D17.5.14 PMOVSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSET_EL0 characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>_EL0.

**Configurations**

AArch64 System register PMOVSET_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMOVSET[31:0].

AArch64 System register PMOVSET_EL0 bits [31:0] are architecturally mapped to External register PMOVSET_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSET_EL0 are UNDEFINED.

**Attributes**

PMOVSET_EL0 is a 64-bit register.

**Field descriptions**

```

```

**Bits [63:32]**

Reserved, RES0.

**C, bit [31]**

Cycle counter overflow set bit.

0b0 When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

0b1 When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<n>, bit [n], for n = 30 to 0**

Event counter overflow set bit for PMEVCNTR<n>_EL0.
If \( N \) is less than 31, then bits [30:31] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, \( N \) is the value in MDCR_EL2.HPMN. Otherwise, \( N \) is the value in PMCR_EL0.HPMN.

- **0b0** When read, means that PMEVCNTR\(<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.
- **0b1** When read, means that PMEVCNTR\(<n>_EL0 has overflowed since this bit was last cleared. When written, sets the PMEVCNTR\(<n>_EL0 overflow bit to 1.

If FEAT_PMUv3p5 is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR\(<n>_EL0[31:0] or unsigned overflow of PMEVCNTR\(<n>_EL0[63:0].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.5.15 PMSEL_EL0, Performance Monitors Event Counter Selection Register

The PMSEL_EL0 characteristics are:

**Purpose**

Selects the current event counter PMEVCNTR\(<n>\)_EL0 or the cycle counter, CCNT.

PMSEL_EL0 is used in conjunction with PMXEVTYPER_EL0 to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR_EL0, to determine the value of a selected event counter.

**Configurations**

AArch64 System register PMSEL_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMSEL[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSEL_EL0 are UNDEFINED.

**Attributes**

PMSEL_EL0 is a 64-bit register.

**Field descriptions**

![Field descriptions diagram]

**Bits [63:5]**

Reserved, RES0.

**SEL, bits [4:0]**

Selects event counter, PMEVCNTR\(<n>\)_EL0, where n is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 occurs.

This field can take any value from 0 (0b00000) to (PMCR.N)-1, or 31 (0b11111).

When PMSEL_EL0.SEL is 0b11111, it selects the cycle counter and:

- A read of the PMXEVTYPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPER_EL0 writes to PMCCFILTR_EL0.
- A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects. For more information, see PMXEVCNTR_EL0.

For more information about the results of accesses to the event counters, see PMXEVTYPER_EL0 and PMXEVCNTR_EL0.

For more information about the number of counters accessible at each Exception level, see MDCR_EL2.HPMN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing PMSEL_EL0**

Accesses to this register use the following encodings in the System register encoding space:
if PSTATE.EL == EL0 then
  if Halted() && HaveEL(EL3) && EDSCR.SDD == '1' then

D17.5.16 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see SW_INCR on page D11-5307.

**Configurations**

AArch64 System register PMSWINC_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMSWINC[31:0].

AArch64 System register PMSWINC_EL0 bits [31:0] are architecturally mapped to External register PMSWINC_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSWINC_EL0 are UNDEFINED.

**Attributes**

PMSWINC_EL0 is a 64-bit register.

**Field descriptions**

**Bits [63:31]**

Reserved, RES0.

**P<n>, bit [n], for n = 30 to 0**

Event counter software increment bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

0b0 No action. The write to this bit is ignored.

0b1 If PMEVCNTR<n>_EL0 is enabled and configured to count the software increment event, increments PMEVCNTR<n>_EL0 by 1. If PMEVCNTR<n>_EL0 is disabled, or not configured to count the software increment event, the write to this bit is ignored.

**Accessing PMSWINC_EL0**

Accesses to this register use the following encodings in the System register encoding space:

**MSR PMSWINC_EL0, <Xt>**

D17.5.17  PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

**Purpose**

Enables or disables EL0 access to the Performance Monitors.

**Configurations**

AArch64 System register PMUSERENR_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMUSERENR[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMUSERENR_EL0 are **UNDEFINED**.

**Attributes**

PMUSERENR_EL0 is a 64-bit register.

**Field descriptions**

| Bits [63:4] | Reserved, RES0. |
| Bits [3:0] | ER, bit [3] |
| Event counter Read. Traps EL0 access to event counters to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. |
| In AArch64 state, trapped accesses are reported using EC syndrome value 0x18. |
| In AArch32 state, trapped accesses are reported using EC syndrome value 0x03. |
| **0b0** EL0 using AArch64: EL0 reads of the PMXEVCNTR_EL0 and PMEVCNTR<0>_EL0, and EL0 read/write accesses to the PMSELR_EL0, are trapped if PMUSERENR_EL0.EN is also 0. |
| EL0 using AArch32: EL0 reads of the PMXEVCNTR and PMEVCNTR<0>, and EL0 read/write accesses to the PMSELR, are trapped if PMUSERENR_EL0.EN is also 0. |
| **0b1** Overrides PMUSERENR_EL0.EN and enables: |
| * RO access to PMXEVCNTR_EL0 and PMEVCNTR<0>_EL0 at EL0. |
| * RW access to PMSELR_EL0 at EL0. |
| * RW access to PMSELR at EL0. |

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

| Cycle counter Read. Traps EL0 access to cycle counter reads to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. |
| In AArch64 state, trapped accesses are reported using EC syndrome value 0x18. |
In AArch32 state, trapped MRC accesses are reported using EC syndrome value 0x03, trapped MRRC accesses are reported using EC syndrome value 0x04.

**0b0** EL0 using AArch64: EL0 read accesses to the PMCCNTR_EL0 are trapped if PMUSERENR_EL0.EN is also 0.
EL0 using AArch32: EL0 read accesses to the PMCCNTR are trapped if PMUSERENR_EL0.EN is also 0.

**0b1** Overrides PMUSERENR_EL0.EN and enables access to:
- PMCCNTR_EL0 at EL0.
- PMCCNTR at EL0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SW, bit [1]**

Traps Software Increment writes to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

In AArch64 state, trapped accesses are reported using EC syndrome value 0x18.
In AArch32 state, trapped accesses are reported using EC syndrome value 0x03.

**0b0** EL0 using AArch64: EL0 writes to the PMSWINC_EL0 are trapped if PMUSERENR_EL0.EN is also 0.
EL0 using AArch32: EL0 writes to the PMSWINC are trapped if PMUSERENR_EL0.EN is also 0.

**0b1** Overrides PMUSERENR_EL0.EN and enables access to:
- PMSWINC_EL0 at EL0.
- PMSWINC at EL0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EN, bit [0]**

Traps EL0 accesses to the Performance Monitor registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states as follows:

- In AArch64 state, MRS or MSR accesses to the following registers are reported using EC syndrome value 0x18:
  - PMCR_EL0, PMOVSCR_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCTRL_EL0, PMCNTSET_EL0, PMCNTENCLR_EL0, PMOVSSET_EL0, PMEVCNTR<n>_<n>_<n>_EL0, PMEVTYPER<n>_<n>_EL0, PMCCFILTR_EL0, PMSWINC_EL0.
  - If FEAT_PMUv3p4 is implemented, PMMIR_EL1.
- In AArch32 state, MRC or MCR accesses to the following registers are reported using EC syndrome value 0x03:
  - PMCR, PMOVSR, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCTRL, PMCNTSET, PMCNTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR, PMSWINC.
  - If FEAT_PMUv3p4 is implemented, PMMIR.
  - If FEAT_PMUv3p1 is implemented, in AArch32 state, PMCEID2, and PMCEID3.
- In AArch32 state, MRRC or MCRR accesses to PMCCNTR are reported using EC syndrome value 0x04.

**0b0** While at EL0, accesses to the specified registers at EL0 are trapped, unless overridden by one of PMUSERENR_EL0.{ER, CR, SW}. 

While at EL0, software can access all of the specified registers. The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing PMUSERENR_EL0

Accesses to this register use the following encodings in the System register encoding space:

D17.5.18 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

**Purpose**
Reads or writes the value of the selected event counter, PMEVCNTR<n>_EL0. PMSELR_EL0.SEL determines which event counter is selected.

**Configurations**
AArch64 System register PMXEVCNTR_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMXEVCTR[31:0].
This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMXEVCNTR_EL0 are UNDEFINED.

**Attributes**
PMXEVCNTR_EL0 is a 64-bit register.

**Field descriptions**

*When FEAT_PMUv3p5 is implemented:*

\[
\begin{array}{c}
63 \\
32 \\
31 \\
0 \\
\end{array}
\]

PMEVCNTR<n>, bits [63:0]
Value of the selected event counter, PMEVCNTR<n>_EL0, where n is the value stored in PMSELR_EL0.SEL.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

\[
\begin{array}{c}
63 \\
32 \\
31 \\
0 \\
\end{array}
\]

Bits [63:32]
Reserved, RES0.

PMEVCNTR<n>, bits [31:0]
Value of the selected event counter, PMEVCNTR<n>_EL0, where n is the value stored in PMSELR_EL0.SEL.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing PMXEVCNTR_EL0

If `FEAT_FGT` is implemented and `PMSELR_EL0.SEL` is greater than or equal to the number of accessible event counters, then the behavior of permitted reads and writes of `PMXEVCNTR_EL0` is as follows:

- If `PMSELR_EL0.SEL` selects an unimplemented event counter, the access is **UNDEFINED**.
- Otherwise, the access is trapped to EL2.

If `FEAT_FGT` is not implemented and `PMSELR_EL0.SEL` is greater than or equal to the number of accessible event counters, then reads and writes of `PMXEVCNTR_EL0` are **CONSTRAINED UNPREDICTABLE**, and the following behaviors are permitted:

- Accesses to the register are **UNDEFINED**.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOOP.
- Accesses to the register behave as if `PMSELR_EL0.SEL` has an **UNKNOWN** value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and `PMSELR_EL0.SEL` is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by `PMUSERENR_EL0.{ER,EN}`.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, `MDCR_EL2.HPMN` identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see `MDCR_EL2.HPMN`.

Accesses to this register use the following encodings in the System register encoding space:

D17.5.19 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

**Purpose**
When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<n>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

**Configurations**
AArch64 System register PMXEVTYPER_EL0 bits [31:0] are architecturally mapped to AArch32 System register PMXEVTYPER[31:0].
This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMXEVTYPER_EL0 are UNDEFINED.

**Attributes**
PMXEVTYPER_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Event type register or PMCCFILTR_EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
</tr>
<tr>
<td>32</td>
</tr>
<tr>
<td>Event type register or PMCCFILTR_EL0</td>
</tr>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**Bits [63:0]**
When PMSELR_EL0.SEL == 31, this register accesses PMCCFILTR_EL0.
Otherwise, this register accesses PMEVTYPER<n>_EL0 where n is the value in PMSELR_EL0.SEL.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing PMXEVTYPER_EL0**
If FEAT_FGT is implemented, and PMSELR_EL0.SEL is not 31 and is greater than or equal to the number of accessible event counters, then the behavior of permitted reads and writes of PMXEVTYPER_EL0 is as follows:
- If PMSELR_EL0.SEL selects an unimplemented event counter, the access is UNDEFINED.
- Otherwise, the access is trapped to EL2.

If FEAT_FGT is not implemented, and PMSELR_EL0.SEL is not 31 and is greater than or equal to the number of accessible event counters, then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:
- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of event counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_EL0.SEL is 31.
• If EL2 is implemented and enabled in the current Security state, PMSELR_EL0 is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see MDCR_EL2.HPMN.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, PMXEVTPER_EL0**

D17.6 Activity Monitors registers

This section lists the Activity Monitors registers in AArch64.
D17.6.1 AMCFGR_EL0, Activity Monitors Configuration Register

The AMCFGR_EL0 characteristics are:

Purpose

Global configuration register for the activity monitors.
Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters.
AMCFGR_EL0 is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch64 System register AMCFGR_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCFGR[31:0].
AArch64 System register AMCFGR_EL0 bits [31:0] are architecturally mapped to External register AMCFGR[31:0].
This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCFGR_EL0 are UNDEFINED.

Attributes

AMCFGR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]
Reserved, RES0.

NCG, bits [31:28]
Defines the number of counter groups.
The number of implemented counter groups is [AMCFGR_EL0.NCG + 1].
If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of 0b0000. Otherwise, this field has a value of 0b0001.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Bits [27:25]
Reserved, RES0.

HDBG, bit [24]
Halt-on-debug supported.
This feature must be supported, and so this bit is 0b1.
0b0 AMCR_EL0.HDBG is RES0.
0b1 AMCR_EL0.HDBG is read/write.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.
Bits [23:14]

Reserved, RAZ.

SIZE, bits [13:8]

Defines the size of activity monitor event counters.
The size of the activity monitor event counters implemented by the activity monitors Extension is
[AMCFGR_EL0.SIZE + 1].

--- Note ---

Software also uses this field to determine the spacing of counters in the memory-map. From Armv8,
the counters are at doubleword-aligned addresses.

---

Reads as 0b111111.
Access to this field is RO.

N, bits [7:0]

Defines the number of activity monitor event counters.
The total number of counters implemented in all groups by the Activity Monitors Extension is
[AMCFGR_EL0.N + 1].
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Accessing AMCFGR_EL0

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, AMCFGR_EL0**

### D17.6.2 AMCG1IDR_EL0, Activity Monitors Counter Group 1 Identification Register

The AMCG1IDR_EL0 characteristics are:

**Purpose**

Defines which auxiliary counters are implemented, and which of them have a corresponding virtual offset register, AMEVCNTVOFF1<n>_EL2 implemented.

**Configurations**

This register is present only when FEAT_AMUv1p1 is implemented. Otherwise, direct accesses to AMCG1IDR_EL0 are UNDEFINED.

**Attributes**

AMCG1IDR_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0</td>
<td></td>
</tr>
</tbody>
</table>

**AMEVCNTOFF1<n>_EL2, bit [n+16], for n = 15 to 0**

Indicates which implemented auxiliary counters have a corresponding virtual offset register, AMEVCNTVOFF1<n>_EL2 implemented.

- **0b0** When read, mean that AMEVCNTR1<n>_EL0 does not have an offset, or is not implemented.
- **0b1** When read, means the offset AMEVCNTVOFF1<n>_EL2 is implemented for AMEVCNTR1<n>_EL0.

**AMEVCNTR1<n>_EL0, bit [n], for n = 15 to 0**

Indicates which auxiliary counters AMEVCNTR1<n>_EL0 are implemented.

- **0b0** When read, means that AMEVCNTR1<n>_EL0 is not implemented.
- **0b1** When read, means that AMEVCNTR1<n>_EL0 is implemented.
Accessing AMCG1IDR_EL0

### D17.6.3 AMCGCR_EL0, Activity Monitors Counter Group Configuration Register

The AMCGCR_EL0 characteristics are:

**Purpose**

Provides information on the number of activity monitor event counters implemented within each counter group.

**Configurations**

AArch64 System register AMCGCR_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCGCR[31:0].

AArch64 System register AMCGCR_EL0 bits [31:0] are architecturally mapped to External register AMCGCR[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCGCR_EL0 are UNDEFINED.

**Attributes**

AMCGCR_EL0 is a 64-bit register.

**Field descriptions**

**Bits [63:16]**

Reserved, RES0.

**CG1NC, bits [15:8]**

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In an implementation that includes FEAT_AMUv1, the permitted range of values is 0x0 to 0x10.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**CG0NC, bits [7:0]**

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

Reads as 0x04.

Access to this field is RO.

**Accessing AMCGCR_EL0**

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, AMCGCR_EL0

D17.6.4 AMCNTENCLR0_EL0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0_EL0 characteristics are:

**Purpose**

Disable control bits for the architected activity monitors event counters, AMEVCNTR0<n>_EL0.

**Configurations**

AArch64 System register AMCNTENCLR0_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCNTENCLR0[31:0].

AArch64 System register AMCNTENCLR0_EL0 bits [31:0] are architecturally mapped to External register AMCNTENCLR0[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0_EL0 are UNDEFINED.

**Attributes**

AMCNTENCLR0_EL0 is a 64-bit register.

**Field descriptions**

Bits [63:16]

Reserved, RES0.

Bits [15:4]

Reserved, RAZ/WI.

This field is reserved for additional architected activity monitor event counters, which Arm might define in a future version of the Activity Monitors architecture.

P<n>, bit [n], for n = 3 to 0

Activity monitor event counter disable bit for AMEVCNTR0<n>_EL0.

**Note**

AMCGCR_EL0.CG0NC identifies the number of architected activity monitor event counters. In an implementation that includes FEAT_AMUv1, the number of architected activity monitor event counters is 4.

Possible values of each bit are:

0b0 When read, means that AMEVCNTR0<n>_EL0 is disabled. When written, has no effect.

0b1 When read, means that AMEVCNTR0<n>_EL0 is enabled. When written, disables AMEVCNTR0<n>_EL0.

The reset behavior of this field is:

- On an AMU reset, this field resets to 0.

**Accessing AMCNTENCLR0_EL0**

Accesses to this register use the following encodings in the System register encoding space:
if PSTATE.EL == EL0 then

D17.6.5  AMCNTENCLR1_EL0, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1_EL0 characteristics are:

**Purpose**

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>_EL0.

**Configurations**

AArch64 System register AMCNTENCLR1_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCNTENCLR1[31:0].

AArch64 System register AMCNTENCLR1_EL0 bits [31:0] are architecturally mapped to External register AMCNTENCLR1[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1_EL0 are UNDEFINED.

**Attributes**

AMCNTENCLR1_EL0 is a 64-bit register.

**Field descriptions**

| Bits [63:16] | Reserved, RES0. |
| P<n>, bit [n], for n = 15 to 0 |

Activity monitor event counter disable bit for AMEVCNTR1<n>_EL0.

When N is less than 16, bits [15:N] are RAZ/WI, where N is the value in AMCGCR_EL0.CG1NC.

Possible values of each bit are:

- **0b0**  When read, means that AMEVCNTR1<n>_EL0 is disabled. When written, has no effect.

- **0b1**  When read, means that AMEVCNTR1<n>_EL0 is enabled. When written, disables AMEVCNTR1<n>_EL0.

The reset behavior of this field is:

- On an AMU reset, this field resets to 0.

**Accessing AMCNTENCLR1_EL0**

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1_EL0 are UNDEFINED.

**Note**

The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR_EL0.NCG == 0b0000.

D17.6.7 AMCNTENSET1_EL0, Activity Monitors Count Enable Set Register 1

The AMCNTENSET1_EL0 characteristics are:

**Purpose**

Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<\text{n}>_EL0.

**Configurations**

AArch64 System register AMCNTENSET1_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCNTENSET1[31:0].

AArch64 System register AMCNTENSET1_EL0 bits [31:0] are architecturally mapped to External register AMCNTENSET1[31:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1_EL0 are UNDEFINED.

**Attributes**

AMCNTENSET1_EL0 is a 64-bit register.

**Field descriptions**

![Field diagram]

Bits [63:16]

Reserved, RES0.

P<\text{n}>, bit \text{n}, for \text{n} = 15 to 0

Activity monitor event counter enable bit for AMEVCNTR1<\text{n}>_EL0.

When \text{N} is less than 16, bits [15:\text{N}] are RAZ/WI, where \text{N} is the value in AMCGCR_EL0.CG1NC.

Possible values of each bit are:

0b0 When read, means that AMEVCNTR1<\text{n}>_EL0 is disabled. When written, has no effect.

0b1 When read, means that AMEVCNTR1<\text{n}>_EL0 is enabled. When written, enables AMEVCNTR1<\text{n}>_EL0.

The reset behavior of this field is:

- On an AMU reset, this field resets to 0.

**Accessing AMCNTENSET1_EL0**

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1_EL0 are UNDEFINED.

**Note**

The number of auxiliary activity monitor counters implemented is zero when AMCFGCR_EL0.NCG == 0b0000.

Accesses to this register use the following encodings in the System register encoding space:

D17.6.8 AMCR_EL0, Activity Monitors Control Register

The AMCR_EL0 characteristics are:

**Purpose**
Global control register for the activity monitors implementation. AMCR_EL0 is applicable to both the architected and the auxiliary counter groups.

**Configurations**
AArch64 System register AMCR_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMCR[31:0].
AArch64 System register AMCR_EL0 bits [31:0] are architecturally mapped to External register AMCR[31:0].
This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMCR_EL0 are UNDEFINED.

**Attributes**
AMCR_EL0 is a 64-bit register.

**Bits [63:18]**
Reserved, RES0.

**CG1RZ, bit [17]**

*When FEAT_AMUv1p1 is implemented:*
Counter Group 1 Read Zero.

0b0 System register reads of AMEVCNTR1<n>_EL0 return the event count at all implemented and enabled Exception levels.

0b1 If the current Exception level is the highest implemented Exception level, system register reads of AMEVCNTR1<n>_EL0 return the event count. Otherwise, reads of AMEVCNTR1<n>_EL0 return a zero value.

**Note**
Reads from the memory-mapped view are unaffected by this field.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [16:11]**
Reserved, RES0.
HDBG, bit [10]

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

- **0b0**: Activity monitors do not halt counting when the PE is halted in Debug state.
- **0b1**: Activity monitors halt counting when the PE is halted in Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [9:0]**

Reserved, RES0.

D17.6.9 AMEVCNTR0<n>_EL0, Activity Monitors Event Counter Registers 0, n = 0 - 3

The AMEVCNTR0<n>_EL0 characteristics are:

**Purpose**

Provides access to the architected activity monitor event counters.

**Configurations**

AArch64 System register AMEVCNTR0<n>_EL0 bits [63:0] are architecturally mapped to
AArch32 System register AMEVCNTR0<n>[63:0].

AArch64 System register AMEVCNTR0<n>_EL0 bits [63:0] are architecturally mapped to
External register AMEVCNTR0<n>[63:0].

This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to
AMEVCNTR0<n>_EL0 are UNDEFINED.

**Attributes**

AMEVCNTR0<n>_EL0 is a 64-bit register.

**Field descriptions**

```
+--------+--------+
| 63     | 32     |
| 31     | 0      |

ACNT
```

**ACNT, bits [63:0]**

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is
a number from 0 to 3.

If FEAT_AMUv1p1 is implemented, HCR_EL2.AMVOFFEN is 1, SCR_EL3.AMVOFFEN is 1,
HCR_EL2.{E2H, TGE} is not {1,1}, and EL2 is implemented in the current Security state, access
to these registers at EL0 or EL1 return (PCount<63:0> - AMEVCNTRVOFF0<n>_EL2<63:0>).

PCount is the physical count returned when AMEVCNTR0<n>_EL0 is read from EL2 or EL3.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

The reset behavior of this field is:

- On an AMU reset, this field resets to 0.

**Accessing AMEVCNTR0<n>_EL0**

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of
AMEVCNTR0<n>_EL0 are UNDEFINED.

--- Note ---

AMECGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

D17.6.14 AMEVTYPE1<n>_EL0, Activity Monitors Event Type Registers 1, n = 0 - 15

The AMEVTYPE1<n>_EL0 characteristics are:

**Purpose**
Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<n>_EL0 counts.

**Configurations**
AArch64 System register AMEVTYPE1<n>_EL0 bits [31:0] are architecturally mapped to AArch32 System register AMEVTYPE1<n>[31:0].
AArch64 System register AMEVTYPE1<n>_EL0 bits [31:0] are architecturally mapped to External register AMEVTYPE1<n>[31:0].
This register is present only when FEAT_AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPE1<n>_EL0 are UNDEFINED.

**Attributes**
AMEVTYPE1<n>_EL0 is a 64-bit register.

**Field descriptions**

**Bits [63:16]**
Reserved, RES0.

**evtCount, bits [15:0]**
Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<n>_EL0.
It is IMPLEMENTATION DEFINED what values are supported by each counter.
If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<n>_EL0, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

The event counted by AMEVCNTR1<n>_EL0 might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<n>_EL0 is enabled, writes to this register have UNPREDICTABLE results.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing AMEVTYPE1<n>_EL0**
If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPE1<n>_EL0 are UNDEFINED.

---
**Note**
AMCGCR_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

Traps EL0 accesses to the activity monitors registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value 0x18:
  - AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.

- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value 0x03, MRCC and MCRR accesses are trapped and reported using EC syndrome value 0x04:
  - AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVCNTR0<n>, AMEVCNTR1<n>, AMEVTYPER0<n>, and AMEVTYPER1<n>.

0b0  EL0 accesses to the activity monitors registers are trapped.

0b1  This control does not cause any instructions to be trapped. Software can access all activity monitor registers at EL0.

**Note**

AMUSERENR_EL0 can always be read at EL0 and is not governed by this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Accessing AMUSERENR_EL0

Accesses to this register use the following encodings in the System register encoding space:

### MRS <Xt>, AMUSERENR_EL0

<table>
<thead>
<tr>
<th>op0</th>

D17.7  Statistical Profiling Extension registers

This section lists the Statistical Profiling Extension registers in AArch64.
D17.7.1 PMBIDR_EL1, Profiling Buffer ID Register

The PMBIDR_EL1 characteristics are:

**Purpose**

Provides information to software as to whether the buffer can be programmed at the current Exception level.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBIDR_EL1 are UNDEFINED.

**Attributes**

PMBIDR_EL1 is a 64-bit register.

**Field descriptions**

Bits [63:12]

Reserved, RES0.

EA, bits [11:8]

External Abort handling. Describes how the PE manages External aborts on writes made by the Statistical Profiling Unit to the Profiling Buffer.

- 0b0000 Not described.
- 0b0001 The PE ignores External aborts on writes made by the Statistical Profiling Unit.
- 0b0010 The External abort generates an SError interrupt at the PE.

All other values are reserved.

From Armv8.8, the value 0b0000 is not permitted.

PMBIDR_EL1.EA describes only External aborts generated by the write to memory. External aborts on a translation table walk made by the Statistical Profiling Unit generate Profiling Buffer management events reported as MMU faults using PMBSR_EL1.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bits [7:6]

Reserved, RES0.

**F, bit [5]**

Flag updates. Describes how address translations performed by the Statistical Profiling Unit manage the Access flag and dirty state.

- 0b0 Hardware management of the Access flag and dirty state for accesses made by the Statistical Profiling Unit is always disabled for all translation stages.
- 0b1 Hardware management of the Access flag and dirty state for accesses made by the Statistical Profiling Unit is controlled in the same way as explicit memory accesses in the Profiling Buffer owning translation regime.
Note

If hardware management of the Access flag is disabled for a stage of translation, an access to a Page or Block with the Access flag bit not set in the descriptor will generate an Access Flag fault.

If hardware management of the dirty state is disabled for a stage of translation, an access to a Page or Block will ignore the Dirty Bit Modifier in the descriptor and might generate a Permission fault, depending on the values of the access permission bits in the descriptor.

From Armv8.8, the value 0 is not permitted.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

P, bit [4]

Programming not allowed. When read at EL3, this field reads as zero. Otherwise, indicates that the Profiling Buffer is owned by a higher Exception level or another Security state. Defined values are:

0b0 Programming is allowed.
0b1 Programming not allowed.

The value read from this field depends on the current Exception level and the Effective values of MDCR_EL3.NSPB, MDCR_EL3.NSPBE, and MDCR_EL2.E2PB:

- If EL3 is implemented, and the owning Security state is Secure state, this field reads as one from:
  - Non-secure EL1 and Non-secure EL2.
  - If FEAT_RME is implemented, Realm EL1 and Realm EL2.
  - If Secure EL2 is implemented and enabled, and MDCR_EL2.E2PB is 0b00, Secure EL1.

- If EL3 is implemented, and the owning Security state is Non-secure state, this field reads as one from:
  - Secure EL1.
  - If Secure EL2 is implemented, Secure EL2.
  - If EL2 is implemented and MDCR_EL2.E2PB is 0b00, Non-secure EL1.
  - If FEAT_RME is implemented, Realm EL1 and Realm EL2.

- If FEAT_RME is implemented, and the owning Security state is Realm state, this field reads as one from:
  - Non-secure EL1 and Non-secure EL2.
  - Secure EL1 and Secure EL2.
  - If MDCR_EL2.E2PB is 0b00, Realm EL1.

- If EL3 is not implemented, EL2 is implemented, and MDCR_EL2.E2PB is 0b00, this field reads as one from EL1.

- Otherwise, this field reads as zero.

Align, bits [3:0]

Defines the minimum alignment constraint for writes to PMBPTR_EL1. Defined values are:

0b0000 Byte.
0b0001 Halfword.
0b0010 Word.
0b0011 Doubleword.
0b0100 16 bytes.
0b0101 32 bytes.
0b0110 64 bytes.
Accessing PMBIDR_EL1

Access to this field is RO.

For more information, see Restrictions on the current write pointer on page D13-5458.

This field has an IMPLEMENTATION DEFINED value.

### Accessing PMBIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

#### MRS <Xt>, PMBIDR_EL1

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b000</td>
<td>0b1001</td>
<td>0b1010</td>
<td>0b111</td>
</tr>
</tbody>
</table>

If this field is non-zero, then every record is a multiple of this size.

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && (!HaveEL(EL3) || SCR_EL3.FGTEn == '1') && HDFGRTR_EL2.PMBIDR_EL1 == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    X[t, 64] = PMBIDR_EL1;
elsif PSTATE.EL == EL2 then
  X[t, 64] = PMBIDR_EL1;
elsif PSTATE.EL == EL3 then
  X[t, 64] = PMBIDR_EL1;
D17.7.2 PMBLIMITR_EL1, Profiling Buffer Limit Address Register

The PMBLIMITR_EL1 characteristics are:

**Purpose**

Defines the upper limit for the profiling buffer, and enables the profiling buffer

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBLIMITR_EL1 are UNDEFINED.

**Attributes**

PMBLIMITR_EL1 is a 64-bit register.

**Field descriptions**

LIMIT, bits [63:12]

Limit address. PMBLIMITR_EL1.LIMIT:Zeros(12) is the address of the first byte in memory after the last byte in the profiling buffer. If the smallest implemented translation granule is not 4KB, then bits[N-1:12] are RES0, where N is the IMPLEMENTATION DEFINED value, Log2(smallest implemented translation granule).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:6]

Reserved, RES0.

PMFZ, bit [5]

*When FEAT_SPEv1p2 is implemented:*

Freeze PMU on SPE event. Stop PMU event counters when PMBSR_EL1.S == 1.

0b0 Do not freeze PMU event counters on Statistical Profiling Buffer Management event.

0b1 Freeze PMU event counters on Statistical Profiling Buffer Management event.

The PMU event counters affected by this control is controlled by PMCR_EL0.FZS and, if EL2 is implemented, MDCR_EL2.HPMFZS. See the descriptions of these control bits for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.
**FM, bits [2:1]**

Fill mode.

- **0b00** Fill mode. Stop collection and raise maintenance interrupt on buffer fill.
- **0b10** When FEAT_SPEv1p2 is implemented: Discard mode. All output is discarded.

All other values are reserved.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**E, bit [0]**

Profiling Buffer enable

- **0b0** All output is discarded.
- **0b1** Profiling buffer enabled.

The reset behavior of this field is:
- On a Warm reset, this field resets to **0**.

### Accessing PMBLIMITR_EL1

D17.7.3 PMBPTR_EL1, Profiling Buffer Write Pointer Register

The PMBPTR_EL1 characteristics are:

**Purpose**

Defines the current write pointer for the profiling buffer.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBPTR_EL1 are UNDEFINED.

**Attributes**

PMBPTR_EL1 is a 64-bit register.

**Field descriptions**

![Field diagram]

**PTR, bits [63:0]**

Current write address. Defines the virtual address of the next entry to be written to the buffer.

The architecture places restrictions on the values software can write to the pointer. For more information see *Restrictions on the current write pointer* on page D13-5458.

**Note**

As a result, an implementation might treat some of bits[M:0], where M is defined by PMBIDR_EL1.Align, as RES0.

On a management interrupt, PMBPTR_EL1 is frozen.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.7.4 PMBSR_EL1, Profiling Buffer Status/syndrome Register

The PMBSR_EL1 characteristics are:

**Purpose**

Provides syndrome information to software when the buffer is disabled because the management interrupt has been raised.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMBSR_EL1 are UNDEFINED.

**Attributes**

PMBSR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>

</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**EC, bits [31:26]**

Event class. Top-level description of the cause of the buffer management event.

**EC == 0b000000**

Other buffer management event. All buffer management events other than those described by other defined Event class codes.

See MSS encoding for other buffer management events.

**EC == 0b011110**

*When FEAT_RME is implemented:*

Granule Protection Check fault, other than GPF, on write to Profiling Buffer.

See MSS encoding for Granule Protection Check fault.

**EC == 0b011111**

Buffer management event for an IMPLEMENTATION DEFINED reason.

See MSS encoding for a buffer management event for an IMPLEMENTATION DEFINED reason.

**EC == 0b100100**

Stage 1 Data Abort on write to Profiling Buffer.

See MSS encoding for stage 1 or stage 2 Data Aborts on write to buffer.

**EC == 0b100101**

Stage 2 Data Abort on write to Profiling Buffer.

See MSS encoding for stage 1 or stage 2 Data Aborts on write to buffer.

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [25:20]**

Reserved, RES0.

**DL, bit [19]**

Partial record lost.

Following a buffer management event other than an asynchronous External abort, indicates whether the last record written to the Profiling Buffer is complete.

- 0\(b\)0  PMBPTR_EL1 points to the first byte after the last complete record written to the Profiling Buffer.
- 0\(b\)1  Part of a record was lost because of a buffer management event or synchronous External abort. PMBPTR_EL1 might not point to the first byte after the last complete record written to the buffer, and so restarting collection might result in a data record stream that software cannot parse. All records prior to the last record have been written to the buffer.

When the buffer management event was because of an asynchronous External abort, this bit is set to 1 and software must not assume that any valid data has been written to the Profiling Buffer.

This bit is RES0 if the PE never sets this bit as a result of a buffer management event caused by an asynchronous External abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EA, bit [18]**

External abort.

- 0\(b\)0  An External abort has not been asserted.
- 0\(b\)1  An External abort has been asserted and detected by the Statistical Profiling Unit.

This bit is RES0 if the PE never sets this bit as the result of an External abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**S, bit [17]**

Service

- 0\(b\)0  PMBIRQ is not asserted.
- 0\(b\)1  PMBIRQ is asserted. All profiling data has either been written to the buffer or discarded.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COLL, bit [16]**

Collision detected.

- 0\(b\)0  No collision events detected.
- 0\(b\)1  At least one collision event was recorded.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MSS, bits [15:0]**

Management Event Specific Syndrome.

Contains syndrome specific to the management event.

The syndrome contents for each management event are described in the following sections.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MSS encoding for stage 1 or stage 2 Data Aborts on write to buffer**

![](image)

**Bits [15:6]**
- Reserved, RES0.

**FSC, bits [5:0]**
- Fault status code
  - 0b000000 Address size fault, level 0 of translation or translation table base register.
  - 0b000001 Address size fault, level 1.
  - 0b000010 Address size fault, level 2.
  - 0b000011 Address size fault, level 3.
  - 0b000100 Translation fault, level 0.
  - 0b000101 Translation fault, level 1.
  - 0b000110 Translation fault, level 2.
  - 0b000111 Translation fault, level 3.
  - 0b001001 Access flag fault, level 1.
  - 0b001010 Access flag fault, level 2.
  - 0b001011 Access flag fault, level 3.
  - 0b010000 When FEAT_LPA2 is implemented:
    - Access flag fault, level 0.
  - 0b010100 When FEAT_LPA2 is implemented:
    - Synchronous External abort on translation table walk or hardware update of translation table, level -1.
  - 0b010101 Synchronous External abort on translation table walk or hardware update of translation table, level -1.
  - 0b010110 Synchronous External abort on translation table walk or hardware update of translation table, level 0.
  - 0b010111 Synchronous External abort on translation table walk or hardware update of translation table, level 1.
  - 0b011100 Synchronous External abort on translation table walk or hardware update of translation table, level 2.
  - 0b011110 Synchronous External abort on translation table walk or hardware update of translation table, level 3.
  - 0b011111 When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.

