if Z == '0' && m != 31 then
    UNDEFINED;
```

[1101011]
0x0 Z0 01 11111 00001 M Rn Rm
Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

bits(64) target = X[n, 64];
bits(64) modifier = if source_is_sp then SP[] else X[m, 64];

if use_key_a then
  target = AuthIA(target, modifier, TRUE);
else
  target = AuthIB(target, modifier, TRUE);

X[30, 64] = PC[] + 4;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL, FALSE);
C6.2.37 BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

Encoding
BR <Xn>

Decode for this encoding
integer n = UInt(Rn);

Assembler symbols
<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation
bits(64) target = X[n, 64];

// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
  if n == 16 || n == 17 then
    BTypeNext = '01';
  else
    BTypeNext = '11';
else
  BTypeNext = '01';
BranchTo(target, BranchType_INDIR, FALSE);
C6.2.38  BRAA, BRAAZ, BRAB, BRABZ

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

**Integer**

(FEAT_PAuth)

```
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 5 | 4 | 0 |
```

**Key A, zero modifier variant**

Applies when Z == 0 && M == 0 && Rm == 11111.

BRAA <Xn>, <Xm|SP>

**Key A, register modifier variant**

Applies when Z == 1 && M == 0.

BRAAZ <Xn>

**Key B, zero modifier variant**

Applies when Z == 0 && M == 1 && Rm == 11111.

BRAB <Xn>, <Xm|SP>

**Key B, register modifier variant**

Applies when Z == 1 && M == 1.

BRABZ <Xn>, <Xm|SP>

**Decode for all variants of this encoding**

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UNDEFINED;

if Z == '0' && m != 31 then
    UNDEFINED;
```
Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

\[
\begin{align*}
\text{bits}(64) \ target &= \ X[n, 64]; \\
\text{bits}(64) \ modifier &= \text{if } \text{source}\_\text{is}\_\text{sp} \ \text{then} \ SP[] \ \text{else} \ X[m, 64]; \\
\text{if use_key_a then} \\
\text{\quad target} &= \text{AuthIA}(target, modifier, \text{TRUE}); \\

\text{BranchTo} (target, \text{BranchType_INDIR, FALSE});
\end{align*}
\]
C6.2.39   BRB

Branch Record Buffer. For more information, see \textit{op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions} on page C5-659.

This instruction is an alias of the \textit{SYS} instruction. This means that:

\begin{itemize}
  \item The encodings in this description are named to match the encodings of \textit{SYS}.
  \item The description of \textit{SYS} gives the operational pseudocode for this instruction.
\end{itemize}

\textbf{System}

(\texttt{FEAT\_BRBE})

\begin{verbatim}
0100 0001 0111 0010 op2 Rt
L   op1  CRn  CRm
\end{verbatim}

\textbf{Encoding}

\texttt{BRB \{\texttt{brb\_op}\}, \{\texttt{Xt}\}}

is equivalent to

\texttt{SYS \#1, C7, C2, \#op2\{, \texttt{Xt}\}}

and is the preferred disassembly when \texttt{SysOp('001', '0111', '0010', op2) == Sys\_BRB}.

\textbf{Assembler symbols}

\begin{itemize}
  \item \texttt{\{\texttt{brb\_op}\}} is a BRB instruction name, as listed for the BRB system instruction group, encoded in the "op2" field. It can have the following values:
  \begin{itemize}
    \item IALL when \texttt{op2 = 100}
    \item INJ when \texttt{op2 = 101}
  \end{itemize}
  \item \texttt{\{\texttt{op2}\}} is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
  \item \texttt{\{\texttt{Xt}\}} is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.
\end{itemize}

\textbf{Operation}

The description of \textit{SYS} gives the operational pseudocode for this instruction.
C6.2.40  BRK

Breakpoint instruction. A BRK instruction generates a Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3c, and captures the value of the immediate argument in ESR_ELx.ISS.

\[
\begin{array}{cccccccccc}
| & | & | & | & | & | & | & | & | & \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & imm\text{16} & 0 & 0 & 0 & 0
\end{array}
\]

**Encoding**

BRK #<imm>

**Decode for this encoding**

if HaveBTIEExt() then
    SetBTypeCompatible(TRUE);

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

AArch64.SoftwareBreakpoint(imm16);
C6.2.41 BTI

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while \( \text{PSTATE.BTYPE} \neq 0b00 \), a BTI instruction compatible with the current value of PSTATE.BTYPE will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand \(<\text{targets}>\) passed to a BTI instruction determines the values of PSTATE.BTYPE which the BTI instruction is compatible with.

\[\text{Note}\]
Within a guarded memory region, when \( \text{PSTATE.BTYPE} \neq 0b00 \), all instructions will generate a Branch Target Exception, other than BRK, BTI,HLT, PACIASP, and PACIBSP, which might not. See the individual instructions for more information.

**System**

(FEAT_BTI)

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 5 4 3 2 1 0 ]
1 1 0 1 0 1 0 0 0 0 1 1 0 0 1 0 0 1 0 0 0 1 1 1 1
```

**Encoding**

BTI \(<\text{targets}>\)

**Decode for this encoding**

```
SystemHintOp op;
if CRm:op2 == '0100 xx0' then
  op = SystemHintOp_BTI;
  // Check branch target compatibility between BTI instruction and PSTATE.BTYPE
  SetBTypeCompatible(BTypeCompatible_BTI(op2<2:1>));
else
  EndOfInstruction();
```

**Assemble symbols**

\(<\text{targets}>\) Is the type of indirection, encoded in the "op2<2:1>" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(omitted)</td>
<td>when op2&lt;2:1&gt; = 00</td>
</tr>

C6.2.42 CASB, CASAB, CASALB, CASLB

Compare and Swap byte in memory reads an 8-bit byte from memory, and compares it against the value held in a
first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed,
the read and write occur atomically such that no other modification of the memory location can take place between
the read and write.

- CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on
page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the
compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is
restored to the values held in the register before the instruction was executed.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.52  CFINV

Invert Carry Flag. This instruction inverts the value of the PSTATE.C flag.

System

(FEAT_FlagM)

Encoding

CFINV

Decode for this encoding

if !HaveFlagManipulateExt() then UNDEFINED;

Operation

PSTATE.C = NOT(PSTATE.C);

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.53  CFP

Control Flow Prediction Restriction by Context prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see CFP RCTX.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

**System**

(FEAT_SPECRES)

```
[31 30 29 28][27 26 25 24][23 22 21 20][19 18 16][15 12][11 8][7][5][4][0] 0
1 1 1 0 1 0 1 0 1 0 0 0 0 1 0 1 1 0 1 1 1 0 0 1 1 1 0 0 1 0 0 1 0 0 Rt
```

**Encoding**

CFP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #4, <Xt>

and is always the preferred disassembly.

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.54   CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{CINC} \ <Wd>, \ <Wn>, \ <\text{cond}>
\]

is equivalent to

\[
\text{CSINC} \ <Wd>, \ <Wn>, \ <Wn>, \ \text{invert}(<\text{cond})
\]

and is the preferred disassembly when \( Rn = Rm \).

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{CINC} \ <Xd>, \ <Xn>, \ <\text{cond}>
\]

is equivalent to

\[
\text{CSINC} \ <Xd>, \ <Xn>, \ <Xn>, \ \text{invert}(<\text{cond})
\]

and is the preferred disassembly when \( Rn = Rm \).

</tbody>
</table>

### Operation

The description of CSINC gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.55  CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf = 0$.

CINV <Wd>, <Wn>, <cond>

is equivalent to

CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when $Rn = Rm$.

64-bit variant

Applies when $sf = 1$.

CINV <Xd>, <Xn>, <cond>

is equivalent to

CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when $Rn = Rm$.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.
**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.56  CLREX

Clear Exclusive clears the local monitor of the executing PE.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 6 5 4 3 2 1 0]
1 1 0 1 0 1 0 0 0 0 0 1 1 0 1 1 1 1
```

**Encoding**

CLREX {#<imm>}

**Decode for this encoding**

// CRm field is ignored

**Assembler symbols**

<imm>  Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

```
ClearExclusiveLocal(ProcessorID());
```
C6.2.57  CLS

Count Leading Sign bits counts the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. This count does not include the most significant bit of the source register.

32-bit variant
Applies when sf == 0.
CLS <Wd>, <Wn>

64-bit variant
Applies when sf == 1.
CLS <Xd>, <Xn>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

integer result;
bits(datasize) operand1 = X[n, datasize];
result = CountLeadingSignBits(operand1);
X[d, datasize] = result<datasize-1:0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C6.2.58 CLZ

Count Leading Zeros counts the number of binary zero bits before the first binary one bit in the value of the source register, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CLZ} \ <Wd>, \ <Wn> 
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CLZ} \ <Xd>, \ <Xn> 
\]

Decoding for all variants of this encoding

\[
\text{integer } d = \text{ UInt}(Rd); \\
\text{integer } n = \text{ UInt}(Rn); \\
\text{integer } \text{datasize} = \text{if } sf = '1' \text{ then } 64 \text{ else } 32; 
\]

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

\[
\text{integer } \text{result}; \\
\text{bits}(\text{datasize}) \text{operand1} = X[n, \text{datasize}]; \\
\text{result} = \text{CountLeadingZeroBits}(\text{operand1}); \\
X[d, \text{datasize}] = \text{result}<\text{datasize}-1:0>; 
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.59   CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when sf == 0.

CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

### 64-bit variant

Applies when sf == 1.

CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

### Assembler symbols

- `<Wn|WSP>` is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn|SP>` is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` is a width specifier, encoded in the "option" field. It can have the following values:
  - `W` when option = 00x
  - `W` when option = 010
  - `X` when option = x11
  - `W` when option = 10x
  - `W` when option = 110
- `<m>` is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

The description of **ADDS (extended register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.60  CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

CMN \(<Wn|WSP>, \#<imm>{, <shift}>\)

is equivalent to

ADDS WZR, <Wn|WSP>, \#<imm> {, <shift>}

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

CMN \(<Xn|SP>, \#<imm>{, <shift}>\)

is equivalent to

ADDS XZR, <Xn|SP>, \#<imm> {, <shift>}

and is always the preferred disassembly.

Assembler symbols

- \(<Wn|WSP>\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Xn|SP>\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<imm>\) Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- \(<shift>\) Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when \( sh = 0 \)
  - LSL #12 when \( sh = 1 \)

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.61   CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when $s_f == 0$.

CMN $<Wn>$, $<Wm>$

is equivalent to

ADDS WZR, $<Wn>$, $<Wm>$

and is always the preferred disassembly.

**64-bit variant**

Applies when $s_f == 1$.

CMN $<Xn>$, $<Xm>$

is equivalent to

ADDS XZR, $<Xn>$, $<Xm>$

and is always the preferred disassembly.

**Assembler symbols**

- $<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<Xn>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Xm>$ Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<shift>$ Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when $shift = 00$
  - LSR when $shift = 01$
  - ASR when $shift = 10$
  - The encoding $shift = 11$ is reserved.
- $<amount>$ For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.62    CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf == 0 \).

\[
\text{CMP} \ <Wn|WSP>, <Wm>{, <extend> {#<amount>}} \\
\text{is equivalent to} \\
\text{SUBS} \ WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}} \\
\text{and is always the preferred disassembly.}
\]

64-bit variant

Applies when \( sf == 1 \).

\[
\text{CMP} \ <Xn|SP>, <R><m>{, <extend> {#<amount>}} \\
\text{is equivalent to} \\
\text{SUBS} \ XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}} \\
\text{and is always the preferred disassembly.}
\]

Assembler symbols

- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in the "option" field. It can have the following values:
  - `W` when option = 00x
  - `W` when option = 010
  - `X` when option = x11
  - `W` when option = 10x
  - `W` when option = 110
- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

---

C6-1276  Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.  ARM DDI 0487I.a  Non-Confidential  ID081822
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- **UXTB** when option = 000
- **UXTH** when option = 001
- **LSL|UXTW** when option = 010
- **UXTX** when option = 011
- **SXTB** when option = 100
- **SXTH** when option = 101
- **SXTW** when option = 110
- **SXTX** when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- **UXTB** when option = 000
- **UXTH** when option = 001
- **UXTW** when option = 010
- **LSL|UXTX** when option = 011
- **SXTB** when option = 100
- **SXTH** when option = 101
- **SXTW** when option = 110
- **SXTX** when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

The description of **SUBS (extended register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.63  **CMP (immediate)**

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the **SUBS (immediate)** instruction. This means that:

- The encodings in this description are named to match the encodings of **SUBS (immediate)**.
- The description of **SUBS (immediate)** gives the operational pseudocode for this instruction.

#### 32-bit variant

Applies when $sf == 0$.

CMP $<Wn|WSP>$, #<imm>{, <shift>}

is equivalent to

SUBS WZR, $<Wn|WSP>$, #<imm> {, <shift>}

and is always the preferred disassembly.

#### 64-bit variant

Applies when $sf == 1$.

CMP $<Xn|SP>$, #<imm>{, <shift>}

is equivalent to

SUBS XZR, $<Xn|SP>$, #<imm> {, <shift>}

and is always the preferred disassembly.

#### Assembler symbols

- $<Wn|WSP>$: Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- $<Xn|SP>$: Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- $<imm>$: Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- $<shift>$: Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  
  - LSL #0 when $sh = 0$
  - LSL #12 when $sh = 1$

#### Operation

The description of **SUBS (immediate)** gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.64  **CMP (shifted register)**

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the **SUBS (shifted register)** instruction. This means that:

- The encodings in this description are named to match the encodings of **SUBS (shifted register)**.
- The description of **SUBS (shifted register)** gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

CMP \(<Wn>, <Wm>{, <shift> #<amount>}\)

is equivalent to

SUBS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

CMP \(<Xn>, <Xm>{, <shift> #<amount>}\)

is equivalent to

SUBS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

### Assembler symbols

- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<shift>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( shift = 00 \)
  - LSR when \( shift = 01 \)
  - ASR when \( shift = 10 \)
  - The encoding \( shift = 11 \) is reserved.
- \(<amount>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.65   CMPP

Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This instruction is an alias of the SUBPS instruction. This means that:

- The encodings in this description are named to match the encodings of SUBPS.
- The description of SUBPS gives the operational pseudocode for this instruction.

**Integer**

(FEAT_MTE)

**Encoding**

CMPP <Xn|SP>, <Xm|SP>

is equivalent to

SUBPS XZR, <Xn|SP>, <Xm|SP>

and is always the preferred disassembly.

**Assembler symbols**

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.

<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

**Operation**

The description of SUBPS gives the operational pseudocode for this instruction.
C6.2.66 CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSNEG instruction. This means that:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0.

CNEG <Wd>, <Wn>, <cond>

is equivalent to

CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit variant

Applies when sf == 1.

CNEG <Xd>, <Xn>, <cond>

is equivalent to

CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.67 CPP

Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. The actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control cache prefetch predictions occurring after the instruction is complete and synchronized.

For more information, see CPP RCTX.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

Encoding

CPP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #7, <Xt>

and is always the preferred disassembly.

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.2.68  CPYFP, CPYFM, CPYFE

Memory Copy Forward-only. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFP, then CPYFM, and then CPYFE.

CPYFP performs some preconditioning of the arguments suitable for using the CPYFM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFE performs the last part of the memory copy.

___ Note ___

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

___ Note ___

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

___ Note ___

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFP, option A (which results in encoding PSTATE.C = 0):

• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + saturated Xn.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFP, option B (which results in encoding PSTATE.C = 1):

• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
• Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
• Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFE, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds \(-1\) the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from \(-Xn\).
• Xd holds the lowest address that the copy is made to \(-Xn\).
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFE, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.69 CPYFPN, CPYFMN, CPYFEN

Memory Copy Forward-only, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPN, then CPYFMN, and then CPYFEN.

CPYFPN performs some preconditioning of the arguments suitable for using the CPYFMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEN performs the last part of the memory copy.

--- Note ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

---

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---

Portable software should not assume that the choice of algorithm is constant.

---

After execution of CPYFPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from -Xn.

• Xd holds the lowest address that the copy is made to -Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.70 CPYFPRN, CPYFMRN, CPYFERN

Memory Copy Forward-only, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRN, then CPYFMRN, and then CPYFERN.

CPYFPRN performs some preconditioning of the arguments suitable for using the CPYFMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERN performs the last part of the memory copy.

--- Note ---
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

--- Note ---
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> === 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.72  CPYFPRTN, CPYFMRTN, CPYFERTN

Memory Copy Forward-only, reads unprivileged, reads and writes non-temporal. These instructions perform a
memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear
consecutively in memory: CPYFPRTN, then CPYFMRTN, and then CPYFERTN.

CPYFPRTN performs some preconditioning of the arguments suitable for using the CPYFMRTN instruction, and
performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTN performs an IMPLEMENTATION
DEFINED amount of the memory copy. CPYFERTN performs the last part of the memory copy.

------ Note ------
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can
be performed.

------ Note ------
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable
for a memory copy only where there is no overlap between the source and destination locations, or where the source
address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is
IMPLEMENTATION DEFINED.

------ Note ------
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the
memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be
copied in the memory copy in total.

For CPYFMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

**C6.2.73 CPYFPRTRN, CPYFMRTRN, CPYFERTRN**

Memory Copy Forward-only, reads unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTRN, then CPYFMRTRN, and then CPYFERTRN.

CPYFPRTRN performs some preconditioning of the arguments suitable for using the CPYFMRTRN instruction, and performs an *IMPLEMENTATION DEFINED* amount of the memory copy. CPYFMRTRN performs an *IMPLEMENTATION DEFINED* amount of the memory copy. CPYFERTRN performs the last part of the memory copy.

--- **Note**

The inclusion of *IMPLEMENTATION DEFINED* amounts of memory copy allows some optimization of the size that can be performed.

---

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is *IMPLEMENTATION DEFINED.*

--- **Note**

Portable software should not assume that the choice of algorithm is constant.

---

After execution of CPYFPRTRN, option A (which results in encoding PSTATE.C = 0):

- If $Xn_{<63>}$ == 1, the copy size is saturated to $0x7FFFFFFFFFFFFFFF$.
- $Xs$ holds the original $Xs +$ saturated $Xn$.
- $Xd$ holds the original $Xd +$ saturated $Xn$.
- $Xn$ holds $-1* $ saturated $Xn +$ an *IMPLEMENTATION DEFINED* number of bytes copied.
- PSTATE.{$N,Z,V}$ are set to {0,0,0}.

After execution of CPYFPRTRN, option B (which results in encoding PSTATE.C = 1):

- If $Xn_{<63>}$ == 1, the copy size is saturated to $0x7FFFFFFFFFFFFFFF$.
- $Xs$ holds the original $Xs +$ an *IMPLEMENTATION DEFINED* number of bytes copied.
- $Xd$ holds the original $Xd +$ an *IMPLEMENTATION DEFINED* number of bytes copied.
- $Xn$ holds the saturated $Xn -$ an *IMPLEMENTATION DEFINED* number of bytes copied.
- PSTATE.{$N,Z,V}$ are set to {0,0,0}.

For CPYFMRTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- $Xn$ is treated as a signed 64-bit number and holds $-1* $ the number of bytes remaining to be copied in the memory copy in total.
- $Xs$ holds the lowest address that the copy is copied from -$Xn$.
- $Xd$ holds the lowest address that the copy is made to -$Xn$.
- At the end of the instruction, the value of $Xn$ is written back with $-1* $ the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- $Xn$ holds the number of bytes remaining to be copied in the memory copy in total.
- $Xs$ holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from -Xn.

• Xd holds the lowest address that the copy is made to -Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTRN option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.74 CPYFPRTWN, CPYFMRTWN, CPYFERTWN

Memory Copy Forward-only, reads unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTWN, then CPYFMRTWN, and then CPYFERTWN.

CPYFPRTWN performs some preconditioning of the arguments suitable for using the CPYFMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTWN performs the last part of the memory copy.

--- Note ---
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.75 CPYFPT, CPYFMT, CPYFET

Memory Copy Forward-only, reads and writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPT, then CPYFMT, and then CPYFET.

CPYFPT performs some preconditioning of the arguments suitable for using the CPYFMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFET performs the last part of the memory copy.

--- Note ---
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

--- Note ---
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0xffffffffffffffff.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0xffffffffffffffff.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFET, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.76 CPYFPTN, CPYFMTN, CPYFETN

Memory Copy Forward-only, reads and writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTN, then CPYFMTN, and then CPYFETN.

CPYFPTN performs some preconditioning of the arguments suitable for using the CPYFMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETN performs the last part of the memory copy.

--- Note ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

--- Note ---

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from -Xn.

• Xd holds the lowest address that the copy is made to -Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.77 CPYFPTRN, CPYFMTRN, CPYFETRN

Memory Copy Forward-only, reads and writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTRN, then CPYFMTRN, and then CPYFETRN.

CPYFPTRN performs some preconditioning of the arguments suitable for using the CPYFMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETRN performs the last part of the memory copy.

— Note —

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

— Note —

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1 * the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from - Xn.
- Xd holds the lowest address that the copy is made to - Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

C6.2.78 CPYFPTWN, CPYFMTWN, CPYFETWN

Memory Copy Forward-only, reads and writes unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTWN, then CPYFMTWN, and then CPYFETWN.

CPYFPTWN performs some preconditioning of the arguments suitable for using the CPYFMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from -Xn.

• Xd holds the lowest address that the copy is made to -Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds \(-1 \times\) the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from \(-Xn\).

• Xd holds the lowest address that the copy is made to \(-Xn\).

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.80 CPYFPWT, CPYFMWT, CPYFEWT

Memory Copy Forward-only, writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWT, then CPYFMWT, and then CPYFEWT.

CPYFPWT performs some preconditioning of the arguments suitable for using the CPYFMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWT, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWT, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.81 CPYFPWTN, CPYFMWTN, CPYFEWTN

Memory Copy Forward-only, writes unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTN, then CPYFMWTN, and then CPYFEWTN.

CPYFPWTN performs some preconditioning of the arguments suitable for using the CPYFMWTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTN performs the last part of the memory copy.

——— Note ————
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

——— Note ————
The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

——— Note ————
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from -Xn.

• Xd holds the lowest address that the copy is made to -Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.82 CPYFPWTRN, CPYFMWTRN, CPYFEWTRN

Memory Copy Forward-only, writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTRN, then CPYFMWTRN, and then CPYFEWTRN.

CPYFPWTRN performs some preconditioning of the arguments suitable for using the CPYFMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTRN performs the last part of the memory copy.

--- Note ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

---

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---

Portable software should not assume that the choice of algorithm is constant.

---

After execution of CPYFPWTRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number and holds \(-1^* the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from \(-Xn.

• Xd holds the lowest address that the copy is made to \(-Xn.

• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes remaining to be copied in the memory copy in total.

• Xs holds the lowest address that the copy is copied from.

• Xd holds the lowest address that the copy is copied to.

• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.83 CPYFPWTWN, CPYFMWTWN, CPYFEWTWN

Memory Copy Forward-only, writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTWN, then CPYFMWTWN, and then CPYFEWTWN.

CPYFPWTWN performs some preconditioning of the arguments suitable for using the CPYFMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTWN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTWN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTWN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xs is written back with the lowest address that has not been copied from.
  — the value of Xd is written back with the lowest address that has not been copied to.

C6.2.84 CPYP, CPYM, CPYE

Memory Copy. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYP, then CPYM, and then CPYE.

CPYP performs some preconditioning of the arguments suitable for using the CPYM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYE performs the last part of the memory copy.

--- Note ---
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYP, the following saturation logic is applied:

If \( X_n \text{<63:55>} \neq 000000000, \) the copy size \( X_n \) is saturated to \( 0x007FFFFFFFFFFFFF \).

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If \((X_s > X_d) \&\& (X_d + \text{saturated} X_n) > X_s\), then direction = forward

Elsif \((X_s < X_d) \&\& (X_s + \text{saturated} X_n) > X_d\), then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYP, option A (which results in encoding PSTATE.C = 0):

- PSTATE.\( \{N,Z,V\} \) are set to \( \{0,0,0\} \).
- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated} X_n \).
  - \( X_d \) holds the original \( X_d + \text{saturated} X_n \).
  - \( X_n \) holds \(-1\)\* saturated \( X_n \) + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - \( X_s \) and \( X_d \) are unchanged.
  - \( X_n \) holds the saturated value of \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYP, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\( \{N,Z,V\} \) are set to \( \{0,0,0\} \).
- If the copy is in the backward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated} X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{saturated} X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\( \{N,Z,V\} \) are set to \( \{1,0,0\} \).
For CPYM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is copied to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is made to.
  - Xd holds the lowest address that the copy is made to.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from.
  — Xd holds the highest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

            PSTATE.<N,Z,C,V> = nzcv;
C6.2.85 CPYN, CPYMN, CPYEN

Memory Copy, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPN, then CPYMN, and then CPYEN.

CPYPN performs some preconditioning of the arguments suitable for using the CPYMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEN performs the last part of the memory copy.

--- Note ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.

• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.86 CPYPRN, CPYMRN, CPYERN

Memory Copy, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRN, then CPYMRN, and then CPYERN.

CPYPRN performs some preconditioning of the arguments suitable for using the CPYMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERN performs the last part of the memory copy.

--- Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

---

For CPYPRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note

Portable software should not assume that the choice of algorithm is constant.