- **0b100001**: Alignment fault.
- **0b100011**: When FEAT_RME is implemented and FEAT_LPA2 is implemented:
  Granule Protection Fault on translation table walk or hardware update of translation table, level -1.
- **0b100100**: When FEAT_RME is implemented:
  Granule Protection Fault on translation table walk or hardware update of translation table, level 0.
- **0b100101**: When FEAT_RME is implemented:
  Granule Protection Fault on translation table walk or hardware update of translation table, level 1.
- **0b100110**: When FEAT_RME is implemented:
  Granule Protection Fault on translation table walk or hardware update of translation table, level 2.
- **0b100111**: When FEAT_RME is implemented:
  Granule Protection Fault on translation table walk or hardware update of translation table, level 3.
- **0b101000**: When FEAT_LPA2 is implemented:
  Granule Protection Fault, not on translation table walk or hardware update of translation table.
- **0b101001**: When FEAT_LPA2 is implemented:
  Address size fault, level -1.
- **0b101011**: When FEAT_LPA2 is implemented:
  Translation fault, level -1.
- **0b110000**: TLB conflict abort.
- **0b110001**: When FEAT_HAFDBS is implemented:
  Unsupported atomic hardware update fault.

All other values are reserved.

It is IMPLEMENTATION DEFINED whether each of the Access Flag fault, asynchronous External abort and synchronous External abort, Alignment fault, and TLB Conflict abort values can be generated by the PE. For more information see Faults and watchpoints on page D13-5464.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### MSS encoding for other buffer management events

![MSS diagram]

**Bits [15:6]**
- Reserved, RES0.

**BSC, bits [5:0]**
- Buffer status code
  - **0b000000**: Buffer not filled
  - **0b000001**: Buffer filled

All other values are reserved. Reserved values might be defined in a future version of the architecture.
Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.7.5 PMSCR_EL1, Statistical Profiling Control Register (EL1)

The PMSCR_EL1 characteristics are:

**Purpose**

Provides EL1 controls for Statistical Profiling.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSCR_EL1 are undefined.

**Attributes**

PMSCR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

If EL2 is enabled in the current Security state, then the value of PMSCR_EL2.PCT might override or modify the meaning of this field.

This field is ignored by the PE when the Profiling Buffer owning Exception level is EL2.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally unknown value.

Otherwise:

Physical Timestamp. Reserved. This field reads as 0b01 and ignores writes. Software should treat this field as UNK/SBZP.

When EL2 is not implemented, the Effective values of CNTVOFF_EL2 and CNTPOFF_EL2 are zero, meaning the virtual counter and physical counter have the same value.
**TS, bit [5]**

Timestamp enable.

0b0  Timestamp sampling disabled.
0b1  Timestamp sampling enabled.

This bit is ignored by the PE if EL2 is implemented and the Profiling Buffer is owned by EL2. For more information, see *Controlling the data that is collected* on page D13-5455.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**PA, bit [4]**

Physical Address sample enable.

0b0  Physical addresses are not collected.
0b1  Physical addresses are collected.

If EL2 is implemented:

- If the Profiling Buffer is owned by EL1, this bit is combined with PMSCR_EL2.PA to determine which address is collected. For more information, see *Controlling the data that is collected* on page D13-5455.
- If the Profiling Buffer is owned by EL2, this bit is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**CX, bit [3]**

CONTEXTIDR_EL1 sample enable.

0b0  CONTEXTIDR_EL1 is not collected.
0b1  CONTEXTIDR_EL1 is collected.

If EL2 is implemented and enabled in the current Security state when an operation is sampled:

- If the PE is at EL2, this bit is ignored by the PE.
- If HCR_EL2.TGE == 1, this bit is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [2]**

Reserved, RES0.

**E1SPE, bit [1]**

EL1 Statistical Profiling Enable.

0b0  Sampling disabled at EL1.
0b1  Sampling enabled at EL1.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E0SPE, bit [0]**

EL0 Statistical Profiling Enable. Controls sampling at EL0 when HCR_EL2.TGE == 0 or if EL2 is disabled or not implemented.

0b0  Sampling disabled at EL0.
0b1  Sampling enabled at EL0.
If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE = 1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.7.6 PMSCR_EL2, Statistical Profiling Control Register (EL2)

The PMSCR_EL2 characteristics are:

**Purpose**

Provides EL2 controls for Statistical Profiling.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSCR_EL2 are UNDEFINED.

**Attributes**

PMSCR_EL2 is a 64-bit register.

**Field descriptions**

Bits [63:8]

Reserved, RES0.

PCT, bits [7:6]

Physical Timestamp. If timestamp sampling is enabled, determines which counter is collected. The behavior depends on the Profiling Buffer owning Exception level.

If FEAT_ECV is implemented, this is a two-bit field as shown. Otherwise, bit[7] is RES0.

0b00 Virtual timestamp. The collected timestamp is the physical counter minus a virtual offset. If any of the following are true, the virtual offset is zero, otherwise the virtual offset is the value of CNTVOFF_EL2:

- The sampled operation executed at EL2 and HCR_EL2.E2H == 1.
- The sampled operation executed at EL0 and HCR_EL2.{E2H,TGE} == {1,1}.

  **Note**

  If the Profiling Buffer owning Exception level is EL1, the virtual offset is always CNTVOFF_EL2.

0b01 If the Profiling Buffer owning Exception level is EL1, then the timestamp value is selected by PMSCR_EL1.PCT.

Otherwise, physical timestamp. The collected timestamp is the physical counter.

0b11 **When FEAT_ECV is implemented:**

If the Profiling Buffer owning Exception level is EL1 and PMSCR_EL1.PCT == 0b00, then guest virtual timestamp. The collected timestamp is the physical counter minus the value of CNTVOFF_EL2.

Otherwise, guest physical timestamp. The collected timestamp is the physical counter minus a physical offset. If any of the following are true, the physical offset is zero, otherwise the physical offset is the value of CNTPOFF_EL2:

- SCR_EL3.ECVEn == 0.
- CNTHCTL_EL2.ECV == 0.
All other values are reserved.

If EL2 is not implemented or EL2 is disabled in the current Security state, then the Effective value of this field is 0b01, other than for a direct read of the register.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**TS, bit [5]**

Timestamp Enable.

0b0 Timestamp sampling disabled.
0b1 Timestamp sampling enabled.

This bit is ignored by the PE when any of the following are true:
• The Profiling Buffer owning Exception level is EL1.
• In Secure state, and either FEAT_SEL2 is not implemented or Secure EL2 is disabled.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**PA, bit [4]**

Physical Address Sample Enable.

0b0 Physical addresses are not collected.
0b1 Physical addresses are collected.

If the Profiling Buffer owning Exception level is EL1, and EL2 is enabled in the current Security state, this bit is combined with PMSCR_EL1.PA to determine which address is collected.

If EL2 is not implemented or EL2 is disabled in the current Security state, the PE ignores the value of this bit and behaves as if this bit is set to 1, other than for a direct read of the register.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**CX, bit [3]**

CONTEXTIDR_EL2 Sample Enable.

0b0 CONTEXTIDR_EL2 is not collected.
0b1 CONTEXTIDR_EL2 is collected.

If EL2 is not implemented or EL2 is disabled in the current Security state, the PE ignores the value of this bit.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [2]**

Reserved, RES0.

**E2SPE, bit [1]**

EL2 Statistical Profiling Enable.

0b0 Sampling disabled at EL2.
0b1 Sampling enabled at EL2.

This bit is RES0 if MDCR_EL2.E2PB != 0b00.

If EL2 is disabled in the current Security state, this bit is ignored by the PE.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
E0HSPE, bit [0]

EL0 Statistical Profiling Enable.

0b0  Sampling disabled at EL0.
0b1  Sampling enabled at EL0.

If MDCR_EL2.E2PB != 0b00, this bit is RES0.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 0.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

"
D17.7.7 PMSEVFR_EL1, Sampling Event Filter Register

The PMSEVFR_EL1 characteristics are:

**Purpose**

Controls sample filtering by events. The overall filter is the logical AND of these filters. For example, if PMSEVFR_EL1.E[3] and PMSEVFR_EL1.E[5] are both set to 1, only samples that have both event 3 (Level 1 unified or data cache refill) and event 5 (TLB walk) set to 1 are recorded.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSEVFR_EL1 are UNDEFINED.

**Attributes**

PMSEVFR_EL1 is a 64-bit register.

**Field descriptions**

E[<x>], bit [x], for x = 63 to 48, 31 to 24, 15 to 12

E[<x>] is the event filter for event <x>. If event <x> is not implemented, or filtering on event <x> is not supported, the corresponding bit is RAZ/WI.

0b0  Event <x> is ignored.
0b1  Do not record samples that have event <x> == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event. This field is ignored by the PE when PMSFCR_EL1.FE == 0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [47:32]**

Reserved, RAZ/WI.
Bits [23:19]  
Reserved, RAZ/WI.

E[18], bit [18]  
When FEAT_SPEv1p1 is implemented and FEAT_SVE is implemented:
Empty predicate.  
0b0 Empty predicate event is ignored.  
0b1 Do not record samples that have the Empty predicate event == 0.  
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.  
The reset behavior of this field is:  
• On a Warm reset, this field resets to an architecturally UNKNOWN value.  
Otherwise:  
Reserved, RAZ/WI.

E[17], bit [17]  
When FEAT_SPEv1p1 is implemented and FEAT_SVE is implemented:
Partial predicate.  
0b0 Partial predicate event is ignored.  
0b1 Do not record samples that have the Partial predicate event == 0.  
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.  
The reset behavior of this field is:  
• On a Warm reset, this field resets to an architecturally UNKNOWN value.  
Otherwise:  
Reserved, RAZ/WI.

E[16], bit [16]  
When FEAT_TME is implemented:  
Transactional  
0b0 Transactional event is ignored.  
0b1 Do not record samples that have the Transactional event == 0.  
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.  
The reset behavior of this field is:  
• On a Warm reset, this field resets to an architecturally UNKNOWN value.  
Otherwise:  
Reserved, RAZ/WI.

When FEAT_SPEv1p1 is implemented:  
Alignment.  
0b0 Alignment event is ignored.  
0b1 Do not record samples that have the Alignment event == 0.  
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.  
The reset behavior of this field is:  
• On a Warm reset, this field resets to an architecturally UNKNOWN value.  
Otherwise:  
Reserved, RAZ/WI.
Bits [10:8]
Reserved, RAZ/WI.

E[7], bit [7]
Mispredicted.
0b0 Mispredicted event is ignored.
0b1 Do not record samples that have the Mispredicted event == 0.
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E[6], bit [6]
When FEAT_SPEv1p2 is implemented:
Not taken.
0b0 Not taken event is ignored.
0b1 Do not record samples that have the Not taken event == 0.
This field is ignored by the PE when PMSFCR_EL1.FE == 0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RAZ/WI.

E[5], bit [5]
TLB walk.
0b0 TLB walk event is ignored.
0b1 Do not record samples that have the TLB walk event == 0.
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [4]
Reserved, RAZ/WI.

E[3], bit [3]
Level 1 data or unified cache refill.
0b0 Level 1 data or unified cache refill event is ignored.
0b1 Do not record samples that have the Level 1 data or unified cache refill event == 0.
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [2]
Reserved, RAZ/WI.

E[1], bit [1]
When the PE supports sampling of speculative instructions:
Architecturally executed.
When the PE supports sampling of speculative instructions:
0b0 Architecturally executed event is ignored.
0b1  Do not record samples that have the Architecturally executed event == 0.
This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

If the PE does not support the sampling of speculative instructions, or always discards the sample
record for speculative instructions, this bit reads as an UNKNOWN value and the PE ignores its value.
The reset behavior of this field is:
•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, UNKNOWN.

**Bit [0]**
Reserved, RAZ/WI.

**Accessing PMSEVFR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

D17.7.8 PMSFCR_EL1, Sampling Filter Control Register

The PMSFCR_EL1 characteristics are:

**Purpose**

Controls sample filtering. The filter is the logical AND of the FL, FT and FE bits. For example, if FE == 1 and FT == 1 only samples including the selected operation types and the selected events will be recorded.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSFCR_EL1 are **UNDEFINED**.

**Attributes**

PMSFCR_EL1 is a 64-bit register.

**Field descriptions**

![Field Diagram]

**Bits [63:19]**

Reserved, RES0.

**ST, bit [18]**

Store filter enable

- **0b0** Do not record store operations
- **0b1** Record all store operations, including vector stores and all atomic operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**LD, bit [17]**

Load filter enable

- **0b0** Do not record load operations
- **0b1** Record all load operations, including vector loads and atomic operations that return data

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**B, bit [16]**

Branch filter enable

- **0b0** Do not record branch and exception return operations
- **0b1** Record all branch and exception return operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Bits [15:4]
Reserved, RES0.

FnE, bit [3]

When FEAT_SPEv1p2 is implemented:
Filter by event, inverted.
0b0 Inverted event filtering disabled.
0b1 Inverted event filtering enabled. Samples including the events selected by PMSNEVFR_EL1 will not be recorded.

If any of the following are true, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FnE == 0:
• PMSFCR_EL1.FnE == 1 and PMSNEVFR_EL1 is zero.
• PMSFCR_EL1.FnE == 1, PMSFCR_EL1.FE == 1, and there exists a value x such that PMSFELV_EL1.E[x] == 1 and PMSNEVFR_EL1.E[x] == 1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

FL, bit [2]
Filter by latency
0b0 Latency filtering disabled
0b1 Latency filtering enabled. Samples with a total latency less than PMSLATFR_EL1.MINLAT will not be recorded

If this field is set to 1 and PMSLATFR_EL1.MINLAT is set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FL is set to 0

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

FT, bit [1]
Filter by operation type. The filter is the logical OR of the ST, LD and B bits. For example, if LD and ST are both set, both load and store operations are recorded
0b0 Type filtering disabled
0b1 Type filtering enabled. Samples not one of the selected operation types will not be recorded

If this field is set to 1 and the PMSFCR_EL1.{ST, LD, B} bits are all set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FT is set to 0

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

FE, bit [0]
Filter by event.
0b0 Event filtering disabled.
0b1 Event filtering enabled. Samples not including the events selected by PMSEVFR_EL1 will not be recorded.

If any of the following are true, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FE == 0:
• PMSFCR_EL1.FE == 1 and PMSEVFR_EL1 is zero.
• FEAT_SPEv1p2 is implemented, PMSEVR_EL1.FnE = 1, PMSEVR_EL1.FE = 1, and there exists a value \( x \) such that PMSEVF_EL1.E[\( x \)] = 1 and PMSEVF_EL1.E[\( x \)] = 1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

### D17.7.9 PMSICR_EL1, Sampling Interval Counter Register

The PMSICR_EL1 characteristics are:

**Purpose**

Software must write zero to PMSICR_EL1 before enabling sample profiling for a sampling session. Software must then treat PMSICR_EL1 as an opaque, 64-bit, read/write register used for context switches only.

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSICR_EL1 are **undefined**.

The value of PMSICR_EL1 does not change whilst profiling is disabled.

**Attributes**

PMSICR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-56</td>
<td>ECOUNT</td>
</tr>
<tr>
<td>55-32</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31-0</td>
<td>COUNT</td>
</tr>
</tbody>
</table>

**ECOUNT, bits [63:56]**

*When PMSIDR_EL1.ERnd == 1:*

Secondary sample interval counter.

This field provides the secondary counter used after the primary counter reaches zero. Whilst the secondary counter is nonzero and profiling is enabled, the secondary counter decrements by 1 for each member of the sample population. The primary counter also continues to decrement since it is also nonzero. When the secondary counter reaches zero, a member of the sampling population is selected for sampling.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES0.

**Bits [55:32]**

Reserved, RES0.

**COUNT, bits [31:0]**

Primary sample interval counter

Provides the primary counter used for sampling.

The primary counter is reloaded when the value of this register is zero and the PE moves from a state or Exception level where profiling is disabled to a state or Exception level where profiling is enabled. Whilst the primary counter is nonzero and sampling is enabled, the primary counter decrements by 1 for each member of the sample population.

When the counter reaches zero, the behavior depends on the values of PMSIDR_EL1.ERnd and PMSIRR_EL1.RND

*If PMSIRR_EL1.RND == 0 or PMSIDR_EL1.ERnd == 0:*

- A member of the sampling population is selected for sampling
The primary counter is reloaded

- If PMSIRR_EL1.RND == 1 and PMSIDR_EL1.ERnd == 1:
  - The secondary counter is set to a random or pseudorandom value in the range 0x00 to 0xFF
  - The primary counter is reloaded

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing PMSICR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, PMSICR_EL1**

D17.7.10 PMSIDR_EL1, Sampling Profiling ID Register

The PMSIDR_EL1 characteristics are:

**Purpose**
Describes the Statistical Profiling implementation to software

**Configurations**
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSIDR_EL1 are UNDEFINED.

**Attributes**
PMSIDR_EL1 is a 64-bit register.

**Field descriptions**

![Field diagram]

Bits [63:25]
Reserved, RES0.

PBT, bit [24]
Previous branch target Address packet. Defined values are:
- 0b0: Previous branch target Address packet not supported.
- 0b1: Previous branch target Address packet support implemented.

FEAT_SPEv1p2 adds the OPTIONAL functionality identified by the value 1.

Format, bits [23:20]

*From Armv8.7:*
Defines the format of the sample records. Defined values are:
- 0b0000: Format 0.

All other values are reserved.

*Otherwise:*
Reserved, RAZ.

CountSize, bits [19:16]
 Defines the size of the counters.
- 0b0010: 12-bit saturating counters.
- 0b0011: From Armv8.8:
  16-bit saturating counters.

All other values are reserved.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.
MaxSize, bits [15:12]

Defines the largest size for a single record, rounded up to a power-of-two. If this is the same as the minimum alignment (PMBIDR_EL1.Align), then each record is exactly this size. Defined values are:

- 0b0100 16 bytes.
- 0b0101 32 bytes.
- 0b0110 64 bytes.
- 0b0111 128 bytes.
- 0b1000 256 bytes.
- 0b1001 512 bytes.
- 0b1010 1KB.
- 0b1011 2KB.

All other values are reserved.

The values 0b0100 and 0b0101 are not permitted for an implementation.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Interval, bits [11:8]

Recommended minimum sampling interval. This provides guidance from the implementer to the smallest minimum sampling interval, N. Defined values are:

- 0b0000 256.
- 0b0010 512.
- 0b0011 768.
- 0b0100 1,024.
- 0b0101 1,536.
- 0b0110 2,048.
- 0b0111 3,072.
- 0b1000 4,096.

All other values are reserved.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bit [7]

Reserved, RES0.

FnE, bit [6]

Filtering by events, inverted. Defined values are:

- 0b0 PMSNEVFR_EL1 is not implemented and PMSFCR_EL1.FnE is RES0.
- 0b1 PMSNEVFR_EL1 and PMSFCR_EL1.FnE are implemented.

FEAT_SPEv1p2 adds the functionality identified by the value 1.

ERnd, bit [5]

Defines how the random number generator is used in determining the interval between samples, when enabled by PMSIRR_EL1.RND. Defined values are:

- 0b0 The random number is added at the start of the interval, and the sample is taken and a new interval started when the combined interval expires.
- 0b1 The random number is added and the new interval started after the interval programmed in PMSIRR_EL1.INTERVAL expires, and the sample is taken when the random interval expires.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

**LDS, bit [4]**

Data source indicator for sampled load instructions. Defined values are:

- 0b0  Loaded data source not implemented.
- 0b1  Loaded data source implemented.

This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

**ArchInst, bit [3]**

Architectural instruction profiling. Defined values are:

- 0b0  Micro-op sampling implemented.
- 0b1  Architecture instruction sampling implemented.

This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

**FL, bit [2]**

Filtering by latency. This bit is RAO.

**FT, bit [1]**

Filtering by operation type. This bit is RAO.

**FE, bit [0]**

Filtering by events. This bit is RAO.

### Accessing PMSIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

D17.7.11   PMSIRR_EL1, Sampling Interval Reload Register

The PMSIRR_EL1 characteristics are:

Purpose
Defines the interval between samples.

Configurations
This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSIRR_EL1 are UNDEFINED.

Attributes
PMSIRR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]
Reserved, RES0.

INTERVAL, bits [31:8]
Bits [31:8] of the PMSICR_EL1 interval counter reload value. Software must set this to a non-zero value. If software sets this to zero, an UNKNOWN sampling interval is used. Software should set this to a value greater than the minimum indicated by PMSIDR_EL1.Interval.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:1]
Reserved, RES0.

RND, bit [0]
Controls randomization of the sampling interval.

0b0  Disable randomization of sampling interval.
0b1  Add (pseudo-)random jitter to sampling interval.

The random number generator is not architected.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.7.12 PMSLATFR_EL1, Sampling Latency Filter Register

The PMSLATFR_EL1 characteristics are:

**Purpose**

Controls sample filtering by latency

**Configurations**

This register is present only when FEAT_SPE is implemented. Otherwise, direct accesses to PMSLATFR_EL1 are UNDEFINED.

**Attributes**

PMSLATFR_EL1 is a 64-bit register.

**Field descriptions**

**Bits [63:16]**

Reserved, RES0.

**MINLAT, bits [15:0]**

Minimum latency. When PMSFCR_EL1.FL is 1, defines the minimum total latency for filtered operations. Samples with a total latency less than PMSLATFR_EL1.MINLAT are not recorded.

If PMSIDR_EL1.CountSize is 0b0010, PMSLATFR_EL1.MINLAT[15:12] is RES0.

This field is ignored by the PE when PMSFCR_EL1.FL == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing PMSLATFR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

D17.7.13 PMSNEVFR_EL1, Sampling Inverted Event Filter Register

The PMSNEVFR_EL1 characteristics are:

**Purpose**

Controls sample filtering by events. The overall inverted filter is the logical OR of these filters. For example, if PMSNEVFR_EL1.E[3] and PMSNEVFR_EL1.E[5] are both set to 1, samples that have either event 3 (Level 1 unified or data cache refill) or event 5 (TLB walk) set to 1 are not recorded.

**Configurations**

This register is present only when FEAT_SPEv1p2 is implemented. Otherwise, direct accesses to PMSNEVFR_EL1 are UNDEFINED.

**Attributes**

PMSNEVFR_EL1 is a 64-bit register.

**Field descriptions**

E[<x>], bit [x], for x = 63 to 48, 31 to 24, 15 to 12

E[<x>] is the event filter for IMPLEMENTATION DEFINED event <x>.

0b0 Event <x> is ignored.

0b1 Do not record samples that have event <x> == 1.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, the corresponding bits of PMSNEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This bit is ignored by the PE when PMSFCR_EL1.FnE == 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When event <x> is not implemented, or filtering on event <x> is not supported, access to this field is RAZ/WI.
Bits [47:32]  
Reserved, RAZ/WI.

Bits [23:19]  
Reserved, RAZ/WI.

E[18], bit [18]  
*When FEAT_SVE is implemented and FEAT_SPEv1p1 is implemented:*
  
  Not empty predicate.
  
  *0b0*  
  Empty predicate event is ignored.
  
  *0b1*  
  Do not record samples that have the Empty predicate event == 1.
  
  This field is ignored by the PE when PMSFCR_EL1.FnE == 0.
  
  The reset behavior of this field is:
  
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RAZ/WI.

E[17], bit [17]  
*When FEAT_SVE is implemented and FEAT_SPEv1p1 is implemented:*
  
  Not partial predicate.
  
  *0b0*  
  Partial predicate event is ignored.
  
  *0b1*  
  Do not record samples that have the Partial predicate event == 1.
  
  This field is ignored by the PE when PMSFCR_EL1.FnE == 0.
  
  The reset behavior of this field is:
  
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RAZ/WI.

E[16], bit [16]  
*When FEAT_TME is implemented:*
  
  Not transactional.
  
  *0b0*  
  Transactional event is ignored.
  
  *0b1*  
  Do not record samples that have the Transactional event == 1.
  
  This field is ignored by the PE when PMSFCR_EL1.FnE == 0.
  
  The reset behavior of this field is:
  
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RAZ/WI.

*When FEAT_SPEv1p1 is implemented:*
  
  Aligned.
  
  *0b0*  
  Misalignment event is ignored.
  
  *0b1*  
  Do not record samples that have the Misalignment event == 1.
  
  This field is ignored by the PE when PMSFCR_EL1.FnE == 0.
  
  The reset behavior of this field is:
  
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.
**Otherwise:**

Reserved, RAZ/WI.

**Bits [10:8]**

Reserved, RAZ/WI.

**E[7], bit [7]**

Correctly predicted.

0b0 Mispredicted event is ignored.

0b1 Do not record samples that have the Mispredicted event == 1.

This field is ignored by the PE when PMSFCR_EL1.FnE == 0.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E[6], bit [6]**

Taken.

0b0 Not taken event is ignored.

0b1 Do not record samples that have the Not taken event == 1.

This field is ignored by the PE when PMSFCR_EL1.FnE == 0.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E[5], bit [5]**

TLB hit.

0b0 TLB walk event is ignored.

0b1 Do not record samples that have the TLB walk event == 1.

This field is ignored by the PE when PMSFCR_EL1.FnE == 0.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [4]**

Reserved, RAZ/WI.

**E[3], bit [3]**

Level 1 data or unified cache hit.

0b0 Level 1 data or unified cache refill event is ignored.

0b1 Do not record samples that have the Level 1 data or unified cache refill event == 1.

This field is ignored by the PE when PMSFCR_EL1.FnE == 0.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [2]**

Reserved, RAZ/WI.

**E[1], bit [1]**

When the PE supports sampling of speculative instructions:

Speculative.

0b0 Architecturally executed event is ignored.

0b1 Do not record samples that have the Architecturally executed event == 1.

This field is ignored by the PE when PMSFCR_EL1.FnE == 0.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RAZ/WI.

**Bit [0]**

Reserved, RAZ/WI.

**Accessing PMSNEVFR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, PMSNEVFR_EL1**

D17.8 Branch Record Buffer Extension registers

This section lists the Branch Record Buffer registers in AArch64.
D17.8.1   BRBCR_EL1, Branch Record Buffer Control Register (EL1)

The BRBCR_EL1 characteristics are:

Purpose

Controls the Branch Record Buffer.

Configurations

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBCR_EL1 are UNDEFINED.

Attributes

BRBCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:24]  
Reserved, RES0.

EXCEPTION, bit [23]  
Enable the recording of entry to EL1 via an exception.

0b0    Disable the recording of Branch records for exceptions when taken to EL1.
0b1    Enable the recording of Branch records for exceptions when taken to EL1.

The reset behavior of this field is:

• On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
• On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

ERTN, bit [22]  
Allow the recording Branch records for exception return instructions from EL1.

0b0    Disable the recording Branch records for exception return instructions from EL1.
0b1    Enable the recording Branch records for exception return instructions from EL1.

The reset behavior of this field is:

• On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
• On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

Bits [21:9]  
Reserved, RES0.
FZP, bit [8]

*When FEAT_PMUv3 is implemented:*

Freeze BRBE on PMU overflow.

- **0b0**: Branch recording is not affected by this control.
- **0b1**: A BRBE freeze event occurs when a PMU overflow occurs.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally **UNKNOWN** value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, RES0.

Bit [7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control.

- **0b01**: Virtual timestamp. The BRBE recorded timestamp is the physical counter value, minus the value of `CNTVOFF_EL2`.
- **0b10**: *When FEAT_ECV is implemented:*
  
  Guest physical timestamp. The BRBE recorded timestamp is the physical counter value minus a physical offset. If any of the following are true, the physical offset is zero, otherwise the physical offset is the value of `CNTPOFF_EL2`:
  
  - EL3 is implemented and `SCR_EL3.ECVEn == 0`.
  - EL2 is implemented and `CNDTHTL_EL2.ECV == 0`.
- **0b11**: Physical timestamp. The BRBE recorded timestamp is the physical counter value.

All other values are reserved.

This field is ignored by the PE when EL2 is implemented and `BRBCR_EL2.TS != 0b00`.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally **UNKNOWN** value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally **UNKNOWN** value.

MPRED, bit [4]

Mask the recording of mispredicts.

- **0b0**: Disable the recording of mispredict information.
- **0b1**: Allow the recording of mispredict information.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally **UNKNOWN** value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally **UNKNOWN** value.

CC, bit [3]

Enable the recording of cycle count information.

- **0b0**: Disable the recording of cycle count information.
- **0b1**: Allow the recording of cycle count information.
The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

Bit [2]
Reserved, RES0.

E1BRE, bit [1]

EL1 Branch recording enable.

0b0 Branch recording prohibited at EL1.

0b1 Branch recording enabled at EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

E0BRE, bit [0]

EL0 Branch recording enable.

0b0 Branch recording prohibited at EL0.

0b1 Branch recording enabled at EL0.

This field is ignored by the PE when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

Bit [7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control.

- **0b00** Timestamp controlled by BRBCR_EL1.TS.
- **0b01** Virtual timestamp. The BRBE recorded timestamp is the physical counter value, minus the value of CNTVOFF_EL2.
- **0b10** *When FEAT_ECV is implemented:* Guest physical timestamp. The BRBE recorded timestamp is the physical counter value minus a physical offset. If any of the following are true, the physical offset is zero, otherwise the physical offset is the value of CNTPOFF_EL2:
  - EL3 is implemented and SCR_EL3.ECVEn == 0.
  - EL2 is implemented and CNTHCTL_EL2.ECV == 0.
- **0b11** Physical timestamp. The BRBE recorded timestamp is the physical counter value.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

MPRED, bit [4]

Mask the recording of mispredicts.

- **0b0** Disable the recording of mispredict information.
- **0b1** Allow the recording of mispredict information.

If EL2 is not implemented, then the Effective value of this field is 1, other than for a direct read of the register.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

CC, bit [3]

Enable the recording of cycle count information.

- **0b0** Disable the recording of cycle count information.
0b1  Allow the recording of cycle count information.
If EL2 is not implemented, then the Effective value of this field is 1, other than for a direct read of
the register.

The reset behavior of this field is:
• On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an
architecturally UNKNOWN value.
• On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an
architecturally UNKNOWN value.

Bit [2]
Reserved, RES0.

E2BRE, bit [1]
EL2 Branch recording enable.
0b0  Branch recording prohibited at EL2.
0b1  Branch recording enabled at EL2.

The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

E0HBRE, bit [0]
EL0 Branch recording enable.
0b0  Branch recording prohibited at EL0 when HCR_EL2.TGE == 1.
0b1  Branch recording enabled at EL0 when HCR_EL2.TGE == 1.

This field is ignored by the PE when any of the following are true:
• HCR_EL2.TGE == 0.
• EL2 is disabled in the current Security state.

The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

Accessing BRBCR_EL2
When HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the register name BRBCR_EL2
or BRBCR_EL1 are not guaranteed to be ordered with respect to accesses using the other register name.

Accesses to this register use the following encodings in the System register encoding space:

|MRS <Xt>, BRBCR_EL1|
|---|---|---|---|---|
|op0| op1| CRn| CRm| op2|
|0b1| 0b001| 0b1001| 0b0000| 0b000|

D17.8.3 BRBFCR_EL1, Branch Record Buffer Function Control Register

The BRBFCR_EL1 characteristics are:

**Purpose**

Functional controls for the Branch Record Buffer.

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBFCR_EL1 are UNDEFINED.

**Attributes**

BRBFCR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:30]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

| Bits [27:23] | Reserved, RES0. |
| CONDDIR, bit [22] | Match on conditional direct branch instructions. |
| 0b0 | Do not match on conditional direct branch instructions. |
| 0b1 | Match on conditional direct branch instructions. |
| The reset behavior of this field is: |
| • On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value. |
| • On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value. |

| 0b0 | Do not match on direct branch with link instructions. |
0b1 Match on direct branch with link instructions.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

**INDCALL, bit [20]**

Match on indirect branch with link instructions.

0b0 Do not match on indirect branch with link instructions.
0b1 Match on indirect branch with link instructions.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

**RTN, bit [19]**

Match on function return instructions.

0b0 Do not match on function return instructions.
0b1 Match on function return instructions.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

**INDIRECT, bit [18]**

Match on indirect branch instructions.

0b0 Do not match on indirect branch instructions.
0b1 Match on indirect branch instructions.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

**DIRECT, bit [17]**

Match on unconditional direct branch instructions.

0b0 Do not match on unconditional direct branch instructions.
0b1 Match on unconditional direct branch instructions.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

**EnI, bit [16]**

Include or exclude matches.

0b0 Include records for matches, and exclude records for non-matches.
0b1     Exclude records for matches, and include records for non-matches.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

Bits [15:8]
Reserved, RES0.

PAUSED, bit [7]
Branch recording Paused status.

0b0     Branch recording is not Paused.
0b1     Branch recording is Paused.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

LASTFAILED, bit [6]

When FEAT_TME is implemented:
Indicates transaction failure or cancellation.

0b0     Indicates that no transactions in a non-prohibited region have failed or been canceled since the last Branch record was generated.
0b1     Indicates that at least one transaction in a non-prohibited region has failed or been canceled since the last Branch record was generated.

The reset behavior of this field is:

- On a Cold reset, when FEAT_BRBEv1p1 is implemented, this field resets to an architecturally UNKNOWN value.
- On a Warm reset, when FEAT_BRBEv1p1 is not implemented, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [5:0]
Reserved, RES0.

Accessing BRBFCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b10 & 0b001 & 0b1001 & 0b0000 & 0b001 \\
\end{array}
\]

D17.8.4  BRBIDR0_EL1, Branch Record Buffer ID0 Register

The BRBIDR0_EL1 characteristics are:

**Purpose**

Indicates the features of the branch buffer unit.

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBIDR0_EL1 are UNDEFINED.

**Attributes**

BRBIDR0_EL1 is a 64-bit register.

**Field descriptions**

```
+-----------------+-----------------+-----------------+-----------------|
| Reserved, RES0  | CC              | FORMAT          | NUMREC          |
+-----------------+-----------------+-----------------+-----------------|
```

**Bits [63:16]**

Reserved, RES0.

**CC, bits [15:12]**

Cycle counter support. Defined values are:
- `0b0101` 20-bit cycle counter implemented.
- All other values are reserved.

**FORMAT, bits [11:8]**

Data format of records of the Branch record buffer. Defined values are:
- `0b0000` Format 0.
- All other values are reserved.

**NUMREC, bits [7:0]**

Number of records supported. Defined values are:
- `0x08` 8 branch records implemented.
- `0x10` 16 branch records implemented.
- `0x20` 32 branch records implemented.
- `0x40` 64 branch records implemented.
- All other values are reserved.

**Accessing BRBIDR0_EL1**

Accesses to this register use the following encodings in the System register encoding space:

D17.8.5 BRBINF<n>_EL1, Branch Record Buffer Information Register <n>, n = 0 - 31

The BRBINF<n>_EL1 characteristics are:

**Purpose**

The information for Branch record n + (BRBFCR_EL1.BANK × 32).

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBINF<n>_EL1 are UNDEFINED.

**Attributes**

BRBINF<n>_EL1 is a 64-bit register.

**Field descriptions**

![Field Diagram]

**Bits [63:47]**

Reserved, RES0.

**CCU, bit [46]**

The number of PE clock cycles since the last Branch record entry is UNKNOWN.

- 0b0 Indicates that the number of PE clock cycles since the last Branch record is indicated by BRBINF<n>_EL1.CC.
- 0b1 Indicates that the number of PE clock cycles since the last Branch record is UNKNOWN.

The value in this field is only valid when BRBINF<n>_EL1.VALID != 0b00.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When BRBINF<n>_EL1.VALID == 0b00, access to this field is RES0.
- Otherwise, access to this field is RO

**CC, bits [45:32]**

The number of PE clock cycles since the last Branch record entry.

The format of this field uses a mantissa and exponent to express the cycle count value, as follows:

- CC bits[7:0] indicate the mantissa M.
- CC bits[13:8] indicate the exponent E.

The cycle count is expressed using the following function:

\[
\text{if IsZero(E) then } \text{UInt}(M) \text{ else } \text{UInt}(1':M:Zeros(UInt(E)-1))
\]

If required, the cycle count is rounded to a multiple of \(2^{(E-1)}\) towards zero before being encoded.

A value of all ones in both the mantissa and exponent indicates the cycle count value exceeded the size of the cycle counter.

The value in this field is only valid when BRBINF<n>_EL1.VALID != 0b00.
The reset behavior of this field is:
  • On a Cold reset, this field resets to an architecturally **UNKNOWN** value.
Accessing this field has the following behavior:
  • RES0 if any of the following are true:
    — BRBINF<n>_EL1.CCU == 1
    — BRBINF<n>_EL1.VALID == 0b00
  • Otherwise, access to this field is RO

**Bits [31:18]**
Reserved, RES0.

**LASTFAILED, bit [17]**

*When FEAT_TME is implemented:*
Indicates transaction failure or cancellation.
  0b0 Indicates that no transactions in a non-prohibited region have failed or been canceled between the previous Branch record and this Branch record.
  0b1 Indicates that at least one transaction in a non-prohibited region has failed or been canceled between the previous Branch record and this Branch record.

The value in this field is only valid when BRBINF<n>_EL1.VALID != 0b00.
The reset behavior of this field is:
  • On a Cold reset, this field resets to an architecturally **UNKNOWN** value.
Accessing this field has the following behavior:
  • When BRBINF<n>_EL1.VALID == 0b00, access to this field is RES0.
  • Otherwise, access to this field is RO

*Otherwise:*
Reserved, RES0.

**T, bit [16]**

*When FEAT_TME is implemented:*
Transactional state.
  0b0 The branch or exception was not executed in Transactional state.
  0b1 The branch or exception was executed in Transactional state.

The value in this field is only valid when BRBINF<n>_EL1.VALID == 0b10 or BRBINF<n>_EL1.VALID == 0b11.
The reset behavior of this field is:
  • On a Cold reset, this field resets to an architecturally **UNKNOWN** value.
Accessing this field has the following behavior:
  • RES0 if any of the following are true:
    — BRBINF<n>_EL1.VALID == 0b00
    — BRBINF<n>_EL1.VALID == 0b01
  • Otherwise, access to this field is RO

*Otherwise:*
Reserved, RES0.

**Bits [15:14]**
Reserved, RES0.

**TYPE, bits [13:8]**
Branch type.
  0b000000 Unconditional direct branch, excluding Branch with link.
0b000001  Indirect branch, excluding Branch with link, Return from subroutine, and Exception return.
0b000010  Direct Branch with link.
0b000011  Indirect Branch with link.
0b000101  Return from subroutine.
0b000111  Exception return.
0b001000  Conditional direct branch.
0b100001  Debug halt.
0b100010  Call.
0b100011  Trap.
0b101000  SError.
0b101010  Instruction debug.
0b101011  Data debug.
0b101100  Alignment.
0b101110  Inst Fault.
0b101101  Data Fault.
0b101100  IRQ.
0b101111  FIQ.
0b111001  Debug State Exit.
All other values are reserved.
The value in this field is only valid when BRBINF<n>_EL1.VALID != 0b00.
The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.
Accessing this field has the following behavior:
• When BRBINF<n>_EL1.VALID == 0b00, access to this field is RES0.
• Otherwise, access to this field is RO

EL, bits [7:6]
The Exception Level at the target address.
0b0  EL0.
0b1  EL1.
0b10 EL2.
0b11 When FEAT_BRBEv1p1 is implemented:
   EL3.
The value in this field is only valid when BRBINF<n>_EL1.VALID == 0b11 or
BRBINF<n>_EL1.VALID == 0b01.
The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.
Accessing this field has the following behavior:
• RES0 if any of the following are true:
   — BRBINF<n>_EL1.VALID == 0b00
   — BRBINF<n>_EL1.VALID == 0b10
• Otherwise, access to this field is RO

MPRED, bit [5]
Branch mispredict.
0b0 Branch was correctly predicted or the result of the prediction was not captured.
0b1 Branch was incorrectly predicted.

The value in this field is only valid when \( \text{BRBINF}_n.\_\text{EL1.VALID} = 0b11 \) or \( \text{BRBINF}_n.\_\text{EL1.VALID} = 0b10 \).

The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally \texttt{UNKNOWN} value.

Accessing this field has the following behavior:
- \texttt{RES0} if any of the following are true:
  - \( \text{BRBINF}_n.\_\text{EL1.VALID} = 0b00 \)
  - \( \text{BRBINF}_n.\_\text{EL1.VALID} = 0b01 \)
  - \( \text{BRBINF}_n.\_\text{EL1.TYPE}[5] = 1 \)
- Otherwise, access to this field is RO

Bits [4:2]
Reserved, \texttt{RES0}.

VALID, bits [1:0]
The Branch record is valid.

\( 0b00 \) This Branch record is not valid.
The values of following fields are not valid:
- \( \text{BRBTGT}_n.\_\text{EL1.ADDRESS} \)
- \( \text{BRBSRC}_n.\_\text{EL1.ADDRESS} \)
- \( \text{BRBINF}_n.\_\text{EL1.MPRED} \)
- \( \text{BRBINF}_n.\_\text{EL1.LASTFAILED} \)
- \( \text{BRBINF}_n.\_\text{EL1.T} \)
- \( \text{BRBINF}_n.\_\text{EL1.EL} \)
- \( \text{BRBINF}_n.\_\text{EL1.TYPE} \)
- \( \text{BRBINF}_n.\_\text{EL1.CC} \)
- \( \text{BRBINF}_n.\_\text{EL1.CCU} \)

\( 0b01 \) This Branch record is valid.
The values of following fields are not valid:
- \( \text{BRBSRC}_n.\_\text{EL1.ADDRESS} \)
- \( \text{BRBINF}_n.\_\text{EL1.T} \)
- \( \text{BRBINF}_n.\_\text{EL1.MPRED} \)

\( 0b10 \) This Branch record is valid.
The values of following fields are not valid:
- \( \text{BRBTGT}_n.\_\text{EL1.ADDRESS} \)
- \( \text{BRBINF}_n.\_\text{EL1.EL} \)

\( 0b11 \) This Branch record is valid.
The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally \texttt{UNKNOWN} value.

**Accessing \text{BRBINF}_n.\_\text{EL1}**

\( \text{BRBINF}_n.\_\text{EL1} \) reads-as-zero if \( n + (\text{BRBFCR.EL1.BANK} \times 32) \geq \text{BRBIDR0.EL1.NUMREC} \).

Accesses to this register use the following encodings in the System register encoding space:

D17.8.6  BRBINFINJ_EL1, Branch Record Buffer Information Injection Register

The BRBINFINJ_EL1 characteristics are:

**Purpose**

The information of a Branch record for injection.

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBINFINJ_EL1 are UNDEFINED.

**Attributes**

BRBINFINJ_EL1 is a 64-bit register.

**Field descriptions**

![Field Descriptions Diagram]

**Bits [63:47]**

Reserved, RES0.

**CCU, bit [46]**

The number of PE clock cycles since the last Branch record entry is UNKNOWN.

- 0b0  Indicates that the number of PE clock cycles since the last Branch record is indicated by BRBINFINJ_EL1.CC.
- 0b1  Indicates that the number of PE clock cycles since the last Branch record is UNKNOWN.

The value in this field is only valid when BRBINFINJ_EL1.VALID != 0b00.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:
- When BRBINFINJ_EL1.VALID == 0b00, access to this field is RES0.
- Otherwise, access to this field is RW.

**CC, bits [45:32]**

The number of PE clock cycles since the last Branch record entry.

The format of this field uses a mantissa and exponent to express the cycle count value, as follows:
- CC bits[7:0] indicate the mantissa M.
- CC bits[13:8] indicate the exponent E.

The cycle count is expressed using the following function:

\[
\text{if } \text{IsZero}(E) \text{ then } \text{UInt}(M) \text{ else } \text{UInt}(\text{UInt}(E)-1)\]

If required, the cycle count is rounded to a multiple of \(2^{(E-1)} \) towards zero before being encoded.

A value of all ones in both the mantissa and exponent indicates the cycle count value exceeded the size of the cycle counter.

The value in this field is only valid when BRBINFINJ_EL1.VALID != 0b00.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:
- RES0 if any of the following are true:
  - BRBINFINJ_EL1.CCU == 1
  - BRBINFINJ_EL1.VALID == 0b00
- Otherwise, access to this field is RW

### Bits [31:18]

Reserved, RES0.

### LASTFAILED, bit [17]

When FEAT_TME is implemented:
Indicates transaction failure or cancellation.
- 0b0 Indicates that no transactions in a non-prohibited region have failed or been canceled between the previous Branch record and this Branch record.
- 0b1 Indicates that at least one transaction in a non-prohibited region has failed or been canceled between the previous Branch record and this Branch record.

The value in this field is only valid when BRBINFINJ_EL1.VALID != 0b00.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:
- When BRBINFINJ_EL1.VALID == 0b00, access to this field is RES0.
- Otherwise, access to this field is RW

Otherwise:
Reserved, RES0.

### T, bit [16]

When FEAT_TME is implemented:
Transactional state.
- 0b0 The branch or exception was not executed in Transactional state.
- 0b1 The branch or exception was executed in Transactional state.

The value in this field is only valid when BRBINFINJ_EL1.VALID == 0b10 or BRBINFINJ_EL1.VALID == 0b11.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:
- RES0 if any of the following are true:
  - BRBINFINJ_EL1.VALID == 0b00
  - BRBINFINJ_EL1.VALID == 0b01
- Otherwise, access to this field is RW

Otherwise:
Reserved, RES0.

### Bits [15:14]

Reserved, RES0.

### TYPE, bits [13:8]

Branch type.
- 0b000000 Unconditional direct branch, excluding Branch with link.
0b000001 Indirect branch, excluding Branch with link, Return from subroutine, and Exception return.
0b000010 Direct Branch with link.
0b000011 Indirect Branch with link.
0b000101 Return from subroutine.
0b000111 Exception return.
0b001000 Conditional direct branch.
0b100001 Debug halt.
0b100010 Call.
0b100011 Trap.
0b100100 SError.
0b100110 Instruction debug.
0b100111 Data debug.
0b101010 Alignment.
0b101011 Inst Fault.
0b101100 Data Fault.
0b101110 IRQ.
0b101111 FIQ.
0b110001 Debug State Exit.

All other values are reserved.
The value in this field is only valid when BRBINFINJ_EL1.VALID != 0b00.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing this field has the following behavior:
• When BRBINFINJ_EL1.VALID == 0b00, access to this field is RES0.
• Otherwise, access to this field is RW

EL, bits [7:6]
The Exception Level at the target address.
0b00 EL0.
0b01 EL1.
0b10 EL2.
0b11 When FEAT_BRBEv1p1 is implemented:
EL3.
The value in this field is only valid when BRBINFINJ_EL1.VALID == 0b11 or BRBINFINJ_EL1.VALID == 0b01.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing this field has the following behavior:
• RES0 if any of the following are true:
  — BRBINFINJ_EL1.VALID == 0b00
  — BRBINFINJ_EL1.VALID == 0b10
• Otherwise, access to this field is RW

MPRED, bit [5]
Branch mispredict.
0b0 Branch was correctly predicted or the result of the prediction was not captured.
0b1  Branch was incorrectly predicted.
The value in this field is only valid when BRBINFINJ_EL1.VALID == 0b11 or
BRBINFINJ_EL1.VALID == 0b10.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing this field has the following behavior:
• RES0 if any of the following are true:
  — BRBINFINJ_EL1.VALID == 0b00
  — BRBINFINJ_EL1.VALID == 0b01
  — BRBINFINJ_EL1.TYPE[5] == 1
• Otherwise, access to this field is RW

Bits [4:2]
Reserved, RES0.

VALID, bits [1:0]
The Branch record is valid.
0b00  This Branch record is not valid.
The values of following fields are not valid:
• BRBTGTINJ_EL1.ADDRESS.
• BRBSRCINJ_EL1.ADDRESS.
• BRBINFINJ_EL1.MPRED.
• BRBINFINJ_EL1.LASTFAILED.
• BRBINFINJ_EL1.T.
• BRBINFINJ_EL1.EL.
• BRBINFINJ_EL1.TYPE.
• BRBINFINJ_EL1.CC.
• BRBINFINJ_EL1.CCU.
0b01  This Branch record is valid.
The values of following fields are not valid:
• BRBSRCINJ_EL1.ADDRESS.
• BRBINFINJ_EL1.T.
• BRBINFINJ_EL1.MPRED.
0b10  This Branch record is valid.
The values of following fields are not valid:
• BRBTGTINJ_EL1.ADDRESS.
• BRBINFINJ_EL1.MPRED.
0b11  This Branch record is valid.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.8.7 BRBSRC\(<n>_EL1, Branch Record Buffer Source Address Register \(<n>, n = 0 - 31\)

The BRBSRC\(<n>_EL1 characteristics are:

**Purpose**

The source address of Branch record \(n + (\text{BRBFCR}_\text{EL1.BANK} \times 32)\).

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBSRC\(<n>_EL1 are UNDEFINED.

**Attributes**

BRBSRC\(<n>_EL1 is a 64-bit register.

**Field descriptions**

ADDRESS, bits [63:0]

Source virtual address of the Branch record.

When an indirect write occurs with a value with ADDRESS bits [63:P] being other than all zeroes or all ones, an UNKNOWN value which is not all zeroes or all ones is written to bits [63:P]. P is defined as the virtual address size supported by the PE, as returned by VAMax(). The value in bits [P-1:0] are the value written.

When an indirect write occurs with a value with ADDRESS bits [63:P] being all zeroes or all ones, the written value is written to bits [63:0], and a read of the register returns the written value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- RES0 if any of the following are true:
  - \(\text{BRBINF}_\text{<n>_EL1.VALID == 0b00}\)
  - \(\text{BRBINF}_\text{<n>_EL1.VALID == 0b01}\)
- Otherwise, access to this field is RO

Accessing BRBSRC\(<n>_EL1

BRBSRC\(<n>_EL1 is RES0 if \(n + (\text{BRBFCR}_\text{EL1.BANK} \times 32) >= \text{BRBIDR0}_\text{EL1.NUMREC}\).

Accesses to this register use the following encodings in the System register encoding space:

D17.8.8 BRBSRCINJ_EL1, Branch Record Buffer Source Address Injection Register

The BRBSRCINJ_EL1 characteristics are:

Purpose

The source address of a Branch record for injection.

Configurations

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBSRCINJ_EL1 are UNDEFINED.

Attributes

BRBSRCINJ_EL1 is a 64-bit register.

Field descriptions

ADDRESS, bits [63:0]

Source virtual address of the Branch record.

When a direct write occurs with a value with ADDRESS bits [63:P] being other than all zeroes or all ones, an UNKNOWN value which is not all zeroes or all ones is written to bits [63:P]. P is defined as the virtual address size supported by the PE, as returned by VAMax(). The value in bits [P-1:0] are the value written.

When a direct write occurs with a value with ADDRESS bits [63:P] being all zeroes or all ones, the written value is written to bits [63:0], and a read of the register returns the written value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- RES0 if any of the following are true:
  - BRBINFINJ_EL1.VALID == 0b00
  - BRBINFINJ_EL1.VALID == 0b01

- Otherwise, access to this field is RW

Accessing BRBSRCINJ_EL1

Accesses to this register use the following encodings in the System register encoding space:

\[ MRS <Xt>, BRBSRCINJ_EL1 \]

D17.8.9 BRBTGT<n>_EL1, Branch Record Buffer Target Address Register <n>, n = 0 - 31

The BRBTGT<n>_EL1 characteristics are:

**Purpose**

The target address of Branch record \( n + (\text{BRBFCR_EL1.BANK} \times 32) \).

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBTGT<n>_EL1 are UNDEFINED.

**Attributes**

BRBTGT<n>_EL1 is a 64-bit register.

**Field descriptions**

ADDRESS, bits [63:0]

Target virtual address of the Branch record.

When an indirect write occurs with a value with ADDRESS bits [63:P] being other than all zeroes or all ones, an **UNKNOWN** value which is not all zeroes or all ones is written to bits [63:P]. P is defined as the virtual address size supported by the PE, as returned by VAMMax(). The value in bits [P-1:0] are the value written.

When an indirect write occurs with a value with ADDRESS bits [63:P] being all zeroes or all ones, the written value is written to bits [63:0], and a read of the register returns the written value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

Accessing this field has the following behavior:

- **RES0** if any of the following are true:
  - \( \text{BRBINF<n>_EL1.VALID} == 0b00 \)
  - \( \text{BRBINF<n>_EL1.VALID} == 0b10 \)

- Otherwise, access to this field is **RO**.

**Accessing BRBTGT<n>_EL1**

BRBTGT<n>_EL1 is **RES0** if \( n + (\text{BRBFCR_EL1.BANK} \times 32) >= \text{BRBIDR0_EL1.NUMREC} \).

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, BRBTGT<m>_EL1**

D17.8.10 BRBTGTINJ_EL1, Branch Record Buffer Target Address Injection Register

The BRBTGTINJ_EL1 characteristics are:

**Purpose**

The target address of a Branch record for injection.

**Configurations**

This register is present only when FEAT_BRBE is implemented. Otherwise, direct accesses to BRBTGTINJ_EL1 are UNDEFINED.

**Attributes**

BRBTGTINJ_EL1 is a 64-bit register.

**Field descriptions**

ADDRESS, bits [63:0]

Target virtual address of the Branch record.

When a direct write occurs with a value with ADDRESS bits [63:P] being other than all zeroes or all ones, an UNKNOWN value which is not all zeroes or all ones is written to bits [63:P]. P is defined as the virtual address size supported by the PE, as returned by VAMax(). The value in bits [P-1:0] are the value written.

When a direct write occurs with a value with ADDRESS bits [63:P] being all zeroes or all ones, the written value is written to bits [63:0], and a read of the register returns the written value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- RES0 if any of the following are true:
  - BRBINFINJ_EL1.VALID == 0b00
  - BRBINFINJ_EL1.VALID == 0b10
- Otherwise, access to this field is RW

Accessing BRBTGTINJ_EL1

Accesses to this register use the following encodings in the System register encoding space:

\[ MRS <Xt>, BRBTGTINJ_EL1 \]

D17.9 RAS registers

This section lists The Reliability, Availability, and Serviceability Extension registers in AArch64.
D17.9.1 DISR_EL1, Deferred Interrupt Status Register

The DISR_EL1 characteristics are:

**Purpose**

Records that an SError interrupt has been consumed by an ESB instruction.

**Configurations**

AArch64 System register DISR_EL1 bits [31:0] are architecturally mapped to AArch32 System register DISR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to DISR_EL1 are UNDEFINED.

**Attributes**

DISR_EL1 is a 64-bit register.

**Field descriptions**

*When DISR_EL1.IDS == 0:*

<table>
<thead>

</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**A, bit [31]**

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [30:25]**

Reserved, RES0.

**IDS, bit [24]**

Indicates the deferred SError interrupt type.

- **0b0**: Deferred error uses architecturally-defined format.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [23:13]**

Reserved, RES0.

**AET, bits [12:10]**

Asynchronous Error Type. See the description of ESR_ELx.AET for an SError interrupt.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
EA, bit [9]
External abort Type. See the description of ESR_ELx.EA for an SError interrupt.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:6]
Reserved, RES0.

DFSC, bits [5:0]
Fault Status Code. See the description of ESR_ELx.DFSC for an SError interrupt.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

When DISR_EL1.IDS == 1:

Bits [63:32]
Reserved, RES0.

A, bit [31]
Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]
Reserved, RES0.

IDS, bit [24]
Indicates the deferred SError interrupt type.
0b1 Deferred error uses IMPLEMENTATION DEFINED format.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]
IMPLEMENTATION DEFINED syndrome. See the description of ESR_ELx[23:0] for an SError interrupt.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DISR_EL1
An indirect write to DISR_EL1 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 occurring in program order after the ESB instruction.
DISR_EL1 is RAZ/WI if EL3 is implemented, the PE is in Non-debug state, SCR_EL3.EA == 1, and any of the following apply:

- At EL2.
- At EL1 and ((SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0) || HCR_EL2.AMO == 0).

Accesses to this register use the following encodings in the System register encoding space:

### D17.9.2 ERRIDR_EL1, Error Record ID Register

The ERRIDR_EL1 characteristics are:

**Purpose**
Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

**Configurations**
AArch64 System register ERRIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERRIDR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRIDR_EL1 are UNDEFINED.

**Attributes**
ERRIDR_EL1 is a 64-bit register.

**Field descriptions**

- **Bits [63:16]**
  Reserved, RES0.

- **NUM, bits [15:0]**
  Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates no records can be accessed through the Error Record System registers.

  Each implemented record is owned by a node. A node might own multiple records.

**Accessing ERRIDR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, ERRIDR_EL1**

D17.9.3 ERRSELR_EL1, Error Record Select Register

The ERRSELR_EL1 characteristics are:

**Purpose**

Selects an error record to be accessed through the Error Record System registers.

**Configurations**

AArch64 System register ERRSELR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERRSELR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRSELR_EL1 are UNDEFINED.

If ERRIDR_EL1 indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR_EL1 is UNDEFINED or RES0.

**Attributes**

ERRSELR_EL1 is a 64-bit register.

**Field descriptions**

![Field descriptions diagram]

Bits [63:16]

Reserved, RES0.

SEL, bits [15:0]

Selects the error record accessed through the ERX registers.

For example, if ERRSELR_EL1.SEL is 0x0004, then direct reads and writes of ERXSTATUS_EL1 access ERR4STATUS.

If ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then all of the following apply:

- The value read back from ERRSELR_EL1.SEL is UNKNOWN.
- One of the following occurs:
  - An UNKNOWN error record is selected.
  - The ERX*_EL1 registers are RAZ/WI.
  - ERX*_EL1 register reads and writes are NOPs.
  - ERX*_EL1 register reads and writes are UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing ERRSELR_EL1**

Accesses to this register use the following encodings in the System register encoding space:
\textit{MRS \textlangle X\rangle, ERRSEL_EL1}

\begin{center}
\begin{tabular}{c c c c c}
\hline
op0 & op1 & CRn & CRm & op2 \\

D17.9.4 ERXADDR_EL1, Selected Error Record Address Register

The ERXADDR_EL1 characteristics are:

Purpose

Accesses ERR<\text{n}>ADDR for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations

AArch64 System register ERXADDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERXADDR[31:0].

AArch64 System register ERXADDR_EL1 bits [63:32] are architecturally mapped to AArch32 System register ERXADDR2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXADDR_EL1 are UNDEFINED.

Attributes

ERXADDR_EL1 is a 64-bit register.

Field descriptions

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR&lt;\text{n}&gt;ADDR</td>
<td></td>

</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR&lt;\text{n}&gt;ADDR</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:0]

ERXADDR_EL1 accesses ERR<\text{n} ADDR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXADDR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXADDR_EL1 is RAZ/WI.
- Direct reads and writes of ERXADDR_EL1 are NOPs.
- Direct reads and writes of ERXADDR_EL1 are UNDEFINED.

ERR<\text{n}>ADDR describes additional constraints that also apply when ERR<\text{n}>ADDR is accessed through ERXADDR_EL1.

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, ERXADDR_EL1

<table>

### ERXCTLR_EL1, Selected Error Record Control Register

The ERXCTLR_EL1 characteristics are:

**Purpose**

Accesses ERR<\text{n}>CTRL for the error record \text{n} selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXCTLR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERXCTRL[31:0].

AAarch64 System register ERXCTRL_EL1 bits [63:32] are architecturally mapped to AArch32 System register ERXCTRL2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXCTLR_EL1 are UNDEFINED.

**Attributes**

ERXCTRL_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR&lt;\text{n}&gt;CTRL</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR&lt;\text{n}&gt;CTRL</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**

ERXCTRL_EL1 accesses ERR<\text{n}>CTRL, where \text{n} is the value in ERRSELR_EL1.SEL.

**Accessing ERXCTRL_EL1**

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXCTRL_EL1 is RAZ/WI.
- Direct reads and writes of ERXCTRL_EL1 are NOPs.
- Direct reads and writes of ERXCTRL_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<\text{n}>CTRL is not present, meaning reads and writes of ERXCTRL_EL1 are **RES0**.

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, ERXCTLR_EL1

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>

D17.9.6 ERXFR_EL1, Selected Error Record Feature Register

The ERXFR_EL1 characteristics are:

**Purpose**

Accesses ERR<\text{n}>FR for the error record <\text{n}> selected by ERRSEL_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch64 System register ERXFR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERXFR[31:0].

AArch64 System register ERXFR_EL1 bits [63:32] are architecturally mapped to AArch32 System register ERXFR2[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXFR_EL1 are UNDEFINED.

**Attributes**

ERXFR_EL1 is a 64-bit register.

**Field descriptions**

![Field Description Diagram](image)

**Bits [63:0]**

ERXFR_EL1 accesses ERR<\text{n}>FR, where <\text{n}> is the value in ERRSEL_EL1.SEL.

**Accessing ERXFR_EL1**

If ERRIDR_EL1.NUM is 0x0000 or ERRSEL_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An **UNKNOWN** error record is selected.
- ERXFR_EL1 is RAZ.
- Direct reads of ERXFR_EL1 are NOPs.
- Direct reads of ERXFR_EL1 are **UNDEFINED**.

Accesses to this register use the following encodings in the System register encoding space:

D17.9.7  ERXMISC0_EL1, Selected Error Record Miscellaneous Register 0

The ERXMISC0_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC0 for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations

AArch64 System register ERXMISC0_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERXMISC0[31:0].

AArch64 System register ERXMISC0_EL1 bits [63:32] are architecturally mapped to AArch32 System register ERXMISC1[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC0_EL1 are UNDEFINED.

Attributes

ERXMISC0_EL1 is a 64-bit register.

Field descriptions

</tbody>
</table>

Bits [63:0]

ERXMISC0_EL1 accesses ERR<n>MISC0, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC0_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC0_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC0_EL1 are NOPs.
- Direct reads and writes of ERXMISC0_EL1 are UNDEFINED.

ERR<n>MISC0 describes additional constraints that also apply when ERR<n>MISC0 is accessed through ERXMISC0_EL1.

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, ERXMISCO_EL1

<tr>
<td>31-0</td>
<td>ERR&lt;\textless n\textgreater&gt;PFGCDN</td>
</tr>
</tbody>
</table>

Bits [63:0]

ERXPFGCDN_EL1 accesses ERR<\textless n\textgreater>PFGCDN, where <\textless n\textgreater> is the value in ERRSEL_EL1.SEL.

Accessing ERXPFGCDN_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSEL_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

If ERRSEL_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<\textless n\textgreater>FR.INJ reads as 0b00. <\textless q\textgreater> is the index of the first error record owned by the same node as error record <\textless n\textgreater>, where <\textless n\textgreater> is the value in ERRSEL_EL1.SEL. If the node owns a single record, then q = n.

If ERRSEL_EL1.SEL is not the index of the first error record owned by a node, then ERR<\textless n\textgreater>PFGCDN is not present, meaning reads and writes of ERXPFGCDN_EL1 are RES0.
ERR<n>PFGCDN describes additional constraints that also apply when ERR<n>PFGCDN is accessed through ERXPFGCDN_EL1.

Accesses to this register use the following encodings in the System register encoding space:

### ERXPFGCTL_EL1, Selected Pseudo-fault Generation Control register

The ERXPFGCTL_EL1 characteristics are:

#### Purpose

Accesses ERR<\text{n}>PFGCTL for the error record \(<\text{n}>\) selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

#### Configurations

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCTL_EL1 are UNDEFINED.

#### Attributes

ERXPFGCTL_EL1 is a 64-bit register.

#### Field descriptions

![Field descriptions diagram]

#### Accessing ERXPFGCTL_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An \text{UNKNOWN} error record is selected.
- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

#### Note

A node does not implement the Common Fault Injection Model Extension if \text{ERR<\text{n}>FR.INJ} reads as 0b00. \(<\text{q}>\) is the index of the first error record owned by the same node as error record \(<\text{n}>\), where \(<\text{n}>\) is the value in ERRSELR_EL1.SEL. If the node owns a single record, then \(q = n\).

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then \text{ERR<\text{n}>PFGCTL} is not present, meaning reads and writes of ERXPFGCTL_EL1 are RES0.
ERR<n>PFGCTL describes additional constraints that also apply when ERR<n>PFGCTL is accessed through ERXPFGCTL_EL1.

Accesses to this register use the following encodings in the System register encoding space:

### ERXPFGF_EL1, Selected Pseudo-fault Generation Feature register

The ERXPFGF_EL1 characteristics are:

#### Purpose

Accesses ERR<\(n\)>PFGF for the error record \(n\) selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

#### Configurations

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGF_EL1 are UNDEFINED.

#### Attributes

ERXPFGF_EL1 is a 64-bit register.

#### Field descriptions

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>ERXPFGF_EL1 accesses ERR&lt;(n)&gt;PFGF, where (n) is the value in ERRSELR_EL1.SEL.</td>
</tr>
<tr>
<td>32-31</td>
<td>ERR&lt;(n)&gt;PFGF</td>
</tr>
<tr>
<td>0</td>
<td>ERR&lt;(n)&gt;PFGF</td>
</tr>
</tbody>
</table>

#### Accessing ERXPFGF_EL1

If ERRIDR_EL1.NUM is \(0x0000\) or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

#### Note

A node does not implement the Common Fault Injection Model Extension if ERR<\(n\)>FR.INJ reads as \(0b00\). \(q\) is the index of the first error record owned by the same node as error record \(n\), where \(n\) is the value in ERRSELR_EL1.SEL. If the node owns a single record, then \(q = n\).

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<\(n\)>PFGF is not present, meaning reads of ERXPFGF_EL1 are RES0.
ERR<\texttt{PFGF} describes additional constraints that also apply when ERR<\texttt{PFGF} is accessed through ERXPFGF_EL1.

Accesses to this register use the following encodings in the System register encoding space:

D17.9.14 ERXSTATUS_EL1, Selected Error Record Primary Status Register

The ERXSTATUS_EL1 characteristics are:

Purpose

Accesses ERR<n>STATUS for the error record <n> selected by ERRSELR_EL1.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations

AArch64 System register ERXSTATUS_EL1 bits [31:0] are architecturally mapped to AArch32 System register ERXSTATUS[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXSTATUS_EL1 are UNDEFINED.

Attributes

ERXSTATUS_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

ERXSTATUS_EL1 accesses ERR<n>STATUS, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXSTATUS_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

• An UNKNOWN error record is selected.
• ERXSTATUS_EL1 is RAZ/WI.
• Direct reads and writes of ERXSTATUS_EL1 are NOPs.
• Direct reads and writes of ERXSTATUS_EL1 are UNDEFINED.

ERR<n>STATUS describes additional constraints that also apply when ERR<n>STATUS is accessed through ERXSTATUS_EL1.

D17.9.15 VDISR_EL2, Virtual Deferred Interrupt Status Register

The VDISR_EL2 characteristics are:

**Purpose**
Records that a virtual SError interrupt has been consumed by an E58 instruction executed at EL1.
An indirect write to VDISR_EL2 made by an E58 instruction does not require an explicit synchronization operation for the value written to be observed by a direct read of one of the following registers occurring in program order after the E58 instruction:
- DISR_EL1.
- DISR.

**Configurations**
AArch64 System register VDISR_EL2 bits [31:0] are architecturally mapped to AArch32 System register VDISR[31:0].
This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VDISR_EL2 are UNDEFINED.
If EL2 is not implemented, this register is RES0 from EL3.
This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**
VDISR_EL2 is a 64-bit register.

**Field descriptions**

Reserved, RES0.

A, bit [31]

Set to 1 when an E58 instruction defers a virtual SError interrupt.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VSESR_EL2.AET.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

Ext, bit [12]

The value copied from VSESR_EL2.ExT.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES0.

FS, bits [10, 3:0]

Fault status code. Set to \(0b10110\) when an E58 instruction defers a virtual SError interrupt.

\(0b10110\)  Asynchronous SError interrupt.

All other values are reserved.

The FS field is split as follows:

- FS[4] is VDISR_EL2[10].
- FS[3:0] is VDISR_EL2[3:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
LPAE, bit [9]

Format.
Set to TTBCR.EAE when an E58 instruction defers a virtual SError interrupt.

0b0 Using the Short-descriptor translation table format.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.

When EL1 is using AArch32 and VDISR_EL2.LPAE == 1:

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an E58 instruction defers a virtual SError interrupt.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VSESR_EL2.AET.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VSESR_EL2.ExT.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

Format.
Set to TTBCR.EAE when an E58 instruction defers a virtual SError interrupt.

0b1 Using the Long-descriptor translation table format.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [8:6]**
Reserved, RES0.

**STATUS, bits [5:0]**
Fault status code. Set to 0b010001 when an ESB instruction defers a virtual SError interrupt.
0b010001 Asynchronous SError interrupt.
All other values are reserved.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing VDISR_EL2**
An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of one of the following registers occurring in program order after the ESB instruction:
- DISR_EL1.
- DISR.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, VDISR_EL2**

D17.9.16  VSESR_EL2, Virtual SError Exception Syndrome Register

The VSESR_EL2 characteristics are:

**Purpose**

Provides the syndrome value reported to software on taking a virtual SError interrupt exception to EL1, or on executing an ESB instruction at EL1.

When the virtual SError interrupt injected using HCR_EL2.VSE is taken to EL1 using AArch64, then the syndrome value is reported in ESR_EL1.

When the virtual SError interrupt injected using HCR_EL2.VSE is taken to EL1 using AArch32, then the syndrome value is reported in DFSR.\{AET, ExT\} and the remainder of DFSR is set as defined by VMSAv8-32. For more information, see Chapter G5 The AArch32 Virtual Memory System Architecture.

When the virtual SError interrupt injected using HCR_EL2.VSE is deferred by an ESB instruction, then the syndrome value is written to VDISR_EL2.

**Configurations**

AArch64 System register VSESR_EL2 bits [31:0] are architecturally mapped to AArch32 System register VDFSR[31:0].

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VSESR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

VSESR_EL2 is a 64-bit register.

**Field descriptions**

*When EL1 is using AArch32:*

![Field Diagram]

**Bits [63:16]**

Reserved, RES0.

**AET, bits [15:14]**

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[15:14] is set to VSESR_EL2.AET.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[15:14] is set to VSESR_EL2.AET.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [13]**

Reserved, RES0.
ExT, bit [12]

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[12] is set to VSESR_EL2.ExT.

When a virtual SError interrupt is deferred by an ES$ instruction, VDISR_EL2[12] is set to VSESR_EL2.ExT.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:0]

Reserved, RES0.

When EL1 is using AArch64:

Bits [63:25]

Reserved, RES0.

IDS, bit [24]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[24] is set to VSESR_EL2.IDS.

When a virtual SError interrupt is deferred by an ES$ instruction, VDISR_EL2[24] is set to VSESR_EL2.IDS.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[23:0] is set to VSESR_EL2.ISS.

When a virtual SError interrupt is deferred by an ES$ instruction, VDISR_EL2[23:0] is set to VSESR_EL2.ISS.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VSESR_EL2

D17.10  Realm Management Extension registers

This section lists the Realm Management Extension registers in AArch64.
D17.10.1 GPCCR_EL3, Granule Protection Check Control Register (EL3)

The GPCCR_EL3 characteristics are:

**Purpose**

The control register for Granule Protection Checks.

**Configurations**

This register is present only when FEAT_RME is implemented. Otherwise, direct accesses to GPCCR_EL3 are UNDEFINED.

**Attributes**

GPCCR_EL3 is a 64-bit register.

**Field descriptions**

![Register Diagram]

**Bits [63:24]**

Reserved, RES0.

**L0GPTSZ, bits [23:20]**

Level 0 GPT entry size.

This field advertises the number of least-significant address bits protected by each entry in the level 0 GPT.

- **0b0000**: 30-bits. Each entry covers 1GB of address space.
- **0b0100**: 34-bits. Each entry covers 16GB of address space.
- **0b0110**: 36-bits. Each entry covers 64GB of address space.
- **0b1001**: 39-bits. Each entry covers 512GB of address space.

All other values are reserved.

Access to this field is RO.

**Bits [19:18]**

Reserved, RES0.

**GPCP, bit [17]**

Granule Protection Check Priority.

This control governs behavior of granule protection checks on fetches of stage 2 Table descriptors.

- **0b0**: GPC faults are all reported with a priority that is consistent with the GPC being performed on any access to physical address space.
- **0b1**: A GPC fault for the fetch of a Table descriptor for a stage 2 translation table walk might not be generated or reported.

All other GPC faults are reported with a priority consistent with the GPC being performed on all accesses to physical address spaces.

This bit is permitted to be cached in a TLB.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GPC, bit [16]
Granule Protection Check Enable.
0b0 Granule protection checks are disabled. Accesses are not prevented by this mechanism.
0b1 All accesses to physical address spaces are subject to granule protection checks, except
for fetches of GPT information and accesses governed by the GPCCR_EL3.GPCP
control.