---

After execution of CPYPRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- $X_n$ is treated as a signed 64-bit number.
- If the copy is in the forward direction ($X_n$ is a negative number), then:
  - $X_n$ holds $-1\times$ the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the lowest address that the copy is copied from -$X_n$.
  - $X_d$ holds the lowest address that the copy is made to -$X_n$.
  - At the end of the instruction, the value of $X_n$ is written back with $-1\times$ the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction ($X_n$ is a positive number), then:
  - $X_n$ holds the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the highest address that the copy is copied from -$X_n+1$.
  - $X_d$ holds the highest address that the copy is copied to -$X_n+1$.
  - At the end of the instruction, the value of $X_n$ is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- $X_n$ holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - $X_s$ holds the lowest address that the copy is copied from.
  - $X_d$ holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of $X_n$ is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of $X_s$ is written back with the lowest address that has not been copied from.
    - the value of $X_d$ is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - $X_s$ holds the highest address that the copy is copied from +1.
  - $X_d$ holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of $X_n$ is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of $X_s$ is written back with the highest address that has not been copied from +1.
    - the value of $X_d$ is written back with the highest address that has not been copied to +1.

For CPYERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- $X_n$ is treated as a signed 64-bit number.
- If the copy is in the forward direction ($X_n$ is a negative number), then:
  - $X_n$ holds $-1\times$ the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the lowest address that the copy is copied from -$X_n$.
  - $X_d$ holds the lowest address that the copy is made to -$X_n$.
  - At the end of the instruction, the value of $X_n$ is written back with 0.
- If the copy is in the backward direction ($X_n$ is a positive number), then:
  - $X_n$ holds the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the highest address that the copy is copied from -$X_n+1$. 

— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.

• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.87  CPYPRT, CPYMRT, CPYERT

Memory Copy, reads unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRT, then CPYMRT, and then CPYERT.

CPYPRT performs some preconditioning of the arguments suitable for using the CPYMRT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1^*\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1^*\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1^*\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.

• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.88 CPYPRTN, CPYMRTN, CPYERTN

Memory Copy, reads unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTN, then CPYMRTN, and then CPYERTN.

CPYPRTN performs some preconditioning of the arguments suitable for using the CPYMRTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTN, option A (which results in encoding PSTATE.C = 0):

• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  — Xs holds the original Xs + saturated Xn.
  — Xd holds the original Xd + saturated Xn.
  — Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• If the copy is in the backward direction, then:
  — Xs and Xd are unchanged.
  — Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTN, option B (which results in encoding PSTATE.C = 1):

• If the copy is in the forward direction, then:
  — Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  — Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to \(-X_n+1\).
— At the end of the instruction, the value of Xn is written back with 0.

For CPYERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

Asmber symbols

<Xd> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field.

<Xs> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field.

<Xn> For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.
For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field.

  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to \(-X_n+1\).
— At the end of the instruction, the value of Xn is written back with 0.

For CPYERTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.90 CPYPRTWN, CPYMRTWN, CPYERTWN

Memory Copy, reads unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTWN, then CPYMRTWN, and then CPYERTWN.

CPYPRTWN performs some preconditioning of the arguments suitable for using the CPYMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{1,0,0\}.
For CPYMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1 \times \) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1 \times \) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1 \times \) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.91 CPYPT, CPYMT, CPYET

Memory Copy, reads and writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPT, then CPYMT, and then CPYET.

CPYPT performs some preconditioning of the arguments suitable for using the CPYMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYET performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}. 
For CPYMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

**C6.2.92 CPYPTN, CPYMTN, CPYETN**

Memory Copy, reads and writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTN, then CPYMTN, and then CPYETN.

CPYPTN performs some preconditioning of the arguments suitable for using the CPYMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETN performs the last part of the memory copy.

--- **Note** ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

--- ---

For CPYPTN, the following saturation logic is applied:

If \( X_{n<63:55>} \neq 000000000 \), the copy size \( X_n \) is saturated to \( 0x007FFFFFFFFFFFFF \).

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If \( (X_{s > X_{d}}) \&\& (X_{d + saturated X_n} > X_{s}) \), then direction = forward
- Elsif \( (X_{s < X_{d}}) \&\& (X_{s + saturated X_n} > X_{d}) \), then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- **Note** ---

Portable software should not assume that the choice of algorithm is constant.

--- ---

After execution of CPYPTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + saturated X_n \).
  - \( X_d \) holds the original \( X_d + saturated X_n \).
  - \( X_n \) holds \( -1^* saturated X_n + an IMPLEMENTATION DEFINED number of bytes copied \).
- If the copy is in the backward direction, then:
  - \( X_s \) and \( X_d \) are unchanged.
  - \( X_n \) holds the saturated value of \( X_n - an IMPLEMENTATION DEFINED number of bytes copied \).

After execution of CPYPTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( X_d \) holds the original \( X_d + an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( X_n \) holds the saturated \( X_n - an IMPLEMENTATION DEFINED number of bytes copied \).
  - PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - \( X_s \) holds the original \( X_s + saturated X_n - an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( X_d \) holds the original \( X_d + saturated X_n - an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( X_n \) holds the saturated \( X_n - an IMPLEMENTATION DEFINED number of bytes copied \).
  - PSTATE.\{N,Z,V\} are set to \{1,0,0\}.  

---
For CPYMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.93 CPYPTRN, CPYMTRN, CPYETRN

Memory Copy, reads and writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTRN, then CPYMTRN, and then CPYETRN.

CPYPTRN performs some preconditioning of the arguments suitable for using the CPYMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETRN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTRN, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTRN, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  — Xs holds the original Xs + saturated Xn.
  — Xd holds the original Xd + saturated Xn.
  — Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• If the copy is in the backward direction, then:
  — Xs and Xd are unchanged.
  — Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTRN, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  — Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  — Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.

• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.94 CPYPTWN, CPYMTWN, CPYETWN

Memory Copy, reads and writes unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTWN, then CPYMTWN, and then CPYETWN.

CPYPTWN performs some preconditioning of the arguments suitable for using the CPYMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETWN performs the last part of the memory copy.

——— Note ————
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

——— Note ————
For CPYPTWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

——— Note ————
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

Assembler symbols

<Xd> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field.

<Xs> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field.

<Xn> For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.
For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field.

CPYPWN, CPYMWN, CPYEWN

Memory Copy, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWN, then CPYMWN, and then CPYEWN.

CPYPWN performs some preconditioning of the arguments suitable for using the CPYMWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWN, the following saturation logic is applied:
If $Xn_{63:55} \neq 000000000$, the copy size $Xn$ is saturated to $0x007FFFFFFFFFFFFF$.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If $(Xs > Xd) \& \& (Xd + \text{saturated } Xn) > Xs$, then direction = forward
Elsif $(Xs < Xd) \& \& (Xs + \text{saturated } Xn) > Xd$, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWN, option A (which results in encoding PSTATE.C = 0):
- PSTATE.$\{N,Z,V\}$ are set to $\{0,0,0\}$.
- If the copy is in the forward direction, then:
  - $Xs$ holds the original $Xs + \text{saturated } Xn$.
  - $Xd$ holds the original $Xd + \text{saturated } Xn$.
  - $Xn$ holds $-1 \times \text{saturated } Xn + \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
- If the copy is in the backward direction, then:
  - $Xs$ and $Xd$ are unchanged.
  - $Xn$ holds the saturated value of $Xn - \text{an IMPLEMENTATION DEFINED number of bytes copied}$.

After execution of CPYPWN, option B (which results in encoding PSTATE.C = 1):
- If the copy is in the forward direction, then:
  - $Xs$ holds the original $Xs + \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - $Xd$ holds the original $Xd + \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - $Xn$ holds the saturated $Xn - \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - PSTATE.$\{N,Z,V\}$ are set to $\{0,0,0\}$.
- If the copy is in the backward direction, then:
  - $Xs$ holds the original $Xs + \text{saturated } Xn - \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - $Xd$ holds the original $Xd + \text{saturated } Xn - \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - $Xn$ holds the saturated $Xn - \text{an IMPLEMENTATION DEFINED number of bytes copied}$.
  - PSTATE.$\{N,Z,V\}$ are set to $\{1,0,0\}$. 
For CPYMWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.96 CPYPWT, CPYMWT, CPYEWT

Memory Copy, writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWT, then CPYMWT, and then CPYEWT.

CPYPWT performs some preconditioning of the arguments suitable for using the CPYMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
Xd holds the highest address that the copy is copied to -Xn+1.
At the end of the instruction, the value of Xn is written back with 0.

For CPYEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

C6.2.97  CPYPWTN, CPYMWTN, CPYEWTN

Memory Copy, writes unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTN, then CPYMWTN, and then CPYEWTN.

CPYPWTN performs some preconditioning of the arguments suitable for using the CPYMWTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTN performs the last part of the memory copy.

--- Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

---

For CPYPWTN, the following saturation logic is applied:

If \(Xn_{63:55} \neq 000000000\), the copy size \(Xn\) is saturated to \(0x007FFFFFFFFFFFF\).

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If \((Xs > Xd) && (Xd + saturated Xn) > Xs\), then direction = forward
- Elsif \((Xs < Xd) && (Xs + saturated Xn) > Xd\), then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note

Portable software should not assume that the choice of algorithm is constant.

---

After execution of CPYPWTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds \(-1^*\) saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to \{1,0,0\}.
For CPYMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

Assembler symbols
<Xd>
For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field.

<Xs>
For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field.

<Xn>
For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.
For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field.

C6.2.98 CPYPWTRN, CPYMWTRN, CPYEWTRN

Memory Copy, writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTRN, then CPYMWTRN, and then CPYEWTRN.

CPYPWTRN performs some preconditioning of the arguments suitable for using the CPYMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTRN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTRN, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.
After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTRN, option A (which results in encoding PSTATE.C = 0):
- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTRN, option B (which results in encoding PSTATE.C = 1):
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

Assembler symbols

<Xd> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field.

<Xs> For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field.

<Xn> For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.
For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field.

C6.2.99 CPYPWTWN, CPYMWTWN, CPYEWTWN

Memory Copy, writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTWN, then CPYMWTWN, and then CPYEWTWN.

CPYPWTWN performs some preconditioning of the arguments suitable for using the CPYMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTWN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTWN, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTWN, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  — Xs holds the original Xs + saturated Xn.
  — Xd holds the original Xd + saturated Xn.
  — Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• If the copy is in the backward direction, then:
  — Xs and Xd are unchanged.
  — Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTWN, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  — Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  — Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  — PSTATE.{N,Z,V} are set to {1,0,0}.
For CPYMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
— Xd holds the highest address that the copy is copied to -Xn+1.
— At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  — Xs holds the lowest address that the copy is copied from.
  — Xd holds the lowest address that the copy is copied to.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the lowest address that has not been copied from.
    — the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  — Xs holds the highest address that the copy is copied from +1.
  — Xd holds the highest address that the copy is copied to +1.
  — At the end of the instruction:
    — the value of Xn is written back with 0.
    — the value of Xs is written back with the highest address that has not been copied from +1.
    — the value of Xd is written back with the highest address that has not been copied to +1.

### Integer

EndOfInstruction();

Assembler symbols

<Xd>
For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an
encoding of the destination address, encoded in the "Rd" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination
address and is updated by the instruction, encoded in the "Rd" field.

<Xs>
For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an
encoding of the source address, encoded in the "Rs" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the source
address and is updated by the instruction, encoded in the "Rs" field.

<Xn>
For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding
of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in
the "Rn" field.
For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of
the number of bytes to be transferred, encoded in the "Rn" field.
For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of
bytes to be transferred and is updated by the instruction to encode the remaining size and
destination, encoded in the "Rn" field.

C6.2.100  CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note: ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

  - The values of the NZCV flags.
C6.2.102 CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

--- Note ---

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

---

```

C6.2.103 CSEL

If the condition is true, Conditional Select writes the value of the first source register to the destination register. If the condition is false, it writes the value of the second source register to the destination register.

32-bit variant
Applies when sf == 0.
CSEL <Wd>, <Wn>, <Wm>, <cond>

64-bit variant
Applies when sf == 1.
CSEL <Xd>, <Xn>, < Xm>, <cond>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

bits(datasize) result;
if ConditionHolds(cond) then
  result = X[n, datasize];
else
  result = X[m, datasize];
X[d, datasize] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.104 CSET

Conditional Set sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CSET } \langle Wd \rangle, <\text{cond}> \\
\text{is equivalent to} \\
\text{CSINC } \langle Wd \rangle, \text{WZR, WZR, invert(<cond>)} \\
\text{and is always the preferred disassembly.}
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CSET } \langle Xd \rangle, <\text{cond}> \\
\text{is equivalent to} \\
\text{CSINC } \langle Xd \rangle, \text{XZR, XZR, invert(<cond>)} \\
\text{and is always the preferred disassembly.}
\]

Assembler symbols

\( \langle Wd \rangle \)

Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\( \langle Xd \rangle \)

Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\( <\text{cond}> \)

Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.105 CSETM

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{CSETM } <Wd>, <\text{cond}>
\]

is equivalent to

\[
\text{CSINV } <Wd>, \text{WZR, WZR, invert(<}\text{cond}>)
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{CSETM } <Xd>, <\text{cond}>
\]

is equivalent to

\[
\text{CSINV } <Xd>, \text{XZR, XZR, invert(<}\text{cond}>)
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{cond}>\) Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

### Operation

The description of CSINV gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
C6.2.106  CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC and CSET. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $\text{sf} == 0$.

$\text{CSINC} <\text{Wd}>, <\text{Wn}>, <\text{Wm}>, <\text{cond}>$

64-bit variant
Applies when $\text{sf} == 1$.

</tr>
</tbody>
</table>

Assembler symbols

- $<\text{Wd}>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Wn}>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{Wm}>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{Xd}>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Xn}>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{ Xm}>$ Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{cond}>$ Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

bits(datasize) result;
if ConditionHolds(cond) then
    result = X[n, datasize];
else
    result = X[m, datasize];
result = result + 1;
X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.107 CSINV

Conditional Select Invert returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV and CSETM. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $sf = 0$.

CSINV $<Wd>, <Wn>, <Wm>, <cond>

64-bit variant
Applies when $sf = 1$.

CSINV $<Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

integer $d = $UInt(Rd);
integer $n = $UInt(Rn);
integer $m = $UInt(Rm);
integer datasize = if $sf == '1'$ then 64 else 32;

Alias conditions

<table>
<thead>

<tr>
<td>CSETM</td>
<td>$Rn == '11111' &amp; &amp; cond != '111x' &amp; &amp; $Rn == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Wm>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xn>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Xm>$ Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

$<cond>$ Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

```plaintext
bits(datasize) result;
if ConditionHolds(cond) then
    result = X[n, datasize];
else
    result = X[m, datasize];
    result = NOT(result);
X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.108   CSNEG

Conditional Select Negation returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias CNEG. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when sf == 0.

CSNEG <Wd>, <Wn>, <Wm>, <cond>

64-bit variant
Applies when sf == 1.

CSNEG <Xd>, <Xn>, <Xm>, <cond>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Alias conditions

<table>

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

bits(datasize) result;
if ConditionHolds(cond) then
    result = X[n, datasize];
else
result = X[m, datasize];
result = NOT(result);
result = result + 1;
X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.109   DC

Data Cache operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.

This instruction is an alias of the SYS instruction. This means that:

• The encodings in this description are named to match the encodings of SYS.
• The description of SYS gives the operational pseudocode for this instruction.

Encoding

DC <dc_op>, <Xt>

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>, <Xt>

and is the preferred disassembly when SysOp(op1,’0111’,CRm,op2) == Sys_DC.

Assembler symbols

<dc_op> Is a DC instruction name, as listed for the DC system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:

- IVAC when op1 = 000, CRm = 0110, op2 = 001
- ISW when op1 = 000, CRm = 0110, op2 = 010
- CSW when op1 = 000, CRm = 1010, op2 = 010
- CISW when op1 = 000, CRm = 1110, op2 = 010
- ZVA when op1 = 011, CRm = 0100, op2 = 001
- CVAC when op1 = 011, CRm = 0100, op2 = 001
- CVAU when op1 = 011, CRm = 1011, op2 = 001
- CIVAC when op1 = 011, CRm = 1110, op2 = 001

When FEAT_MTE2 is implemented, the following values are also valid:

- IGVAC when op1 = 000, CRm = 0110, op2 = 011
- IGWS when op1 = 000, CRm = 0110, op2 = 100
- IGDVAC when op1 = 000, CRm = 0110, op2 = 101
- IGDWS when op1 = 000, CRm = 0110, op2 = 110
- CGSW when op1 = 000, CRm = 1010, op2 = 100
- CGDSW when op1 = 000, CRm = 1010, op2 = 110
- CIGSW when op1 = 000, CRm = 1110, op2 = 100
- CIGDSW when op1 = 000, CRm = 1110, op2 = 110

When FEAT_MTE is implemented, the following values are also valid:

- GVA when op1 = 011, CRm = 0100, op2 = 011
- GZVA when op1 = 011, CRm = 0100, op2 = 100
- CGVAC when op1 = 011, CRm = 1010, op2 = 011
CGDVAC when op1 = 011, CRm = 1010, op2 = 101
CGVAP when op1 = 011, CRm = 1100, op2 = 011
CGDVAP when op1 = 011, CRm = 1100, op2 = 101
CGVADP when op1 = 011, CRm = 1101, op2 = 011
CGDVADP when op1 = 011, CRm = 1101, op2 = 101
CIGVAC when op1 = 011, CRm = 1110, op2 = 011
CIGDVAC when op1 = 011, CRm = 1110, op2 = 101

When FEAT_DPB is implemented, the following value is also valid:
CVAP when op1 = 011, CRm = 1100, op2 = 001

When FEAT_DPB2 is implemented, the following value is also valid:
CVADP when op1 = 011, CRm = 1101, op2 = 001

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation
The description of SYS gives the operational pseudocode for this instruction.
C6.2.110 DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is undefined at EL0 in Non-secure state if EL2 is implemented and HCR_EL2.TGE == 1.
This instruction is always undefined in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS<n> on page H2-10262.

| 31 30 29 28|27 26 25 24|23 22 21 20| 5 4| 3 2 1 0 |
|---|---|---|---|
| 1 1 0 1 0 1 0 0 1 0 1 | imm16 | 0 0 0 0 1 |

**Encoding**

DCPS1 {#<imm>}

**Decode for this encoding**

if !Halted() then UNDEFINED;

**Assembler symbols**

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

**Operation**

DCPSInstruction(LL);
C6.2.111  DCPS2

Debug Change PE State to EL2, when executed in Debug state:

- If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is UNDEFINED at the following exception levels:

- All exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS<n> on page H2-10262.

**Assembler symbols**

<imm> is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

**Operation**

DCPSInstruction(LL);
C6.2.112 DCPS3

Debug Change PE State to EL3, when executed in Debug state:

- If executed at EL3 selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:

- ESCR.SDD == 1.
- EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<\text{n}> instructions, see DCPS<\text{n}> on page H2-10262.

  when '11' domain = MBReqDomain_FullSystem;
case CRm<1:0> of
  when '00' types = MBReqTypes_All; domain = MBReqDomain_FullSystem;
  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;

Assembler symbols

<option> Specifies the limitation on the barrier operation. Values are:

SY     Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST     Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD     Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH    Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST  Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD  Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH    Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST  Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD  Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH  Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page B2-175 or see Data Synchronization Barrier (DSB) on page B2-178.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

**Operation**

DataMemoryBarrier(domain, types);
C6.2.115 DRPS

Debug restore process state

C6.2.116  DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)* on page B2-178.

A DSB instruction with the nXS qualifier is complete when the subset of these memory accesses with the XS attribute set to 0 are complete. It does not require that memory accesses with the XS attribute set to 1 are complete.

This instruction is used by the aliases PSSBB and SSBB. See *Alias conditions on page C6-1489* for details of when each alias is preferred.

**Memory barrier**

```
|31 30 29|28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11|8|7|6|5|4|3|2|1|0|

</tbody>
</table>
All other encodings of CRm, other than the values 0b0000 and 0b0100, that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page B2-175 or see Data Synchronization Barrier (DSB) on page B2-178.

Note

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

For the memory nXS barrier variant: specifies the limitation on the barrier operation. Values are:

- SY: Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as imm2 = 0b11.
- ISH: Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as imm2 = 0b10.
- NSH: Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as imm2 = 0b01.
- OSH: Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as imm2 = 0b00.

<imm> is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation for all encodings

case alias of
    when DSBAlias_SSBB
        SpeculativeStoreBypassBarrierToVA();
    when DSBAlias_PSSBB
        SpeculativeStoreBypassBarrierToPA();
    when DSBAlias_DSB
        if HaveTME() && TSTATE.depth > 0 then
            FailTransaction(TMFailure_ERR, FALSE);
        if !nXS && HaveFeatXS() && HaveFeatHCX() then
            nXS = PSTATE.EL IN {EL0, EL1} && IsHCRXEL2Enabled() && HCRX_EL2.FnXS == '1';
            DataSynchronizationBarrier(domain, types, nXS);
        otherwise
            Unreachable();
    otherwise
        unreachable();
C6.2.117   DVP

Data Value Prediction Restriction by Context prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see DVP RCTX.

This instruction is an alias of the SYS instruction. This means that:

• The encodings in this description are named to match the encodings of SYS.
• The description of SYS gives the operational pseudocode for this instruction.

Encoding

DVP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #5, <Xt>

and is always the preferred disassembly.

Assembler symbols

<Xt>        Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.2.118   EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \).

EON \(<Wd>, <Wn>, <Wm>{, <shift> #<amount>}\)

64-bit variant

Applies when \( sf = 1 \).

EON \(<Xd>, <Xn>, <Xm>{, <shift> #<amount>}\)

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt(Rd)}; \\
\text{integer } n &= \text{UInt(Rn)}; \\
\text{integer } m &= \text{UInt(Rm)}; \\
\text{integer } datasize &= \text{if } sf = '1' \text{ then 64 else 32}; \\
\text{if } sf = '0' \text{ \&\& imm6<5> == '1' then UNDEFINED;}
\end{align*}
\]

\[
\text{ShiftType shift_type} = \text{DecodeShift(shift)}; \\
\text{integer shift_amount} = \text{UInt(imm6)};
\]

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<shift>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10
- ROR when shift = 11

\(<amount>\)

For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;

operand2 = NOT(operand2);

result = operand1 EOR operand2;

X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.119   EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.121 ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores PSTATE from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state on page D1-4645.

ERET is UNDEFINED at EL0.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>

</tr>
</tbody>
</table>
```

**Encoding**

ERET

**Decode for this encoding**

if PSTATE.EL == EL0 then UNDEFINED;

**Operation**

```c
AArch64.CheckForERetTrap(FALSE, TRUE);
bits(64) target = ELR[];
AArch64.ExceptionReturn(target, SPSR[]);
```
C6.2.122   ERETAA, ERETAB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state on page D1-4645.

ERETAA and ERETAB are UNDEFINED at EL0.

Integer

(FEAT_PAuth)

**Operation**

```plaintext
AArch64.CheckForERetTrap(TRUE, use_key_a);
bzts(64) target = ELR[];
bzts(64) modifier = SP[];
if use_key_a then
  target = AuthIA(target, modifier, TRUE);
else
  target = AuthIB(target, modifier, TRUE);
AArch64.ExceptionReturn(target, SPSR[]);
```
C6.2.123   ESB

Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.

This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the Arm(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a NOP.

System

(FEAT_RAS)

```
0 1 0 1 0 1 0 0 0 1 1 0 0 0 0 1 1 0 0 0 0 1 1 1 1

A64 Base Instruction Descriptions
C6.2 Alphabetical list of A64 base instructions

Assembler symbols

<imm> Is a 7-bit unsigned immediate, in the range 0 to 127 encoded in the "CRm:op2" field. The encodings that are allocated to architectural hint functionality are described in the "Hints" table in the "Index by Encoding".

--- Note ---
For allocated encodings of "CRm:op2":
- A disassembler will disassemble the allocated instruction, rather than the HINT instruction.
- An assembler may support assembly of allocated encodings using HINT with the corresponding <imm> value, but it is not required to do so.

Operation

case op of
  when SystemHintOp_YIELD
    Hint_Yield();
  when SystemHintOp_DGH
    Hint_DGH();
  when SystemHintOp_WFE

C6.2.127   HLT

Halt instruction. An HLT instruction can generate a Halt Instruction debug event, which causes entry into Debug state.

```
   | 31 30 29 28|27 26 25 24|23 22 21 20| 5 4 3 2 1 0 |
1 1 0 1 0 1 0 0 0 1 0 | imm16 | 0 0 0 0 0 0 |
```

**Encoding**

HLT #<imm>

**Decode for this encoding**

if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
if HaveBTIExt() then
  SetBTypeCompatible(TRUE);

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

Halt(DebugHalt_HaltInstruction, FALSE);
C6.2.128   HVC

Hypervisor Call causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and SCR_EL3.HCE is set to 0.
- When EL3 is not implemented and HCR_EL2.HCD is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC value 0x16, and the value of the immediate argument.

```
[31 30 29 28|27 26 25 24|23 22 21 20]| | | | 5 4 3 2 1 0 |
1 1 0 1 0 1 0 0|0 0 0|imm16|0 0 0|1 0
```

**Encoding**

HVC #<imm>

**Decode for this encoding**

// Empty.

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

```cpp
if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && !EL2Enabled()) then UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then UNDEFINED;
else AArch64.CallHypervisor(imm16);
```
IC

Instruction Cache operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

```

**Encoding**

IC <ic_op>{, <Xt>}

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when SysOp(op1,'0111',CRm,op2) == Sys_IC.