If any stage of translation is enabled, this bit is permitted to be cached in a TLB.
The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

PGS, bits [15:14]
Physical Granule size.
0b00 4KB.
0b01 64KB.
0b10 16KB.
All other values are reserved.
The value of this field is permitted to be cached in a TLB.
Granule sizes not supported for stage 1 and not supported for stage 2, as defined in
ID_AA64MMFR0_EL1, are reserved. For example, if ID_AA64MMFR0_EL1.TGran16 == 0b0000
and ID_AA64MMFR0_EL1.TGran16_2 == 0b0001, then the PGS encoding 0b10 is reserved.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH, bits [13:12]
GPT fetch Shareability attribute
0b00 Non-shareable.
0b10 Outer Shareable.
0b11 Inner Shareable.
All other values are reserved.
Fetches of GPT information are made with the Shareability attribute that is configured in this field.
If both ORGN and IRGN are configured with Non-cacheable attributes, it is invalid to configure this
field to any value other than 0b10.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ORGN, bits [11:10]
GPT fetch Outer cacheability attribute.
0b00 Normal memory, Outer Non-cacheable.
0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.
Fetches of GPT information are made with the Outer cacheability attributes configured in this field.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IRGN, bits [9:8]

GPT fetch Inner cacheability attribute.

0b00  Normal memory, Inner Non-cacheable.
0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

Fetches of GPT information are made with the Inner cacheability attributes configured in this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Bits [7:3]

Reserved, RES0.

PPS, bits [2:0]

Protected Physical Address Size.

The size of the memory region protected by GPTBR_EL3, in terms of the number of least-significant address bits.

0b000  32 bits, 4GB protected address space.
0b001  36 bits, 64GB protected address space.
0b010  40 bits, 1TB protected address space.
0b011  42 bits, 4TB protected address space.
0b100  44 bits, 16TB protected address space.
0b101  48 bits, 256TB protected address space.
0b110  52 bits, 4PB protected address space.

All other values are reserved.

Configuration of this field to a value exceeding the implemented physical address size is invalid.

The value of this field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Accessing GPCCR_EL3**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRS <Xt>, GPCCR_EL3
\]

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b11 & 0b110 & 0b0010 & 0b0001 & 0b110 \\
\end{array}
\]

  UNDEFINED;
elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  GPCCR_EL3 = X[t, 64];
D17.10.2 GPTBR_EL3, Granule Protection Table Base Register

The GPTBR_EL3 characteristics are:

Purpose

The control register for Granule Protection Table base address.

Configurations

This register is present only when FEAT_RME is implemented. Otherwise, direct accesses to GPTBR_EL3 are UNDEFINED.

Attributes

GPTBR_EL3 is a 64-bit register.

Field descriptions

Bits [63:40]

Reserved, RES0.

BADDR, bits [39:0]

Base address for the level 0 GPT.

This field represents bits [51:12] of the level 0 GPT base address.

The level 0 GPT is aligned in memory to the greater of:

• The size of the level 0 GPT in bytes.
• 4KB.

Bits [x:0] of the base address are treated as zero, where:

• \( x = \max(pps - 10gptsz + 2, 11) \)
• pps is derived from GPCCR_EL3.PPS as follows:

<table>
<thead>
<tr>
<th>GPCCR_EL3.PPS</th>
<th>pps</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>32</td>
</tr>
<tr>
<td>0b001</td>
<td>36</td>
</tr>
<tr>
<td>0b010</td>
<td>40</td>
</tr>
<tr>
<td>0b011</td>
<td>42</td>
</tr>
<tr>
<td>0b100</td>
<td>44</td>
</tr>
<tr>
<td>0b101</td>
<td>48</td>
</tr>
<tr>
<td>0b110</td>
<td>52</td>
</tr>
</tbody>
</table>

• l0gptsz is derived from GPCCR_EL3.L0GPTSZ as follows:

<table>
<thead>
<tr>
<th>GPCCR_EL3.L0GPTSZ</th>
<th>l0gptsz</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>30</td>
</tr>
<tr>
<td>0b0100</td>
<td>34</td>
</tr>
<tr>
<td>0b0110</td>
<td>36</td>
</tr>
<tr>
<td>0b1001</td>
<td>39</td>
</tr>
</tbody>
</table>

If x is greater than 11, then BADDR[x - 12:0] are RES0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing GPTBR_EL3**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, GPTBR_EL3**

<table>

D17.10.3 MFAR_EL3, PA Fault Address Register

The MFAR_EL3 characteristics are:

**Purpose**

Holds the faulting physical address for Granule Protection Check exceptions taken to EL3.

**Configurations**

This register is present only when FEAT_RME is implemented. Otherwise, direct accesses to MFAR_EL3 are UNDEFINED.

**Attributes**

MFAR_EL3 is a 64-bit register.

**Field descriptions**

An exception return at EL3 makes MFAR_EL3 UNKNOWN.

**NS, bit [63]**

Together with the NSE field, reports the physical address space of the access that triggered the Granule Protection Check exception.

<table>
<thead>
<tr>
<th>NSE</th>
<th>NS</th>
<th>Meaning</th>

<td>0b1</td>
<td>Realm.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSE, bit [62]**

Together with the NS field, reports the physical address space of the access that triggered the Granule Protection Check exception.

For a description of the values derived by evaluating NS and NSE together, see MFAR_EL3.NS.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [61:52]**

Reserved, RES0.

**FPA[51:48], bits [51:48]**

*When FEAT_LPA is implemented:*

When FEAT_LPA is implemented, extension to FPA[47:12].
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**FPA[47:12], bits [47:12]**

Bits [47:12] of the faulting physical address.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [11:0]**

Reserved, RES0.

**Accessing MFAR_EL3**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, MFAR_EL3**

D17.11  Generic Timer registers

This section lists the Generic Timer registers in AArch64.
D17.11 CNTFRQ_EL0, Counter-timer Frequency register

The CNTFRQ_EL0 characteristics are:

**Purpose**

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

**Configurations**

AArch64 System register CNTFRQ_EL0 bits [31:0] are architecturally mapped to AArch32 System register CNTFRQ[31:0].

**Attributes**

CNTFRQ_EL0 is a 64-bit register.

**Field descriptions**

**Bits [63:32]**

Reserved, RES0.

**Bits [31:0]**

Clock frequency. Indicates the system counter clock frequency, in Hz.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTFRQ_EL0**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, CNTFRQ_EL0**

```
if PSTATE.EL == EL0 then
  if !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && CNTKCTL_EL1.<EL0PCTEN,EL0VCTEN> == '00' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    AArch64.SystemAccessTrap(EL1, 0x18);
  elsif EL2Enabled() && HCR_EL2.<E2H,TGE> == '11' && CNTKCTL_EL2.<EL0PCTEN,EL0VCTEN> == '00' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    X[t, 64] = CNTFRQ_EL0;
  elsif PSTATE.EL == EL1 then
    X[t, 64] = CNTFRQ_EL0;
  elsif PSTATE.EL == EL2 then
```

D17.11.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

**Purpose**

Controls the generation of an event stream from the physical counter, and access from EL1 to the physical counter and the EL1 physical timer.

**Configurations**

AArch64 System register CNTHCTL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHCTL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

CNTHCTL_EL2 is a 64-bit register.

**Field descriptions**

*When FEAT_VHE is implemented and HCR_EL2.E2H == 1:*

Bits [63:20]

Reserved, RES0.

**CNTPMASK, bit [19]**

*When FEAT_RME is implemented:*

| 0b0 | This control has no affect on CNTP_CTL_EL0.IMASK. |
| 0b1 | CNTP_CTL_EL0.IMASK behaves as if set to 1 for all purposes other than a direct read of the field. |

This bit is RES0 in Non-secure and Secure state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**CNTVMASK, bit [18]**

*When FEAT_RME is implemented:*

| 0b0 | This control has no affect on CNTV_CTL_EL0.IMASK. |
| 0b1 | CNTV_CTL_EL0.IMASK behaves as if set to 1 for all purposes other than a direct read of the field. |
This bit is RES0 in Non-secure and Secure state.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**  
Reserved, RES0.

**EVNTIS, bit [17]**

**When FEAT_ECV is implemented:**  
Controls the scale of the generation of the event stream.

- **0b0** The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[15:0].
- **0b1** The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[23:8].

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**  
Reserved, RES0.

**EL1NVVCT, bit [16]**

**When FEAT_ECV is implemented:**  
Traps EL1 accesses to the specified EL1 virtual timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** If ((HCR_EL2.E2H==1 && HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.
  
If ((HCR_EL2.E2H==0 || HCR_EL2.NV2==1 && HCR_EL2.NV1==0 || HCR_EL2.NV==1), then EL1 accesses to CNTV_CTL_EL02 and CNTV_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**  
Reserved, RES0.

**EL1NVPCT, bit [15]**

**When FEAT_ECV is implemented:**  
Traps EL1 accesses to the specified EL1 physical timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** If ((HCR_EL2.E2H==1 && HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.
  
If (HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 && HCR_EL2.NV1==0 && HCR_EL2.NV==1, then EL1 accesses to CNTP_CTL_EL02 and CNTP_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.
This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**EL1TVCT, bit [14]**

*When FEAT_ECV is implemented:*
Traps EL0 and EL1 accesses to the EL1 virtual counter registers to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.

0b1 If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:
- In AArch64 state, traps EL0 and EL1 accesses to CNTVCT_EL0 to EL2, unless they are trapped by CNTKCTL_EL1.EL0VCTEN.
- In AArch32 state, traps EL0 and EL1 accesses to CNTVCT to EL2, unless they are trapped by CNTKCTL_EL1.EL0VCTEN or CNTKCTL.PL0VCTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.
This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**EL1TVT, bit [13]**

*When FEAT_ECV is implemented:*
Traps EL0 and EL1 accesses to the EL1 virtual timer registers to EL2, when EL2 is enabled for the current Security state.

0b0 This control does not cause any instructions to be trapped.

0b1 If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:
- In AArch64 state, traps EL0 and EL1 accesses to CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 to EL2, unless they are trapped by CNTKCTL_EL1.EL0VTEN.
- In AArch32 state, traps EL0 and EL1 accesses to CNTV_CTL, CNTV_CVAL, and CNTV_TVAL to EL2, unless they are trapped by CNTKCTL_EL1.EL0VTEN or CNTKCTL.PL0VTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.
This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.
ECV, bit [12]

When FEAT_ECV is implemented:

- Enables the Enhanced Counter Virtualization functionality registers.
- **0b0** Enhanced Counter Virtualization functionality is disabled.
- **0b1** When HCR_EL2.E2H, TGE == {1, 1} or SCR_EL3.NS, EEL2 == {0, 0}, then Enhanced Counter Virtualization functionality is disabled.

When SCR_EL3.NS or SCR_EL3.EEL2 are 1, and HCR_EL2.E2H or HCR_EL2.TGE are 0, then Enhanced Counter Virtualization functionality is enabled when EL2 is enabled for the current Security state. This means that:

- An MRS to CNTPCT_EL0 from either EL0 or EL1 that is not trapped will return the value (PCount<63:0> - CNTPOFF_EL2<63:0>).
- The EL1 physical timer interrupt is triggered when 
  \((\text{PCount}<63:0>-\text{CNTPOFF}_\text{EL2}<63:0>-\text{PCVal}<63:0>)\) is greater than or equal to 0. 
  PCount<63:0> is the physical count returned when CNTPCT_EL0 is read from EL2 or EL3. PCVal<63:0> is the EL1 physical timer compare value for this timer.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

- Reserved, RES0.

EL1PTEN, bit [11]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state.

- **0b0** From AArch64 state: EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN.
  From AArch32 state: EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN or CNTKCTL.PL0PTEN.
- **0b1** This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL1PCTEN, bit [10]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRRC or MCRR accesses to CNTPCT are trapped to EL2, reported using EC syndrome value 0x04.

- **0b0** From AArch64 state: EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.
  From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN or CNTKCTL.PL0PCTEN.
- **0b1** This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
EL0PTEN, bit [9]
When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.
When HCR_EL2.TGE is 1, traps EL0 accesses to the physical timer registers to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 registers are trapped to EL2.
     EL0 using AArch32: EL0 accesses to the CNTP_CTL, CNTP_CVAL and CNTP_TVAL registers are trapped to EL2.
0b1  This control does not cause any instructions to be trapped.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]
When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.
When HCR_EL2.TGE is 1, traps EL0 accesses to the virtual timer registers to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 registers are trapped to EL2.
     EL0 using AArch32: EL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to EL2.
0b1  This control does not cause any instructions to be trapped.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]
Selects which bit of CNTPCT_EL0, as seen from EL2, is the trigger for the event stream generated from that counter when that stream is enabled.

If FEAT_ECV is implemented, and CNTHCTL_EL2.EVNTIS is 1, this field selects a trigger bit in the range 8 to 23 of CNTPCT_EL0.
Otherwise, this field selects a trigger bit in the range 0 to 15 of CNTPCT_EL0.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]
Controls which transition of the CNTPCT_EL0 trigger bit, as seen from EL2 and defined by EVNTI, generates an event when the event stream is enabled.

0b0  A 0 to 1 transition of the trigger bit triggers an event.
0b1  A 1 to 0 transition of the trigger bit triggers an event.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]
Enables the generation of an event stream from CNTPCT_EL0 as seen from EL2.

0b0  Disables the event stream.
0b1  Enables the event stream.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0VCTEN, bit [1]
When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.
When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and virtual counter register to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTVCT_EL0 are trapped to EL2.
    EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0PCTEN is also 0.
    EL0 using AArch32: EL0 accesses to the CNTVCT are trapped to EL2.
    EL0 using AArch32: EL0 accesses to the CNTFRQ register are trapped to EL2, if CNTHCTL_EL2.EL0PCTEN is also 0.

0b1  This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EL0PCTEN, bit [0]**

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and physical counter register to EL2.

0b0  EL0 using AArch64: EL0 accesses to the CNTPCT_EL0 are trapped to EL2.
    EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.
    EL0 using AArch32: EL0 accesses to the CNTPCT are trapped to EL2.
    EL0 using AArch32: EL0 accesses to the CNTFRQ and register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.

0b1  This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

This format applies in all Armv8.0 implementations.

It also contains a description of the behavior when EL3 is implemented and EL2 is not implemented.

**Bits [63:20]**

Reserved, RES0.

**CNTPMASK, bit [19]**

*When FEAT_RME is implemented:*

0b0  This control has no affect on CNTP_CTL_EL0.IMASK.

0b1  CNTP_CTL_EL0.IMASK behaves as if set to 1 for all purposes other than a direct read of the field.

This bit is RES0 in Non-secure and Secure state.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**CNTVMASK, bit [18]**

When **FEAT_RME** is implemented:

- 0b0 This control has no affect on CNTV_CTL_EL0.IMASK.
- 0b1 CNTV_CTL_EL0.IMASK behaves as if set to 1 for all purposes other than a direct read of the field.

This bit is RES0 in Non-secure and Secure state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**EVNTIS, bit [17]**

When **FEAT_ECV** is implemented:

- Controls the scale of the generation of the event stream.
- 0b0 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[15:0].
- 0b1 The CNTHCTL_EL2.EVNTI field applies to CNTPCT_EL0[23:8].

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**EL1NVVCT, bit [16]**

When **FEAT_ECV** is implemented:

- Traps EL1 accesses to the specified EL1 virtual timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.
- 0b0 This control does not cause any instructions to be trapped.
- 0b1 If ((HCR_EL2.E2H==1 && HCR_EL2.TGE==1) || HCR_EL2.NV2==0 || HCR_EL2.NV1==1 || HCR_EL2.NV==0), this control does not cause any instructions to be trapped.

If ((HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 && HCR_EL2.NV1==0 && HCR_EL2.NV==1), then EL1 accesses to CNTV_CTL_EL02 and CNTV_CVAL_EL02 are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
EL1NVPCT, bit [15]

When FEAT_ECV is implemented:
Traps EL1 accesses to the specified EL1 physical timer registers using the EL02 descriptors to EL2, when EL2 is enabled for the current Security state.

0b0  This control does not cause any instructions to be trapped.
0b1  If (HCR_EL2.E2H==1 & HCR_EL2.TGE==1) || HCR_EL2.NV2==0 ||
     HCR_EL2.NV1==1 || HCR_EL2.NV==0, this control does not cause any instructions
     to be trapped.

If (HCR_EL2.E2H==0 || HCR_EL2.TGE==0) && HCR_EL2.NV2==1 &&
     HCR_EL2.NV1==0 && HCR_EL2.NV==1, then EL1 accesses to CNTP_CTL_EL02
and CNTP_CVAL_EL02, are trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EL1TVCT, bit [14]

When FEAT_ECV is implemented:
Traps EL0 and EL1 accesses to the EL1 virtual counter registers to EL2, when EL2 is enabled for the current Security state.

0b0  This control does not cause any instructions to be trapped.
0b1  If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:
In AArch64 state, traps EL0 and EL1 accesses to CNTVCT_EL0 to EL2, unless they
are trapped by CNTKCTL_EL1.EL0VCTEN. In AArch32 state, traps EL0 and EL1
accesses to CNTVCT to EL2, unless they are trapped by CNTKCTL_EL1.EL0VCTEN
or CNTKCTL.PL0VCTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EL1TVT, bit [13]

When FEAT_ECV is implemented:
Traps EL0 and EL1 accesses to the EL1 virtual timer registers to EL2, when EL2 is enabled for the current Security state.

0b0  This control does not cause any instructions to be trapped.
0b1  If HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

If HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, then:
• In AArch64 state, traps EL0 and EL1 accesses to CNTV_CTL_EL0,
  CNTV_CVAL_EL0, and CNTV_TVVAL_EL0 to EL2, unless they are trapped by
  CNTKCTL_EL1.EL0VTEN.
In AArch32 state, traps EL0 and EL1 accesses to CNTV_CTL, CNTV_CVAL, and CNTV_TVAL to EL2, unless they are trapped by CNTKCTL_EL1.EL0VTEN or CNTKCTL.PL0VTEN.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 0 other than for the purpose of a direct read.

This control applies regardless of the value of the CNTHCTL_EL2.ECV bit.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

**ECV, bit [12]**

*When FEAT_ECV is implemented:*

Enables the Enhanced Counter Virtualization functionality registers.

0b0  Enhanced Counter Virtualization functionality is disabled.

0b1  When HCR_EL2.{E2H, TGE} == {1, 1} or SCR_EL3.{NS, EEL2} == {0, 0}, then Enhanced Counter Virtualization functionality is disabled.

When SCR_EL3.NS or SCR_EL3.EEL2 are 1, and HCR_EL2.E2H or HCR_EL2.TGE are 0, then Enhanced Counter Virtualization functionality is enabled when EL2 is enabled for the current Security state. This means that:

* An MRS to CNTPCT_EL0 from either EL0 or EL1 that is not trapped will return the value (PCount<63:0> - CNTPOFF_EL2<63:0>).

* The EL1 physical timer interrupt is triggered when ((PCount<63:0> - CNTPOFF_EL2<63:0> - PCVal<63:0>) is greater than or equal to 0. PCount is the physical count returned when CNTPCT_EL0 is read from EL2 or EL3. PCVal<63:0> is the EL1 physical timer compare value for this timer.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

**Bits [11:8]**

Reserved, RES0.

**EVNTI, bits [7:4]**

Selects which bit of CNTPCT_EL0, as seen from EL2, is the trigger for the event stream generated from that counter when that stream is enabled.

If FEAT_ECV is implemented, and CNTHCTL_EL2_EVNTIS is 1, this field selects a trigger bit in the range 8 to 23 of CNTPCT_EL0.

Otherwise, this field selects a trigger bit in the range 0 to 15 of CNTPCT_EL0.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EVNTDIR, bit [3]**

Controls which transition of the CNTPCT_EL0 trigger bit, as seen from EL2 and defined by EVNTI, generates an event when the event stream is enabled.

0b0  A 0 to 1 transition of the trigger bit triggers an event.

0b1  A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.
EVNTEN, bit [2]

Enables the generation of an event stream from CNTPCT_EL0 as seen from EL2.

0\text{b}0 \quad \text{Disables the event stream.}
0\text{b}1 \quad \text{Enables the event stream.}

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

EL1PCEN, bit [1]

Traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to 
  \text{CNTP\_CTL\_EL0, CNTP\_CVAL\_EL0, CNTP\_TVAL\_EL0}
  are trapped to EL2, reported using EC syndrome value \text{0x18}.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 reported using EC syndrome value \text{0x3} and MRRC and MCRR accesses are trapped to EL2, reported using EC syndrome value \text{0x04}:
  \begin{itemize}
  \item \text{CNTP\_CTL, CNTP\_CVAL, CNTP\_TVAL}.
  \end{itemize}

0\text{b}0 \quad \text{From AArch64 state: EL0 and EL1 accesses to the CNTP\_CTL\_EL0, CNTP\_CVAL\_EL0, and CNTP\_TVAL\_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL\_EL1.EL0PTEN. From AArch32 state: EL0 and EL1 accesses to the CNTP\_CTL, CNTP\_CVAL, and CNTP\_TVAL are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL\_EL1.EL0PTEN or CNTKCTL\_PL0PTEN.}
0\text{b}1 \quad \text{This control does not cause any instructions to be trapped.}

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

EL1PCTEN, bit [0]

Traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to \text{CNTPCT\_EL0} are trapped to EL2, reported using EC syndrome value \text{0x18}.
- In AArch32 state, MRRC or MCRR accesses to \text{CNTPCT} are trapped to EL2, reported using EC syndrome value \text{0x04}.

0\text{b}0 \quad \text{From AArch64 state: EL0 and EL1 accesses to the CNTPCT\_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL\_EL1.EL0PCTEN. From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL\_EL1.EL0PCTEN or CNTKCTL\_PL0PCTEN.}
0\text{b}1 \quad \text{This control does not cause any instructions to be trapped.}

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Accessing CNTHCTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHCTL_EL2 or CNTKCTL_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.3 CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register

The CNTHP_CTL_EL2 characteristics are:

**Purpose**
Control register for the EL2 physical timer.

**Configurations**
AArch64 System register CNTHP_CTL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHP_CTL[31:0].

This register is present only when EL3 is implemented or (EL3 is not implemented, EL2 is implemented and FEAT_SEL2 is not implemented). Otherwise, direct accesses to CNTHP_CTL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**
CNTHP_CTL_EL2 is a 64-bit register.

**Field descriptions**

![Field Diagram]

**Bits [63:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:
- **0b0**  Timer condition is not met.
- **0b1**  Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:
- **0b0**  Timer interrupt is not masked by the IMASK bit.
- **0b1**  Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0       Timer disabled.
0b1       Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVAL_EL2 continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

---

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHP_CTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_CTL_EL2 or CNTP_CTL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, CNTHP_CTL_EL2**

D17.11.4 CNTHP_CVAL_EL2, Counter-timer Physical Timer CompareValue register (EL2)

The CNTHP_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the EL2 physical timer.

**Configurations**

AArch64 System register CNTHP_CVAL_EL2 bits [63:0] are architecturally mapped to AArch32 System register CNTHP_CVAL[63:0].

This register is present only when EL3 is implemented or (EL3 is not implemented, EL2 is implemented and FEAT_SEL2 is not implemented). Otherwise, direct accesses to CNTHP_CVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP_CVAL_EL2 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CompareValue</td>
</tr>
<tr>
<td>31</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL2 physical timer CompareValue.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHP_CTL_EL2.ISTATUS is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHP_CVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_CVAL_EL2 or CNTP_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:
**MRS <Xt>, CNTHP_CVAL_EL2**

D17.11.5 CNTHP_TVAL_EL2, Counter-timer Physical Timer TimerValue register (EL2)

The CNTHP_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the EL2 physical timer.

**Configurations**

AArch64 System register CNTHP_TVAL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHP_TVAL[31:0].

This register is present only when EL3 is implemented or (EL3 is not implemented, EL2 is implemented and FEAT_SEL2 is not implemented). Otherwise, direct accesses to CNTHP_TVAL_EL2 are **undefined**.

If EL2 is not implemented, this register is **RES0** from EL3.

**Attributes**

CNTHP_TVAL_EL2 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>RES0</td>
</tr>
<tr>
<td>31-0</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, **RES0**.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:
- If CNTHP_CTL_EL2.ENABLE is 0, the value returned is **UNKNOWN**.
- If CNTHP_CTL_EL2.ENABLE is 1, the value returned is (CNTHP_CVVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHP_CVVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHP_CVVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTHP_CTL_EL2.ISTATUS is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Accessing CNTHP_TVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_TVAL_EL2 or CNTP_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Accesses to this register use the following encodings in the System register encoding space:

D17.11.6 CNTHPS_CTL_EL2, Counter-timer Secure Physical Timer Control register (EL2)

The CNTHPS_CTL_EL2 characteristics are:

**Purpose**
Control register for the Secure EL2 physical timer.

**Configurations**
AArch64 System register CNTHPS_CTL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHPS_CTL[31:0].

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL_EL2 are UNDEFINEd.

**Attributes**

CNTHPS_CTL_EL2 is a 64-bit register.

**Field descriptions**

![Register Diagram]

**Bits [63:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:
0b0 Timer condition is not met.
0b1 Timer condition is met.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:
0b0 Timer interrupt is not masked by the IMASK bit.
0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- **0b0**: Timer disabled.
- **0b1**: Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from `CNTHPS_TVVAL_EL2` continues to count down.

--- **Note** ---

Disabling the output signal might be a power-saving option.

---

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Accessing CNTHPS_CTL_EL2**

Accesses to this register use the following encodings in the System register encoding space:

\[
\begin{array}{cccccc}

D17.11.7  CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue register (EL2)

The CNTHPS_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the Secure EL2 physical timer.

**Configurations**

AArch64 System register CNTHPS_CVAL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHPS_CVAL[31:0].

This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL_EL2 are UNDEFINED.

**Attributes**

CNTHPS_CVAL_EL2 is a 64-bit register.

**Field descriptions**

\[
\begin{array}{c}
\text{CompareValue} \\
63 & 32 \\
31 & 0 \\
\end{array}
\]

**CompareValue, bits [63:0]**

Holds the EL2 physical timer CompareValue.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHPS_CVAL_EL2**

Accesses to this register use the following encodings in the System register encoding space:

D17.11.8 CNTHPS_TVAL_EL2, Counter-timer Secure Physical Timer TimerValue register (EL2)

The CNTHPS_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the Secure EL2 physical timer.

**Configurations**

AArch64 System register CNTHPS_TVAL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHPS_TVAL[31:0].

This register is present only when EL2 is implemented and FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL_EL2 are UNDEFINED.

**Attributes**

CNTHPS_TVAL_EL2 is a 64-bit register.

**Field descriptions**

[Diagram of field descriptions]

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHPS_TVAL_EL2**

Accesses to this register use the following encodings in the System register encoding space:

D17.11.9 CNTHV_CTL_EL2, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL_EL2 characteristics are:

Purpose
Control register for the EL2 virtual timer.

Configurations
AArch64 System register CNTHV_CTL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHV_CTL[31:0].

This register is present only when FEAT_VHE is implemented and (EL3 is implemented or (EL3 is not implemented and FEAT_SEL2 is not implemented)). Otherwise, direct accesses to CNTHV_CTL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes
CNTHV_CTL_EL2 is a 64-bit register.

Field descriptions

Bits [63:3]
Reserved, RES0.

ISTATUS, bit [2]
The status of the timer. This bit indicates whether the timer condition is met:

0b0 Timer condition is not met.
0b1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Access to this field is RO.

IMASK, bit [1]
Timer interrupt mask bit. Permitted values are:

0b0 Timer interrupt is not masked by the IMASK bit.
0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

- **0b0**  Timer disabled.
- **0b1**  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TVAL_EL2 continues to count down.

**Note**

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHV_CTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CTL_EL2 or CNTV_CTL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.10  CNTHV_CVAL_EL2, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the EL2 virtual timer.

**Configurations**

AArch64 System register CNTHV_CVAL_EL2 bits [63:0] are architecturally mapped to AArch32 System register CNTHV_CVAL[63:0].

This register is present only when FEAT_VHE is implemented and (EL3 is implemented or (EL3 is not implemented and FEAT_SEL2 is not implemented)). Otherwise, direct accesses to CNTHV_CVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHV_CVAL_EL2 is a 64-bit register.

**Field descriptions**

CompareValue, bits [63:0]

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHV_CVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CVAL_EL2 or CNTV_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

### D17.11.1 CNTHV_TVAL_EL2, Counter-timer Virtual Timer TimerValue Register (EL2)

The CNTHV_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the EL2 virtual timer.

**Configurations**

AArch64 System register CNTHV_TVAL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHV_TV[31:0].

This register is present only when FEAT_VHE is implemented and (EL3 is implemented or (EL3 is not implemented and FEAT_SEL2 is not implemented)). Otherwise, direct accesses to CNTHV_TVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHV_TVAL_EL2 is a 64-bit register.

**Field descriptions**

![Field Descriptions Diagram]

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHV_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHV_CTL_EL2.ENABLE is 1, the value returned is (CNTHV_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHV_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTHV_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHV_TVAL_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_TVAL_EL2 or CNTV_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, CNTHV_TVAL_EL2**

D17.11.12 CNTHVS_CTL_EL2, Counter-timer Secure Virtual Timer Control register (EL2)

The CNTHVS_CTL_EL2 characteristics are:

**Purpose**

Control register for the Secure EL2 virtual timer.

**Configurations**

AArch64 System register CNTHVS_CTL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHVS_CTL[31:0]. This register is present only when FEAT_SEL2 is implemented and FEAT_VHE is implemented. Otherwise, direct accesses to CNTHVS_CTL_EL2 are UNDEFINED.

**Attributes**

CNTHVS_CTL_EL2 is a 64-bit register.

**Field descriptions**

Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the CNTHVS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0b0 Timer interrupt is not masked by the IMASK bit.
- 0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the CNTHVS_CTL_EL2.ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0b0  Timer disabled.
- 0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHVS_TVAL_EL2 continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.11.13 CNTHVS_CVAL_EL2, Counter-timer Secure Virtual Timer CompareValue register (EL2)

The CNTHVS_CVAL_EL2 characteristics are:

**Purpose**

Holds the compare value for the Secure EL2 virtual timer.

**Configurations**

AArch64 System register CNTHVS_CVAL_EL2 bits [63:0] are architecturally mapped to AArch32 System register CNTHVS_CV[63:0].

This register is present only when FEAT_SEL2 is implemented and FEAT_VHE is implemented. Otherwise, direct accesses to CNTHVS_CVAL_EL2 are UNDEFINED.

**Attributes**

CNTHVS_CVAL_EL2 is a 64-bit register.

**Field descriptions**

CompareValue, bits [63:0]

Holds the Secure EL2 virtual timer CompareValue.

When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTHVS_CVAL_EL2**

Accesses to this register use the following encodings in the System register encoding space:

\[

D17.11.14   CNTHVS_TVAL_EL2, Counter-timer Secure Virtual Timer TimerValue register (EL2)

The CNTHVS_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the Secure EL2 virtual timer.

**Configurations**

AArch64 System register CNTHVS_TVAL_EL2 bits [31:0] are architecturally mapped to AArch32 System register CNTHVS_TVAL[31:0].

This register is present only when FEAT_SEL2 is implemented and FEAT_VHE is implemented. Otherwise, direct accesses to CNTHVS_TVAL_EL2 are UNDEFINED.

**Attributes**

CNTHVS_TVAL_EL2 is a 64-bit register.

**Field descriptions**

![Diagram of register fields]

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHVS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHVS_CTL_EL2.ENABLE is 1, the value returned is (CNTHVS_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHVS_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when ((CNTVCT_EL0 - CNTHVS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D17.11.15 CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

Purpose

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is \{1, 1\}, this register does not cause any event stream from the virtual counter to be generated, and does not control access to the counters and timers. The access to counters and timers at EL0 is controlled by CNTKCTL_EL2.

When FEAT_VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not \{1, 1\}, this register controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Configurations

AArch64 System register CNTKCTL_EL1 bits [31:0] are architecturally mapped to AArch32 System register CNTKCTL[31:0].

Attributes

CNTKCTL_EL1 is a 64-bit register.

Field descriptions

Bits [63:18]

Reserved, RES0.

EVNTIS, bit [17]

When FEAT_ECV is implemented:

Controls the scale of the generation of the event stream.

0b0  The CNTKCTL_EL1.EVNTI field applies to CNTVCT_EL0[15:0].
0b1  The CNTKCTL_EL1.EVNTI field applies to CNTVCT_EL0[23:8].

This control applies regardless of the value of the CNTKCTL_EL2.ECV bit.

The reset behavior of this field is:

•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [16:10]

Reserved, RES0.

EL0PTEN, bit [9]

Traps EL0 accesses to the physical timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

•  In AArch64 state, the following registers are trapped, reported using EC syndrome value 0x18:

  —  CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0.

RES0

RES0

RES0

RES0

EVNTIS

EL0PTEN

EVNTI

EL0VCTEN

EVNDIR

EVNTEN
In AArch32 state, MRC and MCR accesses to the following registers are trapped, reported using EC syndrome value 0x03, MRRC and MCRR accesses are trapped, reported using EC syndrome value 0x04:

- CNTP_CTL, CNTP_CVAL, CNTP_TV AL.

0b0: EL0 accesses to the physical timer registers are trapped to EL1.

0b1: This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EL0VTEN, bit [8]**

Traps EL0 accesses to the virtual timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value 0x18:
  - CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TV AL_EL0.

- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value 0x03, MRRC and MCRR accesses are trapped using EC syndrome value 0x04:
  - CNTV_CTL, CNTV_CVAL, and CNTV_TV AL.

0b0: EL0 accesses to the virtual timer registers are trapped.

0b1: This control does not cause any instructions to be trapped.

When FEAT_VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EVNTI, bits [7:4]**

Selects which bit of CNTVCT_EL0, as seen from EL1, is the trigger for the event stream generated from that counter when that stream is enabled.

If FEAT_ECV is implemented, and CNTKCTL_EL1.EVNTIS is 1, this field selects a trigger bit in the range 8 to 23 of CNTVCT_EL0.

Otherwise, this field selects a trigger bit in the range 0 to 15 of CNTVCT_EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EVNTDIR, bit [3]**

Controls which transition of the CNTVCT_EL0 trigger bit, as seen from EL1 and defined by EVNTI, generates an event when the event stream is enabled.

0b0: A 0 to 1 transition of the trigger bit triggers an event.

0b1: A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EVNTEN, bit [2]**

When FEAT_VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not {1, 1}, enables the generation of an event stream from CNTVCT_EL0 as seen from EL1.

0b0: Disables the event stream.

0b1: Enables the event stream.
When $\text{FEAT\_VHE}$ is implemented and $\text{HCR\_EL2.\{E2H, TGE\}}$ is $\{1, 1\}$, this control does not enable the event stream.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EL0VCTEN, bit [1]**

Traps EL0 accesses to the frequency register and virtual counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and $\text{HCR\_EL2.TGE}$ is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value $0\times18$:
  - $\text{CNTVCT\_EL0}$ and if $\text{CNTKCTL\_EL1.EL0PCTEN}$ is 0, $\text{CNTFRQ\_EL0}$.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value $0\times83$, MRR and MCRR accesses are trapped and reported using EC syndrome value $0\times04$:
  - $\text{CNTVCT}$ and if $\text{CNTKCTL\_EL1.EL0PCTEN}$ is 0, $\text{CNTFRQ}$.

0b0 EL0 accesses to the frequency register and virtual counter registers are trapped.

0b1 This control does not cause any instructions to be trapped.

When $\text{FEAT\_VHE}$ is implemented and $\text{HCR\_EL2.\{E2H, TGE\}}$ is $\{1, 1\}$, this control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EL0PCTEN, bit [0]**

Traps EL0 accesses to the frequency register and physical counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and $\text{HCR\_EL2.TGE}$ is 1, as follows:

- In AArch64 state, the following registers are trapped, reported using EC syndrome value $0\times18$:
  - $\text{CNTPCT\_EL0}$ and if $\text{CNTKCTL\_EL1.EL0VCTEN}$ is 0, $\text{CNTFRQ\_EL0}$.
- In AArch32 state, MCR or MRC accesses the following registers are trapped, reported using EC syndrome value $0\times83$, MCRR or MRRC accesses are trapped and reported using EC syndrome value $0\times04$:
  - $\text{CNTPCT}$ and if $\text{CNTKCTL\_EL1.EL0VCTEN}$ is 0, $\text{CNTFRQ}$.

0b0 EL0 accesses to the frequency register and physical counter register are trapped.

0b1 This control does not cause any instructions to be trapped.

When $\text{FEAT\_VHE}$ is implemented and $\text{HCR\_EL2.\{E2H, TGE\}}$ is $\{1, 1\}$, this control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing CNTKCTL\_EL1

When $\text{HCR\_EL2.E2H}$ is 1, without explicit synchronization, access from EL3 using the mnemonic $\text{CNTKCTL\_EL1}$ or $\text{CNTKCTL\_EL12}$ are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.16  CNTP_CTL_EL0, Counter-timer Physical Timer Control register

The CNTP_CTL_EL0 characteristics are:

**Purpose**
Control register for the EL1 physical timer.

**Configurations**
AArch64 System register CNTP_CTL_EL0 bits [31:0] are architecturally mapped to AArch32 System register CNTP_CTL[31:0].