**Assembler symbols**

<i_c_op> Is an IC instruction name, as listed for the IC system instruction pages, encoded in the "op1:CRm:op2" field. It can have the following values:

- IALLUIS  when op1 = 000, CRm = 0001, op2 = 000
- IALLU    when op1 = 000, CRm = 0101, op2 = 000
- IVAU     when op1 = 011, CRm = 0101, op2 = 001

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.130  IRG

Insert Random Tag inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

**Integer**

(FEAT_MTE)

```
[31 30 29 28|27 26 25 24|23 22 21 20]  16|15 14 13 12|11 10  9 |  5 4 |  0 |
 1 0 0 | 1 1 0 1 0 1 0 | 0 | 0 | 1 | 0 | 0 | Xn | Xd |
```

**Encoding**

IRG <Xd|SP>, <Xn|SP>{, <Xm>}

**Decode for this encoding**

```cpp
if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
integer m = UInt(Xm);
```

**Assembler symbols**

- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- `<Xn|SP>` is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field. Defaults to XZR if absent.

**Operation**

```cpp
bits(64) operand = if n == 31 then SP[] else X[n, 64];
bits(64) exclude_reg = X[m, 64];
bits(16) exclude = exclude_reg<15:0> OR GCR_EL1.Exclude;
bits(4) rtag;
if AArch64.AllocationTagAccessIsEnabled(AccType_NORMAL) then
  if GCR_EL1.RRND == '1' then
    if IsOnes(exclude) then
      rtag = '0000';
    else
      rtag = ChooseRandomNonExcludedTag(exclude);
  else
    bits(4) start = RGSR_EL1.TAG;
    bits(4) offset = AArch64.RandomTag();
    rtag = AArch64.ChooseNonExcludedTag(start, offset, exclude);
  else
    RGSR_EL1.TAG = rtag;
  rtag = '0000';
bits(64) result = AArch64.AddressWithAllocationTag(operand, AccType_NORMAL, rtag);
if d == 31 then
```

```cpp"
SP[] = result;
else
X[d, 64] = result;
C6.2.131 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)* on page B2-175.

```

<table>
<thead>
<tr>

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.136 LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180, except that:

• There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.

• The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see Load/store addressing modes on page C1-234.

data = Mem[address, dbytes, AccType_ORDERED];
X[t, regsize] = ZeroExtend(data, regsize);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.137   LDAPRB

Load-Acquire RCpc Register Byte derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see Load/store addressing modes on page C1-234.

### Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n, 64];

data = Mem[address, 1, AccType.ORDERED];
X[t, 32] = ZeroExtend(data, 32);

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.147   LDARH

Load-Acquire Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180. For information about memory accesses, see Load/store addressing modes on page C1-234.

Note

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

Encoding

LDARH <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n, 64];

data = Mem[address, 2, AccType_ORDERED];
X[t, 32] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.148  LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity on page 2154 and Alignment of data accesses on page 2189. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page 2211. The instruction also has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page 2210. For information about memory accesses, see Load/store addressing modes on page 234.

32-bit variant

Applies when sz == 0.
LDAXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit variant

Applies when sz == 1.
LDAXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if t == t2 then
  Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
  assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNKNOWN rt_unknown = TRUE;  // result is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly LDAXP on page K1-11591.

Assembler symbols

<#t1>  Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<#t2>  Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xt1>  Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X[t, datasize] = bits(datasize) UNKNOWN; // In this case t = t2
elseif elsize == 32 then
    // 32-bit load exclusive pair (atomic)
    data = Mem[address, dbytes, AccType_ORDEREDATOMIC];
    if BigEndian(AccType_ORDEREDATOMIC) then
        X[t, datasize-elsize] = data<datasize-1:elsize>
        X[t2, elsize] = data<elsize-1:0>
    else
        X[t, elsize] = data<elsize-1:0>
        X[t2, datasize-elsize] = data<datasize-1:elsize>
else // elsize == 64
    // 64-bit load exclusive pair (not atomic),
    // but must be 128-bit aligned
    if address != Align(address, dbytes) then
        AArch64.Abort(address, AlignmentFault(AccType_ORDEREDATOMIC, FALSE, FALSE));
    X[t, 64] = Mem[address, 8, AccType_ORDEREDATOMIC];
    X[t2, 64] = Mem[address+8, 8, AccType_ORDEREDATOMIC];

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.149  **LDAXR**

Load-Acquire Exclusive Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores on page B2-211*. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180*. For information about memory accesses see *Load/store addressing modes on page C1-234*.

32-bit variant

Applies when `size == 10`.

LDAXR <Wt>, [<Xn|SP>{,##0}]

64-bit variant

Applies when `size == 11`.

LDAXR <Xt>, [<Xn|SP>{,##0}]

**Decode for all variants of this encoding**

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

**Assembler symbols**

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```plaintext
bits(64) address;
bias(elsize) data;
constant integer dbytes = elsize DIV 8;

data = MemAtomic(address, MemAtomicOp_EOR, value, ldacctype, stacctype);

if t != 31 then
    X[t, 32] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.156 LDEORH, LDEORAH, LDEORALH, LDEORLH

Atomic exclusive OR on halfword in memory atomically loads a 16-bit halfword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDEORAH and LDEORALH load from memory with acquire semantics.
- LDEORLH and LDEORALH store to memory with release semantics.
- LDEORH has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is used by the alias STEORH, STEORLH. See Alias conditions on page C6-1558 for details of when each alias is preferred.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.157 LDEOR, LDEORA, LDEORAL, LDEORL

Atomic exclusive OR on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDEORA and LDEORAL load from memory with acquire semantics.
- LDEORL and LDEORAL store to memory with release semantics.
- LDEOR has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is used by the alias STEOR, STEORL. See Alias conditions on page C6-1560 for details of when each alias is preferred.

Decode for all variants of this encoding

boolean wback = FALSE;
boolean postindex = FALSE;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly LDP on page K1-11592.

Assembler symbols

<Wt1>  Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2>  Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xt1>  Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2>  Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>  For the 32-bit post-index and 32-bit pre-index variant: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4.  

For the 32-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.  

For the 64-bit post-index and 64-bit pre-index variant: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8.  

For the 64-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.167   LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see Load/store addressing modes on page C1-234.

32-bit variant

Applies when \( \text{opc} == 00 \).

\[
\text{LDR} \ <Wt>, \ <\text{label}>
\]

64-bit variant

Applies when \( \text{opc} == 01 \).

\[
\text{LDR} \ <Xt>, \ <\text{label}>
\]

Decode for all variants of this encoding

```python
integer t = UInt(Rt);
MemOp memop = MemOp_LOAD;
boolean signed = FALSE;
integer size;
bits(64) offset;

case opc of
    when '00'
        size = 4;
    when '01'
        size = 8;
    when '10'
        size = 4;
        signed = TRUE;
    when '11'
        memop = MemOp_PREFETCH;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

- \(<Wt>\) is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- \(<Xt>\) is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- \(<\text{label}>\) is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```python
bits(64) address = PC[] + offset;
bits(size*8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);
```
case memop of
  when MemOp_LOAD
    data = Mem[address, size, AccType_NORMAL];
    if signed then
      X[t, 64] = SignExtend(data, 64);
    else
      X[t, size*8] = data;
  when MemOp_PREFETCH
    Prefetch(address, t<4:0>);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.168   LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see *Load/store addressing modes on page C1-234.*

**32-bit variant**

Applies when \text{size} == 10.

\[
\text{LDR} \ <Wt>, [\langle Xn|SP\rangle, (\langle Wm\rangle|\langle Xm\rangle)\{, \langle \text{extend}\rangle \{\langle \text{amount}\rangle\}\}]
\]

**64-bit variant**

Applies when \text{size} == 11.

\[
\text{LDR} \ <Xt>, [\langle Xn|SP\rangle, (\langle Wm\rangle|\langle Xm\rangle)\{, \langle \text{extend}\rangle \{\langle \text{amount}\rangle\}\}]
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } \text{scale} &= \text{UInt}(\text{size}); \\
\text{if } \text{option}<1> &= '0' \text{ then } \text{UNDEFINED}; \quad \text{// sub-word index} \\

\text{integer } \text{shift} &= \text{if } S == '1' \text{ then } \text{scale} \text{ else } 0;
\end{align*}
\]

**Assembler symbols**

- \text{<Wt>} Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \text{<Xt>} Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \text{<Xn|SP>} Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- \text{<Wm>} When \text{option}<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- \text{<Xm>} When \text{option}<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- \text{<extend>} Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when \text{<amount>} is omitted, encoded in the "option" field. It can have the following values:
  - UXTW when \text{option} = 010
  - LSL when \text{option} = 011
  - SXTW when \text{option} = 110
  - SXTX when \text{option} = 111
- \text{<amount>} For the 32-bit variant: is the index shift amount, optional only when \text{<extend>} is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
  - #0 when \text{S} = 0
  - #2 when \text{S} = 1

\[
\begin{array}{c|c}
\text{size} & \text{opc} \\
1 & x \\
1 & 1 \\
1 & 0 \\
1 & 0 \\
1 & 1 \\
\end{array}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c}
& & & & & & & \\
\text{16} & 15 & 13 & 12 & 11 & 10 & 9 & 0 \\
\text{size} & \text{opc} & \text{Rm} & \text{option} & \text{S} & 1 & 0 & \text{Rn} & \text{Rt} \\
\end{array}
\]
For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when $S = 0$
- #3 when $S = 1$

**Shared decode for all encodings**

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
```

**Operation**

```c
bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;
bits(datasize) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];
X[t, regsize] = ZeroExtend(data, regsize);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.169  **LDRAA, LDRAB**

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see *Load/store addressing modes* on page C1-234.

**Key B, pre-indexed variant**

Applies when \( M == 1 \) \&\& \( W == 1 \).

LDRAB <Xt>, [<Xn|SP>{, #<simm>}]!

**Decode for all variants of this encoding**

```c
if !HavePACExt() then UNDEFINED;
integer t = UInt(Rt);
integer n = UInt(Rn);
boolean wback = (W == '1');
boolean use_key_a = (M == '0');
bits(10) SIb = S:imm9;
bits(64) offset = LSL(SignExtend(SIb, 64), 3);
boolean tag_checked = wback || n != 31;
```

**Assembler symbols**

<Xt>  Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<X|SP> is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> is the optional signed immediate byte offset, a multiple of 8 in the range -4096 to 4088, defaulting to 0 and encoded in the "S:imm9" field as <simm>/8.

**Operation**

```c
bits(64) address;
bits(64) data;
boolean wb_unknown = FALSE;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if n == 31 then
    address = SP[];
else
    address = X[n, 64];

if use_key_a then
    address = AuthDA(address, X[31, 64], TRUE);
else
    address = AuthDB(address, X[31, 64], TRUE);

if n == 31 then
    CheckSPAlignment();

address = address + offset;
data = Mem[address, 8, AccType_NORMAL];
X[t, 64] = data;

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    if n == 31 then
        SP[] = address;
    else
        X[n, 64] = address;
```

**Operational Information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.170 LDRB (immediate)

Load Register Byte (immediate) loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/store addressing modes on page C1-234.

Post-index

\[
\begin{array}{c|c|c|c}
| & | & \\
\hline
0 & 0 & 1 & 1 \\
1 & 0 & 0 & 0 \\
| & 1 & 1 & Rn \\
| & 0 & 1 & Rt \\
\end{array}
\]

Encoding

LDRB \(<Wt>, [<Xn|SP>], #<simm>\)

Decode for this encoding

boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);

Pre-index

\[
\begin{array}{c|c|c|c}
| & | & \\
\hline
0 & 0 & 1 & 1 \\
1 & 0 & 0 & 0 \\
| & 1 & 1 & Rn \\
| & 0 & 1 & Rt \\
\end{array}
\]

Encoding

LDRB \(<Wt>, [<Xn|SP>, #<simm>]\)

Decode for this encoding

boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);

Unsigned offset

\[
\begin{array}{c|c|c|c}
| & | & \\
\hline
0 & 0 & 1 & 1 \\
1 & 0 & 0 & 0 \\
| & 1 & 0 & Rn \\
| & 0 & 1 & Rt \\
\end{array}
\]

Encoding

LDRB \(<Wt>, [<Xn|SP>{, #<pimm}>\])

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly LDRB (immediate) on page K1-11594.

Assembler symbols

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<\text{sim}\>) Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

\(<\text{pimm}\>) Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;

boolean wb_unknown = FALSE;
Constraint c;

if wback && n == t && n != 31 then

  X[t, 32] = ZeroExtend(data, 32);

if wback then
  if wb_unknown then
    address = bits(64) UNKNOWN;
  elseif postindex then
    address = address + offset;
  elseif n == 31 then
    SP[] = address;
```
else
  \( x[n, 64] = \text{address}; \)

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.171   LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/store addressing modes on page C1-234.

Extended register variant

Applies when option \(!= 011\).

LDRB \(<Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> \{<amount>\}]

Shifted register variant

Applies when option \(== 011\).

LDRB \(<Wt>, [<Xn|SP>, <Xm>{, LSL <amount}>]

Decode for all variants of this encoding

if option<1> == '0' then UNDEFINED;    // sub-word index

ExtendType extend_type = DecodeRegExtend(option);  

Assembler symbols

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
\(<Wm>\) When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
\(<Xm>\) When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
\(<extend>\) Is the index extend specifier, encoded in the "option" field. It can have the following values:
UXTW when option = 010
SXTW when option = 110
SXTX when option = 111
\(<amount>\) Is the index shift amount, it must be \#0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared decode for all encodings

integer n =.UInt(Rn);
integer t =(UInt(Rt);
integer m = UInt(Rm);
**Operation**

```plaintext
bits(64) offset = ExtendReg(m, extend_type, 0, 64);
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t, 32] = ZeroExtend(data, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.172   LDRH (immediate)

Load Register Halfword (immediate) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/store addressing modes on page C1-234.

C6.2.176   LDRSH (immediate)

Load Register Signed Halfword (immediate) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/store addressing modes on page C1-234.

Post-index

| [31 30 29 28|27 26 25 24|23 22 21 20] | 12|11 10 9 | 5 4 | 0 |
|---|---|---|---|---|
| 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | x | 0 | imm9 | 0 | 1 | Rn | Rt |

32-bit variant

Applies when opc == 11.

LDRSH <Wt>, [<Xn|SP>], #<simm>

64-bit variant

Applies when opc == 10.

LDRSH <Xt>, [<Xn|SP>], #<simm>

Decode for all variants of this encoding

```java
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

| [31 30 29 28|27 26 25 24|23 22 21 20] | 12|11 10 9 | 5 4 | 0 |
|---|---|---|---|---|
| 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | x | 0 | imm9 | 1 | 1 | Rn | Rt |

32-bit variant

Applies when opc == 11.

LDRSH <Wt>, [<Xn|SP>], #<simm>!

64-bit variant

Applies when opc == 10.

LDRSH <Xt>, [<Xn|SP>], #<simm>!

Decode for all variants of this encoding

```java
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```
Unsigned offset

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.177 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about memory accesses see Load/store addressing modes on page C1-234.

32-bit variant

Applies when \( \text{opc} == 11 \).

\[ \text{LDRSH} <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}] \]

64-bit variant

Applies when \( \text{opc} == 10 \).

\[ \text{LDRSH} <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}] \]

Decode for all variants of this encoding

\[
\begin{align*}
\text{if } \text{option}<1> == '0' \text{ then UNDEFINED; } & \quad / / \text{ sub-word index} \\
\text{ExtendType } \text{extend_type} = \text{DecodeRegExtend(option);} \\
\text{integer shift} = \text{if } S == '1' \text{ then 1 else 0;}
\end{align*}
\]

Assembler symbols

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xt>\) Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<Wm>\) When \( \text{option}<0> \) is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

\(<Xm>\) When \( \text{option}<0> \) is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

\(<\text{extend}>\) Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when \( <\text{amount}> \) is omitted. encoded in the "option" field. It can have the following values:

\begin{align*}
\text{UXTW} & \text{ when } \text{option} = 010 \\
\text{LSL} & \text{ when } \text{option} = 011 \\
\text{SXTW} & \text{ when } \text{option} = 110 \\
\text{SXTX} & \text{ when } \text{option} = 111
\end{align*}

\(<\text{amount}>\) Is the index shift amount, optional only when \( <\text{extend}> \) is not LSL. Where it is permitted to be optional, it defaults to \#0. It is encoded in the "S" field. It can have the following values:

\begin{align*}
\#0 & \text{ when } S = 0 \\
\#1 & \text{ when } S = 1
\end{align*}
Shared decode for all encodings

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.179 LDRSW (literal)

Load Register Signed Word (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see Load/store addressing modes on page C1-234.

Encoding

LDRSw <Xt>, <label>

Decode for this encoding

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

bits(64) address = PC[] + offset;
bits(32) data;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);
data = Mem[address, 4, AccType_NORMAL];
X[t, 64] = SignExtend(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.180  **LDRSW (register)**

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see *Load/store addressing modes on page C1-234*.

[![Instruction Format](https://example.com/instruction_format.png)](https://example.com/instruction_format.png)

**Encoding**

\[ \text{LDRSW} \ <Xt>, \ [\langle Xn|\text{SP}\rangle, \ (<Wm>|<Xm>)\{, \ <\text{extend}\} \{<\text{amount}\}\}] \]

**Decode for this encoding**

\[
\begin{align*}
\text{if } \text{option}<1> &= '0' \text{ then UNDEFINED;} \quad \text{// sub-word index} \\
\text{ExtendType} \ \text{extend\_type} &= \text{DecodeRegExtend(option);} \\
\text{integer} \ \text{shift} &= \text{if } S \text{ == '1'} \text{ then } 2 \text{ else } 0;
\end{align*}
\]

**Assembler symbols**

- `<Xt>`: Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>`: When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>`: When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>`: Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when `<amount>` is omitted. encoded in the "option" field. It can have the following values:
  - UXTW: when option = 010
  - LSL: when option = 011
  - SXTW: when option = 110
  - SXTX: when option = 111
- `<amount>`: Is the index shift amount, optional only when `<extend>` is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
  - #0: when S = 0
  - #2: when S = 1

**Shared decode for all encodings**

\[
\begin{align*}
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } t &= \text{UInt}(Rt); \\
\text{integer } m &= \text{UInt}(Rm);
\end{align*}
\]
Operation

address = address + offset;

data = Mem[address, 4, AccType.NORMAL];
X[t, 64] = SignExt(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.181  **LDSETB, LDSETAB, LDSETALB, LDSETLB**

Atomic bit set on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDSETAB and LDSETALB load from memory with acquire semantics.
- LDSETLB and LDSETALB store to memory with release semantics.
- LDSETB has neither acquire nor release semantics.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is used by the alias STSETB, STSETLB. See *Alias conditions* on page C6-1615 for details of when each alias is preferred.

**Integer**

(FEAT_LSE)

```
  0  0  1  1  0  0  0 A R  1  Rs  0  0  1  1  0  0  Rn  |  Rt |
```

- **LDSETAB variant**
  Applies when \( A = 1 \land R = 0 \).
  LDSETAB \(<Ws>, <Wt>, [<Xn|SP>]\)

- **LDSETALB variant**
  Applies when \( A = 1 \land R = 1 \).
  LDSETALB \(<Ws>, <Wt>, [<Xn|SP>]\)

- **LDSETB variant**
  Applies when \( A = 0 \land R = 0 \).
  LDSETB \(<Ws>, <Wt>, [<Xn|SP>]\)

- **LDSETLB variant**
  Applies when \( A = 0 \land R = 1 \).
  LDSETLB \(<Ws>, <Wt>, [<Xn|SP>]\)

**Decode for all variants of this encoding**

```
if !HaveAtomicExt() then UNDEFINED;
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```
Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.183 LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSETA and LDSETAL load from memory with acquire semantics.
- LDSETL and LDSETAL store to memory with release semantics.
- LDSET has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is used by the alias STSET, STSETL. See Alias conditions on page C6-1619 for details of when each alias is preferred.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.196   LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB

Atomic unsigned maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against
the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.
The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMAXAB and LDUMAXALB load from memory with acquire semantics.
- LDUMAXLB and LDUMAXALB store to memory with release semantics.
- LDUMAXB has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on
page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is used by the alias STUAXMB, STUAMLB. See Alias conditions on page C6-1648 for details
of when each alias is preferred.

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.198 LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL

Atomic unsigned maximum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, LDUMAXA and LDUMAXAL load from memory with acquire semantics.
- LDUMAX and LDUMAXAL store to memory with release semantics.
- LDUMAX has neither acquire nor release semantics.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is used by the alias STUMAX, STUMAXL. See *Alias conditions* on page C6-1652 for details of when each alias is preferred.

        Prefetch(address, t<4:0>); \\

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.207   LDURSW

Load Register Signed Word (unscaled) calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/store addressing modes on page C1-234.*

| [31 30 29 28|27 26 25 24|23 22 21 20] | 12|11 10 9 | 5 | 4 | 0 |
|---------------|-----------------|---|---|---|
| 1 0 | 1 1 | 0 | 0 | 1 0 | 0 | imm9 | 0 0 | Rn | Rt |

**Encoding**

LDURSW <Xt>, [<Xn|SP>{, #<simm>}]

**Decode for this encoding**

bits(64) offset = SignExtend(imm9, 64);

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared decode for all encodings**

integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;

**Operation**

bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
   SetTagCheckedInstruction(tag_checked);

if n == 31 then
   CheckSPAlignment();
   address = SP[];
else
   address = X[n, 64];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t, 64] = SignExtend(data, 64);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.208   **LDXP**

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and alignment requirements on page B2-154 and Alignment of data accesses on page B2-189. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-211. For information about memory accesses, see Load/store addressing modes on page C1-234.

### 32-bit variant

Applies when \( sz == 0 \).

\[
\text{LDXP} \ <W_{t1}> , \ <W_{t2}> , \ [<X_n|SP\{,#0}] \\
\]

### 64-bit variant

Applies when \( sz == 1 \).

\[
\text{LDXP} \ <X_{t1}> , \ <X_{t2}> , \ [<X_n|SP\{,#0}] \\
\]

**Decode for all variants of this encoding**

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if (t == t2)
    Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
```

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly LDXP on page K1-11595.

**Assembler symbols**

- \( <W_{t1}> \) Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- \( <W_{t2}> \) Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- \( <X_{t1}> \) Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```plaintext
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X[t, datasize] = bits(datasize) UNKNOWN;    // In this case t = t2
elsif elsize == 32 then
    // 32-bit load exclusive pair (atomic)
    data = Mem[address, dbytes, AccType_ATOMIC];
    if BigEndian(AccType_ATOMIC) then
        X[t, datasize-elsize] = data<datasize-1:elsize>;
        X[t2, elsize] = data<elsize-1:0>;
    else
        X[t, elsize] = data<elsize-1:0>;
        X[t2, datasize-elsize] = data<datasize-1:elsize>;
else // elsize == 64
    // 64-bit load exclusive pair (not atomic),
    // but must be 128-bit aligned
    if address != Align(address, dbytes) then
        AArch64.Abort(address, AlignmentFault(AccType_ATOMIC, FALSE, FALSE));
    X[t, 64] = Mem[address, 8, AccType_ATOMIC];
    X[t2, 64] = Mem[address+8, 8, AccType_ATOMIC];
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.209   LDXR

Load Exclusive Register derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-211. For information about memory accesses see Load/store addressing modes on page C1-234.

32-bit variant

Applies when size == 10.

LDXR <Wt>, [<Xn|SP>{,#0}]

64-bit variant

Applies when size == 11.

LDXR <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer elsize = 8L UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;
```

Assembler symbols

<Wt> is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[0];
else
    address = X[n, 64];
// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
```
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

data = Mem[address, dbytes, AccType_ATOMIC];
X[t, regsize] = ZeroExtend(data, regsize);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.210   LDXRB

Load Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-211. For information about memory accesses see *Load/store addressing modes* on page C1-234.

**Encoding**

LDXRB <Wt>, [<Xn|SP>{,#0}]

**Decode for this encoding**

integer $n = \text{UInt}(Rn)$;
integer $t = \text{UInt}(Rt)$;

boolean tag_checked = $n \neq 31$;

**Assembler symbols**

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if $n == 31$ then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 1);

data = Mem[address, 1, AccType_ATOMIC];
X[t, 32] = ZeroExtend(data, 32);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.211   LDXRH

Load Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-211. For information about memory accesses see Load/store addressing modes on page C1-234.

Encoding

LDXRH <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ATOMIC];
X[t, 32] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**C6.2.212  LSL (register)**

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is an alias of the LSLV instruction. This means that:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{LSL} \ <\text{id}> , \ <\text{in}> , \ <\text{im}>
\]

is equivalent to

\[
\text{LSLV} \ <\text{id}> , \ <\text{in}> , \ <\text{im}>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{LSL} \ <\text{Xd}> , \ <\text{Xn}> , \ <\text{Xm}>
\]

is equivalent to

\[
\text{LSLV} \ <\text{Xd}> , \ <\text{Xn}> , \ <\text{Xm}>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<\text{id}>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{in}>\): Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<\text{im}>\): Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \(<\text{Xd}>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Xn}>\): Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<\text{Xm}>\): Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of LSLV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.213   LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \) \&\& \( \text{imms} \neq 011111 \).

\[
\text{LSL} \ <Wd>, \ <Wn>, \ #<shift>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #(-<shift> \mod 32), \ #(31-<shift>)
\]

and is the preferred disassembly when \( \text{imms} + 1 = \text{immr} \).