**Attributes**
CNTP_CTL_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>62</td>
<td>ISTATUS, bit [2]</td>
</tr>
<tr>
<td>61</td>
<td>IMASK, bit [1]</td>
</tr>
<tr>
<td>60</td>
<td>ENABLE, bit [0]</td>
</tr>
</tbody>
</table>

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:
- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is **UNKNOWN**.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Access to this field is RO.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:
- 0b0 Timer interrupt is not masked by the IMASK bit.
- 0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**ENABLE, bit [0]**
Enables the timer. Permitted values are:
- 0b0 Timer disabled.
- 0b1 Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVVAL_EL0 continues to count down.

--- Note ---
Disabling the output signal might be a power-saving option.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing CNTP_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CTL_EL0 or CNTP_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTP_CTL_EL0
```

<table>

D17.11.17  CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL_EL0 characteristics are:

**Purpose**

Holds the compare value for the EL1 physical timer.

**Configurations**

AArch64 System register CNTP_CVAL_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTP_CVAL[63:0].

**Attributes**

CNTP_CVAL_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompareValue</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompareValue</td>
<td></td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL1 physical timer CompareValue.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTP_CVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CVAL_EL0 or CNTP_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.18 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL_EL0 characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Configurations**

AArch64 System register CNTP_TVAL_EL0 bits [31:0] are architecturally mapped to AArch32 System register CNTP_TVAL[31:0].

**Attributes**

CNTP_TVAL_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31-0</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the EL1 physical timer.

On a read of this register:
- If CNTP_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL_EL0.ENABLE is 1, the value returned is (CNTP_CVAL_EL0 - CNTPCT_EL0).

On a write of this register, CNTP_CVAL_EL0 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTP_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

--- Note ---

The value of CNTPCT_EL0 used in these calculations is the value seen at the Exception Level that the CNTPCT_EL0 register is being read or written from.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTP_TVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_TVAL_EL0 or CNTP_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Accesses to this register use the following encodings in the System register encoding space:

\[ \text{MRS} \ <Xt>, \ \text{CNTP\_TVAL\_EL0} \]

D17.11.19 CNTPCTSS_EL0, Counter-timer Self-Synchronized Physical Count register

The CNTPCTSS_EL0 characteristics are:

**Purpose**

Holds the self-synchronized view of the 64-bit physical count value.

**Configurations**

AArch64 System register CNTPCTSS_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTPCTSS[63:0].

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTPCTSS_EL0 are UNDEFINED.

All reads to the CNTPCTSS_EL0 occur in program order relative to reads to CNTPCT_EL0 or CNTPCTSS_EL0.

This register is a self-synchronised view of the CNTPCT_EL0 counter, and cannot be read speculatively.

**Attributes**

CNTPCTSS_EL0 is a 64-bit register.

**Field descriptions**

### D17.11.20 CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Configurations**

AArch64 System register CNTPCT_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTPCT[63:0].

All reads to the CNTPCT_EL0 occur in program order relative to reads to CNTPCTSS_EL0 or CNTPCT_EL0.

**Attributes**

CNTPCT_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical count value</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical count value</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**

Physical count value.

Reads of CNTPCT_EL0 from EL0 or EL1 return \((\text{PhysicalCountInt}_{63:0} - \text{CNTPOFF}_{EL2}_{63:0})\) if the access is not trapped, and all of the following are true:

- \(\text{CNTHCTL}_{EL2}.ECV\) is 1.
- \(\text{HCR}_{EL2}.\{E2H, TGE\}\) is not \(\{1, 1\}\).

Where \(\text{PhysicalCountInt}_{63:0}\) is the physical count returned when \(\text{CNTPCT}_{EL0}\) is read from EL2 or EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.

**Accessing CNTPCT_EL0**

Accesses to this register use the following encodings in the System register encoding space:

**MRS \(<Xt>, CNTPCT_EL0**

<table>
<thead>
<tr>

    end
elsif PSTATE.EL == EL2 then
    X[t, 64] = PhysicalCountInt();
elsif PSTATE.EL == EL3 then
    X[t, 64] = PhysicalCountInt();
D17.11.21  CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

**Purpose**

Control register for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_CTL_EL1 is a 64-bit register.

**Field descriptions**

```
+-------------------+-------------------+-------------------+
| Reserved, RES0    | Reserved, RES0    | Reserved, RES0    |
| The status of the timer. This bit indicates whether the timer condition is met: | Timer interrupt mask bit. Permitted values are: | Enables the timer. Permitted values are: |
| 0b0 Timer condition is not met. | 0b0 Timer interrupt is not masked by the IMASK bit. | 0b0 Timer disabled. |
| 0b1 Timer condition is met. | 0b1 Timer interrupt is masked by the IMASK bit. | 0b1 Timer enabled. |
```

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from $\text{CNTPS\_TVAL\_EL1}$ continues to count down.

--- Note ---
Disabling the output signal might be a power-saving option.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally \text{UNKNOWN} value.

**Accessing \text{CNTPS\_CTL\_EL1}**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRS <Xt>, CNTPS\_CTL\_EL1}
\]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>

</table>
elsif PSTATE.EL == EL3 then
    CNTPS_CTL_EL1 = X[t, 64];
### D17.11.22 CNTPOFF_EL2, Counter-timer Physical Offset register

The CNTPOFF_EL2 characteristics are:

**Purpose**

Holds the 64-bit physical offset. This is the offset for the AArch64 physical timers and counters when Enhanced Counter Virtualization is enabled.

**Configurations**

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTPOFF_EL2 are UNDEFINED.

The CNTPOFF_EL2 offset applies to:

- Direct reads of the physical counter from EL0 or EL1.
- Indirect reads of the physical counter by the EL1 physical timer.

When EL2 is implemented and enabled in the current Security state, the physical counter uses a fixed physical offset of zero if any of the following are true:

- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.
- HCR_EL2.{E2H, TGE} is {1, 1}.

**Attributes**

CNTPOFF_EL2 is a 64-bit register.

**Field descriptions**

#### Bits [63:0]

Physical offset.

D17.11.23  **CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register**

The CNTPS_CVAL_EL1 characteristics are:

**Purpose**

Holds the compare value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_CVAL_EL1 is a 64-bit register.

**Field descriptions**

**CompareValue, bits [63:0]**

Holds the secure physical timer CompareValue.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when \( \text{CNTPCT_EL0} - \text{CompareValue} \) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTPS_CVAL_EL1**

D17.11.24  CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register

The CNTPS_TVAL_EL1 characteristics are:

**Purpose**

Holds the timer value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Configurations**

There are no configuration notes.

**Attributes**

CNTPS_TVAL_EL1 is a 64-bit register.

**Field descriptions**

![Register Diagram]

**Bits [63:32]**

Reserved, RES0.

**TimerValue, bits [31:0]**

The TimerValue view of the secure physical timer.

On a read of this register:
- If CNTPS_CTL_EL1.ENABLE is 0, the value returned is UNKNOWN.
- If CNTPS_CTL_EL1.ENABLE is 1, the value returned is (CNTPS_CVAL_EL1 - CNTPCT_EL0).

On a write of this register, CNTPS_CVAL_EL1 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTPS_CVAL_EL1) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTPS_TVAL_EL1**

Accesses to this register use the following encodings in the System register encoding space:

     |   ENABLE
```

**Bits [63:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:

- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:

- 0b0 Timer interrupt is not masked by the IMASK bit.
- 0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**
Enables the timer. Permitted values are:

- 0b0 Timer disabled.
- 0b1 Timer enabled.
D17.11 Generic Timer registers

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL_EL0 continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

---

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing CNTV_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CTL_EL0 or CNTV_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