### 64-bit variant

Applies when \( sf = 1 \) \&\& \( N = 1 \) \&\& \( \text{imms} \neq 111111 \).

\[
\text{LSL} \ <Xd>, \ <Xn>, \ #<shift>
\]

is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #(-<shift> \mod 64), \ #(63-<shift>)
\]

and is the preferred disassembly when \( \text{imms} + 1 = \text{immr} \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{shift}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31.
  For the 64-bit variant: is the shift amount, in the range 0 to 63.

### Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.214   LSLV

Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register). The alias is always the preferred disassembly.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{LSLV} \ <Wd>, <Wn>, <Wm>
\]

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{LSLV} \ <Xd>, <Xn>, <Xm>
\]

#### Decode for all variants of this encoding

```cpp
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

#### Assembler symbols

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&lt;Wd&gt;)</td>
<td>Is the 32-bit name of the general-purpose destination register, encoded in the &quot;Rd&quot; field.</td>

</tr>
</tbody>
</table>

#### Operation

```cpp
bits(datasize) result;
bits(datasize) operand2 = X[m, datasize];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
X[d, datasize] = result;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.215 LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the LSRV instruction. This means that:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{LSR } <Wd>, <Wn>, <Wm>
\]

is equivalent to

\[
\text{LSRV } <Wd>, <Wn>, <Wm>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{LSR } <Xd>, <Xn>, <Xm>
\]

is equivalent to

\[
\text{LSRV } <Xd>, <Xn>, <Xm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of LSRV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.216 LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf == 0 \&\& N == 0 \&\& imms == 011111$.

LSR $<Wd>, <Wn>, #<shift>$

is equivalent to

UBFM $<Wd>, <Wn>, #<shift>, #31$

and is always the preferred disassembly.

### 64-bit variant

Applies when $sf == 1 \&\& N == 1 \&\& imms == 111111$.

LSR $<Xd>, <Xn>, #<shift>$

is equivalent to

UBFM $<Xd>, <Xn>, #<shift>, #63$

and is always the preferred disassembly.

### Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<shift>$: For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

### Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.217   LSRV

Logical Shift Right Variable shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register). The alias is always the preferred disassembly.

32-bit variant

Applies when \( sf = 0 \).

\[ \text{LSRV} <Wd>, <Wn>, <Wm> \]

64-bit variant

Applies when \( sf = 1 \).

\[ \text{LSRV} <Xd>, <Xn>, <Xm> \]

**Decode for all variants of this encoding**

- \( \text{integer } d = \text{UInt}(Rd); \)
- \( \text{integer } n = \text{UInt}(Rn); \)
- \( \text{integer } m = \text{UInt}(Rm); \)

**Assembler symbols**

- \( <Wd> \) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Wn> \) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <Wm> \) Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \( <Xd> \) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Xn> \) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <Xm> \) Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

\[
\text{bits(datasize) result; bits(datasize) operand2 = X[m, datasize];}
\]

\[
\text{result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize); X[d, datasize] = result;}
\]
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.218 MADD

Multiply-Add multiplies two register values, adds a third register value, and writes the result to the destination register.

This instruction is used by the alias MUL. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $sf = 0$.

MADD $<Wd>, <Wn>, <Wm>, <Wa>$

64-bit variant
Applies when $sf = 1$.

MADD $<Xd>, <Xn>, <Xm>, <Xa>$

Decode for all variants of this encoding

```java
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if $sf == '1'$ then 64 else 32;
```

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MUL</td>
<td>$Ra == '11111'$</td>
</tr>
</tbody>
</table>

Assembler symbols

- $<Wd>$ is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$ is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- $<Wm>$ is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- $<Wa>$ is the 32-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.
- $<Xd>$ is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$ is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- $<Xm>$ is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

**Operation**

\[
\begin{align*}
\text{bits}(\text{destsize}) \text{ operand1} &= X[n, \text{destsize}] ; \\
\text{bits}(\text{destsize}) \text{ operand2} &= X[m, \text{destsize}] ; \\
\text{bits}(\text{destsize}) \text{ operand3} &= X[a, \text{destsize}] ; \\
\text{integer result} &= ; \\
\text{result} &= \text{UInt}(\text{operand3}) + (\text{UInt}(\text{operand1}) \times \text{UInt}(\text{operand2})) ; \\
X[d, \text{destsize}] &= \text{result}<\text{destsize}-1:0> ;
\end{align*}
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.219   MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This instruction is an alias of the MSUB instruction. This means that:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( s_f = 0 \).

\[
\text{MNEG } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle
\]

is equivalent to

\[
\text{MSUB } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle, \text{WZR}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( s_f = 1 \).

\[
\text{MNEG } \langle Xd \rangle, \langle Xn \rangle, \langle Xm \rangle
\]

is equivalent to

\[
\text{MSUB } \langle Xd \rangle, \langle Xn \rangle, \langle Xm \rangle, \text{XZR}
\]

and is always the preferred disassembly.

### Assembler symbols

- \( \langle Wd \rangle \): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle Wn \rangle \): Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( \langle Wm \rangle \): Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \( \langle Xd \rangle \): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle Xn \rangle \): Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( \langle Xm \rangle \): Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation

The description of MSUB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.220  MOV (to/from SP)

Move between register and stack pointer: \( R_d = R_n \)

This instruction is an alias of the ADD (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

MOV \( <W_d|WSP>, <W_n|WSP> \)

is equivalent to

ADD \( <W_d|WSP>, <W_n|WSP>, #0 \)

and is the preferred disassembly when \( (R_d = '11111' || R_n = '11111') \).

### 64-bit variant

Applies when \( sf = 1 \).

MOV \( <X_d|SP>, <X_n|SP> \)

is equivalent to

ADD \( <X_d|SP>, <X_n|SP>, #0 \)

and is the preferred disassembly when \( (R_d = '11111' || R_n = '11111') \).

### Assembler symbols

- \( <W_d|WSP> \) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( <W_n|WSP> \) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \( <X_d|SP> \) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( <X_n|SP> \) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

### Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.
C6.2.221 MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This instruction is an alias of the MOVN instruction. This means that:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \) \&\& \( hw = 0x \).

\[
\text{MOV } <Wd>, \#<imm>
\]

is equivalent to

\[
\text{MOVN } <Wd>, \#<imm16>, \text{LSL}<shift>
\]

and is the preferred disassembly when \( ! (\text{IsZero}(imm16) \&\& \text{hw} \neq '00') \&\& ! \text{IsOnes}(imm16) \).

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{MOV } <Xd>, \#<imm>
\]

is equivalent to

\[
\text{MOVN } <Xd>, \#<imm16>, \text{LSL}<shift>
\]

and is the preferred disassembly when \( ! (\text{IsZero}(imm16) \&\& \text{hw} \neq '00') \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<imm>\) For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff.
  
  For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
- \(<shift>\) For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<shift>/16\).
  
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<shift>/16\).

### Operation

The description of MOVN gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.222 MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This instruction is an alias of the MOV instruction. This means that:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \) \&\& \( hw = 0x \).

\[
\text{MOV} \ <Wd>, \ #<imm>
\]

is equivalent to

\[
\text{MOVZ} \ <Wd>, \ #<imm16>, \ LSL \ #<shift>
\]

and is the preferred disassembly when \( \neg (\text{IsZero}(\text{imm16}) \&\& \ text{hw} \neq '00') \).

64-bit variant

Applies when \( sf = 1 \).

\[
\text{MOV} \ <Xd>, \ #<imm>
\]

is equivalent to

\[
\text{MOVZ} \ <Xd>, \ #<imm16>, \ LSL \ #<shift>
\]

and is the preferred disassembly when \( \neg (\text{IsZero}(\text{imm16}) \&\& \ text{hw} \neq '00') \).

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<imm>\) For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw".
  For the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".
- \(<shift>\) For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<shift>/16\).
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<shift>/16\).

Operation

The description of MOVZ gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.223 MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This instruction is an alias of the ORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf == 0 \land N == 0 \).

\[
\text{MOV} \langle \text{Wd|WSP} \rangle, \#\langle \text{imm}\rangle
\]

is equivalent to

\[
\text{ORR} \langle \text{Wd|WSP} \rangle, \text{WZR}, \#\langle \text{imm}\rangle
\]

and is the preferred disassembly when \(! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr})\).

64-bit variant

Applies when \( sf == 1 \).

\[
\text{MOV} \langle \text{Xd|SP} \rangle, \#\langle \text{imm}\rangle
\]

is equivalent to

\[
\text{ORR} \langle \text{Xd|SP} \rangle, \text{XZR}, \#\langle \text{imm}\rangle
\]

and is the preferred disassembly when \(! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr})\).

Assembler symbols

\( \langle \text{Wd|WSP} \rangle \)  Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\( \langle \text{Xd|SP} \rangle \)  Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\( \langle \text{imm}\rangle \)  For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.224 MOV (register)

Move (register) copies the value in a source register to the destination register.

This instruction is an alias of the ORR (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

MOV <Wd>, <Wm>

is equivalent to

ORR <Wd>, WZR, <Wm>

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

MOV <Xd>, <Xm>

is equivalent to

ORR <Xd>, XZR, <Xm>

and is always the preferred disassembly.

Assembler symbols

- \(<\text{Wd}>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Wm}>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{Xd}>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Xm}>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.225  MOVK

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

32-bit variant
Applies when sf == 0 && hw == 0x.

MOVK <Wd>, #<imm>{, LSL #<shift>}

64-bit variant
Applies when sf == 1.

MOVK <Xd>, #<imm>{, LSL #<shift>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;
if sf == '0' && hw<1> == '1' then UNDEFINED;
pos = UInt(hw:'0000');

Assembler symbols

<id> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

bits(datasize) result;
result = X[d, datasize];
result<pos+15:pos> = imm16;
X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
   — The values of the data supplied in any of its registers.
The values of the NZCV flags.

The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
C6.2.226   MOVN

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when \( sf == 0 \) && \( hw == 0x \).

\[
\text{MOVN} \ <Wd>, \ #<imm>\{, \ LSL \ #<shift>\}
\]

64-bit variant

Applies when \( sf == 1 \).

\[
\text{MOVN} \ <Xd>, \ #<imm>\{, \ LSL \ #<shift>\}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } datasize &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{integer } pos &= \text{if } sf == '0' \&\& \text{hw<1> == '1'} \text{ then UNDEFINED; } \\
&\phantom{=} \text{pos} = \text{UInt}(\text{hw:'0000'});
\end{align*}
\]

</table>

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

bits(datasize) result;

result = Zeros(datasize);
result<pos+15:pos> = imm16;
X[d, datasize] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MRS

Move System Register allows the PE to read an AArch64 System register into a general-purpose register.

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>

<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

**Encoding**

MRS <Xt>, (<systemreg>|<op0>|<op1>|<Cn>|<Cm>|<op2>)

**Decode for this encoding**

AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);
integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".

The System register names are defined in Chapter D17 AArch64 System Register Descriptions.

<op0> Is an unsigned immediate, encoded in the "o0" field. It can have the following values:

2 when o0 = 0
3 when o0 = 1

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

**Operation**

AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
C6.2.229   MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see PSTATE.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If FEAT_SSBS is implemented, PSTATE.SSBS.
- If FEAT_PAN is implemented, PSTATE.PAN.
- If FEAT_UAO is implemented, PSTATE.UAO.
- If FEAT_DIT is implemented, PSTATE.DIT.
- If FEAT_MTE is implemented, PSTATE.TCO.
- If FEAT_NMI is implemented, PSTATE.ALLINT.
- If FEAT_SME is implemented, PSTATE.SM and PSTATE.ZA.

This instruction is used by the aliases SMSTART and SMSTOP. See Alias conditions on page C6-1710 for details of when each alias is preferred.

Encoding

MSR <pstatefield>, #<imm>

Assembler symbols

<PSTATE FIELD> Is a PSTATE field name. For the MSR instruction, this is encoded in the "op1:op2:CRm" field. It can have the following values:

- **SPSel**: when op1 = 000, op2 = 101, CRm = xxxx
- **DAIFSet**: when op1 = 011, op2 = 110, CRm = xxxx
- **DAIFClr**: when op1 = 011, op2 = 111, CRm = xxxx

When FEAT_UAO is implemented, the following value is also valid:

- **UAO**: when op1 = 000, op2 = 011, CRm = xxxx

When FEAT_PAN is implemented, the following value is also valid:

- **PAN**: when op1 = 000, op2 = 100, CRm = xxxx

When FEAT_NMI is implemented, the following value is also valid:

- **ALLINT**: when op1 = 001, op2 = 000, CRm = 000x

When FEAT_SSBS is implemented, the following value is also valid:

- **SSBS**: when op1 = 011, op2 = 001, CRm = xxxx

When FEAT_DIT is implemented, the following value is also valid:

- **DIT**: when op1 = 011, op2 = 010, CRm = xxxx

When FEAT_SME is implemented, the following values are also valid:

- **SVCRSM**: when op1 = 011, op2 = 011, CRm = 001x
- **SVCRZA**: when op1 = 011, op2 = 011, CRm = 010x
- **SVCRZM2A**: when op1 = 011, op2 = 011, CRm = 011x

When FEAT_MTE is implemented, the following value is also valid:

- **TCO**: when op1 = 011, op2 = 100, CRm = xxxx

See <PSTATE> on page C4-539 when op1 = 000, op2 = 00x, CRm = xxxx.

The following encodings are reserved:

- op1 = 000, op2 = 1lx, CRm = xxxx.
- op1 = 001, op2 = 000, CRm = 001x.
- op1 = 001, op2 = 000, CRm = 01lx.
- op1 = 001, op2 = 000, CRm = 1xxx.
- op1 = 001, op2 = 001, CRm = xxxx.
- op1 = 001, op2 = 01x, CRm = xxxx.
- op1 = 001, op2 = 1xx, CRm = xxxx.
- op1 = 010, op2 = xxx, CRm = xxxx.
- op1 = 011, op2 = 000, CRm = xxxx.
- op1 = 011, op2 = 011, CRm = 000x.
- op1 = 011, op2 = 011, CRm = 1xxx.
- op1 = 011, op2 = 101, CRm = xxxx.
op1 = 1xx, op2 = xxx, CRm = xxxx.

For the SMSTART and SMSTOP aliases, this is encoded in "CRm<2:1>", where 0b01 specifies SVCRSM, 0b10 specifies SVCRZA, and 0b11 specifies SVCRSMZA.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field. Restricted to the range 0 to 1, encoded in "CRm<0>", when <pstatefield> is ALLINT, SVCRSM, SVCRSMZA, or SVCRZA.

**Operation**

```plaintext
case field of
  when PSTATEField_SSBS
    PSTATE.SSBS = CRm<0>;
  when PSTATEField_SP
    PSTATE.SP = CRm<0>;
  when PSTATEField_DAIFSet

    PSTATE.A = PSTATE.A OR CRm<2>;
    PSTATE.I = PSTATE.I OR CRm<1>;
    PSTATE.F = PSTATE.F OR CRm<0>;
  when PSTATEField_DAIFClr
    PSTATE.D = PSTATE.D AND NOT(CRm<3>);
    PSTATE.A = PSTATE.A AND NOT(CRm<2>);
    PSTATE.I = PSTATE.I AND NOT(CRm<1>);
    PSTATE.F = PSTATE.F AND NOT(CRm<0>);
  when PSTATEField_PAN
    PSTATE.PAN = CRm<0>;
  when PSTATEField_UAO
    PSTATE.UAO = CRm<0>;
  when PSTATEField_DIT
    PSTATE.DIT = CRm<0>;
  when PSTATEField_TCO
    PSTATE.TCO = CRm<0>;
  when PSTATEField_ALLINT
    if (PSTATE.EL == EL1 && IsHCRXEL2Enabled() && HCRX_EL2.TALLINT == '1' && CRm<0> == '1') then
      AArch64.SystemAccessTrap(EL2, 0x18);
      PSTATE.ALLINT = CRm<0>;
  when PSTATEField_SVCRSM
    CheckSMEAccess();
    SetPSTATE_SM(CRm<0>);
  when PSTATEField_SVCRZA
    CheckSMEAccess();
    SetPSTATE_ZA(CRm<0>);
  when PSTATEField_SVCRSMZA
    CheckSMEAccess();
    SetPSTATE_SM(CRm<0>);
    SetPSTATE_ZA(CRm<0>);
```
C6.2.230 MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a general-purpose register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30 29 28</td>
<td>27 26 25 24</td>
</tr>
<tr>
<td>0</td>
<td>L</td>
<td></td>
</tr>
</tbody>
</table>

**Encoding**

MSR (<systemreg>|<op0>|<op1>|<Cn>|<Cm>|<op2>), <Xt>

**Decode for this encoding**

AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

**Assembler symbols**

- `<systemreg>` is a System register name, encoded in the "o0:op1:CRn:CRm:op2". The System register names are defined in Chapter D17 AArch64 System Register Descriptions.
- `<op0>` is an unsigned immediate, encoded in the "o0" field. It can have the following values:
  - 2 when o0 = 0
  - 3 when o0 = 1
- `<op1>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cn>` is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- `<Xt>` is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
C6.2.231   MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG. See Alias conditions for details of when each alias is preferred.

\[

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

**Operation**

```c
bits(destsize) operand1 = X[n, destsize];
bits(destsize) operand2 = X[m, destsize];
bits(destsize) operand3 = X[a, destsize];

integer result;
result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
X[d, destsize] = result<destsize-1:0>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.232   MUL

Multiply: \( R_d = R_n \times R_m \)

This instruction is an alias of the MADD instruction. This means that:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{MUL } \langle W_d \rangle, \langle W_n \rangle, \langle W_m \rangle
\]

is equivalent to

\[
\text{MADD } \langle W_d \rangle, \langle W_n \rangle, \langle W_m \rangle, WZR
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{MUL } \langle X_d \rangle, \langle X_n \rangle, \langle X_m \rangle
\]

is equivalent to

\[
\text{MADD } \langle X_d \rangle, \langle X_n \rangle, \langle X_m \rangle, XZR
\]

and is always the preferred disassembly.

Assembler symbols

- \( \langle W_d \rangle \)
  - Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle W_n \rangle \)
  - Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( \langle W_m \rangle \)
  - Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \( \langle X_d \rangle \)
  - Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle X_n \rangle \)
  - Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( \langle X_m \rangle \)
  - Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.
C6.2.233 MVN

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This instruction is an alias of the ORN (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{MVN} <Wd>, <Wm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{ORN} <Wd>, \text{WZR}, <Wm>{, <shift> #<amount>}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{MVN} <Xd>, <Xm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{ORN} <Xd>, \text{XZR}, <Xm>{, <shift> #<amount>}
\]

and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - ROR when \( \text{shift} = 11 \)
- \(<\text{amount}>\) is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 32-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation
The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.234   NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This instruction is an alias of the SUB (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{NEG} \,<Wd>, \,<Wm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUB} \,<Wd>, \,WZR, \,<Wm>{, <shift> #<amount>}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{NEG} \,<Xd>, \,<Xm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUB} \,<Xd>, \,XZR, \,<Xm>{, <shift> #<amount>}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( shift = 00 \)
  - LSR when \( shift = 01 \)
  - ASR when \( shift = 10 \)
  - The encoding \( shift = 11 \) is reserved.
- \(<\text{amount}>\) is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 32-bit variant: the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
**Operation**

The description of **SUB (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.235   NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{NEGS } <Wd>, <Wm>\{, <shift> \#<amount>\}
\]

is equivalent to

\[
\text{SUBS } <Wd>, WZR, <Wm> \{, <shift> \#<amount>\}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{NEGS } <Xd>, <Xm>\{, <shift> \#<amount>\}
\]

is equivalent to

\[
\text{SUBS } <Xd>, XZR, <Xm> \{, <shift> \#<amount>\}
\]

and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - The encoding \( \text{shift} = 11 \) is reserved.
- \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation
The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.236  NGC

Negate with Carry negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This instruction is an alias of the SBC instruction. This means that:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode for this instruction.

Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.237   NGCS

Negate with Carry, setting flags, negates the sum of a register value and the value of NOT (Carry flag), and writes
the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SBCS instruction. This means that:

• The encodings in this description are named to match the encodings of SBCS.
• The description of SBCS gives the operational pseudocode for this instruction.

32-bit variant
Applies when $sf == 0$.

NGCS $<Wd>, <Wm>$
is equivalent to
SBCS $<Wd>, WZR, <Wm>$
and is always the preferred disassembly.

64-bit variant
Applies when $sf == 1$.

NGCS $<Xd>, <Xm>$
is equivalent to
SBCS $<Xd>, XZR, <Xm>$
and is always the preferred disassembly.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wm>$ Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xm>$ Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation
The description of SBCS gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.238  NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

——— Note ————
The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

Encoding

NOP

Decode for this encoding

// Empty.

Operation

// do nothing

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.239 ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN. See Alias conditions for details of when each alias is preferred.

**Asmbluer symbols**

- $<\text{id}>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{in}>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{im}>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{id}>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{in}>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{im}>$ Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{shift}>$ Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when $shift = 00$
LSR  when shift = 01
ASR  when shift = 10
ROR  when shift = 11

<amount>  For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
          For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;

operand2 = NOT(operand2);
result = operand1 OR operand2;
X[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.240 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate). See Alias conditions for details of when each alias is preferred.

### ORR <Wd|WSP>, <Wn>, #<imm>

### ORR <Xd|SP>, <Xn>, #<imm>

#### 32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

\[
\text{ORR } \langle \text{Wd}|\text{WSP} \rangle, \langle \text{Wn} \rangle, \#\langle \text{imm} \rangle
\]

#### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{ORR } \langle \text{Xd}|\text{SP} \rangle, \langle \text{Xn} \rangle, \#\langle \text{imm} \rangle
\]

#### Decode for all variants of this encoding

\[
\begin{array}{|c|c|c|c|c|c|c|c|}
\hline
\text{sf} & 0 & 1 & 0 & 0 & 0 & 0 & N \\
\hline
\text{imms} & \text{imm} & \text{Rn} & \text{Rd} \\
\hline
\end{array}
\]

#### Alias conditions

#### Assembler symbols

- \( \langle \text{Wd}|\text{WSP} \rangle \): Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( \langle \text{Wn} \rangle \): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( \langle \text{Xd}|\text{SP} \rangle \): Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( \langle \text{Xn} \rangle \): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( \langle \text{imm} \rangle \): For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".
### Operation

```
bias(datasize) result;
bias(datasize) operand1 = X[n, datasize];

result = operand1 OR imm;
if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.241 ORR (shifted register)

Bitwise OR (shifted register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MOV (register). See Alias conditions for details of when each alias is preferred.

### 32-bit variant
Applies when \( sf == 0 \).

\[
\text{ORR} \ <W_d>, <W_n>, <W_m>\{, <\text{shift}\> \#<\text{amount}>\}
\]

### 64-bit variant
Applies when \( sf == 1 \).

\[
\text{ORR} \ <X_d>, <X_n>, <X_m>\{, <\text{shift}\> \#<\text{amount}>\}
\]

### Decode for all variants of this encoding

### Assembler symbols

- \(<W_d>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<W_n>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<W_m>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<X_d>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<X_n>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<X_m>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} == 00 \)
LSR  when shift = 01
ASR  when shift = 10
ROR  when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;

result = operand1 OR operand2;
X[d, datasize] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.242 PACDA, PACDZA

Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

**Integer**

Assembler symbols

<Xd>            Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>          Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

if HavePACExt() then
  if source_is_sp then
    X[d, 64] = AddPACIB(X[d, 64], SP[]);
else
   \( x[d, 64] = \text{AddPACIB}(x[d, 64], x[n, 64]) \);
C6.2.247 PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of a PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-267.

For information about memory accesses, see Load/store addressing modes on page C1-234.

**Encoding**

PRFM (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm>}]  

**Decode for this encoding**

bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);

**Assembler symbols**

- `<prfop>` Is the prefetch operation, defined as `<type><target><policy>`.  
  - `<type>` is one of:
    - `PLD` Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.  
    - `PLI` Preload instructions, encoded in the "Rt<4:3>" field as 0b01.  
    - `PST` Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.  
  - `<target>` is one of:
    - `L1` Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.  
    - `L2` Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.  
    - `L3` Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.  
  - `<policy>` is one of:
    - `KEEP` Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.  
    - `STRM` Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.  

For more information on these prefetch operations, see Prefetch memory on page C3-267.

For other encodings of the "Rt" field, use `<imm5>`.

- `<imm5>` Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using `<prfop>`.

- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

- `<pimm>` Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as `<pimm>/8`.  

```
Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

Operation

bits(64) address;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);

if n == 31 then
    address = SP[];
else
    address = X[n, 64];

address = address + offset;

Prefetch(address, t<4:0>);
C6.2.248 PRFM (literal)

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future.         L1     Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
        L2     Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
        L3     Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
        <policy> is one of:
        KEEP    Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
        STRM    Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.
For more information on these prefetch operations, see Prefetch memory on page C3-267.
For other encodings of the "Rt" field, use <imm5>.

<iimm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
When \texttt{option=0} is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when \texttt{amount} is omitted, encoded in the "option" field. It can have the following values:

- \texttt{UXTW} when \texttt{option = 010}
- \texttt{LSL} when \texttt{option = 011}
- \texttt{SXTW} when \texttt{option = 110}
- \texttt{SXTX} when \texttt{option = 111}

Is the index shift amount, optional only when \texttt{extend} is not LSL. Where it is permitted to be optional, it defaults to \#0. It is encoded in the "S" field. It can have the following values:

- \#0 when \texttt{S = 0}
- \#3 when \texttt{S = 1}

**Shared decode for all encodings**

\begin{verbatim}
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);

Operation

bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);
if n == 31 then
    address = SP[];
else
    address = X[n, 64];
address = address + offset;
Prefetch(address, t<4:0>);
\end{verbatim}
C6.2.250  PRFUM

Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of a PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-267.

For information about memory accesses, see Load/store addressing modes on page C1-234.

Encoding

PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<prfop>  Is the prefetch operation, defined as <type><target><policy>.
  <type> is one of:
  PLD    Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
  PLI    Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

  KEEP   Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  STRM   Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-267.

For other encodings of the "Rt" field, use <imm5>.

<imm5>  Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm>  Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
Shared decode for all encodings

    integer n = UInt(Rn);
    integer t = UInt(Rt);

Operation

    bits(64) address;

    if HaveMTE2Ext() then
        SetTagCheckedInstruction(FALSE);

    if n == 31 then
        address = SP[];
    else
        address = X[n, 64];

    address = address + offset;
    Prefetch(address, t<4:0>);
C6.2.251   PSB CSYNC

Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

System

(FEAT_SPE)

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11  8  7  5  4  3  2  1  0 |

```

Encoding

PSB CSYNC

**Decode for this encoding**

```
if !HaveStatisticalProfiling() then EndOfInstruction();
```

Operation

```
ProfilingSynchronizationBarrier();
```
**C6.2.252 PSSBB**

Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

This instruction is an alias of the DSB instruction. This means that:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode for this instruction.

```plaintext
0x0 00 011 0011 01001 00 11111
```

**Encoding**

PSSBB

is equivalent to

DSB #4

and is always the preferred disassembly.

**Operation**

The description of DSB gives the operational pseudocode for this instruction.
C6.2.253  RBIT

Reverse Bits reverses the bit order in a register.

32-bit variant
Applies when \( sf = 0 \).
RBIT \(<Wd>, <Wn>\)

64-bit variant
Applies when \( sf = 1 \).
RBIT \(<Xd>, <Xn>\)

Decode for all variants of this encoding
\[
\begin{align*}
\text{integer } d &= \text{ UInt}(Rd); \\
\text{integer } n &= \text{ UInt}(Rn); \\
\text{integer } \text{datasize} &= \text{ if } sf = '1' \text{ then } 64 \text{ else } 32;
\end{align*}
\]

Assembler symbols
- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation
\[
\begin{align*}
\text{bits(datasize) operand} &= X[n, \text{datasize}]; \\
\text{bits(datasize) result}; \\
\text{for } i = 0 \text{ to } \text{datasize}-1 \\
& \quad \text{result}<(\text{datasize}-1)-i> = \text{operand}<i>; \\
X[d, \text{datasize}] &= \text{result};
\end{align*}
\]

Operational information
If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C6.2.254   RET

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.

Encoding

RET {<Xn>}

Decode for this encoding

integer n = UInt(Rn);

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

bits(64) target = X[n, 64];

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

BranchTo(target, BranchType_RET, FALSE);
C6.2.255 RETAA, RETAB

Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for RETAA, and key B is used for RETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

**Integer**

(FEAT_PAuth)

| 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12 | 11 10  9 |  5  4 |  0 |
|------------|------------|------------|------------|------------|-------|-------|
| 1 1 0 1 0 1 1 1 | 0 1 0 1 1 1 1 1 | 0 0 0 0 1 1 1 1 |

**RETAA variant**

Applies when \( M = 0 \).

RETAA

**RETAB variant**

Applies when \( M = 1 \).

RETAB

**Decode for all variants of this encoding**

```java
boolean use_key_a = (M == '0');
if !HavePACExt() then
  UNDEFINED;
```

**Operation**

```java
bits(64) target = X[30, 64];
bits(64) modifier = SP[];
if use_key_a then
  target = AuthIA(target, modifier, TRUE);
else
  target = AuthIB(target, modifier, TRUE);

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';
BranchTo(target, BranchType_RET, FALSE);
```
C6.2.256 REV

Reverse Bytes reverses the byte order in a register.

This instruction is used by the pseudo-instruction REV64. The pseudo-instruction is never the preferred disassembly.

32-bit variant

Applies when sf == 0 && opc == 10.

REV <Wd>, <Wn>

64-bit variant

Applies when sf == 1 && opc == 11.

REV <Xd>, <Xn>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

integer container_size;

case opc of
  when '00'
    Unreachable();
  when '01'
    container_size = 16;
  when '10'
    container_size = 32;
  when '11'
    if sf == '0' then UNDEFINED;
   container_size = 64;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

bits(datasize) operand = X[n, datasize];
bits(datasize) result;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV 8;
integer index = 0;
integer rev_index;
for c = 0 to containers-1
    rev_index = index + ((elements_per_container - 1) * 8);
    for e = 0 to elements_per_container-1

X[d, datasize] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.259  REV64

Reverse Bytes reverses the byte order in a 64-bit general-purpose register.

When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This instruction is a pseudo-instruction of the REV instruction. This means that:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode for this instruction.

64-bit variant

REV64 <Xd>, <Xn>

is equivalent to

REV  <Xd>, <Xn>

and is never the preferred disassembly.

Assembler symbols

| <Xd> | Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
| <Xn> | Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.260  RMIF

Performs a rotation right of a value held in a general purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

**Integer**

(FEAT_FlagM)

- **Encoding**
  
  RMIF <Xn>, #<shift>, #<mask>

- **Decode for this encoding**
  
  if !HaveFlagManipulateExt() then UNDEFINED;
  integer lsb = UInt(imm6);
  integer n = UInt(Rn);

- **Assembler symbols**
  
  - `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
  - `<shift>` Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
  - `<mask>` Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

- **Operation**
  
  bits(4) tmp;
  bits(64) tmpreg = X[n, 64];
  tmp = (tmpreg:tmpreg)<lsb+3:lsb>;
  if mask<3> == '1' then PSTATE.N = tmp<3>;
  if mask<2> == '1' then PSTATE.Z = tmp<2>;
  if mask<1> == '1' then PSTATE.C = tmp<1>;
  if mask<0> == '1' then PSTATE.V = tmp<0>;

- **Operational information**
  
  If PSTATE.DIT is 1:
  
  - The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
C6.2.261   ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the EXTR instruction. This means that:

• The encodings in this description are named to match the encodings of EXTR.
• The description of EXTR gives the operational pseudocode for this instruction.

32-bit variant
Applies when \( sf = 0 \land N = 0 \land \text{imms} = \text{xxxxx} \).

\[ \text{ROR} \ <Wd>, <Ws>, #<shift> \]

is equivalent to

\[ \text{EXTR} \ <Wd>, <Ws>, <Ws>, #<shift> \]

and is the preferred disassembly when \( Rn = Rm \).

64-bit variant
Applies when \( sf = 1 \land N = 1 \).

\[ \text{ROR} \ <Xd>, <Xs>, #<shift> \]

is equivalent to

\[ \text{EXTR} \ <Xd>, <Xs>, <Xs>, #<shift> \]

and is the preferred disassembly when \( Rn = Rm \).

Assembler symbols

\(<Wd>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Ws>\)  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

\(<Xd>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xs>\)  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

\(<\text{shift}>\)  For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

Operation

The description of EXTR gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.262   ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the RORV instruction. This means that:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

ROR \(<Wd>, <Wn>, <Wm>\)

is equivalent to

RORV \(<Wd>, <Wn>, <Wm>\)

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

ROR \(<Xd>, <Xn>, <Xm>\)

is equivalent to

RORV \(<Xd>, <Xn>, <Xm>\)

and is always the preferred disassembly.

**Assembler symbols**

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

The description of RORV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.263 RORV

Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register). The alias is always the preferred disassembly.

32-bit variant
Applies when $sf == 0$.
RORV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when $sf == 1$.
RORV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);

Assembler symbols

<\Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<\Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<\Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand2 = X[m, datasize];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
X[d, datasize] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.264   SB

Speculation Barrier is a barrier that controls speculation.

The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

System

(FEAT_SB)

Encoding

SB

Decode for this encoding

if !HaveSBExt() then UNDEFINED;

Operation

SpeculationBarrier();
C6.2.265   SBC

Subtract with Carry subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias NGC. See Alias conditions for details of when each alias is preferred.

32-bit variant

PSTATE.<N,Z,C,V> = nzcv;

X[d, datasize] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.267 SBFIZ

Signed Bitfield Insert in Zeros copies a bitfield of `<width>` bits from the least significant bits of the source register to bit position `<lsb>` of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit variant
Applies when `sf == 0 && N == 0`.

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when ` UInt(imms) < UInt(immr)`.

### 64-bit variant
Applies when `sf == 1 && N == 1`.

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when ` UInt(imms) < UInt(immr)`.

### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<lsb>` For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- `<width>` For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

### Operation
The description of SBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \( \text{imms} \) is greater than or equal to \( \text{immr} \), this copies a bitfield of \( (\text{imms} - \text{immr} + 1) \) bits starting from bit position \( \text{immr} \) in the source register to the least significant bits of the destination register.

If \( \text{imms} \) is less than \( \text{immr} \), this copies a bitfield of \( (\text{immr} + 1) \) bits from the least significant bits of the source register to bit position \( (\text{regsize} - \text{immr}) \) of the destination register, where \( \text{regsize} \) is the destination register size of 32 or 64 bits.

In both cases the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW. See Alias conditions on page C6-1778 for details of when each alias is preferred.

- `<lsb>` For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- `<width>` For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.270  SDIV

Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit variant
Applies when \( sf = 0 \).

\[
\text{SDIV} <Wd>, <Wn>, <Wm>
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{SDIV} <Xd>, <Xn>, <Xm>
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt(Rd);} \\
\text{integer } n &= \text{UInt(Rn);} \\
\text{integer } m &= \text{UInt(Rm);} \\
\text{integer } \text{datasize} &= \text{if } sf = \text{'1'} \text{ then } 64 \text{ else } 32;
\end{align*}
\]

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(< Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

\[
\begin{align*}
\text{bits(datasize) operand1} &= X[n, \text{datasize}]; \\
\text{bits(datasize) operand2} &= X[m, \text{datasize}]; \\
\text{integer } \text{result} &= ; \\
\text{if } \text{IsZero(operand2)} \text{ then } \\
\text{result} &= 0; \\
\text{else } \\
\text{result} &= \text{RoundTowardsZero(Real(Int(operand1, FALSE)) / Real(Int(operand2, FALSE)))}; \\
X[d, \text{datasize}] &= \text{result}<\text{datasize}-1:0>;
\end{align*}
\]
C6.2.271 SETF8, SETF16

Set the PSTATE.NZV flags based on the value in the specified general-purpose register. SETF8 treats the value as an 8 bit value, and SETF16 treats the value as an 16 bit value.

The PSTATE.C flag is not affected by these instructions.

**Integer**

integer n = UInt(Rn);
```

**Assembler symbols**

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

```
bits(32) tmpreg = X[n, 32];
PSTATE.N = tmpreg<msb>;
PSTATE.Z = if (tmpreg<msb:0> == Zeros(msb + 1)) then '1' else '0';
PSTATE.V = tmpreg<msb> EOR tmpreg<msb>;
//PSTATE.C unchanged;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.272 SETGP, SETGM, SETGE

Memory Set with tag setting. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGP, then SETGM, and then SETGE.

SETGP performs some preconditioning of the arguments suitable for using the SETGM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGM performs an IMPLEMENTATION DEFINED amount of the memory set. SETGE performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0xfffffffffffffff0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0xfffffffffffffff0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.
For SETGE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -$1$ the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -$Xn$.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

C6.2.273  SETGPN, SETGMN, SETGEN

Memory Set with tag setting, non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPN, then SETGMN, and then SETGEN.

SETGPN performs some preconditioning of the arguments suitable for using the SETGMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETGEN performs the last part of the memory set.

—— Note ———

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

—— Note ———

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.
For SETGEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

C6.2.274 SETGPT, SETGMT, SETGET

Memory Set with tag setting, unprivileged. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPT, then SETGMT, and then SETGET.

SETGPT performs some preconditioning of the arguments suitable for using the SETGMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMT performs an IMPLEMENTATION DEFINED amount of the memory set. SETGET performs the last part of the memory set.

——— Note ————

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

——— Note ————

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  — the value of Xd is written back with the lowest address that has not been set.
For SETGET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- \( X_n \) is treated as a signed 64-bit number.
- \( X_n \) holds \(-1 \times \) the number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to \(-X_n\).
- At the end of the instruction, the value of \( X_n \) is written back with 0.

For SETGET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- \( X_n \) holds the number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of \( X_n \) is written back with 0.
  - the value of \( X_d \) is written back with the lowest address that has not been set.

C6.2.275   SETGPTN, SETGMTN, SETGETN

Memory Set with tag setting, unprivileged and non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPTN, then SETGMTN, and then SETGETN.

SETGPTN performs some preconditioning of the arguments suitable for using the SETGMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMTN performs an IMPLEMENTATION DEFINED amount of the memory set. SETGETN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

Note

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.
For SETGETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

C6.2.276 SETP, SETM, SETE

Memory Set. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETP, then SETM, and then SETE.

SETP performs some preconditioning of the arguments suitable for using the SETM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETM performs an IMPLEMENTATION DEFINED amount of the memory set. SETE performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

After execution of SETP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

For SETM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  — the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  — the value of Xd is written back with the lowest address that has not been set.

For SETE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
• Xn holds -$1^*$ the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -$Xn$.
• At the end of the instruction, the value of Xn is written back with 0.

For SETE, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xd is written back with the lowest address that has not been set.

C6.2.277 SETPN, SETMN, SETEN

Memory Set, non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPN, then SETMN, and then SETEN.

SETPN performs some preconditioning of the arguments suitable for using the SETMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETEN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

Note

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to \(0x7FFFFFFFFFFFFFFF\).
- Xd holds the original Xd + saturated Xn.
- Xn holds \(-1\times\text{saturated Xn} + \text{an IMPLEMENTATION DEFINED number of bytes set}\).
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

After execution of SETPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to \(0x7FFFFFFFFFFFFFFF\).
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

For SETMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds \(-1\times\text{number of bytes remaining to be set in the memory set in total}\).
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with \(-1\times\text{the number of bytes remaining to be set in the memory set in total}\).

For SETMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
• Xn holds -1* the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For SETEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xd is written back with the lowest address that has not been set.

C6.2.278   SETPT, SETMT, SETET

Memory Set, unprivileged. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPT, then SETMT, and then SETET.

SETPT performs some preconditioning of the arguments suitable for using the SETMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMT performs an IMPLEMENTATION DEFINED amount of the memory set. SETET performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0xffffffffffffffff.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0xffffffffffffffff.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
• Xn holds \(-1^n\) the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For SETET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xd is written back with the lowest address that has not been set.

C6.2.279  SETPTN, SETMTN, SETETN

Memory Set, unprivileged and non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPTN, then SETMTN, and then SETETN.

SETPTN performs some preconditioning of the arguments suitable for using the SETMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMTN performs an IMPLEMENTATION DEFINED amount of the memory set. SETETN performs the last part of the memory set.

--- Note ---

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

--- Note ---

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

--- Note ---

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1 * saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1 * number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1 * the number of bytes remaining to be set in the memory set in total.

For SETMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
• Xn holds -1\(^*\) the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For SETETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  — the value of Xn is written back with 0.
  — the value of Xd is written back with the lowest address that has not been set.

`// Empty.`

**Operation**

`SendEvent();`
C6.2.281   SEVL

Send Event Local is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop which starts with a WFE instruction.

SendEventLocal();

Encoding
SEVL

Decode for this encoding
// Empty.

Operation
SendEventLocal();
C6.2.282  SMADDL

Signed Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL. See Alias conditions for details of when each alias is preferred.

```
unsigned long results = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d, 64] = results<63:0>;
```

**Encoding**

SMADDL <Xd>, <Wn>, <Wm>, <Xa>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMULL</td>
<td>Ra == '1111'</td>
</tr>
</tbody>
</table>

**Assembler symbols**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

**Operation**

```
bits(32) operand1 = X[n, 32];
bits(32) operand2 = X[m, 32];
bits(64) operand3 = X[a, 64];

integer result;
result = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d, 64] = result<63:0>;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.283 SMC

Secure Monitor Call causes an exception to EL3.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value 0x17, that is taken to EL3.

If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

Encoding

SMC #<imm>

Decode for this encoding

// Empty.

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

AArch64.CheckForSMCUndefOrTrap(imm16);
AArch64.CallSecureMonitor(imm16);
C6.2.284 SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>Encoding</th>
<th>SMNEGL &lt;Xd&gt;, &lt;Wn&gt;, &lt;Wm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>is equivalent to</td>
</tr>
<tr>
<td></td>
<td>SMSUBL &lt;Xd&gt;, &lt;Wn&gt;, &lt;Wm&gt;, XZR</td>
</tr>
</tbody>
</table>

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**C6.2.285 SMSTART**

Enables access to Streaming SVE mode and SME architectural state.

SMSTART enters Streaming SVE mode, and enables the SME ZA storage.

SMSTART SM enters Streaming SVE mode, but does not enable the SME ZA storage.

SMSTART ZA enables the SME ZA storage, but does not cause an entry to Streaming SVE mode.

This instruction is an alias of the MSR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of MSR (immediate).
- The description of MSR (immediate) gives the operational pseudocode for this instruction.

- `<option>`: Is an optional mode, encoded in the "CRm<2:1>" field. It can have the following values:
  - SM: when CRm<2:1> = 01
  - ZA: when CRm<2:1> = 10
  - [no specifier]: when CRm<2:1> = 11
  - The encoding CRm<2:1> = 00 is reserved.

- `<pstatefield>`: Is a PSTATE field name. For the MSR instruction, this is encoded in the "op1:op2:CRm" field. It can have the following values:
  - SPSel: when op1 = 000, op2 = 101, CRm = xxxx
  - DAIFSet: when op1 = 011, op2 = 110, CRm = xxxx
  - DAIFClr: when op1 = 011, op2 = 111, CRm = xxxx

When FEAT_UAO is implemented, the following value is also valid:

- UAO: when op1 = 000, op2 = 011, CRm = xxxx

When FEAT_PAN is implemented, the following value is also valid:

- PAN: when op1 = 000, op2 = 100, CRm = xxxx

When FEAT_NMI is implemented, the following value is also valid:

- ALLINT: when op1 = 001, op2 = 000, CRm = 000x

When FEAT_SBS is implemented, the following value is also valid:

- SSBS: when op1 = 011, op2 = 001, CRm = xxxx
When FEAT_DIT is implemented, the following value is also valid:
DIT when op1 = 011, op2 = 010, CRm = xxxx

When FEAT_SME is implemented, the following values are also valid:
SVCRSM when op1 = 011, op2 = 011, CRm = 001x
SVCRZA when op1 = 011, op2 = 011, CRm = 010x
SVCRSMZA when op1 = 011, op2 = 011, CRm = 011x

When FEAT_MTE is implemented, the following value is also valid:
TC0 when op1 = 011, op2 = 100, CRm = xxxx

See PSTATE on page C4-539 when op1 = 000, op2 = 00x, CRm = xxxx.
See PSTATE on page C4-539 when op1 = 000, op2 = 010, CRm = xxxx.

The following encodings are reserved:
• op1 = 000, op2 = 11x, CRm = xxxx.
• op1 = 001, op2 = 000, CRm = 001x.
• op1 = 001, op2 = 000, CRm = 01xx.
• op1 = 001, op2 = 000, CRm = 1xxx.
• op1 = 001, op2 = 001, CRm = xxxx.
• op1 = 001, op2 = 01x, CRm = xxxx.
• op1 = 001, op2 = 1xx, CRm = xxxx.
• op1 = 010, op2 = xxx, CRm = xxxx.
• op1 = 011, op2 = 000, CRm = xxxx.
• op1 = 011, op2 = 011, CRm = 000x.
• op1 = 011, op2 = 011, CRm = 1xxx.
• op1 = 011, op2 = 101, CRm = xxxx.
• op1 = 1xx, op2 = xxx, CRm = xxxx.

For the SMSTART and SMSTOP aliases, this is encoded in "CRm<2:1>", where 0b01 specifies SVCRSM, 0b10 specifies SVCRZA, and 0b11 specifies SVCRSMZA.

**Operation**

The description of MSR (immediate) gives the operational pseudocode for this instruction.
C6.2.286   SMSTOP

Disables access to Streaming SVE mode and SME architectural state.
SMSTOP exits Streaming SVE mode, and disables the SME ZA storage.
SMSTOP SM exits Streaming SVE mode, but does not disable the SME ZA storage.
SMSTOP ZA disables the SME ZA storage, but does not cause an exit from Streaming SVE mode.

This instruction is an alias of the MSR (immediate) instruction. This means that:
• The encodings in this description are named to match the encodings of MSR (immediate).
• The description of MSR (immediate) gives the operational pseudocode for this instruction.

System
(FEAT_SME)

Encoding
SMSTOP {<option>}

is equivalent to
MSR <$pstatefield$>, #0

and is always the preferred disassembly.

Assembler symbols

<option>  Is an optional mode, encoded in the "CRm<2:1>" field. It can have the following values:
    SM     when CRm<2:1> = 01
    ZA     when CRm<2:1> = 10
    [no specifier] when CRm<2:1> = 11
    The encoding CRm<2:1> = 00 is reserved.

<pstatefield>  Is a PSTATE field name. For the MSR instruction, this is encoded in the "op1:op2:CRm" field. It can have the following values:
    SPSel  when op1 = 000, op2 = 101, CRm = xxxx
    DAIFSset when op1 = 011, op2 = 110, CRm = xxxx
    DAIFClr when op1 = 011, op2 = 111, CRm = xxxx
    When FEAT_UAO is implemented, the following value is also valid:
    UAO    when op1 = 000, op2 = 011, CRm = xxxx
    When FEAT_PAN is implemented, the following value is also valid:
    PAN    when op1 = 000, op2 = 100, CRm = xxxx
    When FEAT_NMI is implemented, the following value is also valid:
    ALLINT when op1 = 001, op2 = 000, CRm = 000x
    When FEAT_SSBS is implemented, the following value is also valid:
    SSBS   when op1 = 011, op2 = 001, CRm = xxxx
When FEAT_DIT is implemented, the following value is also valid:

\[ \text{DIT} \quad \text{when } op1 = 011, \ op2 = 010, \ CRm = xxxx \]

When FEAT_SME is implemented, the following values are also valid:

\[ \text{SVCRSM} \quad \text{when } op1 = 011, \ op2 = 011, \ CRm = 001x \]
\[ \text{SVCRZA} \quad \text{when } op1 = 011, \ op2 = 011, \ CRm = 010x \]
\[ \text{SVCRSMZA} \quad \text{when } op1 = 011, \ op2 = 011, \ CRm = 011x \]

When FEAT_MTE is implemented, the following value is also valid:

\[ \text{TC0} \quad \text{when } op1 = 011, \ op2 = 100, \ CRm = xxxx \]

See \textit{PSTATE} on page C4-539 when \( op1 = 000, \ op2 = 00x, \ CRm = xxxx \).
See \textit{PSTATE} on page C4-539 when \( op1 = 000, \ op2 = 010, \ CRm = xxxx \).

The following encodings are reserved:

- \( op1 = 000, \ op2 = 11x, \ CRm = xxxx \).
- \( op1 = 001, \ op2 = 000, \ CRm = 001x \).
- \( op1 = 001, \ op2 = 000, \ CRm = 01xx \).
- \( op1 = 001, \ op2 = 000, \ CRm = 1xxx \).
- \( op1 = 001, \ op2 = 001, \ CRm = xxxx \).
- \( op1 = 001, \ op2 = 01x, \ CRm = xxxx \).
- \( op1 = 001, \ op2 = 1xx, \ CRm = xxxx \).
- \( op1 = 010, \ op2 = xxx, \ CRm = xxxx \).
- \( op1 = 011, \ op2 = 000, \ CRm = xxxx \).
- \( op1 = 011, \ op2 = 001, \ CRm = 000x \).
- \( op1 = 011, \ op2 = 011, \ CRm = 1xxx \).
- \( op1 = 011, \ op2 = 101, \ CRm = xxxx \).
- \( op1 = 1xx, \ op2 = xxx, \ CRm = xxxx \).

For the SMSTART and SMSTOP aliases, this is encoded in "CRm<2:1>"", where 0b01 specifies SVCRSM, 0b10 specifies SVCRZA, and 0b11 specifies SVCRSMZA.

\section*{Operation}

The description of \textit{MSR (immediate)} gives the operational pseudocode for this instruction.
C6.2.287 SMSUBL

Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL. See Alias conditions for details of when each alias is preferred.

Encoding

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Xd</td>
<td>64-bit name of the general-purpose destination register, encoded in the &quot;Rd&quot; field.</td>
</tr>
<tr>
<td>Wn</td>
<td>32-bit name of the first general-purpose source register holding the multiplicand, encoded in the &quot;Rn&quot; field.</td>
</tr>
<tr>
<td>Wm</td>
<td>32-bit name of the second general-purpose source register holding the multiplier, encoded in the &quot;Rm&quot; field.</td>
</tr>
<tr>
<td>Xa</td>
<td>64-bit name of the third general-purpose source register holding the minuend, encoded in the &quot;Ra&quot; field.</td>
</tr>
</tbody>
</table>

Operation

```
bits(32) operand1 = X[n, 32];
bits(32) operand2 = X[m, 32];
bits(64) operand3 = X[a, 64];

integer result;
result = Int(operand3, FALSE) - (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d, 64] = result<63:0>;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.288 SMULH

Signed Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

Encoding

SMULH <Xd>, <Xn>, <Xm>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

bits(64) operand1 = X[n, 64];
bits(64) operand2 = X[m, 64];

integer result;
result = Int(operand1, FALSE) * Int(operand2, FALSE);
X[d, 64] = result<127:64>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.289   SMULL

Signed Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of SMADDL.
- The description of SMADDL gives the operational pseudocode for this instruction.

```
[31 30 29 28|27 26 25 24|23 22 21 20] | 16|15 14 | 10 9 | 5 4 | 0 |
  1 0 0 | 1 1 0 1 0 | 0 1 | Rm | 0 | 1 1 1 | Rn | Rd |

Encoding
SMULL <Xd>, <Wn>, <Wm>

is equivalent to
SMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd>     Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>     Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>     Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.290  SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.

- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB.

This instruction is an alias of the DSB instruction. This means that:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode for this instruction.

### Encoding

SSBB

is equivalent to

DSB #0

and is always the preferred disassembly.

### Operation

The description of DSB gives the operational pseudocode for this instruction.
C6.2.291   ST2G

Store Allocation Tags stores an Allocation Tag to two Tag granules of memory. The address used for the store is
calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is
calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

Post-index

(Feat_MTE)

```
[31 30 29 28 | 27 26 25 24 | 23 22 21 20] | 12 | 11 10 9 | 5 4 | 0 |
1 1 0 1 1 0 0 1 | 1 0 1 | imm9 | 0 1 | Xn | Xt
```

Encoding

ST2G <Xt|SP>, [<Xn|SP>], #<imm>

Decode for this encoding

if !HaveMTEExt() then UNDEFINED;
integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);

| 0 0 1 1 | 0 0 0 0 | R 1 | Rs | 0 0 0 0 | 0 0 | Rn | 1 1 1 1 |

#### No memory ordering variant

Applies when \( R == 0 \).

STADDB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDADDB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

#### Release variant

Applies when \( R == 1 \).

STADDLB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDADDLB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

### Assembler symbols

- \(<Ws>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.296   STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDH does not have release semantics.
- STADDLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDADDH, LDADDAH, LDADDALH, LDADDLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

C6.2.316 STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity on page B2-154 and Alignment of data accesses on page B2-189. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180. For information about memory accesses, see Load/store addressing modes on page C1-234.

```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);  // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;  // store UNKNOWN value
        when Constraint_UNDEF   UNDEFINED;
        when Constraint_NOP     EndOfInstruction();
    if s == n && n != 31 then
        Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
        assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
        case c of
            when Constraint_UNKNOWN rn_unknown = TRUE;  // address is UNKNOWN
            when Constraint_UNDEF   UNDEFINED;
            when Constraint_NOP     EndOfInstruction();
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STLXP on page K1-11596.
Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag Checked);
if n == 31 then
  CheckSPAlignment();
  address = SP[];
elif rn_unknown then
  address = bits(64) UNKNOWN;
else
  address = X[n, 64];
if rt_unknown then
  data = bits(datasize) UNKNOWN;
else
  bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
  bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
  data = if BigEndian(AccType_ORDEREDATOMIC) then el1:el2 else el2:el1;
  bit status = '1';
  // Check whether the Exclusives monitors are set to include the
  // physical memory locations corresponding to virtual address
  // range [address, address+dbytes-1].
  if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
// to the same physical locations after address translation.
Mem[address, dbytes, AccType.ORDERED_ATOMIC] = data;
status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.317  **STLXR**

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-211. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-180. For information about memory accesses see *Load/store addressing modes* on page C1-234.

  when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
  when Constraint_UNDEF  UNDEFINED;
  when Constraint_NOP   EndOfInstruction();

### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors*, and particularly STLXR on page K1-11596.
Assembler symbols

<\(s\)> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<\(t\)> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<\(w\)> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<\(n|SP\)> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
- Memory is not updated.
- <\(s\)> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

\[
\begin{align*}
\text{bits(64)} & \text{ address;} \\
\text{bits(elsize)} & \text{ data;} \\
\text{constant integer } d\text{bytes }= \frac{\text{elsize}}{8}; \\
\text{if HaveMTE2Ext()} & \text{ then} \\

\text{if } \text{rt\_unknown then} \\
\text{ data } & = \text{bits(elsize) UNKNOWN;} \\
\text{else} \\
\text{ data } & = \text{X}[t, \text{elsize}]; \\
\text{bit status } & = '1'; \\
\text{// Check whether the Exclusives monitors are set to include the} \\
\text{// physical memory locations corresponding to virtual address} \\
\text{// range [address, address+dbytes-1].} \\
\text{if AArch64.ExclusiveMonitorsPass(address, dbytes) then} \\
\text{// This atomic write will be rejected if it does not refer} \\
\text{// to the same physical locations after address translation.} \\
\text{Mem}[address, dbytes, AccType\_ORDEREDATOMIC] = data;} \\
\text{status } & = \text{ExclusiveMonitorsStatus();} \\
\text{X}[s, 32] & = \text{ZeroExtend(status, 32);} \\
\end{align*}
\]
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.318 STLXRB

Store-Release Exclusive Register Byte stores a byte from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180. For information about memory accesses see Load/store addressing modes on page C1-234.

Encoding

STLXRB \(<Ws>\), \(<Wt>\), \([<Xn>|{SP}>\{,#0}\] \)

Decode for this encoding

\[
\begin{align*}
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } t &= \text{UInt}(Rt); \\
\text{integer } s &= \text{UInt}(Rs); & \quad \text{// ignored by all loads and store-release}
\end{align*}
\]

\[
\begin{align*}
\text{boolean tag_checked} &= n \neq 31; \\
\text{boolean rt\_unknown} &= \text{FALSE}; \\
\text{boolean rn\_unknown} &= \text{FALSE}; \\
\end{align*}
\]

\[
\begin{align*}
\text{if } s &= t \text{ then} \\
\text{Constraint } c &= \text{ConstrainUnpredictable(Unpredictable\_DATAOVERLAP);} \\
\text{assert } c \text{ IN \{Constraint\_UNKNOWN, Constraint\_UNDEF, Constraint\_NOP\};} \\
\text{case } c \text{ of} \\
\text{when } \text{Constraint\_UNKNOWN} & \text{ rt\_unknown = TRUE;} & \quad \text{// store UNKNOWN value} \\

\text{when } \text{Constraint\_UNDEF} & \text{ UNDEFINED;} \\
\text{when } \text{Constraint\_NOP} & \text{ EndOfInstruction();}
\end{align*}
\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STLXRB on page K1-11597.

Assembler symbols

\(<Ws>\) Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

\[
\begin{align*}
0 & \quad \text{If the operation updates memory.} \\
1 & \quad \text{If the operation fails to update memory.}
\end{align*}
\]

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xn>|{SP}>\{,#0\] Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts
If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```c
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[ ];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 1) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, AccType_ORDEREDATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s, 32] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.319   STLXRH

Store-Release Exclusive Register Halfword stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180. For information about memory accesses see Load/store addressing modes on page C1-234.

Encoding

STLXRH <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs); // ignored by all loads and store-release

boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // store UNKNOWN value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
    endcase;
else if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
    endcase;
endif;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STLXRH on page K1-11597.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<w>\) is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];

bit status = '1';
// Check whether the Exclusives monitors are set to include the // physical memory locations corresponding to virtual address // range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer // to the same physical locations after address translation.
    Mem[address, 2, AccType_ORDEREDATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.320  STNP

Store Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about memory accesses, see Load/store addressing modes on page C1-234. For information about Non-temporal pair instructions, see Load/store non-temporal pair on page C3-259.

        SP[] = address;
    else
        X[n, 64] = address;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/store addressing modes on page C1-234.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

### 32-bit variant

Applies when size == 10.

STR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

### 64-bit variant

Applies when size == 11.

STR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

#### Decode for all variants of this encoding

```plaintext
integer scale = UInt(size);
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

#### Assembler symbols

- **<Wt>** Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- **<Xt>** Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- **<Xn|SP>** Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- **<Wm>** When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- **<Xm>** When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- **<extend>** Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:
  - UXTW when option = 010
  - LSL when option = 011
  - SXTW when option = 110
  - SXTX when option = 111
- **<amount>** For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
  - #0 when S = 0
#2 when $S = 1$

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

#0 when $S = 0$
#3 when $S = 1$

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);

integer datasize = 8 << scale;

Operation

bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;
bits(datasize) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = address + offset;
data = X[t, datasize];
Mem[address, datasize DIV 8, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.324 STRB (immediate)

Store Register Byte (immediate) stores the least significant byte of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about memory accesses, see Load/store addressing modes on page C1-234.

    SP[] = address;
else
    X[n, 64] = address;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.325  STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a 32-bit register to the calculated address. For information about memory accesses, see Load/store addressing modes on page C1-234.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

Extended register variant

Applies when option != 011.

STRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

Shifted register variant

Applies when option == 011.

STRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]  

Decode for all variants of this encoding

if option<1> == '0' then UNDEFINED;    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
<extend> Is the index extend specifier, encoded in the "option" field. It can have the following values:
  UXTW when option = 010
  SXTW when option = 110
  SXTX when option = 111
<amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
**Operation**

bits(64) offset = ExtendReg(m, extend_type, 0, 64);
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n >= 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = address + offset;

data = X[t, 8];
Mem[address, 1, AccType_NORMAL] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.326   STRH (immediate)

Store Register Halfword (immediate) stores the least significant halfword of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about memory accesses, see Load/store addressing modes on page C1-234.

Post-index

address = address + offset;

data = X[t, 16];
Mem[address, 2, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.328  STSETB, STSETLB

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- **STSETB** does not have release semantics.
- **STSETLB** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-180.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is an alias of the LDSETB, LDSETAB, LDSETALB, LDSETLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

**Integer**

(FEAT_LSE)

```
| 31 30 29 28| 27 26 25 24| 23 22 21 20 | 16|15|14|12|11|10| 9 | 5| 4 | 0 |

```

**No memory ordering variant**

Applies when R == 0.

STSETB \(<Ws>\), \([<Xn>|SP>]\)

is equivalent to

LDSETB \(<Ws>\), WZR, \([<Xn>|SP>]\)

and is always the preferred disassembly.

**Release variant**

Applies when R == 1.

STSETLB \(<Ws>\), \([<Xn>|SP>]\)

is equivalent to

LDSETLB \(<Ws>\), WZR, \([<Xn>|SP>]\)

and is always the preferred disassembly.

**Assembler symbols**

- \(<Ws>\)   
  Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

- \(<Xn>|SP>\)  
  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.329 STSETH, STSETLH

Atomic bit set on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETH does not have release semantics.
- STSETLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDSETH, LDSETAH, LDSETALH, LDSETLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETH, LDSETAH, LDSETALH, LDSETLH.
- The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

Integer

(FEAT_LSE)

\[

\end{array}
\]

No memory ordering variant

Applies when \( R == 0 \).

STSETH \(<Ws>\), \([<Xn|SP>]\)

is equivalent to

LDSETH \(<Ws>\), WZR, \([<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R == 1 \).

STSETLH \(<Ws>\), \([<Xn|SP>]\)

is equivalent to

LDSETLH \(<Ws>\), WZR, \([<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

- \(<Ws>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.330  STSET, STSETL

Atomic bit set on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit
doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back
to memory.

- STSET does not have release semantics.
- STSETL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDSET, LDSETA, LDSETAL, LDSETL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL,
  LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this
  instruction.

### Integer

 1 x 1 1 1 0 0 0 0 R 1 Rs 0 0 1 1 0 0 Rn 1 1 1 1 1
```

#### 32-bit LDSET alias variant

Applies when `size == 10 && R == 0`.

STSET `<Ws>`, `<Xn|SP>`

is equivalent to

LDSET `<Ws>`, `WZR`, `<Xn|SP>`

and is always the preferred disassembly.

#### 32-bit LDSETL alias variant

Applies when `size == 10 && R == 1`.

STSETL `<Ws>`, `<Xn|SP>`

is equivalent to

LDSETL `<Ws>`, `WZR`, `<Xn|SP>`

and is always the preferred disassembly.

#### 64-bit LDSET alias variant

Applies when `size == 11 && R == 0`.

STSET `<Xs>`, `<Xn|SP>`

is equivalent to

LDSET `<Xs>`, `XZR`, `<Xn|SP>`

and is always the preferred disassembly.
64-bit LDSETL alias variant

Applies when size == 11 && R == 1.

STSETL <Xs>, [<Xn|SP>]

is equivalent to

LDSETL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETEAL, LDSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.331 STSMAXB, STSMAXLB

Atomic signed maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- STSMAXB does not have release semantics.
- STSMAXLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.
- The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode for this instruction.

<td></td>
</tr>
</tbody>
</table>
```

**No memory ordering variant**

Applies when \( R = 0 \).

STSMAXB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDSMAXB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

**Release variant**

Applies when \( R = 1 \).

STSMAXLB \(<Ws>, [<Xn|SP>]\)

is equivalent to

LDSMAXLB \(<Ws>, WZR, [<Xn|SP>]\)

and is always the preferred disassembly.

**Assembler symbols**

- \(<Ws>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- \(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### C6.2.332 STSMAXH, STSMAXLH

Atomic signed maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- **STSMAXH** does not have release semantics.
- **STSMAXLH** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-180.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is an alias of the LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.
- The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

- \(<Xn|SP>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.333  STSMAX, STSMAXL

Atomic signed maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- STSMAX does not have release semantics.
- STSMAXL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.
- The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode for this instruction.

is equivalent to

LDSMAX \(<Xs>\), XZR, [\(<Xn>|\text{SP}\>]\)

and is always the preferred disassembly.
64-bit LDSMAXL alias variant

Applies when size == 11 \&\& R == 1.

\texttt{STSMAXL <Xs>, [<Xn|SP>]}

is equivalent to

\texttt{LDSMAXL <Xs>, XZR, [<Xn|SP>]}

and is always the preferred disassembly.

Assembler symbols

\texttt{<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.}

\texttt{<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.}

\texttt{<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.}

Operation

The description of \texttt{LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL} gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.334   STSMINB, STSMINLB

Atomic signed minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- STSMINB does not have release semantics.
- STSMINLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.
- The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode for this instruction.

STSMINL <Xs>, [<Xn|SP>]

is equivalent to

LDSMINL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<w> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSMIN, LDSMINA, LDSMINAL, LDSMINL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.337   STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for
the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value
of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the
instruction is executed. For information about memory accesses, see Load/store addressing modes on page C1-234.

32-bit variant

Applies when size == 10.
STTR <Wt>, [<Xn|SP>{, #<simm>}]  

64-bit variant

Applies when size == 11.
STTR <Xt>, [<Xn|SP>{, #<simm>}]  

Decode for all variants of this encoding

integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded
in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype;
unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');

if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;
integer datasize = 8 << scale;
boolean tag_checked = n != 31;

**Operation**

bits(64) address;
bits(datasize) data;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];
address = address + offset;
data = X[t, datasize];
Mem[address, datasize DIV 8, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.338  STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/store addressing modes on page C1-234.

Encoding

STTRB <Wt>, [<Xn|SP>{, #<simm>}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
AccType actype;
unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');

address = address + offset;

data = X[t, 16];
Mem[address, 2, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.340  STUMAXB, STUMAXLB

Atomic unsigned maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- **STUMAXB** does not have release semantics.
- **STUMAXLB** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-180.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is an alias of the **LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB** instruction. This means that:

- The encodings in this description are named to match the encodings of **LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB**.
- The description of **LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB** gives the operational pseudocode for this instruction.

**Integer**

(FEAT_LSE)

```
[31 30 29 28|27 26 25 24|23 22 21 20]  16|15 14 12|11 10 9 | 5 4 | 0 |
  0 0 1 1 1 0 0 0 0 R 1 Rs 0 1 1 0 0 0 Rn 1 1 1 1 1
```

**No memory ordering variant**

Applies when \( R = 0 \).

**STUMAXB** <\( Ws \), [\( Xn | SP \)]

is equivalent to

**LDUMAXB** <\( Ws \), WZR, [\( Xn | SP \)]

and is always the preferred disassembly.

**Release variant**

Applies when \( R = 1 \).

**STUMAXLB** <\( Ws \), [\( Xn | SP \)]

is equivalent to

**LDUMAXLB** <\( Ws \), WZR, [\( Xn | SP \)]

and is always the preferred disassembly.

**Assembler symbols**

- <\( Ws \)> is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <\( Xn | SP \)> is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.341   STUMAXH, STUMAXLH

Atomic unsigned maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAXH does not have release semantics.
- STUMAXLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.
- The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

**No memory ordering variant**

Applies when R == 0.

STUMAXH <Ws>, [<Xn|SP>]

is equivalent to

LDUMAXH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**Release variant**

Applies when R == 1.

STUMAXLH <Ws>, [<Xn|SP>]

is equivalent to

LDUMAXLH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**Assembler symbols**

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of `LDUMAXH`, `LDUMAXAH`, `LDUMAXALH`, `LDUMAXLH` gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.342  **STUMAX, STUMAXL**

Atomic unsigned maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- **STUMAX** does not have release semantics.
- **STUMAXL** stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-180.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

This instruction is an alias of the LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

1 x 1 1 1 0 0 0 0 R 1 Rn 0 1 1 0 0 0 Rn 1 1 1 1
```

**32-bit LDUMAX alias variant**

Applies when `size == 10 && R == 0`.

STUMAX `<Ws>`, `<Xn|SP>`

is equivalent to

LDUMAX `<Ws>`, WZR, `<Xn|SP>`

and is always the preferred disassembly.

**32-bit LDUMAXL alias variant**

Applies when `size == 10 && R == 1`.

STUMAXL `<Ws>`, `<Xn|SP>`

is equivalent to

LDUMAXL `<Ws>`, WZR, `<Xn|SP>`

and is always the preferred disassembly.

**64-bit LDUMAX alias variant**

Applies when `size == 11 && R == 0`.

STUMAX `<Xs>`, `<Xn|SP>`

is equivalent to

LDUMAX `<Xs>`, XZR, `<Xn|SP>`

and is always the preferred disassembly.
64-bit LDUMAXL alias variant

 Applies when size == 11 && R == 1.

 STUMAXL <Xs>, [<Xn|SP>]

 is equivalent to

 LDUMAXL <Xs>, XZR, [<Xn|SP>]

 and is always the preferred disassembly.

Assembler symbols

 <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

 <Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

 <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

 The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

Operational information

 If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.343  STUMINB, STUMINLB

Atomic unsigned minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINB does not have release semantics.
- STUMINLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

For information about memory accesses see Load/store addressing modes on page C1-234.

This instruction is an alias of the LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.
- The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode for this
instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.346 STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/store addressing modes on page C1-234.

32-bit variant

Applies when size == 10.

STUR <Wt>, [<Xn|SP>{, #<simm>}]

64-bit variant

Applies when size == 11.

STUR <Xt>, [<Xn|SP>{, #<simm>}]

Decode for all variants of this encoding

integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
integer datasize = 8 ⋅ scale;
boolean tag_checked = n != 31;

Operation

bits(64) address;
bits(datasize) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
address = X[n, 64];
address = address + offset;
data = X[t, datasize];
Mem[address, datasize DIV 8, AccType_NORMAL] = data;

Operational information
If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.347  STURB

Store Register Byte (unscaled) calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about memory accesses, see Load/store addressing modes on page C1-234.

**Encoding**

STURB \(<Wt>, [<Xn|SP>{, #<simm}>] \)

else  
    address = X[n, 64];

address = address + offset;

data = X[t, 16];
Mem[address, 2, AccType_NORMAL] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.349 STXP

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity on page B2-154 and Alignment of data accesses on page B2-189. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses, see Load/store addressing modes on page C1-234.

32-bit variant

Applies when sz == 0.

STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit variant

Applies when sz == 1.

STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
  Constraint c = ConstraineUnpredictable(Unpredictable_DATAOVERLAP);
  assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNKNOWN rt_unknown = TRUE; // store UNKNOWN value
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();
  if s == n & n != 31 then
    Constraint c = ConstraineUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
      when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
      when Constraint_UNDEF UNDEFINED;
      when Constraint_NOP EndOfInstruction();

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STXP on page K1-11599.
Assembler symbols

\(<\text{Ws}>\)
Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0  If the operation updates memory.
1  If the operation fails to update memory.

\(<\text{Xt1}>\)
Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<\text{Xt2}>\)
Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<\text{Wt1}>\)
Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<\text{Wt2}>\)
Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<\text{Xn}|\text{SP}>\)
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<\text{Ws}>\) is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If \(\text{AArch64.ExclusiveMonitorsPass() \ returns \ True}\), the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If \(\text{AArch64.ExclusiveMonitorsPass() \ returns \ False}\) and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

\begin{verbatim}
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
if HaveMTE2Ext() then
  SetTagCheckedInstruction(tag_checked);
if n == 31 then
  CheckSPAlignment();
  address = SP[];
elif rn_unknown then
  address = bits(64) UNKNOWN;
else
  address = X[n, 64];
if rt_unknown then
  data = bits(datasize) UNKNOWN;
else
  bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
  bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
  data = if BigEndian(AccType_ATOMIC) then el1:el2 else el2:el1;
  bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
  // This atomic write will be rejected if it does not refer
\end{verbatim}
// to the same physical locations after address translation.
Mem[address, dbytes, AccType_ATOMIC] = data;
status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);

Operational information
If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.350  STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. For information about memory accesses see Load/store addressing modes on page C1-234.

### 32-bit variant

Applies when size == 10.

STXR `<Ws>`, `<Wt>`, `[<Xn|SP>{,#0}]`

### 64-bit variant

Applies when size == 11.

STXR `<Ws>`, `<Xt>`, `[<Xn|SP>{,#0}]`

#### Decode for all variants of this encoding

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release
integer elsize = 8 << UInt(size);
boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF   UNDEFINED;
        when Constraint_NOP     EndOfInstruction();
    if s == n && n != 31 then
        Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
        assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
        case c of
            when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
            when Constraint_UNDEF   UNDEFINED;
            when Constraint_NOP     EndOfInstruction();
```

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STXR on page K1-11599.

#### Assembler symbols

`<Ws>`

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0      If the operation updates memory.
If the operation fails to update memory.

\(<X_t>\) Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<W_t>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<X_n|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<W_s>\) is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If \(\text{AArch64.ExclusiveMonitorsPass()}\) returns \(\text{TRUE}\), the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If \(\text{AArch64.ExclusiveMonitorsPass()}\) returns \(\text{FALSE}\) and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

\]

**Operational information**

If \(\text{PSTATE.DIT} = 1\), the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.351  STXRB

Store Exclusive Register Byte stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-211. The memory access is atomic.

For information about memory accesses see Load/store addressing modes on page C1-234.

            when Constraint_UNKNOWN rn_unknown = TRUE;  // address is UNKNOWN
            when Constraint_UNDEF   UNDEFINED;
            when Constraint_NOP     EndOfInstruction();
```

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors, and particularly STXRB on page K1-11599.

**Assembler symbols**

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0       If the operation updates memory.
1       If the operation fails to update memory.