### MRS <Xt>, CNTV_CTL_EL0

D17.11.26 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

**Purpose**
Holds the compare value for the virtual timer.

**Configurations**
AArch64 System register CNTV_CVAL_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTV_CVAL[63:0].

**Attributes**
CNTV_CVAL_EL0 is a 64-bit register.

**Field descriptions**

```
<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CompareValue</td>
</tr>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**CompareValue, bits [63:0]**

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTV_CVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CVAL_EL0 or CNTV_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.27  CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL_EL0 characteristics are:

**Purpose**
Holds the timer value for the EL1 virtual timer.

**Configurations**
AArch64 System register CNTV_TVAL_EL0 bits [31:0] are architecturally mapped to AArch32 System register CNTV_TVAL[31:0].

**Attributes**
CNTV_TVAL_EL0 is a 64-bit register.

**Field descriptions**

![Field diagram]

**Bits [63:32]**
Reserved, RES0.

**TimerValue, bits [31:0]**
The TimerValue view of the EL1 virtual timer.

On a read of this register:
- If CNTV_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL_EL0.ENABLE is 1, the value returned is (CNTV_CVAL_EL0 - CNTVCT_EL0).

On a write of this register, CNTV_CVAL_EL0 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTV_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTV_TVAL_EL0**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_TVAL_EL0 or CNTV_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

D17.11.28 CNTVCTSS_EL0, Counter-timer Self-Synchronized Virtual Count register

The CNTVCTSS_EL0 characteristics are:

**Purpose**

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT_EL0 minus the virtual offset visible in CNTVOFF_EL2.

**Configurations**

AArch64 System register CNTVCTSS_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTVCTSS[63:0].

This register is present only when FEAT_ECV is implemented. Otherwise, direct accesses to CNTVCTSS_EL0 are UNDEFINED.

All reads to the CNTVCTSS_EL0 occur in program order relative to reads to CNTVCT_EL0 or CNTVCTSS_EL0.

This register is a self-synchronised view of the CNTVCT_EL0 counter, and cannot be read speculatively.

**Attributes**

CNTVCTSS_EL0 is a 64-bit register.

**Field descriptions**

![Field descriptions diagram](image)

**Bits [63:0]**

Self-synchronized virtual count value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTVCTSS_EL0**

Accesses to this register use the following encodings in the System register encoding space:

D17.11.29 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

**Purpose**

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value minus the virtual offset visible in CNTVOFF_EL2.

**Configurations**

AArch64 System register CNTVCT_EL0 bits [63:0] are architecturally mapped to AArch32 System register CNTVCT[63:0].

The value of this register is the same as the value of CNTPCT_EL0 in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented, HCR_EL2.E2H is 1, and this register is read from EL2.
- When EL2 is implemented and enabled in the current Security state, HCR_EL2.{E2H, TGE} is {1, 1}, and this register is read from EL0 or EL2.

All reads to the CNTVCT_EL0 occur in program order relative to reads to CNTVCTSS_EL0 or CNTVCT_EL0.

**Attributes**

CNTVCT_EL0 is a 64-bit register.

**Field descriptions**

![Virtual count value](image)

**Bits [63:0]**

Virtual count value.

The reset behavior of this field is:

D17.11.30 CNTVOFF_EL2, Counter-timer Virtual Offset register

The CNTVOFF_EL2 characteristics are:

**Purpose**

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT_EL0 and the virtual count value visible in CNTVCT_EL0.

**Configurations**

AArch64 System register CNTVOFF_EL2 bits [63:0] are architecturally mapped to AArch32 System register CNTVOFF[63:0].

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

--- Note ---

When EL2 is implemented and enabled in the current Security state, and is using AArch64, the virtual counter uses a fixed virtual offset of zero in the following situations:

- HCR_EL2.E2H is 1, and CNTVCT_EL0 is read from EL2.
- HCR_EL2.{E2H, TGE} is {1, 1}, and either:
  - CNTVCT_EL0 is read from EL0 or EL2.
  - CNTVCT is read from EL0.

---

**Attributes**

CNTVOFF_EL2 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>Virtual offset</td>
</tr>
</tbody>
</table>

The value of this field is treated as zero-extended in all counter calculations. The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CNTVOFF_EL2**

Accesses to this register use the following encodings in the System register encoding space:

Part E
The AArch32 Application Level Architecture
Chapter E1
The AArch32 Application Level Programmers’ Model

This chapter gives an Application level description of the programmers’ model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

- About the Application level programmers’ model on page E1-7128.
- The Application level programmers’ model in AArch32 state on page E1-7129.
- Advanced SIMD and floating-point instructions on page E1-7140.
- About the AArch32 System register interface on page E1-7158.
- Exceptions on page E1-7159.
E1.1 About the Application level programmers’ model

This chapter contains the programmers’ model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers’ model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different Exception levels that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information, see Arm architectural concepts on page A1-39.

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

• It means that the operating system can allocate system resources to an application in a unique or shared manner.

• It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

Application level software is generally unaware of its Security state, and of any virtualization. For more information, see The Armv8-A security model on page G1-8905 and The effect of implementing EL2 on the Exception model on page G1-8910.

--- Note ---

• When an implementation includes EL3, application and operating system software normally executes in Non-secure state.

• Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as privileged execution.

• In this manual, the terms CONSTRAINED UNPREDICTABLE, IMPLEMENTATION DEFINED, OPTIONAL, RES0, RES1, UNDEFINED, UNKNOWN, and UNPREDICTABLE have Arm-specific meanings, as defined in the Glossary. In body text, these terms are shown in SMALL CAPS, for example IMPLEMENTATION DEFINED.
The AArch32 Application Level Programmers’ Model

E1.2 The Application level programmers’ model in AArch32 state

The following sections give more information about the application level programmers’ model in AArch32 state:

- Instruction sets, arithmetic operations, and register files.
- Core data types and arithmetic in AArch32 state.
- The general-purpose registers, and the PC, in AArch32 state on page E1-7131.
- Process state, PSTATE on page E1-7133.
- Jazelle support on page E1-7139.

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in The general-purpose registers, and the PC, in AArch32 state on page E1-7131, these registers include the registers SP (R13) and LR (R14), which have specialized uses. Core data types and arithmetic in AArch32 state gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in The SIMD and floating-point register file on page E1-7140. Advanced SIMD and floating-point instructions on page E1-7140 gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>8 bits.</td>
</tr>
<tr>
<td>Halfword</td>
<td>16 bits.</td>
</tr>
<tr>
<td>Word</td>
<td>32 bits.</td>
</tr>
<tr>
<td>Doubleword</td>
<td>64 bits.</td>
</tr>
</tbody>
</table>

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses, see Atomicity in the Arm architecture on page E2-7164.

When any of the data types is described as unsigned, the N-bit data value represents a non-negative integer in the range 0 to \(2^{N-1}\), using normal binary format.

When any of these types is described as signed, the N-bit data value represents an integer in the range \(-2^{(N-1)}\) to \(+2^{(N-1)}-1\), using two's complement format.
The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

--- Note ---
These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the Advanced SIMD instructions that operate on a separate register file that provides registers of up to 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

### Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in Appendix K16 Arm Pseudocode Definition defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in Operators on page K16-11816.
- By use of pseudocode helper functions defined in the main text.
- By a sequence of the form:
  1. Use of the $\text{Int}()$, $\text{UInt}()$, and $\text{Int}()$ built-in functions defined in Converting bitstrings to integers on page K16-11828 to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
  3. Use of either the bitstring extraction operator defined in Bitstring concatenation and slicing on page K16-11817 or of the saturation helper functions described in Pseudocode description of saturation on page E1-7131 to convert an unbounded integer result into a bitstring result that can be written to a register.

### Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

#### Logical Shift Left

The $\text{LSL()}$ pseudocode function moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

#### Logical Shift Right

The $\text{LSR()}$ pseudocode function moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

#### Arithmetic Shift Right

The $\text{ASR()}$ pseudocode function moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

#### Rotate Right

The $\text{ROR()}$ pseudocode function moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

#### Rotate Right with Extend

The $\text{RRX()}$ pseudocode function moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.
Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see Addition and subtraction on page K16-11818.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode, the AddWithCarry() function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

An important property of the AddWithCarry() function is that if:

\[(\text{result}, \text{nzcv}) = \text{AddWithCarry}(x, \text{NOT}(y), \text{carry\_in})\]

Then:

- If \(\text{carry\_in} == '1'\), then \(\text{result} == x-y\) with:
  - \(\text{nzcv}<0> == '1'\) if signed overflow occurred during the subtraction.
  - \(\text{nzcv}<1> == '1'\) if unsigned borrow did not occur during the subtraction, that is, if \(x>y\).
- If \(\text{carry\_in} == '0'\), then \(\text{result} == x-y-1\) with:
  - \(\text{nzcv}<0> == '1'\) if signed overflow occurred during the subtraction.
  - \(\text{nzcv}<1> == '1'\) if unsigned borrow did not occur during the subtraction, that is, if \(x>y\).

Taken together, this means that the \(\text{carry\_in}\) and \(\text{nzcv}<1>\) output in AddWithCarry() calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

Pseudocode description of saturation

Some instructions perform saturating arithmetic, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo \(2^N\). This is supported in pseudocode by:

- The SignedSatQ() and UnsignedSatQ() functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The SignedSat() and UnsignedSat() functions when only the saturated result is required.

\(\text{SatQ}(i, N, \text{unsigned})\) returns either \(\text{UnsignedSatQ}(i, N)\) or \(\text{SignedSatQ}(i, N)\) depending on the value of its third argument, and \(\text{Sat}(i, N, \text{unsigned})\) returns either \(\text{UnsignedSat}(i, N)\) or \(\text{SignedSat}(i, N)\) depending on the value of its third argument.

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
  - R13 is usually identified as SP.
  - R14 is usually identified as LR.
- The PC (program counter), which can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP. Instructions that can access SP can use SP as a general-purpose register.
The A32 instruction set provides more general access to SP, and it can be used as a general-purpose register.

--- Note ---

Using SP for any purpose other than as a stack pointer might break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

---

Software can refer to SP as R13.

LR, the link register

The link register can be used to hold return link information, and some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the program counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, Arm deprecates the use of PC for any purpose other than as the program counter. See Writing to the PC for more information.

Software can refer to PC as R15.

See AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-8917 for the system level view of these registers.

--- Note ---

In general, Arm strongly recommends using the names SP, LR, and PC instead of R13, R14, and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to registers R8 to R15, rather than to registers R8 to R12, the SP, LR, and PC. These two descriptions of the group of registers have exactly the same meaning.

---

Writing to the PC

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
  - Encoding T2 of ADD, ADDS (register) on page F5-7456.
  - Encoding T1 of MOV, MOVS (register) on page F5-7719.
  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.

- The B, BL, CBNZ, CBZ, CHKA, HB, HBL, HBLP, HBP, TBB, and TBH instructions remain in the same instruction set state and branch to the value written to the PC.
  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.

- The BLX (immediate) instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.

- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - BLX (register), BX, and BXJ.
— LDR instructions with <Rt> equal to the PC.
— POP and all forms of LDM except LDM (exception return), when the register list includes the PC.
— In A32 state only, ADC, ADD, ADR, AND, ASR (immediate), BIC, EOR, LSL (immediate), LSR (immediate), MOV, MVN, ORR, ROR (immediate), RRS, RSB, RSC, SBC, and SUB instructions with <Rd> equal to the PC and without flag-setting specified.

For details of how an interworking address specifies the new instruction set state and instruction address, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC.

——— Note ————

The register-shifted register instructions, which are available only in the A32 instruction set and are summarized in Data-processing register (register shift) on page F4-7386, are CONstrained UNPREDICTABLE if they attempt to write to the PC, see Using R15 by instruction on page K1-11563.

——— Note ————

• Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see Exception return to an Exception level using AArch32 on page G1-8951.
• Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the R[n] function, with an index parameter n, are:
• Reading or writing R0-R12, SP, and LR, using n = 0-12, 13, and 14 respectively.
• Reading the PC, using n = 15.

Pseudocode description of general-purpose register and PC operations on page G1-8919 describes accesses to these registers.

Descriptions of A32 store instructions that store the PC value use the PCStoreValue() pseudocode function to specify the PC value stored by the instruction.

Writing an address to the PC causes either a simple branch to that address or an interworking branch that also selects the instruction set to execute after the branch. A simple branch is performed by the BranchWritePC() function.

An interworking branch is performed by the BXWritePC() function.

The LoadWritePC() and ALUWritePC() functions are used for two cases where the behavior was systematically modified between architecture versions.

E1.2.4 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

——— Note ————

In this chapter, references to PSTATE link to the more appropriate of:
• The Application-level view of PSTATE given in this section.
• The System-level description in Process state, PSTATE on page G1-8921.
The following PSTATE information is accessible at EL0:

**The Condition flags**

Flag-setting instructions set these. They are:

- **N** Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
  - 1 if the result is negative.
  - 0 if the result is positive or zero.

- **Z** Zero Condition flag. Set to:
  - 1 if the result of the instruction is zero.
  - 0 otherwise.
  
  A result of zero often indicates an equal result from a comparison.

- **C** Carry Condition flag. Set to:
  - 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
  - 0 otherwise.

- **V** Overflow Condition flag. Set to:
  - 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
  - 0 otherwise.

Conditional instructions test the N, Z, C, and V Condition flags, combining them with the *Condition code* for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see *Conditional execution on page F1-7229*.

**The overflow or saturation flag**

- **Q** Some instructions can set this. For those instructions that can, the PE:
  - Sets it to 1 if the instruction indicates overflow or saturation.
  - Leaves it unchanged otherwise.

  For more information, see *Pseudocode description of saturation on page E1-7131*.

**The greater than or equal flags**

- **GE[3:0]** The instructions described in *Parallel addition and subtraction instructions on page F2-7266* update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later SEL instruction. For more information, see *SEL on page F5-7880*.

PSTATE also contains PE state controls. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

**Instruction set state**

- **J, T** The current instruction set state, as shown in Table E1-1. The J bit is RES0, see the Note in this section.

<table>
<thead>
<tr>
<th>J</th>
<th>T</th>

</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>T32</td>
</tr>
</tbody>
</table>

A32 The PE is executing the A32 instruction set, summarized in *Chapter F4.A32 Instruction Set Encoding*. 
The PE is executing the T32 instruction set, summarized in Chapter F3 T32 Instruction Set Encoding.

--- Note ---

Encoding with J==1 before Armv8, Jazelle, and T32EE states

In previous versions of the Arm architecture, the encoding \{1, 0\} selected Jazelle state, and encoding \{1, 1\} selected T32EE state. From the introduction of Armv8, the architecture does not support either of these states, and these are encodings for unimplemented instruction set states, see Unimplemented instruction sets on page G1-8927. AArch32 state requires a Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-8927.

The IT block state

\[ \text{IT}[7:0] \]  

The If-Then controls for the T32 IT instruction, which applies to the IT block of instructions that immediately follow the IT instruction. See IT on page F5-7580 for a description of the IT instruction and its associated IT block.

For more information about the use of \text{PSTATE.IT}, see Use of \text{PSTATE.IT} on page E1-7137.

Endianness mapping

\[ E \]  

For data accesses, controls the endianness:

- 0 Little-endian.
- 1 Big-endian.

If an implementation does not provide:

- Big-endian support for data accesses, this bit is \text{RES0}.
- Little-endian support for data accesses, this bit is \text{RES1}.

Instruction fetches are always little-endian, and ignore \text{PSTATE.E}.

Timing control bits

\[ \text{DIT} \]  

Data Independent Timing (DIT) bit. For more information, see About the DIT bit on page E1-7139.

This bit is implemented only when \text{FEAT_DIT} is implemented.

On a reset to AArch32 state, this bit is set to 0.

Accessing PSTATE fields at EL0

The following sections describe which PSTATE fields can be directly accessed at EL0, and how they can be accessed:

- The Application Program Status Register, APSR.
- The SETEND instruction on page E1-7136.

The Application Program Status Register, APSR

At EL0, some PSTATE fields can be accessed using the Special-purpose Application Program Status Register (APSR). The APSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.
The APSR bit assignments are:

The APSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Z</td>
<td>C</td>
<td>V</td>
<td>Q</td>
<td>RES0</td>
<td>RES0</td>
<td>GE[3:0]</td>
<td>RES0</td>
<td>RES0</td>
<td>RES1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **N, Z, C, V, bits [31:28]**
  - The PSTATE Condition flags.

- **Q, bit [27]**
  - The PSTATE overflow or saturation flag.

- **Bits[26:24]**
  - Reserved, RES0. Software can use MSR instructions that write the top byte of the APSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

- **Bits[23:20, 15:0]**
  - Reserved bits that are allocated to system features, or are available for future expansion.

Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as **Do-Not-Modify** (DNM) bits. For more information about the reserved bits, see *The Current Program Status Register, CPSR on page G1-8923*.

These bits are **UNKNOWN** on a Read, and it is permitted that, on a read of APSR:

- Bit[22] returns the value of PSTATE.PAN.
- Bit[9] returns the value of PSTATE.E.
- Bits[4:0] return the value of PSTATE.M[4:0]. Bit[4] is RES1 indicating that the PE is in AArch32 state.

--- **Note**

This is an exception to the general rule that an **UNKNOWN** field must not return information that cannot be obtained, at the current Privilege level, by an architected mechanism.

- **GE[3:0], bits [19:16]**
  - The PSTATE greater than or equal flags.

The other PSTATE fields cannot be accessed by using the APSR.

The system level alias for the APSR is the CPSR. The CPSR is a superset of the APSR. See *The Current Program Status Register, CPSR on page G1-8923*.

Writes to the PSTATE fields have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the APSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

**The SETEND instruction**

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

- **SETEND BE** Sets PSTATE.E to 1, for big-endian operation.
- **SETEND LE** Sets PSTATE.E to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see *SETEND on page F5-7882*. Arm deprecates use of the SETEND instruction.
Use of PSTATE.IT

PSTATE.IT provides the If-Then controls for the T32 IT instruction, which applies to the IT block of instructions that immediately follow the IT instruction.

PSTATE.IT divides into two subfields:

- IT[7:5]  
  Holds the base condition for the current IT block. The base condition is the top three bits of the Condition code specified by the <firstcond> field of the IT instruction.

- IT[4:0]  
  Encodes:
  - Implicitly, the size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field, as shown in Table E1-2.
  - For each instruction in the IT block, the least significant bit of the Condition code. This is encoded in the IT block entries that Table E1-2 shows as Nx.

  Note
  Changing the least significant bit of a Condition code from 0 to 1 has the effect of inverting the Condition code.

Both subfields are all zeros when no IT block is active.

When an IT instruction is executed, PSTATE.IT is set according to the <firstcond> field of the instruction and the Then and Else (T and E) parameters in the instruction, see IT on page F5-7580. This means that, on executing an IT instruction, the initial state of PSTATE.IT depends on the number of instructions in the IT block, as Table E1-2 shows:

<table>
<thead>
<tr>
<th>Number of instructions in IT block</th>
<th>PSTATE.IT bits</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>cond_base</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>cond_base</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>cond_base</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>cond_base</td>
<td></td>
</tr>
<tr>
<td>Not executing an IT instruction</td>
<td>000</td>
<td>No IT block is active</td>
</tr>
</tbody>
</table>

In Table E1-2, N1 refers to the first instruction in the IT block, and N2, N3, and N4 refer to the second, third, and fourth instructions in the IT block if they are present.

When permitted, an instruction in an IT block is conditional, see Conditional instructions on page F2-7257 and Conditional execution on page F1-7229. The Condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, PSTATE.IT[4:0] is left-shifted by one bit, so that PSTATE[4] always relates to the next instruction to be executed.
Table E1-3 shows how PSTATE.IT during the execution of an IT instruction with four instructions in the IT block.

Table E1-3 Updates to PSTATE.IT when executing an IT instruction with a four-instruction IT block

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

A few instructions, for example BKPT, cannot be conditional and therefore are always executed ignoring the current value of PSTATE.IT.

For details of what happens if an instruction in an IT block takes an exception, see Overview of exception entry on page G1-8936.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in PSTATE.IT advancing to execution where no IT block is active.

Implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable use of IT for some instructions, making them UNDEFINED. When an implementation includes ITD control fields, Changes to an ITD control by an instruction in an IT block describes the permitted CONSTRAINED UNPREDICTABLE behaviors if an instruction in an IT block changes the value of an ITD control to disable the use of the IT instruction.

On a branch or an exception return, if PSTATE.IT is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is CONSTRAINED UNPREDICTABLE.

PSTATE.IT affects instruction execution only in T32 state. In A32 state, PSTATE.IT must be 0b00000000, otherwise the behavior is CONSTRAINED UNPREDICTABLE.

For more information, see CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-11564.

Changes to an ITD control by an instruction in an IT block

In an implementation that includes SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD controls, if an instruction in an IT block changes an ITD control so that the IT instruction using the IT block would be disabled, then one of the following behaviors applies:

- The change to the ITD field, once synchronized, has no effect on the execution of instructions in the current IT block, but applies only to any subsequent execution of an IT instruction to which the control applies.
- Synchronizing the change to the ITD field guarantees that all bits of PSTATE.IT are cleared to 0.

In addition, after the change to the ITD field has been synchronized, any remaining instructions in the IT block that would be made UNDEFINED by the new value of ITD are either:

- Executed normally.
- Treated as UNDEFINED.

The choice between the options described in this section is determined by the implementation, and any choice can vary between different changes to an ITD control by an instruction in an IT block.
Pseudocode description of PSTATE PE state fields

The pseudocode function `CurrentInstrSet()` returns the current instruction set. The pseudocode function `SelectInstrSet()` selects a new instruction set.

PSTATE.IT advances after normal execution of an IT block instruction. This is described by the `AArch32.ITAdvance()` pseudocode function.

The pseudocode function `InITBlock()` tests whether the current instruction is in an IT block. The pseudocode function `LastInITBlock()` tests whether the current instruction is the last instruction in an IT block.

The `BigEndian()` pseudocode function tests whether big-endian data memory accesses are currently selected.

### E1.2.5 About the DIT bit

When the value of CPSR.DIT is 1:

- The instructions listed in CPSR are required to have:
  - Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
  - Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.
  - All loads and stores have their timing insensitive to the value of the data being loaded or stored.

/player/cpsr

Note

When the value of CPSR.DIT is 0, the architecture makes no statement about the timing properties of any instructions.

A corresponding DIT bit is added to PSTATE in AArch64 state, and to CPSR in AArch32 state.

When an exception is taken from AArch32 state to AArch32 state, CPSR.DIT is copied to SPSR.DIT.

When an exception is taken from AArch32 state to AArch64 state, CPSR.DIT is copied to SPSR_ELx.DIT.

When an exception returns to AArch32 state from AArch32 state, SPSR.DIT is copied to CPSR.DIT.

When an exception returns to AArch32 state from AArch64 state, SPSR_ELx.DIT is copied to CPSR.DIT.

CPSR.DIT bit can be written using an MSR instruction at any Exception Level in AArch32 state, and read using an MRS instruction at any Exception Level.

### E1.2.6 Jazelle support

The architecture requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in `Trivial implementation of the Jazelle extension` on page G1-8927.
E1.3 Advanced SIMD and floating-point instructions

In general, the architecture requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see Implications of not including Advanced SIMD and floating-point support on page E1-7153.

The Advanced SIMD instructions perform packed Single Instruction Multiple Data (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations. When FEAT_FP16 is implemented, half-precision floating-point can also be used for data processing.

These instructions permit floating-point exceptions, such as Overflow or Divide by Zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. The architecture also optionally supports the trapping of floating-point exceptions. For more information about floating-point exceptions, see Floating-point exceptions and exception traps on page E1-7148.

The Advanced SIMD and floating-point instructions also provide the following conversion functions:

- Between half-precision floating-point and single-precision floating point, in both directions.
- From double-precision, floating-point to single-precision floating point or integer.
- When FEAT_AA32BF16 is implemented, between single-precision floating-point and BFloat16 floating-point.

Some Advanced SIMD instructions support polynomial arithmetic over \{0, 1\}, as described in Polynomial arithmetic over \{0, 1\} on page A1-54.

For system level information about the Advanced SIMD and Floating-point implementation, see Advanced SIMD and floating-point support on page G1-8996.

The following sections give more information about the Advanced SIMD and floating-point instructions:

- The SIMD and floating-point register file.
- Data types supported by the Advanced SIMD implementation on page E1-7142.
- Advanced SIMD and floating-point System registers on page E1-7142.
- Floating-point data types and arithmetic on page E1-7142.
- Flushing denormalized numbers to zero on page E1-7143.
- Floating-point exceptions and exception traps on page E1-7148.
- Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-7153.
- Implications of not including Advanced SIMD and floating-point support on page E1-7153.
- Pseudocode description of floating-point operations on page E1-7153.

E1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, which comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. Figure E1-1 on page E1-7141 shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0-Q15.
- Thirty-two 64-bit doubleword registers, D0-D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in Q0 and Q1 and a 128-bit vector in Q1.
Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, which can be viewed as:

- Thirty-two 64-bit doubleword registers, D0-D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0-S31. Only half of the set is accessible in this view.

**Note**

In AArch32 state, half-precision floating point values are always represented using the bottom 16 bits of a single word register, S0-S31. When a half-precision value is written to a single word register, the top 16 bits of that register are set to 0.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

![Figure E1-1 SIMD and floating-point register file, AArch32 operation](image-url)

The mapping between the registers is as follows:

- S<2n> maps to the least significant half of D<n>.
- S<2n+1> maps to the most significant half of D<n>.
- D<2n> maps to the least significant half of Q<n>.
- D<2n+1> maps to the most significant half of Q<n>.

For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.
Pseudocode description of the SIMD and Floating-point register file

The functions \_Dclone, S[], and D[] provide the S0-S31, D0-D31, and Q0-Q15 views of the Advanced SIMD and floating-point registers:

The \texttt{Din[]} function returns a doubleword register from the \_Dclone copy of the SIMD and Floating-point register file, and the Qin[] function returns a quadword register from that register file.

--- Note ---

The \texttt{CheckAdvSIMDEnabled()} function copies the D[] register file to \_Dclone[], see \textit{Pseudocode description of enabling SIMD and floating-point functionality on page G1-9035}.

---

E1.3.2 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. \textit{Advanced SIMD vector formats in AArch32 state on page A1-44} describes these formats.

Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In \textit{Advanced SIMD vector formats in AArch32 state on page A1-44, Figure A1-3 on page A1-46 shows the Advanced SIMD vector formats}.

\textit{Pseudocode description of Advanced SIMD vectors}

The pseudocode function \texttt{Elem[]} accesses the element of a specified index and size in a vector.

---

E1.3.3 Advanced SIMD and floating-point System registers

The Advanced SIMD and floating-point instructions have a shared register space for System registers. The only register in this space that is accessible at the Application level is the FPSCR.

Writes to the FPSCR can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See \textit{Advanced SIMD and floating-point System registers on page G1-8998} for the system level view of the registers.

These registers can be described as the \textit{SIMD and floating-point System registers}.

---

E1.3.4 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types. When \texttt{FEAT\_FP16} is implemented, it also supports the half-precision floating-point data type for data processing operations. When \texttt{FEAT\_AA32BF16} is implemented, it also supports the BFloat16 floating-point storage format.

\textit{Arm standard floating-point arithmetic} means IEEE 754 floating-point arithmetic with the restrictions described in \textit{Floating-point support on page A1-55}, including supporting only the input and output values described in \textit{Arm standard floating-point input and output values on page A1-57}.

The AArch32 Advanced SIMD instructions support single-precision and, when \texttt{FEAT\_FP16} is implemented, half-precision Arm standard floating-point arithmetic.
The following sections describe the Advanced SIMD and floating-point formats:

- **Double-precision floating-point format** on page A1-51.
- **BFloat16 floating-point format** on page A1-52.

The following sections describe features of Advanced SIMD and floating-point processing:

- **Flushing denormalized numbers to zero.**
- **NaN handling and the Default NaN** on page A1-60.

### E1.3.5 Flushing denormalized numbers to zero

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and Intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization. If a number satisfies the condition \(0 < \text{Abs}(<result>) < \text{MinNorm}\), it is treated as a denormalized number.

\(\text{MinNorm}\) is defined as follows:

- For half-precision numbers, \(\text{MinNorm} = 2^{-14}\).
- For single-precision and BFloat16 numbers, \(\text{MinNorm} = 2^{-126}\).
- For double-precision numbers, \(\text{MinNorm} = 2^{-1022}\).

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

#### Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed. If a floating-point operation has an input denormalized number that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For Advanced SIMD and floating-point instructions, other than \textit{FABS} and \textit{FNEG}, that process half-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If \text{FPSCR.FZ16} is 0, denormalized half-precision inputs are not flushed to zero.
- If \text{FPSCR.FZ16} is 1, flushing denormalized inputs to zero occurs as follows:
  - If an instruction does not convert a half-precision input to a higher precision output, all input denormalized numbers are flushed to zero.
  - If an instruction converts a half-precision input to a higher precision output, input denormalized numbers are not flushed to zero.

For Advanced SIMD and scalar floating-point instructions, other than \textit{FABS} and \textit{FNEG}, that process single-precision, or double-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If \text{FPSCR.FZ} is 0, flushing denormalized inputs to zero occurs as follows:
  - For Advanced SIMD floating-point instructions, all single-precision and double-precision inputs that are denormalized numbers are flushed to zero.
For scalar floating-point instructions, single-precision and double-precision inputs that are denormalized numbers are not flushed to zero.

- If FPSCR.FZ is 1, for all A32, and T32 instructions, single-precision, and double-precision inputs that are denormalized numbers are flushed to zero.

If FEAT_AA32BF16 is implemented, for Advanced SIMD and scalar floating-point instructions, other than FABS and FNNEG, that process BF16 inputs, flushing denormalized inputs to zero is treated as follows:

- Instructions that convert from single-precision floating-point values to BF16 format flush denormalized inputs to zero.
- For any value of FPSCR.FZ, VDOT (vector), VDOT (by element), and VMMLA instructions flush all BF16 inputs that are denormalized numbers to zero.

**Flushing to zero of denormalized numbers as Intermediate results of some BF16 instructions**

BF16 arithmetic instructions VDOT (by element), VDOT (vector), and VMMLA, convert BF16 input values to IEEE single-precision format, and calculate N-way dot-products, accumulating the products in single-precision accumulators.

If FEAT_AA32BF16 is implemented, for Advanced SIMD and floating-point instructions, if a BF16 arithmetic instruction processes an Intermediate result that is a single-precision denormalized number, the Intermediate result is unconditionally flushed to zero.

**Flushing denormalized outputs to zero**

If flushing denormalized outputs to zero is enabled for an instruction and a data type, and an output from that instruction is a denormalized number of that data type, the output operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has an output denormalized number that is flushed to zero, for all purposes within the instruction other than calculating floating-point exceptions, all outputs that are denormalized numbers are treated as though they were zero with the same sign as the output.

For Advanced SIMD and floating-point instructions, other than FABS and FNNEG, that generate half-precision outputs, flushing denormalized outputs to zero can be controlled as follows:

- If FPSCR.FZ16 is 0, denormalized half-precision outputs are not flushed to zero.
- If FPSCR.FZ16 is 1, flushing denormalized outputs to zero occurs as follows:
  - If the instruction does not convert a half-precision input to a higher precision output, all output denormalized numbers are flushed to zero.
  - If the instruction converts a half-precision input to a higher precision output, output denormalized numbers are not flushed to zero.

For Advanced SIMD and scalar floating-point instructions, other than FABS and FNNEG, that process single-precision, or double-precision inputs, flushing denormalized outputs to zero can be controlled as follows:

- If FPSCR.FZ is 0, flushing denormalized outputs to zero occurs as follows:
  - For Advanced SIMD floating-point instructions, all single-precision and double-precision outputs that are denormalized numbers are flushed to zero.
  - For scalar floating-point instructions, single-precision and double-precision outputs that are denormalized numbers are not flushed to zero.
- If FPSCR.FZ is 1, for all A32, and T32 instructions, single-precision, and double-precision outputs that are denormalized numbers are flushed to zero.

If FEAT_AA32BF16 is implemented, for Advanced SIMD and scalar floating-point instructions, other than FABS and FNNEG, that generate BF16 outputs, flushing denormalized outputs to zero can be controlled as follows:

- BF16 arithmetic instructions flush denormalized outputs to zero.
• If FPSCR.FZinstructions that convert from single-precision floating-point values to BF16 format flush
denormalized outputs to zero.
• VDOT (vector), VDOT (by element), and VMMLA instructions flush all BF16 outputs that are denormalized
numbers to zero regardless of the value of FPSCR.FZ.

E1.3.6 NaN handling and the Default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the
mantissa. The Arm architecture also defines a Default NaN which does not follow this format.

The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a
speculative result of a floating-point calculation not involving NaN inputs.

The Default NaN

The Default NaN is encoded as described in Table E1-4 on page E1-7145.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign bit</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Exponent</td>
<td>0x1F</td>
<td>0xFF</td>
<td>0x7FF</td>
<td>0xFF</td>
</tr>
<tr>
<td></td>
<td></td>
<td>bits[21:0] == 0</td>
<td>bits[50:0] == 0</td>
<td>bits[5:0] == 0</td>
</tr>
</tbody>
</table>

If FPSCR.DN is 1, for Advanced SIMD and floating-point instructions other than FABS, FMAX*, FMIN* and FNEG, if any
input to a floating-point operation performed by the instruction is a NaN, the output of the floating-point operation
is the Default NaN.

For FABS, FNEG, FMAX*, and FMIN*, Default NaN behavior is explained in the instruction description.

If FPSCR.DN is 0, for floating-point processing the Default NaN is not used for NaN propagation.

If VDOT (vector), VDOT (by element), and VMMLA instructions generate a NaN, the NaN is the default NaN.
regardless of the setting of FPSCR.DN.

If a floating-point instruction performs a floating-point operation, and that instruction generates an untrapped
Invalid Operation floating-point exception for a reason other than one of the inputs being a signaling NaN, the
output is the Default NaN.

NaN handling

The IEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm
architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and a
different number of fraction bits from its source. See instruction descriptions for details.

NaN propagation

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the
instruction and the number of operands.
If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

• If the input NaN is a quiet NaN, the output NaN is the same as the input NaN.

• If the input NaN is a signaling NaN, the output NaN is derived as follows:
  — If the handling of a signaling NaN by the instruction generates an Invalid Operation exception, the output NaN is the quieted version of the input NaN.
  — If the handling of a signaling NaN by the instruction does not generate an Invalid Operation exception, the output NaN is the same as the input NaN. This case applies for FABS, FNEG, and FTSSEL instructions.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

• If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.

• If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

• If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

• If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, when an operand is described as *first* this relates to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

If FPSCR.DN is 0, for Advanced SIMD, floating-point, or BF16 instructions that perform a floating-point operation, other than FABS, FNEG, FMAX*, and FMIN*, NaN outputs that derive from NaN inputs are derived as follows:

• If all of the following apply, an instruction outputs a quiet NaN derived from the first signaling NaN operand:
  — At least one operand is a signaling NaN.
  — The instruction is not trapped.

• If all of the following apply, an instruction outputs a quiet NaN derived from the first NaN operand:
  — At least one operand is a NaN, but none of the operands is a signaling NaN.
  — The instruction is not trapped.

If an output NaN is derived from an input NaN, the pseudocode functions FPAbs(), and FPNeg() can change the sign of the NaN,

### E1.3.7 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field FPSCR.RMode or by the instruction.

The rounding mode control field FPSCR.RMode can select the following rounding modes:

• Round to Nearest (RN) mode.
• Round towards Plus Infinity (RP) mode.
• Round towards Minus Infinity (RM) mode.
• Round towards Zero (RZ) mode.
The following two additional rounding modes are not selected by FPSCR.RMode, but are used by some instructions:

- Round to Odd mode.
- Round to Nearest with ties to away mode.

**Round to Nearest mode**

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

**Round towards Plus Infinity mode**

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

**Round towards Minus Infinity mode**

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

**Round towards Zero mode**

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

**Round to Nearest with Ties to Away**

Round to Nearest with Ties to Away rounding mode is used by the VCVTA (Advanced SIMD), VCVTA (floating-point), VRINTA (Advanced SIMD), and VRINTA (floating-point) instructions.

Round to Nearest with Ties to Away rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity, the sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the larger number.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.
Round to Odd mode

Round to Odd mode is not defined by IEEE 754.

For BF16 instructions, if an intermediate format has at least two more bits of precision than the result format, Round to Odd mode is used and operates as follows:

- If the rounded value is inexact, the least significant bit of the fraction is set to 1.
- If the value is too large to represent in the single-precision format, the rounded value is a single-precision Infinity, the sign of the rounded value is the same as the sign of the value before rounding.

E1.3.8 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

Note

An Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an operation, rather than on an instruction.

The architecture does not support asynchronous reporting of floating-point exceptions.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated, and all statements about synchronous exception generation from that floating-point exception do not apply to the implementation.

If an implementation supports synchronous exception generation for a floating-point exception, then the registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception.

On return from a synchronous floating-point exception, software might not restore the cumulative exception flags.

Trapped floating-point exceptions are taken to the following levels:

- If a trapped floating-point exception occurs at EL0, the exception level it is taken to is as follows:
  - If EL2 is using AArch32 and HCR.TGE is 1, the exception is taken to EL2.
  - If EL2 is using AArch64 and HCR_EL2.TGE is 1, the exception is taken to EL2
  - Otherwise, the exception is taken to EL1
- If a trapped floating-point exception occurs at EL1, it is taken to EL1.
- If a trapped floating-point exception occurs at EL2, it is taken to EL2.
- If a trapped floating-point exception occurs at EL3, it is taken to EL3.

If a trapped floating-point exception is taken to an Exception level that is using AArch64, then it is reported in the ELR_ELx for the target Exception level, as described in Exception entry on page D1-4641.
If the exception is taken to an Exception level that is using AArch32, then it is taken as an Undefined Instruction exception, see *Undefined Instruction exception* on page G1-8964. The FPEXC identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

**Input Denormal exceptions**

The cumulative floating-point exception bit FPSCR.IDC, and the trap enable bit FPSCR.IDE both relate to Input Denormal exceptions.

If a single-precision or double-precision floating-point input is flushed to zero, an Input Denormal exception is generated.

If a half-precision floating-point value is flushed to zero, an Input Denormal exception is not generated.

**Inexact exceptions**

The cumulative floating-point exception bit FPSCR.IXC, and the trap enable bit FPSCR.IXE both relate to Inexact exceptions.

If a denormalized output is flushed to zero, an Inexact exception is not generated.

If a result is not flushed to zero, and the result does not equal the result computed with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

**Underflow exceptions**

The cumulative floating-point exception bit FPSR.UFC, and the trap enable bit FPSCR.UFE both relate to Underflow exceptions.

For the purpose of underflow floating-point exception generation, a denormalized number is detected before rounding is applied.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then the underflow exception is generated as follows:

- If FPSCR.UFE is 0, and the result is inexact, then the underflow floating-point exception is generated.
- If FPSCR.UFE is 1, for both exact and inexact results, the underflow floating-point exception is generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is generated. The Underflow exception is not trapped regardless of the value of FPSCR.UFE.

**Overflow exceptions**

The cumulative floating-point exception bit FPSCR.OFC, and the trap enable bit FPSCR.OFE both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the rounding mode and the sign of the result before rounding as follows:

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision’s largest finite number with the sign of the result before rounding.
Divide by Zero exceptions

The cumulative floating-point exception bit FPSCR.DZC, and the trap enable bit FPSCR.DZE both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

For the purpose of Divide by Zero exception generation, testing for zero occurs after flushing of denormalized numbers to zero.

A denormalized dividend that is flushed to zero is treated as zero and prevents Divide by Zero from occurring.

If the dividend is a finite nonzero, normalized number, and the divisor is a denormalized number, the divisor is treated as zero and causes Divide by Zero to occur.

For the reciprocal and reciprocal square root estimate functions, the dividend is assumed to be $+1.0$. This means that a zero or denormalized operand to these functions causes generation of a Divide by Zero floating-point exception.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

Invalid Operation exceptions

The cumulative floating-point exception bit FPSCR.IOC, and the trap enable bit FPSCR.IOE both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN, and the instruction is not FABS or FNEG.
- Magnitude subtraction of infinities.
- Multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Square root of an operand that is less than zero.

For the purpose of Invalid Operation Exception generation, testing for zero occurs after flushing of denormalized numbers to zero. So a denormalized input that is flushed to zero is treated as zero.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation exception.

For the signaling compare instructions FCMPE and FCCMPE, if either of the source operands is any type of NaN, the instruction generates an Invalid Operation floating-point exception.

Floating-point exception traps

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- The floating-point exceptions can be trapped, by setting trap enable bits in the FPSCR, see Floating-point exceptions and exception traps on page E1-7148, and:
  - When a trap is not enabled the corresponding floating-point exception updates the corresponding FPSCR cumulative bit, but does not generate an exception.
  - When a trap is enabled the corresponding floating-point exception does not update the FPSCR, but generates an exception. In this case, bits in the FPEXC indicate which floating-point exceptions have occurred.
• The definition of the Underflow floating-point exception is different in the trapped and cumulative exception cases. In the trapped case, the definition is:
  — The trapped Underflow floating-point exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
• As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in Combinations of floating-point exceptions.
• For Invalid Operation floating-point exceptions, for details of which quiet NaN is produced as the default result, see NaN handling and the Default NaN on page A1-60.
• For Overflow floating-point exceptions, the sign bit of the default result is determined normally for the overflowing operation.
• For Divide by Zero floating-point exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-5 shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxNorm</td>
<td>The maximum normalized number of the destination precision.</td>
</tr>
<tr>
<td>RM</td>
<td>Round towards Minus Infinity mode, as defined in the IEEE 754 standard.</td>
</tr>
<tr>
<td>RN</td>
<td>Round to Nearest mode, as defined in the IEEE 754 standard.</td>
</tr>
<tr>
<td>RP</td>
<td>Round towards Plus Infinity mode, as defined in the IEEE 754 standard.</td>
</tr>
<tr>
<td>RZ</td>
<td>Round towards Zero mode, as defined in the IEEE 754 standard.</td>
</tr>
</tbody>
</table>

For more information about the IEEE 754 descriptions of the rounding modes, see Floating-point standards, and terminology on page A1-57.

### Table E1-5 Results of untrapped floating-point exceptions

### Combinations of floating-point exceptions

Many pseudocode functions perform floating-point operations, including FixedToFP(), FPAdd(), FCompare(), FCompareEQ(), FCompareGE(), FCompareGT(), FDiv(), FMax(), FMin(), FMul(), FMulAdd(), FRecipEstimate(), FRecipStep(), FPRSQRTEstimate(), FPRSQRTStep(), FPSqrt(), FPSub(), and FPToFixed(). All of these operations can generate floating-point exceptions.

**Note**

FPAbs() and FPMeg() are not classified as floating-point operations because:
• They cannot generate floating-point exceptions.
• The floating-point operation behavior described in the following sections does not apply to them:
  — Flushing denormalized numbers to zero on page A1-58.
  — NaN handling and the Default NaN on page A1-60.
More than one exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more floating-point exceptions caused by an operation is trapped, the behavior of the instruction depends on the priority of the exceptions:

- If the higher priority floating-point exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority floating-point exception is provided.

  Note

  Information about the lower priority floating-point exception might be provided in:

  — The FPEXC, if the exception generated by the trap is taken to an Exception level that is using AArch32.
  — The ESR_ELx.ISS field, if the exception generated by the trap is taken to an Exception level that is using AArch64.

  However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

  Apart from this, the lower priority floating-point exception is ignored in this case.

- If the higher priority floating-point exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority floating-point exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority.

For example, a VMLA.F32 instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact floating-point exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any floating-point exception on the multiplication. The same applies to Invalid Operation floating-point exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal floating-point exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is CONSTRAINED UNPREDICTABLE which of an Input Denormal floating-point exception on the addition and a floating-point exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal floating-point exception does not depend on the result of the multiplication. The same applies to an Invalid Operation floating-point exception on the addition caused by the addend being a signaling NaN.

  Note

The VFMA instruction performs a vector addition and a vector multiplication as a single operation. The VFMS instruction performs a vector subtraction and a vector multiplication as a single operation.
E1.3.9 Controls of Advanced SIMD operation that do not apply to floating-point operation

Earlier architectures permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. From the introduction of Armv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in earlier architectures. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in:
  - Advanced SIMD data-processing on page F3-7314, for the T32 instruction set.
  - Advanced SIMD data-processing on page F4-7422, for the A32 instruction set.
- All instructions with encodings defined in:
  - Advanced SIMD element or structure load/store on page F3-7350, for the T32 instruction set.
  - Advanced SIMD element or structure load/store on page F4-7434, for the A32 instruction set.
- The form of the VDUP instruction described in VDUP (general-purpose register) on page F6-8370.
- The byte and halfword forms of the VMOV instructions described in each of:
  - VMOV (general-purpose register to scalar) on page F6-8550.
  - VMOV (scalar to general-purpose register) on page F6-8554.

The controls of this functionality are:

- The CPACR.ASEDIS field.
- The HCPTR.TASE field.

In an implementation that supports Advanced SIMD functionality, support for each of these controls is optional:

- If the CPACR.ASEDIS control is not supported then the CPACR.ASEDIS field is RAZ/WI. This is equivalent to the control permitting the execution of Advanced SIMD instructions at EL1 and EL0.
- If the HCPTR.TASE control is not supported then the HCPTR.TASE field is RAZ/WI. This means the HCPTR does not provide a control that can trap Non-secure execution of Advanced SIMD instructions to Hyp mode.

E1.3.10 Implications of not including Advanced SIMD and floating-point support

In general, the architecture requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, Arm might produce or license an Armv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the CPACR.[cp10, cp11] fields is RES0.
- The CPACR.ASEDIS bit is RES0.
- Each of the HCPTR.[TASE, TCP10, TCP11] fields is RES1.
- Each of the NSACR.[NSASEDIS, cp10, cp11] fields is RES0.
- The FPEXC register is UNDEFINED.

E1.3.11 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the architecture:

- Generation of specific floating-point values on page E1-7154.
- Floating-point negation and absolute value on page E1-7154.
- Floating-point value unpacking on page E1-7154.
- Floating-point exception and NaN handling on page E1-7154.
- Floating-point rounding on page E1-7154.
- Selection of Arm standard floating-point arithmetic on page E1-7154.
- Floating-point comparisons on page E1-7155.
• Floating-point maximum and minimum on page E1-7155.
• Floating-point addition and subtraction on page E1-7155.
• Floating-point multiplication and division on page E1-7155.
• Floating-point fused multiply-add on page E1-7155.
• Floating-point reciprocal estimate and step on page E1-7155.
• Floating-point square root on page E1-7156.
• Floating-point reciprocal square root estimate and step on page E1-7156.
• Floating-point conversions on page E1-7157.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The sign argument is '0' for the positive version and '1' for the negative version:
• FPInfinity().
• FPMaxNormal().
• FPZero().
• FPTwo().
• FPThree().
• FPDefaultNaN().

Floating-point negation and absolute value

The floating-point negation and absolute value operations affect only the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

The floating-point negation operation is described by the pseudocode function FPNeg(). The floating-point absolute value operation is described by the pseudocode function FPAbs().

Floating-point value unpacking

The FPUnpack() function determines the type of a floating-point number, defined by FPType{}, and its numerical value. It also does flush-to-zero processing on input operands.

Floating-point exception and NaN handling

The FPProcessException() procedure checks whether a floating-point exception is trapped, and handles it accordingly. The floating-point exception types are defined by FPExc{}.

The FPProcessNaN() function processes a NaN operand, producing the correct result value and generating an Invalid Operation floating-point exception if necessary. The FPProcessNaNs() function performs the standard NaN processing for a two-operand operation. The FPProcessNaNs3() function performs the standard NaN processing for a three-operand operation.

Floating-point rounding

The FPRound() function rounds and encodes a floating-point result to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

Selection of Arm standard floating-point arithmetic

The StandardFPSCRValue() function returns the FPSCR value that selects Arm standard floating-point arithmetic. Most of the arithmetic functions have a Boolean fpscr_controlled argument that is TRUE for Floating-point operations and FALSE for Advanced SIMD operations, and that selects between using the real FPSCR value and this value.
Floating-point comparisons

The FPCompare() function compares two floating-point numbers, producing a \{N, Z, C, V\} Condition flags result as shown in Table E1-6:

<table>
<thead>
<tr>
<th>Comparison result</th>
<th>N</th>
<th>Z</th>
<th>C</th>
<th>V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equal</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Less than</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Greater than</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Unordered</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

This result defines the operation of the V_CMP floating-point instruction. The V_CMP instruction writes these flag values in the FPSR. After using a VMRS instruction to transfer them to the APSR, they can control conditional execution as shown in Table F1-1 on page F1-7229.

The FPCompareEQ(), FPCompareGE(), and FPCompareGT() functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

Floating-point maximum and minimum

The FPMAX() function returns the maximum of two floating-point numbers. The FPMIN() function returns the minimum of two floating-point numbers.

Floating-point addition and subtraction

The FPADD() function adds two floating-point numbers. The FPSUB() function subtracts one floating-point number from another floating-point number.

Floating-point multiplication and division

The FPMUL() function multiplies two floating-point numbers. The FPDIV() function divides one floating-point number by another floating-point number.

Floating-point fused multiply-add

The FPMULADD() function performs a floating-point fused multiply-add.

Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The VRECPE instruction produces the initial estimate of the reciprocal. It uses the pseudocode functions:

- FPREcipEstimate().
- UnsignedRecipEstimate().
Table E1-7 shows the results where input values are out of range.

Table E1-7 VRECPE results for out of range inputs

<table>
<thead>
<tr>
<th>Number type</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>&lt;= 0x7FFFFFFF</td>
<td>0xFFFFFFFF</td>
</tr>
<tr>
<td>Floating-point</td>
<td>NaN</td>
<td>Default NaN</td>
</tr>
<tr>
<td>Floating-point</td>
<td>±0 or denormalized number</td>
<td>±infinity a</td>
</tr>
<tr>
<td>Floating-point</td>
<td>±infinity</td>
<td>±0</td>
</tr>
<tr>
<td>Floating-point</td>
<td>Absolute value &gt;= 2(^{126})</td>