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Aborts**
If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<ws>\) is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[ ];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 1) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s, 32] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.352 STXRH

Store Exclusive Register Halfword stores a halfword from a register to memory if the PE has exclusive access to
the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.
See *Synchronization and semaphores* on page B2-211. The memory access is atomic.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

```
[31 30 29 28|27 26 25 24|23 22 21 20] 16 15 14 10 9 5 4 0
0 1 0 0 1 0 0 0 0 0 1 1 1 1 1
size L 0 0 Rt2
```

**Encoding**

STXRH \(<Ws>\), \(<Wt>\), \([<Xn|SP>\{,#0}\] \)

**Decode for this encoding**

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs); // ignored by all loads and store-release

boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // store UNKNOWN value
        when Constraint_UNDEF   UNDEFINED;
        when Constraint_NOP     EndOfInstruction();
    if s == n && n != 31 then
        Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
        assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
        case c of
            when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
            when Constraint_UNDEF   UNDEFINED;
            when Constraint_NOP     EndOfInstruction();
```

**Assembler symbols**

\(<Ws>\) Is the 32-bit name of the general-purpose register into which the status result of the store exclusive
is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<Ws>\) is not updated.
A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
b bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

**Operational information**

If `PSTATE.DIT` is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.353   STZ2G

Store Allocation Tags, Zeroing stores an Allocation Tag to two Tag granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

C6.2.356   SUB (extended register)

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit variant
Applies when sf == 0.
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant
Applies when sf == 1.
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
datatype datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Assembler symbols

<Wd|WSP>  Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP>  Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm>  Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd|SP>  Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP>  Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R>  Is a width specifier, encoded in the "option" field. It can have the following values:
   W     when option = 00x
   W     when option = 010
   X     when option = x11
   W     when option = 10x
   W     when option = 11x

<m>  Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UTXW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.357   **SUB (immediate)**

Subtract (immediate) subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.

- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when `sh = 0`
  - LSL #12 when `sh = 1`

**Operation**

```plaintext```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[<datasize-1:0>] else X[n, datasize];
bits(datasize) operand2;

operand2 = NOT(imm);
(result, -) = AddWithCarry(operand1, operand2, '1');
```

---
if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.358 SUB (shifted register)

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias NEG (shifted register). See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when sf == 1.

SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>Rn == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>shift = 00</td>
</tr>
<tr>
<td>LSR</td>
<td>shift = 01</td>
</tr>
<tr>
<td>ASR</td>
<td>shift = 10</td>
</tr>
<tr>
<td>(reserved)</td>
<td>shift = 11</td>
</tr>
</tbody>
</table>

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```c
bits(datasize) result;
basis(datasize) operand1 = X[n, datasize];
basis(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
X[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.359 SUBG

Subtract with Tag subtracts an immediate value scaled by the Tag granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

PSTATE.<N,Z,C,V> = nzcv;
X[d, 64] = result;
C6.2.362   SUBS (extended register)

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional
left shift amount, from a register value, and writes the result to the destination register. The argument that is extended
from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the
result.

This instruction is used by the alias CMP (extended register). See Alias conditions for details of when each alias is
preferred.

32-bit variant

Applies when sf == 0.

SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant

Applies when sf == 1.

SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn"
field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn"
field.
<R>   Is a width specifier, encoded in the "option" field. It can have the following values:
W    when option = 00x
W    when option = 010
X    when option = x11
W    when option = 10x
W    when option = 110

<m>  Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in
the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:
UXTB  when option = 000
UXTH  when option = 001
LSL|UXTW when option = 010
UXTX  when option = 011
SXTB  when option = 100
SKTH  when option = 101
SXTW  when option = 110
SXTX  when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when
"imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:
UXTB  when option = 000
UXTH  when option = 001
UXTW  when option = 010
LSL|UXTX when option = 011
SXTB  when option = 100
SKTH  when option = 101
SXTW  when option = 110
SXTX  when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3"
is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in
the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL,
and is optional when <extend> is present but not LSL.

Operation

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);

SWPAH variant

Applies when A == 1 && R == 0.

SWPAH <Ws>, <Wt>, [Xn|SP]

SWPALH variant

Applies when A == 1 && R == 1.

SWPALH <Ws>, <Wt>, [Xn|SP]

SWPH variant

Applies when A == 0 && R == 0.

SWPH <Ws>, <Wt>, [Xn|SP]

SWPLH variant

Applies when A == 0 && R == 1.

SWPLH <Ws>, <Wt>, [Xn|SP]

Decode for all variants of this encoding

```c
if !HaveAtomicExt() then UNDEFINED;

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDATOMICRW else AccType_ATOMICRW;
boolean tag_checked = n != 31;
```
Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(16) data;
bits(16) store_value;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();

store_value = X[s, 16];
data = MemAtomic(address, MemAtomicOp_SWP, store_value, ldacctype, stacctype);
X[t, 32] = ZeroExtend(data, 32);
C6.2.368  **SWP, SWPA, SWPAL, SWPL**

Swap word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, SWPA and SWPAL load from memory with acquire semantics.
- SWP and SWPAL store to memory with release semantics.
- SWP has neither acquire nor release semantics.

For information about memory accesses see *Load/store addressing modes* on page C1-234.

C6.2.369  SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0 \&\& N == 0$.

SXTB <Wd>, <Wn>

is equivalent to

SBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1 \&\& N == 1$.

SXTB <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #7

and is always the preferred disassembly.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.370  SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf == 0 \) \&\& \( N == 0 \).

\[ \text{SXTH} <Wd>, <Wn> \]
is equivalent to

\[ \text{SBFM} <Wd>, <Wn>, #0, #15 \]
and is always the preferred disassembly.

64-bit variant

Applies when \( sf == 1 \) \&\& \( N == 1 \).

\[ \text{SXTH} <Xd>, <Wn> \]
is equivalent to

\[ \text{SBFM} <Xd>, <Xn>, #0, #15 \]
and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.371  SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

64-bit variant

SXTW <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #31

and is always the preferred disassembly.

Assembler symbols

<Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn>  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<Wn>  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.372  SYS

System instruction. For more information, see `op0==0b01`, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659 for the encodings of System instructions.

This instruction is used by the aliases AT, BRB, CFP, CPP, DC, DVP, IC, and TLBI. See Alias conditions for details of when each alias is preferred.

Encoding
SYS #<op1>, <Cn>, <Crn>, #<op2>{, <Xt>}

Decode for this encoding
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Alias conditions

**Encoding**

SYSL \(<Xt>\), \#<op1>, \(<Cn>\), \(<Cm>\), \#<op2>

**Decode for this encoding**

```c
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);
```

```c
integer t = UInt(Rt);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys.crm = UInt(CRm);
```

**Assembler symbols**

\(<Xt>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

\(<op1>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\(<Cn>\) Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

\(<Cm>\) Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\(<op2>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

**Operation**

// No architecturally defined instructions here.

```c
AArch64.SysInstrWithResult(1, sys_op1, sys_crn, sys.crm, sys_op2, t);
```
C6.2.374   TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

```
|31 30 29 28 27 26 25 24 23|19 18 | | | 5 4 | 0 |
b5 0 1 1 0 1 1 1 b40 imm14 | | | Rt
```

**Encoding**

TBNZ <R><t>, #<imm>, <label>

**Decode for this encoding**

```c
integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);
```

**Assembler symbols**

- `<R>` Is a width specifier, encoded in the "b5" field. It can have the following values:
  - W when b5 = 0
  - X when b5 = 1
  - In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

- `<t>` Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

- `<imm>` Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

- `<label>` Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

**Operation**

```c
bits(datasize) operand = X[t, datasize];
if operand<bit_pos> == op then
   BranchTo(PC[] + offset, BranchType_DIR, TRUE);
```
C6.2.375  TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

Encoding

TBZ $<R><t>$, #<imm>, <label>

Decode for this encoding

integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler symbols

$<R>$  Is a width specifier, encoded in the "b5" field. It can have the following values:
   W  when b5 = 0
   X  when b5 = 1

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

$<t>$  Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

$<imm>$  Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

$<label>$  Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datasize) operand = X[t, datasize];
if operand<bit_pos> == op then
   BranchTo(PC[] + offset, BranchType_DIR, TRUE);
C6.2.376 TCANCEL

This instruction exits Transactional state and discards all state modifications that were performed transactionally. Execution continues at the instruction that follows the TSTART instruction of the outer transaction. The destination register of the TSTART instruction of the outer transaction is written with the immediate operand of TCANCEL.

System
(FEAT_TME)

Encoding
TCANCEL #<imm>

Decode for this encoding
if !HaveTME() then UNDEFINED;
boolean retry = (imm16<15> == '1');
bits(15) reason = imm16<14:0>;

Assembler symbols
<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation
CheckTMEEnabled();
if TSTATE.depth > 0 then
    FailTransaction(TMFailure_CNCL, retry, FALSE, reason);
C6.2.377   TCOMMIT

This instruction commits the current transaction. If the current transaction is an outer transaction, then Transactional
state is exited, and all state modifications performed transactionally are committed to the architectural state.
TCOMMIT takes no inputs and returns no value.

Execution of TCOMMIT is UNDEFINED in Non-transactional state.

System

(FEAT_TME)

```
[31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 ]
[1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 0 1 1 0 0 0 0 1 1 1 1 1 1]
```

Encoding

TCOMMIT

Decode for this encoding

if !HaveTME() then UNDEFINED;

Operation

CheckTMEEnabled();

if TSTATE.depth == 0 then
  UNDEFINED;

if TSTATE.depth == 1 then
  CommitTransactionalWrites();
  ClearExclusiveLocal(ProcessorID());
  TSTATE.depth = TSTATE.depth - 1;
C6.2.378 TLBI

TLB Invalidate operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

### Encoding

TLBI <tlbi_op>{, <Xt>}

is equivalent to

SYS #<op1>, <Crn>, <Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when SysOp(op1,Crn,Crn,op2) == Sys_TLBI.

### Assembler symbols

- `<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Crn>` Is a name 'Crn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- `<tlbi_op>` Is a TLBI instruction name, as listed for the TLBI system instruction group, encoded in the "op1:CRn:CRm:op2" field. It can have the following values:
  - VMALLE1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 000
  - VAEI1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 001
  - ASIDEI1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 010
  - VAAE1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 011
  - VALEI1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 101
  - VAALIE1IS when op1 = 000, Crn = 1000, Crm = 0011, op2 = 111
  - VMALLE1 when op1 = 000, Crn = 1000, Crm = 0111, op2 = 000

\(<Xt>\) Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rx" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.379 TSTART

This instruction starts a new transaction. If the transaction started successfully, the destination register is set to zero. If the transaction failed or was canceled, then all state modifications that were performed transactionally are discarded and the destination register is written with a non-zero value that encodes the cause of the failure.

System

(FEAT_TME)

| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 8 |7 6 5 4 |0  |
| 1 1 0 1 0 1 0 1 0 0 1 0 0 1 1 0 0 1 1 0 0 1 0 0 0 0 0 1 1 | Rt |

Encoding

TSTART <Xt>

Decode for this encoding

if !HaveTME() then UNDEFINED;
integer t =_UINT(Rt);

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

Operation

CheckTMEEnabled();

boolean IsEL1Regime;
bit tme;
bit tmt;
case PSTATE_EL of
when EL0
 IsEL1Regime = S1TranslationRegime() == EL1;
 if IsEL1Regime then

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

**Operation**

CheckTMEEnabled();

X[t, 64] = (TSTATE.depth)<63:0>;
C6.2.381 TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If FEAT_TRF is not implemented, this instruction executes as a NOP.

System

(FEAT_TRF)

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11  8  7  5  4  3  2  1  0 |
| 1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 1 0 0 1 0 0 1 0 1 1 1 1 1 |

Encoding

TSB CSYNC

Decode for this encoding

if !HaveSelfHostedTrace() then EndOfInstruction();

Operation

TraceSynchronizationBarrier();
C6.2.382 TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: \( Rn \ AND \ imm \)

This instruction is an alias of the ANDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

\[
\text{TST} \ <Wn>, \ #<imm>
\]

is equivalent to

\[
\text{ANDS} \ \text{WZR}, \ <Wn>, \ #<imm>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{TST} \ <Xn>, \ #<imm>
\]

is equivalent to

\[
\text{ANDS} \ \text{XZR}, \ <Xn>, \ #<imm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{imm}>\) For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

### Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
C6.2.383 TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ANDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf == 0 \).

\[
\text{TST} \ <Wn>, <Wm>{, <shift> #<amount>} \]

is equivalent to

\[
\text{ANDS} \ WZR, <Wn>, <Wm>{, <shift> #<amount>} \]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf == 1 \).

\[
\text{TST} \ <Xn>, <Xm>{, <shift> #<amount>} \]

is equivalent to

\[
\text{ANDS} \ XZR, <Xn>, <Xm>{, <shift> #<amount>} \]

and is always the preferred disassembly.

### Assembler symbols

- \( <Wn> \) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <Wm> \) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \( <Xn> \) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( < Xm> \) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \( <shift> \) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( shift = 00 \)
  - LSR when \( shift = 01 \)
  - ASR when \( shift = 10 \)
  - ROR when \( shift = 11 \)
- \( <amount> \) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.384 UBFIZ

Unsigned Bitfield Insert in Zeros copies a bitfield of \(<width>\) bits from the least significant bits of the source register to bit position \(<\text{lsb}>\) of the destination register, setting the destination bits above and below the bitfield to zero.

This instruction is an alias of the \textbf{UBFM} instruction. This means that:

- The encodings in this description are named to match the encodings of \textbf{UBFM}.
- The description of \textbf{UBFM} gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \(sf == 0 \land N == 0\).

\[
\text{UBFIZ } <Wd>, <Wn>, #<\text{lsb}>, #<width>
\]

is equivalent to

\[
\text{UBFM } <Wd>, <Wn>, #(-<\text{lsb} \mod 32)>, #(<width>-1)
\]

and is the preferred disassembly when \(\text{UInt}(\text{immr}) < \text{UInt}(\text{imms})\).

### 64-bit variant

Applies when \(sf == 1 \land N == 1\).

\[
\text{UBFIZ } <Xd>, <Xn>, #<\text{lsb}>, #<width>
\]

is equivalent to

\[
\text{UBFM } <Xd>, <Xn>, #(-<\text{lsb} \mod 64)>, #(<width>-1)
\]

and is the preferred disassembly when \(\text{UInt}(\text{imms}) < \text{UInt}(\text{immr})\).

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{lsb}>\) For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<width>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32.<\text{lsb}>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64.<\text{lsb}>.

### Operation

The description of \textbf{UBFM} gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.385  UBFM

Unsigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \(<\text{imms}>\) is greater than or equal to \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>-<\text{immr}>+1)\) bits starting from bit position \(<\text{immr}>\) in the source register to the least significant bits of the destination register.

If \(<\text{imms}>\) is less than \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-<\text{immr}>)\) of the destination register, where \(\text{regsize}\) is the destination register size of 32 or 64 bits.

In both cases the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See Alias conditions on page C6-2015 for details of when each alias is preferred.

32-bit variant

Applies when \(s\ f == 0 \&\& N == 0\).

\[\text{UBFM } <\text{Wd}>, <\text{Wn}>, #<\text{immr}>, #<\text{imms}>\]

64-bit variant

Applies when \(s\ f == 1 \&\& N == 1\).

\[\text{UBFM } <\text{Xd}>, <\text{Xn}>, #<\text{immr}>, #<\text{imms}>\]

Decode for all variants of this encoding

integer \(d\) = UInt(Rd);
integer \(n\) = UInt(Rn);
integer \(\text{datasize}\) = if \(s\ f == '1'\) then 64 else 32;

integer \(r\);
bits(datasize) \(wmask\);
bits(datasize) \(tmask\);

if \(s\ f == '1' \&\& N != '1'\) then UNDEFINED;
if \(s\ f == '0' \&\& (N != '0' || immr<5> != '0' || imms<5> != '0')\) then UNDEFINED;

\(r\) = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE, datasize);

- `<imms>`: For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

bits(datasize) src = X[n, datasize];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, r) AND wmask;

// combine extension bits and result bits
X[d, datasize] = bot AND tmask;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C6.2.386  UBFX

Unsigned Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf == 0 \&\& N == 0 \).

\[
\text{UBFX} \ <Wd>, \ <Wn>, \ #<lsb>, \ #<width>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #<lsb>, \ #(<lsb>+<width>-1)
\]

and is the preferred disassembly when \( \text{BFXPreferred}(sf, \ opc<1>, \ imms, \ immr) \).

### 64-bit variant

Applies when \( sf == 1 \&\& N == 1 \).

\[
\text{UBFX} \ <Xd>, \ <Xn>, \ #<lsb>, \ #<width>
\]

is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #<lsb>, \ #(<lsb>+<width>-1)
\]

and is the preferred disassembly when \( \text{BFXPreferred}(sf, \ opc<1>, \ imms, \ immr) \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<lsb>\) For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- \(<width>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

### Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.387  UDF

Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>

<td></td>
</tr>
</tbody>
</table>
```

**Encoding**

UDF #<imm>

**Decode for this encoding**

// The imm16 field is ignored by hardware.

UNDEFINED;

**Assembler symbols**

<imm> is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

**Operation**

// No operation.
C6.2.388   UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit variant
Applies when \(sf == 0\).
UDIV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when \(sf == 1\).
UDIV <Xd>, <Xn>, < Xm>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) operand1 = X[n, datasize];
bits(datasize) operand2 = X[m, datasize];
integer result;

if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero(Real(Int(operand1, TRUE)) / Real(Int(operand2, TRUE)));
X[d, datasize] = result<datasize-1:0>;
```
C6.2.389 UMADDL

Unsigned Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL. See Alias conditions for details of when each alias is preferred.

Encoding

UMADDL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>UMULL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n, 32];
bits(32) operand2 = X[m, 32];
bits(64) operand3 = X[a, 64];

integer result;

result = Int(operand3, TRUE) + (Int(operand1, TRUE) * Int(operand2, TRUE));

X[d, 64] = result<63:0>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.390 UMNEGL

Unsigned Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode for this instruction.

**Encoding**

UMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

UMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

**Assembler symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

The description of UMSUBL gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.391 UMSUBL

Unsigned Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL. See Alias conditions for details of when each alias is preferred.

Encoding

UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Alias conditions

<table>
<thead>

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n, 32];
bits(32) operand2 = X[m, 32];
bits(64) operand3 = X[a, 64];

integer result;
result = Int(operand3, TRUE) - (Int(operand1, TRUE) * Int(operand2, TRUE));
X[d, 64] = result<63:0>;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.392 UMULH

Unsigned Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

Encoding

UMULH <Xd>, <Xn>, <Xm>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

Assembler symbols

- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
bits(64) operand1 = X[n, 64];
bits(64) operand2 = X[m, 64];

integer result;

result = Int(operand1, TRUE) * Int(operand2, TRUE);
X[d, 64] = result<127:64>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.393  UMULL

Unsigned Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode for this instruction.

Encoding

UMULL <Xd>, <Wn>, <Wm>

is equivalent to

UMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn>  Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm>  Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.394 UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

\[
\text{UXTB} \ <Wd>, \ <Wn>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #0, \ #7
\]

and is always the preferred disassembly.

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

#### Operation

The description of UBFM gives the operational pseudocode for this instruction.

#### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.395 UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

UXTH <\#d>, <\#n>

is equivalent to

UBFM <\#d>, <\#n>, #0, #15

and is always the preferred disassembly.

#### Assembler symbols

- \(<\#d>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\#n>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

#### Operation

The description of UBFM gives the operational pseudocode for this instruction.

#### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.396   WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any
PE in the multiprocessor system. For more information, see Wait for Event on page D1-4676.

As described in Wait for Event on page D1-4676, the execution of a WFE instruction that would otherwise cause entry
to a low-power state can be trapped to a higher Exception level.

Encoding

WFE

Decode for this encoding

// Empty.

Operation

integer localtimeout = 1 << 64;    // No local timeout event is generated
Hint_WFE(localtimeout, WFxType_WFE);
C6.2.397 WFET

Wait For Event with Timeout is a hint instruction that indicates that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait for Event* on page D1-4676.

As described in *Wait for Event* on page D1-4676, the execution of a WFET instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

**System**

WFET <Xt>

**Decode for this encoding**

if !HaveFeatWFxT() then UNDEFINED;

integer d = UInt(Rd);

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rd" field.

**Operation**

integer localtimeout = UInt(X[d, 64]);

if Halted() && ConstrantUnpredictableBool(Unpredictable_WFxTDEBUG) then EndOfInstruction();

Hint_WFE(localtimeout, WFxType_WFET);
C6.2.398 WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see Wait for Interrupt mechanism on page D1-4678.

As described in Wait for Interrupt mechanism on page D1-4678, the execution of a WFI instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

Encoding

WFI

Decode for this encoding

// Empty.

Operation

```
integer localtimeout = 1 << 64; // No local timeout event is generated
Hint_WFI(localtimeout, WFxType_WFI);
```
C6.2.399 WFIT

Wait For Interrupt with Timeout is a hint instruction that indicates that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. For more information, see Wait for Interrupt mechanism on page D1-4678.

As described in Wait for Interrupt mechanism on page D1-4678, the execution of a WFIT instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

Decode for this encoding

if !HaveFlagFormatExt() then UNDEFINED;

Operation

\[
\begin{align*}
\text{bit } n &= \text{NOT(PSTATE.C) AND NOT(PSTATE.Z);} \\
\text{bit } z &= \text{PSTATE.Z AND PSTATE.C;} \\
\text{bit } c &= \text{PSTATE.C OR PSTATE.Z;} \\
\text{bit } v &= \text{NOT(PSTATE.C) AND PSTATE.Z;} \\
\text{PSTATE.N} &= n; \\
\text{PSTATE.Z} &= z; \\
\text{PSTATE.C} &= c; \\
\text{PSTATE.V} &= v;
\end{align*}
\]
C6.2.401 XPACD, XPARI, XPARLR

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPARI and XPARD, and is in LR for XPARLR.

The XPARD instruction is used for data addresses, and XPARI and XPARLR are used for instruction addresses.

**Integer**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
Operation for all encodings

if HavePACExt() then
    X[d, 64] = Strip(X[d, 64], data);
C6.2.402  YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction on page B1-146.

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 | 8 7 6 5 4 3 2 1 0 |

`hint_yield();`
This chapter describes the A64 Advanced SIMD and floating-point instructions.

It contains the following sections:

- About the SME instructions on page C9-4542.
- Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-2042.
C7.1 About the A64 Advanced SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-2042 gives full descriptions of the A64 instructions that are in the following instruction groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding on page C4-388 in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following subsections:

- Register size.
- Output element control.
- Data types on page C7-2041.
- Condition flags and related instructions on page C7-2041.

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see Advanced SIMD vector formats on page A1-43.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, INS.
- Load structure into a single lane, for example LD3.
- All second-part narrowing operations, for example SHRN2.

C7.1.2 Output element control

When FEAT_AFP is implemented, the FPCR.NEP bit controls how output elements are determined for the scalar Advanced SIMD instructions for elements other than the lowest element of the vector.

If FPCR.NEP == 1, the following instructions determine output elements as follows:

- The 3-input floating-point scalar versions of FMLA (by element) and FMLS (by element) take output elements other than the lowest element from the <Hd>, <Sd>, or <Dd> register.
- The 3-input floating-point FMADD, FMSUB, FNADD, and FNMSUB instructions take output elements other than the lowest element from the <Ha>, <Sa>, or <Da> register.
- The 2-input floating-point scalar versions of FCMGE (register), FCMGT (register), FCMEQ (register), FACGE, FACGT, take output elements other than the lowest element from the <Hm>, <Sm>, or <Dm> register.
- The 2-input floating-point scalar versions of FMULX, FRECPS, FRSQRTS, FABD, FMUL (by element), FMUL (scalar), FDIV (scalar), FADD (scalar), FSUB (scalar), FMAX (scalar), FMIN (scalar), FMAXNM (scalar), FMINNM (scalar), FMUL (scalar), take output elements other than the lowest element from the <Hn>, <Sn>, or <Dn> register.
- For 1-input floating-point scalar versions of the instructions FCVTNS (vector), FCVTMS (vector), FCVTAS (vector), FCVTPS (vector), SCVT (vector, integer), UCVT (vector, integer) FCVTZS (vector, integer), FCVTZU (vector, integer), FCVTVU (vector), FCVTMU (vector), FCVTAU (vector), FCVTU (vector), SCVT (vector, fixed-point), UCVT (vector, fixed-point), FCVTZ (vector, fixed-point), FCVTZU
C7.1 About the A64 Advanced SIMD and floating-point instructions

C7.1.3 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating-points.
- Signed and unsigned integers.
- Polynomials over \{0, 1\}.
- When FEAT_FCMA is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

--- Note ---

- AArch32 Advanced SIMD operations always use Arm standard floating-point arithmetic, regardless of the rounding mode specified by the AArch64 FPCR or the AArch32 FPSCR.
- In AArch64 state, floating-point multiply-add operations are always performed as fused operations, but AArch32 state provides both fused and chained multiply-add instructions.

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example SHRN2, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example SMLAL2, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialized head or tail handling, or both.

C7.1.4 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point FCSEL and FCOMP instructions are equivalent to the integer CSEL and CCMP instructions.
- Floating-point FCMP, FCMPE, FCMPO, and FCMPO instructions set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point F3CVTZS instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example FCMPZ.

--- Note ---

FCMP and FCMPE differ from the A32/T32 VCM and VCMPE instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an FCMP or FCMPE operation in the PSTATE.{N, Z, C, V} field.

If FEAT_FlagM2 is implemented, base instructions XAFLAG and AXFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See Table C6-1 on page C6-1168.
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions

This section lists every section in the Advanced SIMD and floating-point categories of the A64 instruction set. For details of the format used, see Structure of the A64 assembler language on page C1-228.
C7.2.1 ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

Encoding

ABS \langle V \rangle \langle d \rangle, \langle V \rangle \langle n \rangle

Decode for this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd) ; \\
\text{integer } n &= \text{UInt}(Rn) ; \\
\text{if } \text{size} \neq '11' \text{ then UNDEFINED;} \\
\text{integer } \text{esize} &= 8 \ll \text{UInt(size)}; \\
\text{integer } \text{datasize} &= \text{esize}; \\
\text{integer } \text{elements} &= 1; \\
\text{boolean } \text{neg} &= (U == '1');
\end{align*}
\]

**Vector**

Encoding

ABS \langle Vd \rangle \langle T \rangle, \langle Vn \rangle \langle T \rangle

Decode for this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd) ; \\
\text{integer } n &= \text{UInt}(Rn) ; \\
\text{if } \text{size}:Q \neq '110' \text{ then UNDEFINED;} \\
\text{integer } \text{esize} &= 8 \ll \text{UInt(size)}; \\
\text{integer } \text{datasize} &= \text{if } Q == '1' \text{ then 128 else 64}; \\
\text{integer } \text{elements} &= \text{datasize} \div \text{esize}; \\
\text{boolean } \text{neg} &= (U == '1');
\end{align*}
\]

Assembler symbols

\[
\langle V \rangle \text{ Is a width specifier, encoded in the } "\text{size}" \text{ field. It can have the following values:}
\]

\[
\begin{align*}
D & \text{ when } \text{size} = 11 \\
\text{The following encodings are reserved:}
\end{align*}
\]

- size = 0x.
• size = 10.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>T</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>when size = 00, Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>when size = 00, Q = 1</td>
</tr>
<tr>
<td>4H</td>
<td>when size = 01, Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>when size = 01, Q = 1</td>
</tr>
<tr>
<td>2S</td>
<td>when size = 10, Q = 0</td>
</tr>
<tr>
<td>4S</td>
<td>when size = 10, Q = 1</td>
</tr>
<tr>
<td>2D</td>
<td>when size = 11, Q = 1</td>
</tr>
</tbody>
</table>

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];
bits(datasize) result;
integer element;
for e = 0 to elements-1
   element = SInt(Elem[operand, e, esize]);
   if neg then
      element = -element;
   else
      element = Abs(element);
   Elem[result, e, esize] = element<esize-1:0>;
V[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.2  ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
0   1   0   1   1   1   0 | size  1 | Rm   1   0   0   0   1 | Rn   Rd
```

Encoding

ADD <V><d>, <V><n>, <V><m>

Decode for this encoding

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

Vector

```
0   Q   0   0   1   1   1   0 | size  1 | Rm   1   0   0   0   1 | Rn   Rd
```

Encoding

ADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

Assembler symbols

&lt;V&gt;  Is a width specifier, encoded in the "size" field. It can have the following values:

D    when size = 11

The following encodings are reserved:

•    size = 0x.
• size = 10.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8B</td>
<td>size = 00, Q = 0</td>
</tr>
<tr>
<td>16B</td>
<td>size = 00, Q = 1</td>
</tr>
<tr>
<td>4H</td>
<td>size = 01, Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>size = 01, Q = 1</td>
</tr>
<tr>
<td>2S</td>
<td>size = 10, Q = 0</td>
</tr>
<tr>
<td>4S</td>
<td>size = 10, Q = 1</td>
</tr>
<tr>
<td>2D</td>
<td>size = 11, Q = 1</td>
</tr>
</tbody>
</table>

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;
V[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.3 ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN, RADDHN2.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Encoding

ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n, 2*datasize];
bias(2*datasize) operand2 = V[m, 2*datasize];
bias(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bias(2*esize) element1;
bias(2*esize) element2;
bias(2*esize) sum;
for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.4   ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Encoding

ADDP <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize * 2;

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
  0 when size = 11
  The following encodings are reserved:
  • size = 0x.
  • size = 10.
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<T> Is the source arrangement specifier, encoded in the "size" field. It can have the following values:
  2D when size = 11
  The following encodings are reserved:
  • size = 0x.
  • size = 10.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];
V[d, esize] = Reduce(ReduceOp_ADD, operand, esize);
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.5   ADDP (vector)

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28|27 26 25 24|23 22 21 20] 16|15 14 13 12|11 10 9 | 5 4 | 0  
0 Q 0 1 1 1 0 | size 1 | Rm 1 0 1 1 1 1 | Rn Rd
```

**Encoding**

ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

**Assembler symbols**

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
```

CheckFPAdvSIMDEnabled64();
for e = 0 to elements-1
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
    Elem[result, e, esize] = element1 + element2;

V[d, datasize] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.6   ADDV

Add across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes
the scalar result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Encoding
ADDV <V><d>, <Vn>.<T>

Decode for this encoding
integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols
<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
8 when size = 00
H when size = 01
S when size = 10
The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
4S when size = 10, Q = 1
The following encodings are reserved:
• size = 10, Q = 0.
• size = 11, Q = x.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];
V[d, esize] = Reduce(ReduceOp_ADD, operand, esize);

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.7 AESD

AES single round decryption.

\text{result } &= \text{AESInvMixColumns}(\text{operand}) ; \\
V[d, 128] &= \text{result} ;
\end{align*}
\]

*Operational information*

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.10 AESMC

AES mix columns.

Encoding
AESMC <Vd>.16B, <Vn>.16B

Decode for this encoding

\[ \text{integer } d = \text{UInt}(Rd); \]
\[ \text{integer } n = \text{UInt}(Rn); \]
\[ \text{if } \text{!HaveAESExt()} \text{ then UNDEFINED;} \]

Assembler symbols

\[ <Vd> \quad \text{Is the name of the SIMD&FP destination register, encoded in the } "Rd" \text{ field.} \]
\[ <Vn> \quad \text{Is the name of the SIMD&FP source register, encoded in the } "Rn" \text{ field.} \]

Operation

\[ \text{AArch64.CheckFPAdvSIMDEnabled();} \]
\[ \text{bits}(128) \text{ operand} = V[n, 128]; \]
\[ \text{bits}(128) \text{ result}; \]
\[ \text{result} = \text{AESMixColumns}(\text{operand}); \]
\[ V[d, 128] = \text{result}; \]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.11   AND (vector)

Bitwise AND (vector). This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 | 15 14 13 12 | 11 10 9 | 8 7 6 5 | 4 3 2 1 | 0 | 0 0 0 0 1 1 $0$ | 0 0 1 1 1 Rm | 0 0 0 1 1 1 Rn | Rd
```

Encoding

```
AND <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

```
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
```

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
result = operand1 AND operand2;
V[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.12  BCAX

Bit Clear and Exclusive OR performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when FEAT_SHA3 is implemented.

Advanced SIMD

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va> Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m, 128];
bits(128) Vn = V[n, 128];
bits(128) Va = V[a, 128];
V[d, 128] = Vn EOR (Vm AND NOT(Va));

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.13 BFCVT

Floating-point convert from single-precision to BFloat16 format (scalar) converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

Single-precision to BFloat16

(FCAT_BF16)

```
|31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10| 9 | 5 | 4 | 0 |

```

**Encoding**

BFCVT <Hd>, <Sn>

**Decode for this encoding**

```c
if !HaveBF16Ext() then UNDEFINED;
integer n = UInt(Rn);
integer d = UInt(Rd);
```

**Assembler symbols**

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPEnabled64();

bits(32) operand = V[n, 32];
FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d, 128] else Zeros(128);

Elem[result, 0, 16] = FPConvertBF(operand, fpcr);
V[d, 128] = result;
```
C7.2.14 BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector) reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The BFCVTN instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero, while the BFCVTN2 instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

**Vector single-precision to BFloat16**

**Decode for this encoding**

if !HaveBF16Ext() then UNDEFINED;
integer n = UInt(Rn);
integer d = UInt(Rd);
integer part = UInt(Q);
integer elements = 64 DIV 16;

**Assembler symbols**

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

-absent- when Q = 0
-present- when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

-4H- when Q = 0
-8H- when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(128) operand = V[n, 128];
bits(64) result;

for e = 0 to elements-1
    Elem[operand, e, 32] = FPConvertBF(Elem[operand, e, 32], FPCR[]);
Vpart[d, part, 64] = result;
C7.2.15 BFDOT (by element)

BFloat16 floating-point dot product (vector, by element). This instruction delimits the source vectors into pairs of BFloat16 elements.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is \{1, 1\}.
- Generates only the default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Generates only the default NaN, as if FPCR.DN is 1.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the effective value of the FPCR in the current execution mode, and captured in the FPSR.

The BFloat16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

**Vector**

    sum = BFDotAdd(sum, elt1_a, elt1_b, elt2_a, elt2_b, FPCR[]);
    Elem[result, e, 32] = sum;
V[d, datasize] = result;
```

C7.2.17  BFMLALB, BFMLALT (by element)

BFLOAT16 floating-point widening multiply-add long (by element) widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and the indexed element in the second source vector from BFLOAT16 to single-precision format. The instruction then multiplies and adds these values without intermediate rounding to single-precision elements of the destination vector that overlap with the corresponding BFLOAT16 elements in the first source vector.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

V[d, 128] = result;
C7.2.19 BFMMLA

BFLOAT16 floating-point matrix multiply-accumulate into 2x2 matrix.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, this instruction:

- Performs two unfused sums-of-products within each two pairs of adjacent BFLOAT16 elements while multiplying the 2x4 matrix of BFLOAT16 values in the first source vector with the 4x2 matrix of BFLOAT16 values in the second source vector. The intermediate single-precision products are rounded before they are summed and the intermediate sum is rounded before accumulation into the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating two 2-way unfused dot products per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Generates only the default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs two fused sums-of-products within each two pairs of adjacent BFLOAT16 elements while multiplying the 2x4 matrix of BFLOAT16 values in the first source vector with the 4x2 matrix of BFLOAT16 values in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating two 2-way fused dot products per destination element.
- Generates only the default NaN, as if FPCR.DN is 1.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the effective value of the FPCR in the current execution mode, and captured in the FPSR.

**Note**

Arm expects that the BFMMLA instruction will deliver a peak BFLOAT16 multiply throughput that is at least as high as can be achieved using two BFDOT instructions, with a goal that it should have significantly higher throughput.

**Vector**

(Feat_BF16)

```
   [31 30 29 28 27 26 25 24 23 22 21 20 16 15 14 13 12 11 10 9 5 4 0]

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(128) op1 = V[n, 128];
bits(128) op2 = V[m, 128];
bits(128) acc = V[d, 128];

V[d, 128] = BFMatMulAdd(acc, op1, op2);
C7.2.20  BIC (vector, immediate)

Bitwise bit Clear (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 16-bit variant

Applies when `cmode == 10x1`.

```assembly
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

### 32-bit variant

Applies when `cmode == 0xx1`.

```assembly
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

### Decode for all variants of this encoding

```plaintext
integer rd = UInt(Rd);

  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11111'
    // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UNDEFINED;
    operation = ImmediateOp_MOVI;
imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

### Assembler symbols

- `<Vd>` Is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>` For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `4H` when `Q = 0`
  - `8H` when `Q = 1`
For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

25 \text{ when } Q = 0

45 \text{ when } Q = 1

\text{<imm8>} \quad \text{Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".}

\text{<amount>} \quad \text{For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:}

0 \text{ when } \text{cmode}<1> = 0

8 \text{ when } \text{cmode}<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0 \text{ when } \text{cmode}<2:1> = 00

8 \text{ when } \text{cmode}<2:1> = 01

16 \text{ when } \text{cmode}<2:1> = 10

24 \text{ when } \text{cmode}<2:1> = 11

defaulting to 0 if LSL is omitted.

\end{verbatim}

Operational information

If PSTATE.DIT is 1:
\begin{itemize}
  \item The execution time of this instruction is independent of:
  \begin{itemize}
    \item The values of the data supplied in any of its registers.
    \item The values of the NZCV flags.
  \end{itemize}
\end{itemize}
The response of this instruction to asynchronous exceptions does not vary based on:

— The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.32   CMGT (zero)

Compare signed Greater than zero (vector). This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is greater than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

**Assembler symbols**

<\V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11
The following encodings are reserved:

- size = 0x
- size = 10.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

</n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

</m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

The encoding size = 11, Q = 0 is reserved.

</v> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

</v> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
boolean test_passed;
for e = 0 to elements-1
  element1 = Elem[operand1, e, esize];
  element2 = Elem[operand2, e, esize];
  if and_test then
    test_passed = !IsZero(element1 AND element2);
  else
    test_passed = (element1 == element2);
  Elem[result, e, esize] = if test_passed then Ones(esize) else Zeros(esize);
V[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.38  CNT

Population Count per byte. This instruction counts the number of bits that have a value of one in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Encoding

CNT <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '00' then UNDEFINED;
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1

The following encodings are reserved:

- size = 01, Q = x.
- size = 1x, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];
bits(datasize) result;

integer count;
for e = 0 to elements-1
  count = BitCount(Elem[operand, e, esize]);
  Elem[result, e, esize] = count<esize-1:0>;
V[d, datasize] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.39   DUP (element)

Duplicate vector element to vector or scalar. This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

Scalar

```
| 31 30 29 28 27 26 25 24 23 22 21 20 | 15 14 13 12 11 10  9 |  5  4 |  0 |
|  0  1  0  1  1  1  0  0  0  0 | imm5  0  0  0  0  1 | Rn | Rd |
```

Encoding

DUP <V><d>, <Vn>.<T>[<index>]

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;
```

Vector

```
| 31 30 29 28 27 26 25 24 23 22 21 20 | 15 14 13 12 11 10  9 |  5  4 |  0 |
|  0  1  0  0  0  0  1  0  0  0  0  0 | imm5  0  0  0  0  1 | Rn | Rd |
```

Encoding

DUP <Vd>.<T>, <Vn>.<Ts>[<index>]

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer elements = 1;
```
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<T>
For the scalar variant: is the element width specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

For the vector variant: is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

- 8B when imm5 = xxxx1, Q = 0
- 16B when imm5 = xxxx1, Q = 1
- 4H when imm5 = xxx10, Q = 0
- 8H when imm5 = xxx10, Q = 1
- 2S when imm5 = xx100, Q = 0
- 4S when imm5 = xx100, Q = 1
- 2D when imm5 = x1000, Q = 1

The following encodings are reserved:

- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<Ts>
Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<V>
Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index>
Is the element index encoded in the "imm5" field. It can have the following values:

- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xxx10
- imm5<4:3> when imm5 = xx100
- imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<d>
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n, idxdsize];
bits(datasize) result;
bits(esize) element;

    element = Elem[operand, index, esize];
    for e = 0 to elements-1
        Elem[result, e, esize] = element;
    V[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**C7.2.40  DUP (general)**

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Encoding**

DUP <Vd>.<T>, <R><n>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

// imm5<4:size+1> is IGNORED

if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

- **8B** when imm5 = xxxx1, Q = 0
- **16B** when imm5 = xxxx1, Q = 1
- **4H** when imm5 = xxx10, Q = 0
- **8H** when imm5 = xxx10, Q = 1
- **2S** when imm5 = xx100, Q = 0
- **4S** when imm5 = xx100, Q = 1
- **2D** when imm5 = x1000, Q = 1

The following encodings are reserved:

- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

- **W** when imm5 = xxxx1
- **W** when imm5 = xxxx10
- **W** when imm5 = xx100
- **X** when imm5 = x1000
The encoding imm5 = x0000 is reserved. Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n, esize];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
    V[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.41 EOR (vector)

Bitwise Exclusive OR (vector). This instruction performs a bitwise Exclusive OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Encoding

EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
88 when Q = 0
168 when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = V[n, datasize];
operand1 = V[m, datasize];
operand2 = Zeros(datasize);
operand3 = Ones(datasize);
V[d, datasize] = operand1 EOR ((operand2 EOR operand4) AND operand3);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.42   EOR3

Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when FEAT_SHA3 is implemented.

Advanced SIMD

(Feat_SHA3)

<table>

Decode for this encoding

if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va> Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m, 128];
bits(128) Vn = V[n, 128];
bits(128) Va = V[a, 128];
V[d, 128] = Vn EOR Vm EOR Va;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.43  EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.

![Diagram showing the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.]

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28|27 26 25 24|23 22 21 20] | 16|15 14 | 11 10 9 | 5 4 | 0 |
0 | Q | 1 | 0 | 1 | 1 | 0 | 0 | 0 | Rm | 0 | imm4 | 0 | Rn | Rd |
```

**Encoding**

EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>

**Decode for this encoding**

```plaintext
d = UInt(Rd);
n = UInt(Rn);
m = UInt(Rm);

if Q == '0' && imm4<3> == '1' then UNDEFINED;

datasize = if Q == '1' then 128 else 64;
position = UInt(imm4) << 3;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<index>` Is the lowest numbered byte element to be extracted, encoded in the "Q:imm4" field. It can have the following values:
  - imm4<2:0> when Q = 0, imm4<3> = 0
  - imm4 when Q = 1, imm4<3> = x
The encoding $Q = 0$, imm4<3> = 1 is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m, datasize];
bits(datasize) lo = V[n, datasize];
bits(datasize*2) concat = hi:lo;

V[d, datasize] = concat<position+datasize-1:position>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.44   FABD

Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
**C7.2.46 FABS (scalar)**

Floating-point Absolute value (scalar). This instruction calculates the absolute value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Half-precision variant**

Applies when $ftype == 11$.

FABS $<Hd>$, $<Hn>$

**Single-precision variant**

Applies when $ftype == 00$.

FABS $<Sd>$, $<Sn>$

**Double-precision variant**

Applies when $ftype == 01$.

FABS $<Dd>$, $<Dn>$

**Decode for all variants of this encoding**

```c
integer d = Uint(Rd);
integer n = Uint(Rn);

integer esize;
case ftype of
    when '00' esize = 32;
    when '01' esize = 64;
    when '10' UNDEFINED;
    when '11'
        if HaveFP16Ext() then
            esize = 16;
        else
            UNDEFINED;
end case;
```

**Assembler symbols**

- $<Dd>$ is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- $<Dn>$ is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- $<Hd>$ is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- $<Hn>$ is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- $<Sd>$ is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- $<Sn>$ is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPEnabled64();

FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d, 128] else 0<127:0>;

bits(esize) operand = V[n, esize];

Elem[result, 0, esize] = FPAbs(operand);
V[d, 128] = result;
C7.2.47 FACGE

Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CheckFPEnabled64();
bits(esize) operand1 = V[n, esize];
bits(esize) operand2 = V[m, esize];

FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[n, 128] else Zeros(128);

Elem[result, 0, esize] = FPAdd(operand1, operand2, fpcr);
V[d, 128] = result;
```
C7.2.51 FADDP (scalar)

Floating-point Add Pair of elements (scalar). This instruction adds two floating-point vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler symbols

<V> For the half-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

- H when sz = 0
The encoding \( sz = 1 \) is reserved.

For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

- \( S \) when \( sz = 0 \)
- \( D \) when \( sz = 1 \)

\(<d>\) is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Vn>\) is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<T>\) For the half-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- \( 2H \) when \( sz = 0 \)
- The encoding \( sz = 1 \) is reserved.

For the single-precision and double-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- \( 2S \) when \( sz = 0 \)
- \( 2D \) when \( sz = 1 \)

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];
V[d, esize] = Reduce(ReduceOp_FADD, operand, esize);
```
C7.2.52 FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Half-precision

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>  
For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H  when Q = 0
- 8H  when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 2S  when sz = 0, Q = 0
- 4S  when sz = 0, Q = 1
- 2D  when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn>  
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>  
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    if pair then
        element1 = Elem[concat, 2*e, esize];
        element2 = Elem[concat, (2*e)+1, esize];
    else
        element1 = Elem[operand1, e, esize];
        element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPAdd(element1, element2, FPCR[]);
V[d, datasize] = result;
```
C7.2.53 FCADD

Floating-point Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding
the real part of the number. Each element holds a floating-point value. It performs the following computation on the
 corresponding complex number element pairs from the two source registers:

• Considering the complex number from the second source register on an Argand diagram, the number is
rotated counterclockwise by 90 or 270 degrees.

• The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  4H when size == 01, Q == 0
  8H when size == 01, Q == 1
  2S when size == 10, Q == 0
  4S when size == 10, Q == 1
  2D when size == 11, Q == 1

The following encodings are reserved:
• size == 00, Q == x.
size = 11, Q = 0.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<rotate>  Is the rotation, encoded in the "rot" field. It can have the following values:

90 when rot = 0
270 when rot = 1

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(esize) element1;
bits(esize) element3;

for e = 0 to (elements DIV 2)-1
  case rot of
    when '0'
      element1 = FPNeg(Elem[operand2, e*2+1, esize]);
      element3 = Elem[operand2, e*2, esize];
    when '1'
      element1 = Elem[operand2, e*2+1, esize];
      element3 = FPNeg(Elem[operand2, e*2, esize]);
  Elem[result, e*2, esize] = FPAdd(Elem[operand1, e*2, esize], element1, FPCR[]);
  Elem[result, e*2+1, esize] = FPAdd(Elem[operand1, e*2+1, esize], element3, FPCR[]);

V[d, datasize] = result;
C7.2.54   FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.\{N, Z, C, V\} flags. If the condition does not pass then the PSTATE.\{N, Z, C, V\} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant

Applies when ftype == 11.

FCCMP <Hn>, <Hm>, #<nzcv>, <cond>

Single-precision variant

Applies when ftype == 00.

FCCMP <Sn>, <Sm>, #<nzcv>, <cond>

Double-precision variant

Applies when ftype == 01.

FCCMP <Dn>, <Dm>, #<nzcv>, <cond>

Decode for all variants of this encoding

integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UNDEFINED;
  when '11'
    if HaveFP16Ext() then
datasize = 16;
else
  UNDEFINED;

bits(4) flags = nzcv;

Assembler symbols

<Dn>     Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Dm>     Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

CheckFPEnabled64();

bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2;
operand2 = V[m, datasize];
if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, FALSE, FPCR[]);
PSTATE.<N,Z,C,V> = flags;

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C7.2.55  **FCCMPE**

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the **PSTATE.** {N, Z, C, V} flags. If the condition does not pass then the **PSTATE.** {N, Z, C, V} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if HaveFP16Ext() then
data = 16;
  else
    UNDEFINED;

bits(4) flags = nzcv;
```

### Assembler symbols

- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<\text{n}> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<\text{m}> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<\text{s}> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<\text{m}> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<\text{cond}> Is one of the standard conditions, encoded in the "cond" field in the standard way.

**Operation**

\begin{verbatim}
CheckFPEnabled64();

bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2;
operand2 = V[m, datasize];
if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, TRUE, FPCR[]);
PSTATE.<\text{N,Z,C,V}> = flags;
\end{verbatim}

**Operational information**

The IEEE 754 standard specifies that the result of a comparison is precisely one of \(<, ==, >\) or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to \(N=0, Z=0, C=1,\) and \(V=1.\)

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C7.2.56 FCMEQ (register)

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    Elem[result, e, esize] = if test_passed then Ones(esize) else Zeros(esize);

V[d, 128] = result;
C7.2.57  FCMEQ (zero)

Floating-point Compare Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.61  FCMGT (zero)

Floating-point Compare Greater than zero (vector). This instruction reads each floating-point value in the source
SIMD&FP register and if the value is greater than zero sets every bit of the corresponding vector element in the
destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the
destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

C7.2.62 FCMLA (by element)

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on
complex numbers from the first source register and the destination register with the specified complex number from
the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is
  rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a
    rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was
    a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination
  register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate
rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
    S when sz = 0
    D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    4H when Q = 0
    8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
    2S when sz = 0, Q = 0
    4S when sz = 0, Q = 1
    2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];

    Elem[result, e, esize] = if test_passed then Ones(esize) else Zeros(esize);

V[d, datasize] = result;
C7.2.65 FCMLT (zero)

Floating-point Compare Less than zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean cmp_with_zero = (opc<0> == '1');

Assembler symbols

<\Dn> For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<\Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<\Hn> For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<\Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<\Sn> For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
  For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<\Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPEnabled64();

bits(datasize) operand1 = V[n, datasize];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0', datasize) else V[m, datasize];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR[]);

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C7.2.67  FCMPE

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page A1-64.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d, datasize] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.69   FCVT

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FPRounding rounding = FPRounding_TIEAWAY;
boolean unsigned = (U == '1');
```

Vector single-precision and double-precision

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
 0 1 1 1 0 0 1 1 1 0 0 1 1 0 0 1 0 0 0 | 1 1 1 0 0 1 0 1 0 Rn Rd
```

**Encoding**

FCVTAS <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPRounding_TIEAWAY;
boolean unsigned = (U == '1');
```

**Assembler symbols**

- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<V> is a width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1

d is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H when Q = 0
8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n, datasize];

bits(esize) element;
FPCTYPE fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);
bits(128) result = if merge then V[d, 128] else Zeros(128);

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, fpcr, rounding, esize);

V[d, 128] = result;
C7.2.71  **FCVTAS (scalar)**

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps on page A1-64*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<th>5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>sf 0 0 1 1 1 1 0</td>
<td>type 1 0 0 1 0 0 0 0 0 0 0 0</td>
<td>Rn</td>
</tr>
</tbody>
</table>
```

### Half-precision to 32-bit variant

Applies when `sf == 0 && ftype == 11`.

FCVTAS `<Wd>`, `<Hn>`

### Half-precision to 64-bit variant

Applies when `sf == 1 && ftype == 11`.

FCVTAS `<Xd>`, `<Hn>`

### Single-precision to 32-bit variant

Applies when `sf == 0 && ftype == 00`.

FCVTAS `<Wd>`, `<Sn>`

### Single-precision to 64-bit variant

Applies when `sf == 1 && ftype == 00`.

FCVTAS `<Xd>`, `<Sn>`

### Double-precision to 32-bit variant

Applies when `sf == 0 && ftype == 01`.

FCVTAS `<Wd>`, `<Dn>`

### Double-precision to 64-bit variant

Applies when `sf == 1 && ftype == 01`.

FCVTAS `<Xd>`, `<Dn>`

### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;

case ftype of
```
when '00'
  fltsize = 32;
when '01'
  fltsize = 64;
when '10'
  UNDEFINED;
when '11'
  if HaveFP16Ext() then
    fltsize = 16;
  else
    UNDEFINED;

Assembler symbols

<Wd>  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn>  Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hn>  Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn>  Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPEnabled64();

FPCRType fpcr = FPCR[];
bits(fltsize) fltval;
bits(intsize) intval;

fltval = V[n, fltsize];
intval = FPToFixed(fltval, 0, FALSE, fpcr, FPRounding_TIEAWAY, intsize);
X[d, intsize] = intval;