<td>±0</td>
</tr>
</tbody>
</table>

a. FPSCR.DZC is set to 1

The Newton-Raphson iteration:

\[ x_{n+1} = x_n \left(2-\frac{dx_n}{x_0}\right) \]

converges to \((1/d)\) if \(x_0\) is the result of VRECPE applied to \(d\).

The VRECP instruction performs a \((2 - \text{op1} \times \text{op2})\) calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the FPRecipStep() pseudocode function.

Table E1-8 shows the results where input values are out of range.

Table E1-8 VRECP results for out of range inputs

<table>
<thead>
<tr>
<th>Input Vn[i]</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any NaN</td>
<td>-</td>
<td>Default NaN</td>
</tr>
<tr>
<td>±0.0 or denormalized number</td>
<td>±infinity</td>
<td>2.0</td>
</tr>
<tr>
<td>±infinity</td>
<td>±0.0 or denormalized number</td>
<td>2.0</td>
</tr>
</tbody>
</table>

Floating-point square root

The FPSqrt() function returns the square root of a floating-point number.

Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the pseudocode functions:

- FPSqrtEstimate().
- UnsignedRSqrtEstimate().
Table E1-9 shows the results where input values are out of range.

### Table E1-9 VRSQRTE results for out of range inputs

<table>
<thead>
<tr>
<th>Number type</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>&lt;= 0x3FFFFFFF</td>
<td>0xFFFFFFFF</td>
</tr>
<tr>
<td>Floating-point</td>
<td>NaN, -(normalized number), -infinity</td>
<td>Default NaN</td>
</tr>
<tr>
<td>Floating-point</td>
<td>-0 or -(denormalized number)</td>
<td>- infinity</td>
</tr>
<tr>
<td>Floating-point</td>
<td>+0 or +(denormalized number)</td>
<td>+infinity</td>
</tr>
<tr>
<td>Floating-point</td>
<td>+infinity</td>
<td>+0</td>
</tr>
</tbody>
</table>

a. FPSCR.DZC is set to 1.

The Newton-Raphson iteration:

\[ x_{n+1} = x_n \frac{(3-dx_n^2)}{2} \]

converges to \( \frac{1}{\sqrt{d}} \) if \( x_0 \) is the result of VRSQRT applied to \( d \).

The VRSQRTS instruction performs a \( (3 – op1 \times op2)/2 \) calculation and can be used with two multiplications to perform a step of this iteration. The functionality of this instruction is defined by the FPRSqrtStep() pseudocode function.

Table E1-10 shows the results where input values are out of range.

### Table E1-10 VRSQRTS results for out of range inputs

<table>
<thead>
<tr>
<th>Input Vn[i]</th>
<th>Input Vm[i]</th>
<th>Result Vd[i]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any NaN</td>
<td>-</td>
<td>Default NaN</td>
</tr>
<tr>
<td>-</td>
<td>Any NaN</td>
<td>Default NaN</td>
</tr>
<tr>
<td>±0.0 or denormalized number</td>
<td>±infinity</td>
<td>1.5</td>
</tr>
<tr>
<td>±infinity</td>
<td>±0.0 or denormalized number</td>
<td>1.5</td>
</tr>
</tbody>
</table>

FPRSqrtStep() calls the FPHalvedSub() pseudocode function.

### Floating-point conversions

The FPConvert() pseudocode function performs conversions between half-precision, single-precision, and double-precision floating-point numbers.

The FPToFixed() and FixedToFP() functions perform conversions between floating-point numbers and integers or fixed-point numbers.
E1.4 About the AArch32 System register interface

AArch32 state provides a System register encoding space, which is indexed by the parameter set \{coproc, opc1, CRn, CRm, opc2\}, and a set of System register access instructions. This encoding space is used for:

- System registers.
- System instructions, for:
  - Cache and branch predictor maintenance.
  - Address translation.
  - TLB maintenance.

This encoding space uses only the coproc values 0b111x.

Note

The encoding space with coproc values 0b101x is redefined to provide Advanced SIMD and floating-point functionality.

The coproc encodings provide access to System register encoding space as follows:

- The (coproc==0b1111) encodings provide system control functionality, by providing access to System registers and System instructions. This includes architecture and feature identification, as well as control, status information and configuration support.

  The following sections give a general description of these encodings:
  - About the System registers for VMSAv8-32 on page G5-9281.
  - AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space on page G7-9304.
  - Functional grouping of VMSAv8-32 System registers on page G5-9286.

  These encodings also provide:
  - The Performance Monitor registers. For more information, see Chapter D11 The Performance Monitors Extension.
  - The Activity Monitor registers. For more information, see Chapter D12 The Activity Monitors Extension.

  The (coproc==0b1110) encodings provide access to additional registers, which support:
  - Debug, see Chapter G2 AArch32 Self-hosted Debug.
  - The Jazelle identification registers, see Jazelle support on page E1-7139.

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G8-9323 gives information more information about permitted accesses to the System registers in AArch32 state.

Most functionality in the (coproc==0b111x) encoding space cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0.

For more information:

- About this encoding space, including the naming of the parameters that index the space, see The AArch32 System register interface on page G1-8993.
- About the System interface access instructions, see System register access instructions on page F2-7277.
E1.5 Exceptions

The Arm architecture uses the following terms to describe various types of exceptional condition:

**Exceptions**

In the Arm architecture, an exception causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also causes entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

--- Note ---

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

---

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and Hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in *Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929*. In an implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The `SMC` instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The `HVC` instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The `BKPT` instruction causes a Breakpoint Instruction exception, which is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The `WFI` (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wakeup event occurs, see *Wait For Interrupt on page G1-8991*. This means the hardware might enter a low-power state until the wakeup event occurs.
- The `WFE` (Wait for Event) instruction provides a hint that nothing needs to be done until either an SEV instruction generates an event, or another WFE wakeup event occurs, see *Wait For Event and Send Event on page G1-8988*. This means the hardware might enter a low-power state until the wakeup event occurs.

**Floating-point exceptions**

These relate to exceptional conditions encountered during floating-point arithmetic, such as Divide by Zero or Overflow. For more information, see:

- *Floating-point exceptions and exception traps on page E1-7148.*
- The `FPEXC` and `FPSCR` register descriptions.
Chapter E2
The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

• About the Arm memory model on page E2-7162.
• Atomicity in the Arm architecture on page E2-7164.
• Definition of the memory model on page E2-7168.
• Ordering of translation table walks on page E2-7187.
• Caches and memory hierarchy on page E2-7188.
• Alignment support on page E2-7193.
• Endian support on page E2-7195.
• Memory types and attributes on page E2-7198.
• Mismatched memory attributes on page E2-7208.
• Synchronization and semaphores on page E2-7211

Note

In this chapter, System register names usually link to the description of the register in Chapter G8 AArch32 System Register Descriptions, for example SCTLR.
E2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be reordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.

This section contains:
- Address space.
- Memory type overview.

E2.1.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo $2^{32}$.

The result of an address calculation is UNKNOWN if it overflows or underflows the 32-bit address range $A[31:0]$.

Memory accesses use the MemA[], MemO[], MemU[], and MemU_unpriv[] pseudocode functions:
- The MemA[] function makes an aligned access of the required type.
- The MemO[] function makes an ordered access of the required type.
- The MemU[] function makes an unaligned access of the required type.
- The MemU_unpriv[] function makes an unaligned, unprivileged access of the required type.

Each of these functions calls Mem_with_type[] function, which specifies the required access. This calls AArch32.MemSingle[], which performs an atomic, little-endian read of size bytes.

The AccType enumeration defines the different access types.

Note

- Chapter G4 The AArch32 System Level Memory Model and Chapter G5 The AArch32 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also reference pseudocode descriptions of these operations.
- For references to the pseudocode that relates to memory accesses, see Basic memory access on page G4-9142, Unaligned memory access on page G4-9142, and Aligned memory access on page G4-9142.

E2.1.2 Memory type overview

The architecture provides the following mutually-exclusive memory types:

- **Normal** This is generally used for bulk memory operations, both read/write and read-only operations.
- **Device** The Arm architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.
Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See Gathering on page E2-7204.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See Reordering on page E2-7205.
- They indicate whether a write can be acknowledged other than at the end point. See Early Write Acknowledgement on page E2-7205.

For more information on Normal memory and Device memory, see Memory types and attributes on page E2-7198.

——— Note ————

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A Note in Device memory on page E2-7202 describes how these memory types map onto the memory types used from the introduction of Armv8.
E2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The Arm architecture description refers to two types of atomicity, single-copy atomicity and multi-copy atomicity. The atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Requirements for single-copy atomicity.
- Properties of single-copy atomic accesses on page E2-7165.
- Multi-copy atomicity on page E2-7165.
- Requirements for multi-copy atomicity on page E2-7166.
- Concurrent modification and execution of instructions on page E2-7166.

For more information about the memory types, see Memory type overview on page E2-7162.

E2.2.1 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by LDREXD and STREXD instructions to doubleword-aligned locations.

LDM, LDC, LDRD, STM, STC, STRD, PUSH, POP, RFE, SRS, VLDM, VLDR, VSTM, and VSTR instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

LDRD and STRD accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

Note

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 32 bits, or smaller.
- The elements are naturally-aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.
In this section, the terms before the write operation and after the write operation mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned. See Data Abort exception on page G1-8975 and, when FEAT_LSMAOC is implemented, Taking an interrupt or other exception during a multiple-register load or store on page G1-8963.

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

Note
The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:
- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
  - At 32-bit granularity in A32 state.
  - At 16-bit granularity in T32 state.
- Translation table walks are performed using accesses that are single-copy atomic:
  - At 32-bit granularity when using Short-descriptor format translation tables.
  - At 64-bit granularity when using Long-descriptor format translation tables.

**E2.2.2 Properties of single-copy atomic accesses**

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.

2. For a single-copy atomic load instruction \( L_1 \) that overlaps a single-copy atomic store instruction \( S_2 \), if one of the overlapping reads generated by \( L_1 \) Reads-from one of the overlapping writes generated by \( S_2 \), then none of the overlapping writes generated by \( S_2 \) are Coherence-after the corresponding overlapping reads generated by \( L_1 \).

For more information, see Definition of the memory model on page E2-7168.

**E2.2.3 Multi-copy atomicity**

In a multiprocessing system, writes to a memory location are multi-copy atomic if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note
Writes that are not coherent are not multi-copy atomic.
E2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The memory model is Other-multi-copy atomic. For more information, see Ordering constraints on page E2-7174.

E2.2.5 Concurrent modification and execution of instructions

The architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification are:

• When executing the A32 instruction set, a B, BKPT, BL, HVC, ISB, NOP, SMC, or SVC instruction.
• When executing the T32 instruction set. a 16-bit B, BKPT, BLX, BX, NOP, or SVC instruction.

In addition, for the 32-bit T32 instructions, for which Instruction encodings on page F1-7224 describes the meaning of \{hw1, hw2\}:

• hw1 of a 32-bit BL (immediate) instruction can be concurrently modified to hw1 of another BL (immediate) instruction:
  — This means that some of the most significant bits of the immediate value can be modified.
• hw1 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw1 of another BLX immediate instruction:
  — This means that some of the most significant bits of the immediate value can be modified.
• hw1 of a 32-bit BL (immediate) or BLX (immediate) instruction can be concurrently modified to a T32 16-bit B, BX, BLX, BKPT, or SVC instruction. This modification also works in reverse.
• hw2 of a 32-bit BL (immediate) instruction can be concurrently modified to hw2 of another BL (immediate) instruction with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.
• hw2 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw2 of another BLX (immediate) instruction with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.
• hw2 of a 32-bit B (immediate) instruction with a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction with a condition field with a different immediate:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.
• hw2 of a 32-bit B (immediate) instruction without a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction without a condition field:
  — This means that some bits of the immediate value, including the least significant bits, can be modified.

   — Note ————

• In the T32 instruction set:
  — The only encodings of BKPT and SVC are 16-bit.
  — The only encoding of BL is 32-bit.
• The ISB instruction can be concurrently modified and executed in the A32 and A64 instruction sets, but not in the T32 instruction set.

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

• The instruction originally fetched.
• A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.
For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:
   - Coherency example for self-modifying code
   - Enter this code with <Rt> containing a new 32-bit instruction, to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line instead of STR for a 16-bit instruction.

\[
\begin{align*}
\text{STR} \ <\text{Rt}>, \ [\text{Rn}] & \quad \text{Clean data cache by MVA to point of unification (PoU)} \\
\text{DCCMVAU} \ Rn & \quad \text{Clean data cache by MVA to point of unification (PoU)} \\
\text{DSB} & \quad \text{Ensure visibility of the data stored} \\
\text{ICIMVAU} \ Rn & \quad \text{Invalidate instruction cache by VA to PoU} \\
\text{BPIMVA} \ Rn & \quad \text{Invalidate branch predictor by MVA to PoU} \\
\text{DSB} & \quad \text{Ensure visibility of the data stored}
\end{align*}
\]

**Note**

- The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
- If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

\[
\text{ISB} \quad ; \text{Synchronize fetched instruction stream}
\]

For more information about the required synchronization operation, see *Synchronization and coherency issues between data and instruction accesses* on page E2-7190.

For information about memory accesses caused by instruction fetches, see *Ordering constraints* on page E2-7174.
E2.3 Definition of the memory model

This section describes observation and ordering in the memory model. It contains the following subsections:

- Basic definitions.
- Dependency definitions on page E2-7170.
- Ordering relations on page E2-7172.
- Ordering constraints on page E2-7174.
- Internal visibility requirement on page E2-7174.
- External ordering constraints on page E2-7174.
- Completion and endpoint ordering on page E2-7176.
- Ordering of instruction fetches on page E2-7178.
- Restrictions on the effects of speculation on page E2-7179.
- Memory barriers on page E2-7181.

For more information on endpoint ordering of memory accesses, see Reordering on page E2-7205.

In the memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see Memory types and attributes on page E2-7198.

The architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- Chapter G4 The AArch32 System Level Memory Model.
- Chapter G5 The AArch32 Virtual Memory System Architecture.

See also Mismatched memory attributes on page E2-7208.

E2.3.1 Basic definitions

The memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

Observer

An Observer refers to a processing element or mechanism in the system, such as a peripheral device, that can generate reads from, or writes to, memory.

Common Shareability Domain

For the purpose of this section, all Observers are assumed to belong to a Common Shareability Domain. All read and write effects access only Normal memory locations in a Common Shareability Domain, and excludes the situations described in Mismatched memory attributes on page E2-7208.

Location

A Location is a byte that is associated with an address in the physical address space.

Note

It is expected that an operating system will present the illusion to the application programmer that is consistent with a location also being considered as a byte that is associated with an address in the virtual address space.

Effects

The Effects of an instruction can be:

- Register effects.
- Memory effects.
- Barrier effects.
- Branching effects.
The effects of an instruction $I_1$ are said to appear in program order before the effects of an instruction $I_2$ if and only if $I_1$ occurs before $I_2$ in the order specified by the program. Each effect generated by an instruction has a unique identifier, which characterizes it amongst the events generated by the same instruction.

**Register effect**

The *Register effects* of an instruction are register reads or register writes of that instruction. For an instruction that accesses registers, a register read effect is generated for each register read by the instruction and a register write effect is generated for each register written by the instruction. An instruction may generate both read and write register Register effects.

**Memory effect**

The *Memory effects* of an instruction are the memory reads or writes generated by that instruction. For an instruction that accesses memory, a memory read effect is generated for each Location read by the instruction and a memory write effect is generated for each Location written by the instruction. An instruction may generate both read and write Memory effects.

**Branching effect**

The *Branching effects* of an instruction are effects which correspond to a branching decision being taken.

---

**Note**

Conditional and compare-and-swap instructions do not create Branching effects.

---

**Intrinsic order**

There is a per-instruction *Intrinsic order* relation that provides a partial order over the effects of that instruction, according to the operation of that instruction.

The operation of an instruction is defined by the pseudocode in Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions.

**Reads-from-register**

The *Reads-from-register* relation couples register read and write effects to the same register such that each register read effect is paired with exactly one register write effect in the execution of a program. A register read effect $R_2$ Reads-from-register a register write effect $W_1$ to the same register if and only if $R_2$ takes its data from $W_1$. By construction $W_1$ must be in program order before $R_2$ and there must be no intervening write to the same register in program order between $W_1$ and $R_2$.

**Reads-from**

The *Reads-from* relation couples memory read and write effects to the same Location such that each memory read effect is paired with exactly one memory write effect in the execution of a program. A memory read effect $R_2$ from a Location Reads-from a memory write effect $W_1$ to the same Location if and only if $R_2$ takes its data from $W_1$.

**Coherence order**

There is a per-location *Coherence order* relation that provides a total order over all memory write effects from all coherent Observers to that Location, starting with a notional memory write effect of the initial value. The Coherence order of a Location represents the order in which memory write effects to the Location arrive at memory.

**Local read successor**

A memory read effect $R_2$ of a Location is the *Local read successor* of a memory write effect $W_1$ from the same Observer to the same Location if and only if $W_1$ appears in program order before $R_2$ and there is not a memory write effect $W_3$ from the same Observer to the same Location appearing in program order between $W_1$ and $R_2$. 
Local write successor

A memory write effect \( W_2 \) of a Location is a *Local write successor* of a memory read or write effect \( RW_1 \) from the same Observer to the same Location if and only if \( RW_1 \) appears in program order before \( W_2 \).

Coherence-after

A memory write effect \( W_2 \) to a Location is *Coherence-after* another memory write effect \( W_1 \) to the same Location if and only if \( W_2 \) is sequenced after \( W_1 \) in the Coherence order of the Location.

A memory write effect \( W_2 \) to a Location is Coherence-after a memory read effect \( R_1 \) of the same location if and only if \( R_1 \) Reads-from a memory write effect \( W_3 \) to the same Location and \( W_2 \) is Coherence-after \( W_3 \).

Observed-by

A memory read or write effect \( RW_1 \) from an Observer is *Observed-by* a memory write effect \( W_2 \) from a different Observer if and only if \( W_2 \) is coherence-after \( RW_1 \).

A memory write effect \( W_1 \) from an Observer is Observed-by a memory read effect \( R_2 \) from a different Observer if and only if \( R_2 \) Reads-from \( W_1 \).

---

**Note**
The Observed-by relation only relates Memory effects generated by different Observers.

---

Overlapping accesses

Two Memory effects overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Single-copy-atomic-ordered-before

A memory read effect \( R_1 \) is *Single-copy-atomic-ordered-before* another memory read effect \( R_2 \) if and only if all of the following statements are true:

- \( R_1 \) and \( R_2 \) are memory read effects generated by the same instruction.
- \( R_1 \) is not a Local read successor of a memory write effect.
- \( R_2 \) is a Local read successor of a memory write effect.

DMB FULL

A DMB FULL is a DMB with neither the LD or the ST qualifier.

Where this section refers to DMB without any qualification, then it is referring to all types of DMB. Unless a specific shareability domain is defined, a DMB applies to the Common Shareability Domain.

All properties that apply to DMB also apply to the corresponding DSB.

Context synchronization instruction

A *Context synchronization instruction* is one of the following:

- An ISB instruction.
- An instruction that generates a synchronous exception.
- An exception return instruction.
- A DCPS or DRPS instruction.

E2.3.2 Dependency definitions

**Dependency through registers**

A *Dependency through registers* from a first effect \( E_1 \) to a second effect \( E_2 \) exists within a PE if and only if at least one of the following applies:

- \( E_1 \) is a register write effect \( W_1 \) which has not been generated by a Store Exclusive, \( E_2 \) is a register read effect \( R_2 \) and \( R_2 \) Reads-from-register \( W_1 \).
• E₁ and E₂ have been generated by the same instruction and E₁ is before E₂ in the Intrinsic order of that instruction.
• There is a Dependency through registers from E₁ to a third effect E₃, and there is a Dependency through registers from E₃ to E₂.

Address dependency

An Address dependency from a memory read effect R₁ to a Memory effect RW₂ exists if and only if there is a Dependency through registers from R₁ to a Register effect E₃ generated by RW₂, and E₃ affects the address part of RW₂, and either:
• RW₂ is a memory write effect W₂.
• RW₂ is a memory read effect R₂ and there is no Branching effect D₄ such that there is a Dependency through registers from R₁ to D₄ and from D₄ to R₂.

Data dependency

A Data dependency from a memory read effect R₁ to a memory write effect W₂ exists if and only if there is a Dependency through registers from R₁ to a Register effect E₃ generated by W₂, and E₃ affects the data part of W₂.

Control dependency

A Control dependency from a memory read effect R₁ to a subsequent Memory effect RW₂ exists if and only if either:
• There is a Dependency through registers from R₁ to a Branching effect B₃ and B₃ is in program order before RW₂.
• There is a Dependency through registers from R₁ to the determination of a synchronous exception on an instruction generating an effect RW₃, and RW₂ appears in program order after RW₃.

Note

This notion is under review. Arm’s intent is that a branch instruction between a read and a write, where the branch condition is dependent on the read, will provide order, regardless of whether the branch is taken. This applies only to branch instructions and not to conditional selection or other conditional data processing instructions. A formal definition of this change will be issued soon as an erratum to the Architecture Reference Manual.

Pick Basic dependency

A Pick Basic dependency from a read Register effect or read Memory effect R₁ to a Register effect or Memory effect E₂ exists if and only if one of the following applies:
• There is a Dependency through registers from R₁ to E₂.
• There is an Intrinsic Control dependency from R₁ to E₂.
• There is a Pick Basic dependency from R₁ to an Effect E₃ and there is a Pick Basic dependency from E₃ to E₂.

Pick Address dependency

A Pick Address dependency from a read Register effect or read Memory effect R₁ to a read or write Memory effect RW₂ exists if and only if all of the following apply:
• There is a Pick Basic dependency from R₁ to a Register effect E₃.
• There is an Intrinsic data dependency from the Register effect E₃ to RW₂.
• The Register effect E₃ affects the address of the location accessed by RW₂.

Pick Data dependency

A Pick Data dependency from a read Register effect or read Memory effect R₁ to a write Memory effect W₂ exists if and only if all of the following apply:
• There is a Pick Basic dependency from R₁ to a Register effect E₃.
• There is an Intrinsic data dependency from the Register effect \( E_3 \) to \( RW_2 \).
• The Register effect \( E_3 \) affects the value written by \( W_2 \).

### Pick Control dependency

A Pick Control dependency from a read Register effect or read Memory effect \( R_1 \) to an effect \( E_2 \) exists if and only if all of the following apply:

- There is a Pick Basic dependency from \( R_1 \) to a Branching effect \( BR_3 \).
- The Branching effect \( BR_3 \) is in program order before \( E_2 \).

### Pick dependency

A Pick dependency from a read Register effect or read Memory effect \( R_1 \) to an effect \( E_2 \) exists if and only if one of the following applies:

- There is a Pick Basic dependency from \( R_1 \) to \( E_2 \).
- There is a Pick Address dependency from \( R_1 \) to \( E_2 \).
- There is a Pick Data dependency from \( R_1 \) to \( E_2 \).
- There is a Pick Control dependency from \( R_1 \) to \( E_2 \).

### E2.3.3 Ordering relations

#### Dependency-ordered-before

A dependency creates externally-visible order between a memory read effect and another Memory effect generated by the same Observer. A memory read effect \( R_1 \) is Dependency-ordered-before a memory read or write effect \( RW_2 \) from the same Observer if and only if \( R_1 \) appears in program order before \( RW_2 \) and any of the following cases apply:

- There is an Address dependency or a Data dependency from \( R_1 \) to \( RW_2 \).
- \( RW_2 \) is a memory write effect \( W_2 \) and there is a Control dependency from \( R_1 \) to \( W_2 \).
- \( RW_2 \) is a memory read effect \( R_2 \) generated by an instruction appearing in program order after an instruction that generates a Context synchronization event \( E_3 \), and there is a Control dependency from \( R_1 \) to \( E_3 \).
- \( RW_2 \) is a memory write effect \( W_2 \) appearing in program order after a memory read or write effect \( RW_3 \) and there is an Address dependency from \( R_1 \) to \( RW_3 \).
- \( RW_2 \) is a Local read successor \( R_2 \) of a memory write effect \( W_3 \) and there is an Address dependency or a Data dependency from \( R_1 \) to \( W_3 \).

#### Pick-ordered-before

A read Register effect or read Memory effect \( R_1 \) is Pick-ordered-before a read or write Memory effect \( RW_2 \) from the same Observer if and only if \( R_1 \) appears in program order before \( RW_2 \) and any of the following cases apply:

- \( RW_2 \) is a write Memory effect \( W_2 \) and there is a Pick dependency from \( R_1 \) to \( W_2 \).
- \( RW_2 \) is a read Memory effect \( R_2 \) generated by an instruction appearing in program order after an instruction that generates a Context synchronization event \( E_3 \), and there is a Pick Control dependency from \( R_1 \) to \( E_3 \).
- \( RW_2 \) is a Memory effect generated by an instruction appearing in program order after an instruction that generates a Context synchronization event \( E_3 \), there is a Pick Address dependency from \( R_1 \) to an effect \( E_4 \) and \( E_4 \) is in program order before \( E_3 \).
- \( RW_2 \) is a write Memory effect \( W_2 \), there is a Pick Address dependency from \( R_1 \) to a read or write Memory effect \( RW_3 \) and \( W_2 \) is program-order-after \( RW_3 \).
Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write Memory effect RW1 is Atomic-ordered-before a read or a write Memory effect RW2 from the same Observer if and only if RW1 appears in program order before RW2 and either of the following cases apply:

- RW1 is a read Memory effect R1 and RW2 is a write Memory effect W2 such that R1 and W2 are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same Location.
- RW1 is a read Memory effect R1 generated by an atomic instruction (resp. a Load-Exclusive instruction) and RW2 is a read Memory effect R2 generated by an instruction with Acquire or AcquirePC semantics such that R2 is a Local read successor of the write Memory effect W3 generated by the same atomic instruction as R1 (resp. the successful Store-Exclusive instruction paired with the Load-Exclusive instruction that generated R1).

For more information, see Synchronization and semaphores on page E2-7211.

Barrier-ordered-before

Barrier instructions order prior Memory effects before subsequent Memory effects generated by the same Observer. A memory read or write effect RW1 is Barrier-ordered-before a memory read or write effect RW2 from the same Observer if and only if RW1 appears in program order before RW2 and any of the following cases apply:

- RW1 appears in program order before a DMB FULL that appears in program order before RW2.
- RW1 is a memory write effect W1 and is generated by an atomic instruction with both Acquire and Release semantics.
- RW1 is a memory write effect W1 generated by an instruction with Release semantics and RW2 is a memory read effect R2 generated by an instruction with Acquire semantics.
- RW1 is a memory read effect R1 and appears in program order before a DMB LD that appears in program order before RW2.
- RW1 is a memory read effect R1 and is generated by an instruction with Acquire or AcquirePC semantics.
- RW1 is a memory write effect W1 and RW2 is a memory write effect W2 appearing in program order before a DMB ST that appears in program order before W2.
- RW2 is a memory write effect W2 and is generated by an instruction with Release semantics.

Locally-ordered-before

Dependencies, Local write successor, load/store-exclusive, atomic and barrier instructions can be composed within an Observer to create externally-visible order. A memory read or write effect RW1 is Locally-ordered-before a memory read or write effect RW2 from the same Observer if and only if any of the following apply:

- RW1 is a memory write effect W1 and RW2 is a memory write effect W2 that is equal to or generated by the same instruction as a Local write successor of RW1.
- RW1 is Pick-ordered-before RW2.
- RW1 is Dependency-ordered-before RW2.
- RW1 is Atomic-ordered-before RW2.
- RW1 is Barrier-ordered-before RW2.
- RW1 is Locally-ordered-before a memory read or write effect that is Locally-ordered-before RW2.

Pick-locally-ordered-before

A read or a write Memory effect RW1 is Pick-locally-ordered-before a read or a write Memory effect RW2 from the same Observer if and only if all of the following apply:

- There is a Pick Basic dependency from RW1 to an effect E3.
E2.3 Definition of the memory model

E2.3.4 Ordering constraints

The memory model is described as being Other-multi-copy atomic. The definition of Other-multi-copy atomic is as follows:

**Other-multi-copy atomic**

In an Other-multi-copy atomic system, it is required that a memory write effect from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.

The Other-multi-copy atomic property of the memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be Architecturally well-formed. An implementation that is executing a program is only permitted to exhibit behavior consistent with an Architecturally well-formed execution.

**Architecturally well-formed**

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and any of the three alternative External ordering constraints.

E2.3.5 Internal visibility requirement

For a memory read or write effect RW₁ that appears in program order before a memory read or write effect RW₂ to the same Location, the **Internal visibility requirement** requires that exactly one of the following statements is true:

- RW₂ is a write Memory effect W₂.
- E₃ is Locally-ordered-before W₂.

E2.3.6 External ordering constraints

The memory model offers the following three alternative representations of the **External ordering constraint**:

- **External visibility requirement**.
- **External completion requirement**.
- **External global completion requirement**.

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and one of the three alternative representations in the External ordering constraints.

**External visibility requirement**

Ordered-before

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A memory read or write effect RW₁ is Ordered-before a memory read or write effect RW₂ if and only if any of the following cases apply:

- RW₁ is Observed-by a memory read or write effect RW₃ that is generated by the same instruction as RW₂.
• RW₁ is Locally-ordered-before RW₂.
• RW₁ is Pick-locally-ordered-before RW₂.
• RW₁ is Ordered-before a memory read or write effect that is Ordered-before RW₂.

For a memory read or write effect RW₁ from an Observer that is Ordered-before a memory read or write effect RW₂ from a different Observer, the External visibility requirement requires that RW₂ is not Observed-by RW₁. This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

Informally, if a Memory effect M₁ from an Observer is Ordered-before another Memory effect M₂ from a different Observer, then M₁ will be seen to occur before M₂ by all Observers in the system.

Completes-before order

The Completes-before order is a total order that corresponds to the order in which Memory effects complete within the system. The following effects constitute a single entry in the Completes-before order:
• Writes from the same instruction.
• Reads from the same instruction which read from external writes.
• Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Completes-before order.

Completes-before

A memory read or write effect RW₁ Completes-before a memory read or write effect RW₂ if and only if RW₁ appears in the Completes-before order before RW₂.

Deriving Reads-from and Coherence order from the Completes-before order

The Completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:
• For a memory read effect R₁ of a memory location by an Observer, then:
  — If there is a memory write effect W₂ to the same Location from the same Observer and all of the following are true:
    — W₂ appears in program order before R₁.
    — R₁ Completes-before W₂.
    — There are no writes to the Location appearing in program order between W₂ and R₁ then R₁ Reads-from W₂.
  — Otherwise, R₁ Reads-from its closest preceding write in the Completes-before order to the same Location. If no such write exists, then R₁ Reads-from the initial value of the memory location.
• The Coherence order of writes to a memory location is the order in which those writes appear in the Completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

External completion requirement

A memory read or write effect RW₁ Globally-completes-before a memory read or write effect RW₂ if and only if any of the following statements are true:
• RW₁ is Locally-ordered-before RW₂.
• RW₁ is Pick-locally-ordered-before RW₂.
• RW₁ is a memory read effect R₁ and RW₂ is a memory read effect R₂ and R₁ is Single-copy-atomic-ordered-before R₂.
**Globally-completes-before order**

The *Globally-completes-before order* is a total order that corresponds to the order in which Memory effects globally-complete within the system. The following effects constitute a single entry in the Globally-completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Globally-completes-before order.

**Globally-completes-before**

A memory read or write effect RW₁ *globally-completes-before* a memory read or write effect RW₂ if and only if RW₁ appears in the Globally-completes-before order before RW₂.

**Deriving Reads-from and Coherence order from the Globally-completes-before order**

The Globally-completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:

- A memory read effect R₁ of a memory location by an Observer Reads-from its closest preceding write in the Globally-completes-before order to the same Location. If no such write exists, then R₁ Reads-from the initial value of the memory location.
- The Coherence order of writes to a memory location is the order in which those writes appear in the Globally-completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Globally-completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

**External global completion requirement**

The *External global completion requirement* requires that a memory read or write effect RW₁ Globally-completes-before a memory read or write effect RW₂ if and only if any of the following statements are true:

- RW₁ is Locally-ordered-before RW₂ and either:
  - RW₁ is a memory write effect.
  - RW₁ is a memory read effect R₁ and either:
    - R₁ is not a Local read successor of a memory write effect.
    - R₁ is a Local read successor of a memory write effect that is Locally-ordered-before RW₂.
    - R₁ is a Local read successor of a memory write effect that is Pick-locally-ordered-before RW₂.
- RW₁ is a memory read effect R₁ and RW₂ is a memory read effect R₂ and R₁ is Single-copy-atomic-ordered-before R₂.

**E2.3.7 Completion and endpoint ordering**

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

- A memory read effect R₁ to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after R₁.
Any translation table walks associated with R1 are complete for that shareability domain.

- A memory write effect W1 to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after W1.
  - Any read to the same Location by an Observer within the shareability domain will either Reads-from W1 or Reads-from a memory write effect that is Coherence-after W1.
  - Any translation table walks associated with the write are complete for that shareability domain.

- A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.

- A cache or branch predictor maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache, branch predictor, or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

**Note**

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:

- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

**Note**

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

### Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and write to a peripheral which is defined as the Peripheral coherence order:

**Memory-mapped peripheral**

A Memory-mapped peripheral occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

**Peripheral coherence order**

The Peripheral coherence order of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

**Note**

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.
For a memory read or write effect RW₁ and a memory read or write effect RW₂ to the same peripheral, then RW₁ will appear in the Peripheral coherence order for the peripheral before RW₂ if either of the following cases apply:

- RW₁ and RW₂ are accesses using Non-cacheable or Device attributes and RW₁ is Ordered-before RW₂.
- RW₁ and RW₂ are accesses using Device-nGnRE or Device-nGnRnE attributes and RW₁ appears in program order before RW₂.

**Out-of-band-ordered-before**

A memory read or write effect RW₁ is Out-of-band-ordered-before a memory read or write effect RW₂ if and only if either of the following cases apply:

- RW₁ appears in program order before a DSB instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW₂.
- RW₁ is Ordered-before a memory read or write effect RW₃ and RW₃ is Out-of-band-ordered-before RW₂.

If a Memory effect M₁ is Out-of-band-ordered-before a memory read or write effect M₂, then M₁ is seen to occur before M₂ by all Observers.

### E2.3.8 Ordering of instruction fetches

For two memory locations A and B, if A has been written to with an updated value and been made coherent with the instruction fetches of the shareability domain before B has been written to with an updated value by an observer in the same shareability domain, then where, for an observer in the shareability domain, an instruction read from B appears in program order before an instruction fetched from A, if the instruction read from B contains the updated value of B then the instruction read from A appearing later in program order will contain the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

- **CTR.{DIC, IDC} == {0, 0}**
  - The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

- **CTR.{DIC, IDC} == {1, 0}**
  - The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

- **CTR.{DIC, IDC} == {0, 1}**
  - The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

- **CTR.{DIC, IDC} == {1, 1}**
  - The write is complete for the shareability domain.

--- **Note** ---

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When **CTR.DIC == 0**, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the ICDMAU instructions of a different core.
 — When CTR.DIC == 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

### E2.3.9 Restrictions on the effects of speculation

The Arm architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- Each load from a location using a particular VA after an exception entry that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry.
- Any load from a location using a particular VA before an exception entry that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception entry.
- Any load from a location using a particular VA before an exception return that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- When data is loaded under speculation with a Translation fault, it cannot be used to form an address or generate condition codes to be used by other instructions in the speculative sequence.
- When data is loaded under speculation from a location without a Translation fault for the translation regime being speculated in, the data cannot be used to form an address or generate condition codes to be used by other instructions in the speculative sequence.
- When data is loaded as a result of speculative accesses made after TLBI + DSB + ERET using a translation that was invalidated by the TLBI, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence. The execution timing of any other instructions in the speculative sequence is not a function of the data loaded.
- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.
- Changes to Special-purpose registers can occur speculatively.
- Execute-never controls apply to speculative instruction fetching. See Access permissions for instruction execution on page G5-9196.
- When writing new instructions to memory, there is no requirement for an SB instruction to prevent speculative execution of the old code. See Instruction cache maintenance instructions on page K13-11773.

--- **Note**

The prohibition of using data loaded under speculation with faults to form addresses, condition codes or SVE predicate values does not prohibit the use of value predicted data from such locations for such purposes, so long as the training of the data value prediction was from the hardware defined context that is using the prediction. A consequence of this is that training of value prediction cannot be based on data loaded under speculation with a translation or Permission fault.

--- **Speculative Store Bypass Safe (SSBS)**

When FEAT_SSBS is implemented, CPSR.SSBS is a control that can be set by software to indicate whether hardware is use, in a manner that is potentially speculatively exploitable, a speculative value in a register that has been loaded from memory using a load instruction that speculatively read an entry for the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

A speculative value in a register is used in a potentially speculatively exploitable manner if it is used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence or if the execution timing of any other instructions in the speculative sequence is a function of the data loaded under speculation.
When the value of CPSR.SSBS is 0, hardware is not permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of CPSR.SSBS is 1, hardware is permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

--- **Note** ---

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.

- Software written for architectures from Armv8.0 to Armv8.4 will set SPSR.SSBS to 0. This means that CPSR.SSBS will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.

---

**Further restrictions on the effects of speculation from Armv8.5**

From Armv8.5, there are some further restrictions on the effects of speculation in addition to those in Armv8.0:

- Data loaded under speculation with a Permission or Domain fault cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence. The execution timing of any other instructions in the speculative sequence is not a function of the data loaded under speculation.

- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address or to generate condition codes to be used by other instructions in the speculative sequence.

--- **Note** ---

As the effects of speculation are not architecturally visible, this restriction level requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

---

- For all execution prediction resources that predict address or register values, speculative execution at one hardware defined context should be separated in a hard-to-determine manner from control by a different hardware defined context. In the case of this definition, the hardware defined context is determined by:
  
  — The Exception level.
  — The Security state.
  — When executing at EL1 and when EL2 is enabled in the current Security state, the VMID.
  — When executing at EL0 and using the EL1&0 translation regime, the ASID and, when EL2 is enabled in the current Security state, the VMID.
  — When executing at EL0 and using the EL2&0 translation regime, the ASID.

--- **Note** ---

— The definition of “hard-to-determine manner” is left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.

— The architecture does not require that prediction resources that simply predict the direction of a branch are separated in this way.

---

- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.

- Changes to Special-purpose registers can occur speculatively.
E2.3.10 Memory barriers

The Arm architecture is a weakly ordered memory architecture that supports out of order completion. Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
- Context synchronization.

The following subsections describe the memory barrier instructions:

- **Instruction Synchronization Barrier (ISB).**
- **Data Memory Barrier (DMB) on page E2-7182.**
- **Data Synchronization Barrier (DSB) on page E2-7182.**
- **Speculation Barrier (SB) on page E2-7183.**
- **Consumption of Speculative Data Barrier (CSDB) on page E2-7183.**
- **Speculative Store Bypass Barrier (SSBB) on page E2-7183.**
- **Physical Speculative Store Bypass Barrier (PSSBB) on page E2-7184.**
- **Trace Synchronization Barrier (TSB CSYNC) on page E2-7184.**
- **Shareability and access limitations on the data barrier operations on page E2-7185.**
- **Load-Acquire, Store-Release on page E2-7186.**

--- Note ---

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are available only when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

AArch32 state also supports the legacy barrier instructions CP15DMB, CP15DSB, and CP15ISB. These instructions are executed as MCRs using the appropriate encoding, and are accessible from EL0. However, for performance reasons Arm deprecates any use of these operations, and strongly recommends that software uses the DMB, DSB, and ISB instructions described in this section instead. Optionally, an implementation can support a CP15BEN control that supervisory software can use to disable use of these instructions, meaning the corresponding MCR encodings are UNDEFINED. When the CP15BEN control is supported, setting one of the following CP15BEN fields to 0 makes execution of CP15DMB, CP15DSB, and CP15ISB UNDEFINED:

- SCTLR_EL1.CP15BEN, for execution of these instructions at EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.CP15BEN, for execution of these instructions at EL0 or EL1 when EL1 is using AArch32.
- HSCTLR.CP15BEN, for execution of these instructions at EL2 when EL2 is using AArch32.

**Instruction Synchronization Barrier (ISB)**

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction take effect only after the ISB has been executed.

The pseudocode function for the operation of an ISB is `InstructionSynchronizationBarrier()`.
See also Memory barriers on page G4-9144.

**Data Memory Barrier (DMB)**

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB instruction is covered formally in the Definition of the memory model on page E2-7168 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB instruction is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are Observed-by that PE.

The use of a DMB instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The pseudocode function for the operation of a DMB instruction is DataMemoryBarrier().

**Data Synchronization Barrier (DSB)**

A DSB instruction is a memory barrier that ensures that memory accesses that occur before the DSB instruction have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB at EL2 ensures that any memory accesses caused by speculative translation table walks from the Non-secure PL1&0 translation regime have been observed.

For more information, see Use of out-of-context translation regimes on page G5-9152.

A DSB executed by a PE, PEE, completes when all of the following apply:

- All explicit memory effects of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, the following instructions issued by PEE before the DSB are complete for the required shareability domain:
  - All cache maintenance instructions.
  - All AArch32 TLB maintenance instructions.
  - All PSB CYNC instructions.
- If the required access types of the DSB is reads and writes, completion of a DSB instruction executed by PEE ensures that:
  - All previous TLB maintenance operations generated by AArch32 TLB maintenance instructions executed at EL1 by PEE when HCRX_EL2.FnXS is 1 are finished for all PEs in the shareability domain of the DSB instruction.
  - All previous TLB maintenance operations generated by AArch32 TLB maintenance instructions are finished for all PEs in the shareability domain of the DSB instruction.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes, other than:

- Being fetched from memory and decoded.
- Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.
- If FEAT_ETS is not implemented, having any virtual addresses of loads and stores translated.

The pseudocode function for the operation of a DSB is DataSynchronizationBarrier().

See also Memory barrier instructions on page G4-9141 and Memory barriers on page G4-9144.
Speculation Barrier (SB)

An SB is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that an instruction that could generate an exception does not generate an exception.

Speculative execution of an SB instruction:

- Cannot be as a result of control flow speculation.
- Cannot be as a result of data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when:

- It is known that it is not speculative.
- All the predicted data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

Note

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction.

Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:

- Data value predictions of any instructions.
- PSTATE.\{N,Z,C,V\} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE prediction state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE.\{N,Z,C,V\} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.\{N,Z,C,V\} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

Speculative Store Bypass Barrier (SSBB)

The SSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB instruction.
• When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  — The store is to the same location as the load.
  — The store uses the same virtual address as the load.
  — The store appears in program order after the SSBB instruction.

**Physical Speculative Store Bypass Barrier (PSSBB)**

The PSSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

• When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  — The store is to the same location as the load.
  — The store appears in program order before the PSSBB instruction.

• When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  — The store is to the same location as the load.
  — The store appears in program order after the PSSBB instruction.

--- Note ---
The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

--- Trace Synchronization Barrier (TSB CSYNC) ---

The TSB CSYNC instruction is a barrier instruction that preserves the relative order of accesses to System registers due to trace operations and other accesses to the same registers.

A trace operation is an operation of the trace unit generating trace for an instruction when FEAT_TRF is implemented and enabled.

A TSB CSYNC is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more Context synchronization events are required to ensure that TSB CSYNC is executed in the necessary order.

If trace is generated between a Context synchronization event and a TSB CSYNC operation, these trace operations may be reordered with respect to the TSB CSYNC operation, and therefore may not be synchronized.

The following situations are synchronized using a TSB CSYNC:

• A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
  — A is executed in program order before a Context synchronization event C.
  — C is in program order before a TSB CSYNC operation T.
  — B is executed in program order after T.

• A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
  — A is executed in program order before a Context synchronization event C1.
  — C1 is in program order before TSB CSYNC operation T.
  — T is executed in program order before a second Context synchronization event C2.
  — B is executed in program order after C2.
A TSB CSYNC is not needed when a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:
• A is executed in program order after a Context synchronization event C.
• B is executed in program order before C.

The pseudocode function for the operation of a TSB CSYNC is TraceSynchronizationBarrier().

**Shareability and access limitations on the data barrier operations**

The DMB and DSB instructions can each take an optional limitation argument that specifies:
• The shareability domain over which the instruction must operate. This is one of:
  — Full system.
  — Outer Shareable.
  — Inner Shareable.
  — Non-shareable.

Full system applies to all the observers in the system and, as such, encompasses the Inner and Outer Shareable domains of the processor.

—— Note ———
The distinction between Full system and Outer Shareable is applicable only for Normal Non-cacheable memory accesses and Device memory accesses.

——— Note ————
This form of a DMB or DSB instruction can be described as a load-load/store barrier.

For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page E2-7182 or Data Synchronization Barrier (DSB) on page E2-7182.

Table E2-1 on page E2-7185 shows how these options are encoded in the <option> field of the instruction.

**Table E2-1 Encoding of the DMB and DSB <option> parameter**

<table>
<thead>
<tr>
<th>Accesses</th>
<th>Shareability domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the barrier</td>
<td>After the barrier</td>
</tr>
<tr>
<td>Reads and writes</td>
<td>Reads and writes</td>
</tr>
<tr>
<td>Writes</td>
<td>Writes</td>
</tr>
<tr>
<td>Reads</td>
<td>Reads and writes</td>
</tr>
</tbody>
</table>

If no <option> is specified then the instruction operates for read and write accesses, over the full system, meaning the operation is the same as for the SY option. See the instruction descriptions for more information:
• DMB on page F5-7555.
• DSB on page F5-7558.

——— Note ————
ISB also supports an optional limitation argument that can contain only one value that corresponds to full system operation, see ISB on page F5-7578.
Load-Acquire, Store-Release

The architecture provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

The full definition of the Load-Acquire instruction is covered formally in the Definition of the memory model on page E2-7168 and this introduction to the Load-Acquire instruction is not intended to contradict that section.

The basic principle of a Load-Acquire instruction is to introduce order between the memory access generated by the Load-Acquire instruction and the memory accesses appearing in program order after the Load-Acquire instruction, such that the memory access generated by the Load-Acquire instruction is Observed-by each PE, to the extent that PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the Definition of the memory model on page E2-7168 and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PE executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PE executing the Store-Release instruction is required to observe them coherently, Observed-by the PE before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

In addition, the use of a Load-Acquire or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire and Store-Release, other than LDAEXD and STLEXD, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

LDAEXD and STLEXD access two data elements. The address supplied to the instructions must be doubleword-aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction has the release semantics only if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.

- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

Table E2-2 on page E2-7186 summarizes the Load-Acquire/Store-release instructions.

E2.4 Ordering of translation table walks

If FEAT_ETS is implemented, and a memory access RW₁ is Ordered-before a second memory access RW₂, then RW₁ is also Ordered-before any translation table walk generated by RW₂ that generates any of the following:
   • A Translation fault.
   • An Address size fault.
   • An Access flag fault.
**E2.5 Caches and memory hierarchy**

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. The architecture defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Implication of caches for the application programmer on page E2-7189.
- Preloading caches on page E2-7191.

### E2.5.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

**Spatial locality**

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

**Temporal locality**

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. The architecture permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

### E2.5.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, a memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure E2-1 on page E2-7189 shows an example of such a system in a system that supports virtual addressing.
The AArch32 Application Level Memory Model

E2.5 Caches and memory hierarchy

Figure E2-1 Multiple levels of cache in a memory hierarchy

--- Note ---
In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in Figure E2-1.

--- Note ---
Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU) and Point of Coherency (PoC). For more information, including the definitions of PoU and PoC, see About cache maintenance in AArch32 state on page G4-9119.

--- Note ---
FEAT_DPB adds architectural support for an additional conceptual point, Point of Persistence, but this support is provided only in AArch64 state. For more information, see About cache maintenance in AArch64 state on page D7-5050.

The Cacheability and Shareability memory attributes

Cacheability and Shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

**Cacheability** This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

**Shareability** This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about the Cacheability and Shareability attributes, see Memory types and attributes on page E2-7198.

**E2.5.3 Implication of caches for the application programmer**

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.
For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.

- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

### Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory on page E2-7200 and Shareable, Inner Shareable, and Outer Shareable Normal memory on page E2-7199.

---

**Note**

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

### Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization event on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The Arm architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context synchronization events and cache maintenance instructions. These can be accessed only from an Exception level that is higher than EL0, and therefore require a system call, see Exception-generating and exception-handling instructions on page F2-7275. The following code sequence can be used for this purpose:

```assembly
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction, to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn ; Clean data cache by MVA to point of unification (PoU)
DSB ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn ; Invalidate branch predictor by MVA to PoU
DSB ; Ensure completion of the invalidations
ISB ; Synchronize the fetched instruction stream
```
A write has been made coherent with an instruction fetch of a shareability domain when:

\( \text{CTR.\{DIC, IDC\}} = \{0, 0\} \)

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

\( \text{CTR.\{DIC, IDC\}} = \{1, 0\} \)

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

\( \text{CTR.\{DIC, IDC\}} = \{0, 1\} \)

The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

\( \text{CTR.\{DIC, IDC\}} = \{1, 1\} \)

The write is complete for the shareability domain.

--- Note ---

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.

- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions on page E2-7166.

## E2.5.4 Preloading caches

The Arm architecture provides the memory system hints PLD (Preload Data), PLDW (Preload Data With Intent To Write) and PLI (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as \texttt{NOP}s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is reported using an SError interrupt and taken using an asynchronous Data Abort exception. For more information, see Data Abort exception on page G1-8975.

A PLD, PLDW, or PLI instruction can only cause allocation to software-visible caching structures such caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

A PLD, PLDW, or PLI instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.
Note

In each case, the entire list applies to each of PLD, PLDW, and PLI.

A PLD, PLDW, or PLI instruction is guaranteed not to access any type of Device memory.

A PLI instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor. Therefore in a VMSA implementation, if all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by instruction fetches.

The pseudocode enumeration `PrefetchHint` defines the prefetch hint types.

The `Hint_Prefetch()` pseudocode function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PLD, PLI, and PLDW, see:

- **PLD, PLDW (immediate)** on page F5-7776.
- **PLD (literal)** on page F5-7779.
- **PLD, PLDW (register)** on page F5-7781.
- **PLI (immediate, literal)** on page F5-7784.
- **PLI (register)** on page F5-7787.
E2.6 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment.
- Unaligned data access.
- Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE on page E2-7194.
- Unaligned data access restrictions on page E2-7194.
- Generation of Alignment faults by load/store multiple accesses to Device memory on page E2-7194.

For more information about Alignment faults, see Alignment faults on page G5-9247.

E2.6.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

E2.6.2 Unaligned data access

An A-profile implementation must support unaligned data accesses to Normal memory by some load and store instructions. As Table E2-3 on page E2-7193 shows, software can control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception:

- By setting SCTLR.A, for unaligned accesses from any mode other than Hyp mode.
- By setting HSCTLR.A, for unaligned accesses from Hyp mode.

Table E2-3 Alignment requirements of load/store instructions

<td>As specified by :&lt;align&gt;</td>
<td>Alignment fault</td>
</tr>
</tbody>
</table>

a As specified by :<align>
E2.6.3  Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in Table E2-3 on page E2-7193 and that loads the PC has CONSTRAINED UNPREDICTABLE behavior if the address it loads from is not word-aligned, see Loads and Stores to unaligned locations on page K1-11564. This overrules any permitted load/store behavior shown in Table E2-3 on page E2-7193.

E2.6.4  Unaligned data access restrictions

The following points apply to unaligned data accesses:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see Atomicity in the Arm architecture on page E2-7164.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

E2.6.5  Generation of Alignment faults by load/store multiple accesses to Device memory

When FEAT_LSMAOC is implemented and the value of the applicable nTLSMD field is 0, any memory access by an AArch32 Load Multiple or Store Multiple instruction to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable nTLSMD field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the LDM or STM instruction is executed.
E2.7 Endian support

*General description of endianness in the Arm architecture* describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:
- *Instruction endianness.*
- *Data endianness on page E2-7196.*
- *Endianness of memory-mapped peripherals on page E2-7197.*

**E2.7.1 General description of endianness in the Arm architecture**

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, *Figure E2-2* shows, for big-endian and little-endian memory systems, the relationship between:
- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in *Figure E2-2* have the following definitions:
- **MSByte**  Most significant byte.
- **LSByte**  Least significant byte.

In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1.*

**E2.7.2 Instruction endianness**

The mapping of instruction memory is always little-endian.
E2.7.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-4 on page E2-7196 shows the element sizes of all the load/store instructions, for all instruction sets.

Table E2-4 Element size of load/store instructions

<table>
<thead>
<tr>
<th>Instructions</th>
<th>Element size</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDRB, LDXRB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB</td>
<td>Byte</td>
</tr>
<tr>
<td>LDRH, LDXRH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH</td>
<td>Halfword</td>
</tr>
<tr>
<td>LDR, LDRT, LDREX, STR, STRT, STREX</td>
<td>Word</td>
</tr>
<tr>
<td>LDRD, LDREXD, STRD, STREXD</td>
<td>Word</td>
</tr>
<tr>
<td>All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM</td>
<td>Word</td>
</tr>
<tr>
<td>LDC, STC</td>
<td>Word</td>
</tr>
<tr>
<td>Forms of VLDM, VLDR, VPUSH, VPOP, VSTM, VSTR that transfer 32-bit Si registers</td>
<td>Word</td>
</tr>
<tr>
<td>Forms of VLDM, VLDR, VPUSH, VPOP, VSTM, VSTR that transfer 64-bit Di registers</td>
<td>Doubleword</td>
</tr>
<tr>
<td>VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4</td>
<td>Element size of the Advanced SIMD access</td>
</tr>
</tbody>
</table>

CPSR.E determines the data endianness.

The data size used for endianness conversions:

• Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.

• Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information, see Endianness in Advanced SIMD on page E2-7197.

Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-5 on page E2-7196 shows the instructions that provide this functionality in the A32 and T32 instruction sets.

Table E2-5 Byte reversal instructions

<table>
<thead>
<tr>
<th>Function</th>
<th>T32/A32 instruction</th>
<th>Notes</th>

</tr>
</tbody>
</table>
Endianness in Advanced SIMD

Advanced SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

\[
\text{VLD1.16 } \{D0\}, [R1]
\]

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

For information about the alignment of Advanced SIMD instructions, see Alignment support on page E2-7193.

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in Chapter J1 Armv8 Pseudocode.

E2.7.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see Chapter H8 About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 Recommended External Interface to the Performance Monitors.
- A memory-mapped register interface to the Activity Monitors, see Chapter I4 Recommended External Interface to the Activity Monitors.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.
- The memory-mapped register interface to an Arm trace component. See, for example, the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.
E2.8 Memory types and attributes

The ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page E2-7202.
- Memory access restrictions on page E2-7207.

E2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time.
- Writes to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See Multi-register loads and stores that access Normal memory on page E2-7202.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
  - Memory accesses return UNKNOWN values.
  - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page E2-7164 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page E2-7199.
- Non-shareable Normal memory on page E2-7200.
- Cacheability attributes for Normal memory on page E2-7200.
See also:

- *Multi-register loads and stores that access Normal memory* on page E2-7202.
- *Atomicity in the Arm architecture* on page E2-7164.
- *Memory barriers* on page E2-7181. For accesses to Normal memory, a `DMB` instruction is required to ensure the required ordering.
- *Concurrent modification and execution of instructions* on page E2-7166.

**Shareable Normal memory**

A Normal memory location has a Shareability attribute that is defined as one of:

- Inner Shareable.
- Outer Shareable.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, which hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page E2-7190.

---

**Note**

- System designers can use the Shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherence of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the Shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different PEs.

- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

---

**Shareable, Inner Shareable, and Outer Shareable Normal memory**

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

---

**Note**

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.

- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

---

The details of the use of the Shareability attributes are system-specific. *Example E2-1 on page E2-7200* shows how they might be used.
Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different Shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same Shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable Shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable Shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

**Non-shareable Normal memory**

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

**Cacheability attributes for Normal memory**

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information, see *Cacheability, cache allocation hints, and cache transient hints on page G4-9116.*

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases, see *Mismatched memory attributes on page E2-7208.*
The cacheability attributes provide a mechanism of coherency control with observers that lie outside the Shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

• A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.

• A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

--- Note ---
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

• Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.

• No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.

• An implementation might not have any outer cache.

Example E2-2, Example E2-3, and Example E2-4 on page E2-7202 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

--- Note ---
• L1 cache is the level closest to the PE, see Memory hierarchy on page E2-7188.

• When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the Shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example E2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

• The Inner cacheability attribute applied to L1 and L2 cache.

• The Outer cacheability attribute applied to L3 cache.

--- Example E2-3 Implementation with three inner and no outer cache levels ---

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.
Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

E2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Device memory are:

- **Gathering**  Identified as G or nG, see *Gathering* on page E2-7204.
- **Reordering** Identified as R or nR, see *Reordering* on page E2-7205.
- **Early Write Acknowledgement** Identified as E or nE, see *Early Write Acknowledgement* on page E2-7205.

The Device memory types are:

- **Device-nGnRnE**  Device non-Gathering, non-Reordering, No Early Write Acknowledgement. Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
- **Device-nGnRE**  Device non-Gathering, non-Reordering, Early Write Acknowledgement. Equivalent to the Device memory type in earlier versions of the architecture.
- **Device-nGRE**  Device non-Gathering, Reordering, Early Write Acknowledgement. Armv8 added this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory. The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.
- **Device-GRE**  Device Gathering, Reordering, Early Write Acknowledgement. Armv8 added this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden. The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.
Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.

- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

- Earlier versions of the Arm architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.
  
  An exception to this applies:
  - Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

  Note

  - An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page E2-7164 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program defines only a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
  - Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory type completes in finite time.

- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit memory write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.

- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.

- A memory location with any Device memory attribute cannot be allocated into a cache.

- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two writes of Device memory type to the same location might be merged before they reach the endpoint, unless both writes have the non-Gathering attribute or there is an ordered-before relationship between the two writes.

- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.

- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.

- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.
This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

In the Non-secure PL1&0 translation regime in systems where HCR.TGE=1 and HCR.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of HSR.ISS.[24] to be 0.

See also Memory access restrictions on page E2-7207.

The memory types for translation table walks cannot be defined as any Device memory type within the TCR. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR.PTW bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See Multi-register loads and stores that access Device memory on page E2-7206.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.
--- Note ---

• A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  — The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
  — The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  — The accesses are not generated by a Store-Release instruction.

• The Arm architecture defines only programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

--- Note ---

• The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.

• The Arm architecture defines only programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

• Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
• Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
• Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.
If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgment of a write comes from the endpoint, it is guaranteed that:
  - Only the endpoint of the write access returns a write acknowledgement of the access.
  - No earlier point in the memory system returns a write acknowledgement.

- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgment of a write comes from the endpoint, the acknowledgement of a write is not required to come from the endpoint.

--- Note ---

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

---

This means that a DSB barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system if that is required by the system architecture.

Peripherals are an example of system endpoints that require that the acknowledgment of a write comes from the endpoint.

--- Note ---

- The Early Write Acknowledgement attribute affects only where the endpoint acknowledgment is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.

- The areas of the physical memory map for which write acknowledgment from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgment from the endpoint.

- Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgment from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgment from the endpoint.

- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a DSB instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgment from the endpoint.

---

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

The architecture permits that the non-speculative execution of an instruction that loads or stores more than one general-purpose or SIMD and floating-point register might result in repeated accesses to the same address.

For an LDRD, STRD, or LDM instruction with a register list that includes the PC, or an STM instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.
For a \texttt{VLDM} and \texttt{VSTM} instruction with a register list that does not include the PC, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.

For a \texttt{LDM} or \texttt{STM} instruction with a register list that does not include the PC:

- When \texttt{FEAT\_LSMAOC} is not implemented, and when \texttt{FEAT\_LSMAOC} is implemented and the value of the applicable LSMAOE field is 1, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.

- When \texttt{FEAT\_LSMAOC} is implemented and the value of the applicable LSMAOE field is 0, no memory accesses are required to be ordered.

- When \texttt{FEAT\_LSMAOC} is implemented and the value of the applicable nTLSMD field is 0, any memory access to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable LSMAOE or nTLSMD field is the field in the \texttt{SCTLR\_EL1}, \texttt{SCTLR\_EL2}, \texttt{HSCTLR}, or \texttt{SCTLR} register that applies to the Exception level and Security state at which the \texttt{LDM} or \texttt{STM} instruction is executed.

Armv8.2 deprecates software relying on accesses to Device memory made by a single \texttt{LDM} or \texttt{STM} instruction not being reordered.

\section*{E2.8.3 Memory access restrictions}

The following restrictions apply to memory accesses:

- For two explicit memory read effects to any two adjacent bytes in memory, $p$ and $p+1$, generated by the same instruction, and for two explicit memory write effects to any two adjacent bytes in memory, $p$ and $p+1$, that are generated by the same instruction:
  - The bytes $p$ and $p+1$ must have the same memory type and Shareability attributes. otherwise the results are \texttt{CONSTRAINED UNPREDICTABLE}. For example, an \texttt{LDC}, \texttt{LDM}, \texttt{LDRD} \texttt{STC}, \texttt{STM} or \texttt{STRD} instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is \texttt{CONSTRAINED UNPREDICTABLE}.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes $p$ and $p+1$.

For the permitted \texttt{CONSTRAINED UNPREDICTABLE} behavior, see \textit{Crossing a page boundary with different memory types or Shareability attributes on page K1-11573}.

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross a 4KB address boundary then behavior is \texttt{CONSTRAINED UNPREDICTABLE} and \textit{Crossing a 4KB boundary with a Device access on page K1-11573} describes the permitted behaviors.

\begin{itemize}
  \item \textbf{Note}
  \begin{itemize}
    \item The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
    \item This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.
    \item Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
  \end{itemize}
\end{itemize}
E2.9 Mismatched memory attributes

Mismatched memory attributes are controlled by privileged software. For more information, see Chapter G5 The AArch32 Virtual Memory System Architecture.

Physical memory Locations are accessed with mismatched attributes if all accesses to the Location do not use a common definition of all of the following attributes of that Location:

• Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
• Shareability.
• Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

— Note —

In this document, the terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes the only software visible effects are one or more of the following:

• Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  — A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  — Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
• There might be a loss of coherency when multiple agents attempt to access a memory Location.
• There might be a loss of properties derived from the memory type, as described in later bullets in this section.
• If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
• Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

• Prohibition of speculative read accesses.
• Prohibition on Gathering.
• Prohibition on Reordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   • All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   • Either:
     — In the Non-secure PL1&0 translation regime, HCR2.MIOCNCE has a value of 0.
     — All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
   • Either:
     — All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
     — All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.
2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   • Any Device memory type.
   • Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   • Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   • Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a Location all assign the same Shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a Shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   • Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   • After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
   • Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   • Executing a DMB barrier instruction, with scope that applies to the common Shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

   ——— Note ———
   In AArch32 state, cache maintenance instructions can be accessed only from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see Exception-generating and exception-handling instructions on page F2-7275. For information about the AArch32 cache maintenance instructions, see AArch32 cache and branch predictor support on page G4-9113.

   In all cases:
   • Location refers to any byte within the current coherency granule.
   • A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   • In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering of cache and branch predictor maintenance instructions on page G4-9132.

   ——— Note ———
   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:
   • Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
• A DMB barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

      --- Note ---
      The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

      --- Note ---
      As described in Non-cacheable accesses and instruction caches on page D7-5049, a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache. Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.
### E2.10 Synchronization and semaphores

The architecture provides non-blocking synchronization of shared memory, using **synchronization primitives**. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

--- **Note**

Use of the synchronization primitives scales for multiprocessing system designs.

Table E2-6 on page E2-7211 shows the synchronization primitives and the associated CLREX instruction.

<sup>a</sup> Instruction in the T32 and A32 instruction sets.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is **IMPLEMENTATION DEFINED**, see *Marking and the size of the marked memory block* on page E2-7217. A Store-Exclusive instruction to any address in the marked block clears the marking.

--- **Note**

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- [Exclusive access instructions and Non-shareable memory locations](#)
- [Exclusive access instructions and shareable memory locations](#)
- [Marking and the size of the marked memory block](#)
- [Context switch support](#)
- [Load-Exclusive and Store-Exclusive instruction usage restrictions](#)
- [Use of WFE and SEV instructions by spin-locks](#)
E2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a local Exclusives monitor, or local monitor, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:
- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  — If the store took place the status value is 0.
  — Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is set.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is clear.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure E2-4 on page E2-7213 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.
For the local monitor state machine, as shown in Figure E2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 must not indefinitely delay forward progress of execution.

E2.10.2 Exclusive access instructions and shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.
For shareable memory locations, exclusive access instructions rely on:

- A local monitor for each PE in the system, which marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations on page E2-7212, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.
  The local monitor can ignore accesses from other PEs in the system.

- A global monitor that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the Shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

Note
For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is constrained unpredictable, see Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-7217.

Note
The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The implementation defined aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note
To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granularity, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
The AArch32 Application Level Memory Model

E2.10 Synchronization and semaphores

- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault status code of:
  - DFSR.STATUS = 0b110101 when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = 0b10101 when using the Short-descriptor translation table format.

If the IMPLEMENTATION DEFINED MMU fault is generated for the Non-secure PL1&0 translation regime then:
- If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
- Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an Arm PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:
- Some address ranges.
- Some memory types.

**Operation of the global Exclusives monitor**

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

--- **Note** ---

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:
- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.
In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the Shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:

- In the Exclusive Access state is set.
- In the Open Access state is clear.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see Wait For Event and Send Event on page G1-8988.

Figure E2-5 shows the state machine for PE(n) in a global monitor.

For more information about marking, see Marking and the size of the marked memory block on page E2-7217.

---

**Note**

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 shows only how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can update only the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
• When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

• It is IMPLEMENTATION DEFINED:
  — Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  — Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

E2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size $2^a$ bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the Exclusives reservation granule. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4 - 512 words.

Note

This definition means that the Exclusives reservation granule is:

• 4 words in an implementation where $a$ is 4.
• 512 words in an implementation where $a$ is 11.

For example, in an implementation where $a$ is 4, a successful LDREXB of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

E2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

E2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/Store-Exclusive instruction pair, LoadExcl/StoreExcl, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table E2-6 on page E2-7211. In this context, a LoadExcl/StoreExcl pair comprises two instructions in the same thread of execution:

• The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target VA of a StoreExcl is different from the VA of the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  — The StoreExcl either passes or fails, the status value returned by the StoreExcl is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.
Note

This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched addresses, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched addresses.

— The data at the address accessed by the LoadExcl, and at the address accessed by the StoreExcl, is UNKNOWN.

This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExcl instruction is the same as the transaction size of the preceding LoadExcl instruction executed in that thread. If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  — The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

Note

This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes.

— The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl have the same transaction size.

- LoadExcl/StoreExcl loops are guaranteed to make forward progress only if, for any LoadExcl/StoreExcl loop within a single thread of execution, the software meets all of the following conditions:
  1. Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory effects, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, ISB barriers, or indirect branches.
  2. Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:
     • There are no stores or PLDW instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
     • There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
     • There are no direct or indirect System register writes, other than changes to the flag fields in the CPSR or FPSCR, caused by data processing or comparison instructions.
     • There are no direct or indirect address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
     • All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the LoadExcl/StoreExcl loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:
  — Performing stores to a PA covered by the Exclusives monitor.
  — Prefetching with intent to write to a PA covered by the Exclusives monitor.
  — Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.
  — Executing instruction cache invalidate all instructions.
  — Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.
• Implementations can benefit from keeping the LoadExcl and StoreExcl operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

• The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.

• After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.

• For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:
  — The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

     Note

This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with changed memory attributes, and fail for other instances of a LoadExcl/StoreExcl pair with changed memory attributes.

— The data at the address accessed by the StoreExcl is UNKNOWN.

     Note

Another bullet point in this list covers the case where the memory attributes of a LoadExcl/StoreExcl pair differ as a result of using different VAs with different attributes that point to the same PA.

• The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.

     Note

Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

• If the mapping of the VA to PA is changed between the LoadExcl instruction and the StoreExcl instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries on page G5-9221, if the StoreExcl is performed after another write to the same PA as the StoreExcl, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the StoreExcl will not pass its monitor check.

     Note

Arm expects that, in many implementations, either:
  — The TLB invalidation will clear either the local or global monitor.
  — The PA will be checked between the LoadExcl and StoreExcl.

• The Exclusive Access state for an address accessed by a PE can be lost as a result of a PLDW instruction to the same PA executed by another PE. This means that a very high rate of repeated PLDW accesses to a memory location might impede the forward progress of another PE.
Note
In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

E2.10.6 Use of WFE and SEV instructions by spin-locks

The architecture provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait For Event and Send Event on page G1-8988. However, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note
This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
Part F

The AArch32 Instruction Sets
Chapter F1
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- Format of instruction descriptions on page F1-7224.
- Standard assembler syntax fields on page F1-7228.
- Conditional execution on page F1-7229.
- Shifts applied to a register on page F1-7231.
- Memory accesses on page F1-7233.
- Encoding of lists of general-purpose registers and the PC on page F1-7234.
- General information about the T32 and A32 instruction descriptions on page F1-7235.
- Additional pseudocode support for instruction descriptions on page F1-7248.
- Additional information about Advanced SIMD and floating-point instructions on page F1-7249.
F1.1 Format of instruction descriptions

The instruction descriptions in Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions and Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions normally use the following format:

• Instruction section title.
• Introduction to the instruction.
• A description of each encoding of the instruction.
• Assembler syntax.
• Pseudocode describing how the instruction operates.
• Notes, if applicable.

Each of these items is described in more detail in the following subsections.

F1.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F1.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F1.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labeled as:

• A1, A2, A3 … for the first, second, third, and any additional A32 encodings.
• T1, T2, T3 … for the first, second, third, and any additional T32 encodings.

Each instruction encoding description consists of:

• An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. Sometimes, multiple syntax variants are given. These are written in a typewriter font using the conventions described in Assembler syntax prototype line conventions on page F1-7226. The correct one to use can be indicated by:
  — A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading Flag setting, rotate right with extend variant in the description of the A1 encoding of the ADC, ADCS (register) instructions in A1 on page F5-7446.
  — An annotation to the syntax, such as Inside IT block or Outside IT block. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in T1 on page F5-7447.

In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants, and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax AND R0, R0, R8 ensures selection of a 32-bit encoding but AND R0, R0, R1 selects a 16-bit encoding.
For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction, then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture prefers the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

  Software can use the .W and .N qualifiers to specify the required encoding width, see Standard assembler syntax fields on page F1-7228.

- If multiple encodings of the same length can encode the instruction, the Assembler syntax subsection says which encoding is preferred, and how software can, instead, select the other encodings.

Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

--- Note ---

In some cases, an instruction is available in one instruction set but not in another. The Assembler syntax subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111 described in Branch, branch with link, and block data transfer on page F4-7400, System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-7402, and Unconditional instructions on page F4-7420 cannot have a Condition code, but the equivalent T32 instructions often can, and this usually appears in the Assembler syntax subsection as a statement that the A32 instruction cannot be conditional. However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, to produce more readable disassembled code.

- An encoding diagram, where:
  - For a 32-bit A32 encoding diagram, the bits are numbered from 31-0.
  - For a 16-bit T32 encoding diagram, the bits are numbered from 15-0.

    This halfword can be described as hw1 of the instruction.

  - For a 32-bit T32 encoding diagram, the bits are numbered from 15-0 for each halfword, as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

    In this case, the left-hand halfword in the diagram is identified as hw1, and the right-hand halfword is identified as hw2.

Where instructions are stored using the standard little-endian instruction endianness:

- The encoding diagram for an A32 instruction at address A shows, from left to right, the bytes at addresses A+3, A+2, A+1, A.

- The encoding diagram for a 32-bit T32 instruction shows bytes in the order A+1, A for hw1, followed by bytes A+3, A+2 for hw2.

- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the Operation subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix K16 Arm Pseudocode Definition.

F1.1.4 Assembler symbols

The Assembly symbols describe the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- Descriptions of all variable or optional fields of the syntax.
Some syntax fields are standardized across all or most instructions. Standard assembler syntax fields on page F1-7228 describes these fields.

By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP, or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

- Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.
- In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is available only when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is available only if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. Arm recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

**Assembler syntax prototype line conventions**

The following conventions are used in assembler syntax prototype lines and their subfields:

- Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence requires only the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

- If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as add = TRUE. The assembler must use only encodings that produce that output.

- Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text. Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

- In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:
  - Must treat the # as optional where an instruction syntax description shows it as optional.
  - Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

  ______ Note _______

Arm recommends that UAL assemblers treat all uses of # shown in this manual as optional.

______

**spaces**

Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.
This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

**F1.1.5 Pseudocode describing how the instruction operates**

The *Operation for all classes* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix K16 *Arm Pseudocode Definition*. 
F1.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<>  Is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F1-7229 for the range of available conditions and their encoding. If <> is omitted, it defaults to always (AL).

<>  Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

.N  Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W  Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory .W qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

--- Note ---

When assembling to the A32 instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.
F1.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR Condition flags. Table F1-1 on page F1-7229 lists the available conditions.

Table F1-1 Condition codes

<table>
<thead>
<tr>
<th>cond</th>
<th>Mnemonic extension</th>
<th>Meaning (integer)</th>
<th>Meaning (floating-point)</th>
<th>Condition flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EQ</td>
<td>Equal</td>
<td>Equal</td>
<td>Z == 1</td>
</tr>
<tr>
<td>0001</td>
<td>NE</td>
<td>Not equal</td>
<td>Not equal, or unordered</td>
<td>Z == 0</td>

<td>Z == 0 and N == V</td>
</tr>
<tr>
<td>1101</td>
<td>LE</td>
<td>Signed less than or equal</td>
<td>Less than, equal, or unordered</td>
<td>Z == 1 or N != V</td>
</tr>
<tr>
<td>1110</td>
<td>None (AL) (^d)</td>
<td>Always (unconditional)</td>
<td>Always (unconditional)</td>
<td>Any</td>
</tr>
</tbody>
</table>

a. Unordered means at least one NaN operand.
b. HS (unsigned higher or same) is a synonym for CS.
c. LO (unsigned lower) is a synonym for CC.
d. AL is an optional mnemonic extension for always, except in IT instructions. For details, see IT on page F5-7580.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information, see Conditional instructions on page F2-7257 and IT on page F5-7580. Some conditional branch instructions do not require a preceding IT instruction, because they include a Condition code in their encoding.

Implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable use of IT for some instructions, making them UNDEFINED. For more information, see:

- Disabling or enabling PL0 and PL1 use of AArch32 optional functionality on page G1-9004.
- Disabling or enabling EL2 use of AArch32 optional functionality on page G1-9013.

In A32 instructions, bits[31:28] of the instruction contain either:

- The Condition code, see The Condition code field in A32 instruction encodings.
- 0b1111 for some A32 instructions that can only be executed unconditionally.

F1.3.1 The Condition code field in A32 instruction encodings

Every conditional A32 instruction contains a 4-bit Condition code field, the cond field, in bits 31-28:

<table>
<thead>
<tr>
<th>cond</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

\[^b\] HS (unsigned higher or same) is a synonym for CS.
\[^c\] LO (unsigned lower) is a synonym for CC.
\[^d\] AL is an optional mnemonic extension for always, except in IT instructions. For details, see IT on page F5-7580.
This field contains one of the values 0b0000-0b1110, as shown in Table F1-1 on page F1-7229. Most instruction mnemonics can be extended with the letters defined in the Mnemonic extension on page F1-7229 column of that table.

If the always (AL) condition is specified, the instruction is executed irrespective of the value of the Condition flags. The absence of a Condition code on an instruction mnemonic implies the AL Condition code.

**F1.3.2 Pseudocode description of conditional execution**

The AArch32.CurrentCond() function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see B on page F5-7491), it returns the 4-bit cond field of the encoding.
- For all other T32 instructions:
  - If PSTATE.IT<3:0> != '0000' it returns PSTATE.IT<7:4>.
  - If PSTATE.IT<7:0> == '00000000' it returns '1110'.
  - Otherwise, execution of the instruction is CONSTRAINED UNPREDICTABLE.

For more information, see Process state, PSTATE on page E1-7133.

The ConditionPassed() function uses this condition specifier and the Condition flags to determine whether the instruction must be executed, by calling the ConditionHolds() function.

Chapter J1 Armv8 Pseudocode includes the definitions of these functions.

Undefined Instruction exception on page G1-8964 describes the handling of conditional instructions that are UNDEFINED, UNPREDICTABLE, or CONSTRAINED UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see Limitations of the instruction pseudocode on page K16-11810.
F1.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details, see Constant shifts.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F1.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions. <shift> is an optional shift to be applied to <Rm>. It can be any one of:

(omitted) No shift.

LSL <n> Logical shift left <n> bits. 1 <= <n> <= 31.

LSR <n> Logical shift right <n> bits. 1 <= <n> <= 32.

ASR <n> Arithmetic shift right <n> bits. 1 <= <n> <= 32.

ROR <n> Rotate right <n> bits. 1 <= <n> <= 31.

RRX Rotate right one bit, with extend. Bit[0] is written to shifter_carry_out, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

—— Note ———

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes <shift> into two type bits and five immediate bits, as follows:

(omitted) type = 0b00, immediate = 0.

LSL <n> type = 0b00, immediate = <n>.

LSR <n> type = 0b01.

If <n> < 32, immediate = <n>.

If <n> == 32, immediate = 0.

ASR <n> type = 0b10.

If <n> < 32, immediate = <n>.

If <n> == 32, immediate = 0.

ROR <n> type = 0b11, immediate = <n>.

RRX type = 0b11, immediate = 0.
F1.4.2 Register controlled shifts

These are available only in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

- **ASR**: Arithmetic shift right, encoded as type = 0b10.
- **LSL**: Logical shift left, encoded as type = 0b00.
- **LSR**: Logical shift right, encoded as type = 0b01.
- **ROR**: Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F1.4.3 Pseudocode description of instruction-specified shifts and rotates

The pseudocode enumeration `SRType()` defines the shift types. Shift and rotate instruction decode is described by the pseudocode function:

- `DecodeImmShift()` for a constant shift.
- `DecodeRegShift()` for a register controlled shift.

Shift and rotate operations are made by the pseudocode function `Shift()`.
F1.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>] \]

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>]! \]

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rm>, <offset>] \]

In each case, \(<Rn>\) is the base register. \(<offset>\) can be:

- An immediate constant, such as \(<imm8>\) or \(<imm12>\).
- An index register, \(<Rm>\).
- A shifted index register, such as \(<Rm>, \text{LSL} #<shift>\).

For information about unaligned access, endianness, and exclusive access, see:

- Alignment support on page E2-7193.
- Endian support on page E2-7195.
- Synchronization and semaphores on page E2-7211.
F1.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `{registers}` field, which provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit register_list field. This section gives more information about these and other possible register list encodings.

In a register_list field, each bit corresponds to a single register, and if the `{registers}` field of the assembler instruction includes Rt then register_list<tt> is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.
  
  The exceptions to this rule are:
  
  — The T1 encoding of POP uses an 8-bit register list, and an additional bit, P, that corresponds to the PC. This means it can access any of R0-R7 and the PC.
  
  — The T1 encoding of PUSH uses an 8-bit register list, and an additional bit, M, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, M, corresponding to the LR, and P, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, M, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.
  
  The exception to this rule is:
  
  — The System instructions LDM (exception return) and LDM (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of POP, and the T3 and A2 encodings of PUSH, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the Rt field.

--- Note

POp is a load operation, and PUSH is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, registers, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

--- Note

Some Advanced SIMD and floating-point instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `{list}` field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-7442 defines the use and encoding of this field.
F1.7 General information about the T32 and A32 instruction descriptions

Chapter F3 T32 Instruction Set Encoding describes the T32 instruction encodings, and Chapter F4 A32 Instruction Set Encoding describes the A32 instruction encodings. The following subsections give more information about the descriptions of these instructions and their encodings:

- Execution of instructions in debug state.
- Fixed values in AArch32 instruction and System register descriptions.
- UNDEFINED, UNPREDICTABLE, and CONstrained UNPREDICTABLE instruction set space on page F1-7236.
- T32 and A32 Advanced SIMD and floating-point instruction encodings on page F1-7237.
- The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions on page F1-7241.
- The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions on page F1-7242.
- Modified immediate constants in T32 and A32 instructions on page F1-7243.

F1.7.1 Execution of instructions in debug state

In general, except for the instructions described in Debug state on page F2-7276, the T32 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state on page H2-10243.

Note

- A32 instructions cannot be executed in Debug state.
- For many T32 instructions, execution is unchanged in Debug state. Executing instructions in Debug state on page H2-10243 identifies these instructions.

F1.7.2 Fixed values in AArch32 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ      Read-As-Zero. See Read-As-Zero (RAZ).

In diagrams, a RAZ bit can be shown as 0.

(0), RES0  Reserved. Should-Be-Zero (SBZ) or RES0.

In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (0)(0)(0) or as (000).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. For more information, see the Glossary definition of RES0.

Note

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,
The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO
Read-As-One. See Read-As-One (RAO).
In diagrams, a RAO bit can be shown as 1.

(1), RES1
Reserved. Should-Be-One (SBO) or RES1.
In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates an SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).
In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. For more information, see the Glossary definition of RES1.

Note
Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES1 fields.

The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

Note
In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the Glossary. However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:

- A bit marked as (0) has the value 1.
- A bit marked as (1) has the value 0.

F1.7.3 UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE.
  
  From the introduction of Armv8-A, the architecturally UNPREDICTABLE behavior in AArch32 state is greatly reduced. Most cases that earlier versions of the architecture describe as UNPREDICTABLE become either:
  
  — CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
  
  — Fully predictable.
  
  For more information, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in Chapter F3 T32 Instruction Set Encoding or Chapter F4 A32 Instruction Set Encoding.

An instruction is UNPREDICTABLE only if:

- It is declared as UNPREDICTABLE in an instruction description or in Chapter F3 or Chapter F4, and Appendix K1 does not redefine the behavior as CONSTRAINED UNPREDICTABLE.

  The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively. In most cases, Armv8 makes these cases CONSTRAINED UNPREDICTABLE, as described in SBZ or SBO fields T32 and A32 in instructions on page K1-11566.
Unless otherwise specified, T32 and A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

--- Note ---

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The System instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

---

For more information about UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page G1-8964.

### F1.7.4 T32 and A32 Advanced SIMD and floating-point instruction encodings

The T32 and A32 encodings of Advanced SIMD and floating-point instructions are described in Chapter F3 *T32 Instruction Set Encoding* and in Chapter F4 *A32 Instruction Set Encoding*. This means:

- The instruction groups, and the set of instructions in each group, are identical for T32 and A32.
- For each instruction:
  - Each T32 encoding is exactly equivalent to an A32 encoding.
  - There is no T32 encoding without an equivalent A32 encoding, and no A32 encoding without an equivalent T32 encoding.

---

- In the T32 instruction sets, the Advanced SIMD and floating-point instructions have 32-bit encodings.
- In the base instruction sets, some instructions are common to the T32 and A32 instruction sets, whereas other instructions have equivalent but not identical functionality in the two instruction sets.

32-bit T32 encodings are described as two contiguous halfwords, \(\{\text{hw1, hw2}\}\), as described in *Instruction encodings* on page F1-7224. In general:

- \(\text{hw1}\) of a T32 encoding maps onto bits\([31:16]\) of an equivalent A32 encoding.
- \(\text{hw2}\) of a T32 encoding maps onto bits\([15:0]\) of an equivalent A32 encoding.

However, the different structures of the T32 instruction encoding space and the A32 instruction encoding space mean that:

- For a given Advanced SIMD and floating-point instruction group:
  - The positions of the fields that identify the instruction, or instruction encoding, within the instruction group might differ between the T32 encodings and the A32 encodings.
  - However, the field values that identify the instruction of instruction encoding are identical for the T32 encoding and the A32 encoding.

The remainder of this section describes the equivalence of the T32 and A32 encodings for each of the Advanced SIMD and floating-point instruction groups.

### Advanced SIMD data-processing

The T32 encoding of the Advanced SIMD data-processing group is:
The A32 encoding of the Advanced SIMD data-processing group is:

\[
\begin{array}{ccccccccccc}
| 31 | 25 | 24 | 23 | 22 | 5 | 4 | 3 | 0 | \\
\hline
1111001 \\
\hline
\end{array}
\]

The encodings in this group are identified by:

- \( \text{hw1}[15:13] \) of the T32 encoding is equivalent to bits\([27:25]\) of the A32 encoding, and:
  - Has the value \( 0b111 \) in the T32 encoding.
  - Has the value \( 0b001 \) in the A32 encoding.

- \( \text{hw1}[11:8] \) of the T32 encoding is equivalent to bits\([31:28]\) of the A32 encoding, and has the value \( 0b111 \).

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

<table>
<thead>
<tr>
<th>T32 encoding</th>
<th>A32 encoding</th>
<th>Field size</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0:op1</td>
<td>op0</td>
<td>2 bits</td>
</tr>
<tr>
<td>op2</td>
<td>op1</td>
<td>15 bits</td>
</tr>
<tr>
<td>op3</td>
<td>op2</td>
<td>1 bit</td>
</tr>
<tr>
<td>op4</td>
<td>op3</td>
<td>1 bit</td>
</tr>
</tbody>
</table>

**Advanced SIMD element or structure load/store**

The T32 encoding of the Advanced SIMD element or structure load/store group is:

\[
\begin{array}{cccccccccccc}
| 15 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | 10 | 9 | 0 | \\
\hline
1111001 \\
\hline
\end{array}
\]

The A32 encoding of the Advanced SIMD element or structure load/store group is:

\[
\begin{array}{cccccccccccc}
| 31 | 24 | 23 | 22 | 21 | 20 | 19 | 12 | 11 | 10 | 9 | 0 | \\
\hline
1110100 \\
\hline
\end{array}
\]

The encodings in this group are identified by:

- \( \text{hw1}[15:12] \) of the T32 encoding is equivalent to bits\([31:28]\) of the A32 encoding, and has the value \( 0b1111 \).
• hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and:
  — Has the value 0b1001 in the T32 encoding.
  — Has the value 0b0100 in the A32 encoding.
• hw1[4] of the T32 encoding is equivalent to bit[20] of the A32 encoding, and has the value 0b0.

op0, op1, and op2 are the fields that identify the instructions, or instruction encodings, within this group, and they are in equivalent positions in the T32 and A32 encodings.

**Advanced SIMD and floating-point load/store and 64-bit register moves**

The T32 encoding of the Advanced SIMD and floating-point load/store and 64-bit register moves group is:

<table>
<thead>
<tr>
<th>15</th>
<th>8</th>
<th>5 4</th>
<th>0</th>
<th>15</th>
<th>11</th>
<th>8</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110110</td>
<td>op0</td>
<td>101</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The A32 encoding of the Advanced SIMD and floating-point load/store and 64-bit register moves group is:

<table>
<thead>
<tr>
<th>31</th>
<th>27 24</th>
<th>21 20</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>#=1111 110</td>
<td>op0</td>
<td>101</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The encodings in the group are identified by:

• hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  — Has the value 0b1110 in the T32 encoding.
  — Can have any value other than 0b1111 in the A32 encoding.
    This range of values is required because A32 instructions in this group can be executed conditionally, see *Conditional execution* on page F1-7229.
• hw1[11:9] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and has the value 0b110.
• hw2[11:9] of the T32 encoding is equivalent to bits[23:21] of the A32 encoding, and has the value 0b110.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

**Advanced SIMD and floating-point 32-bit register moves**

The T32 encoding of the Advanced SIMD and floating-point 32-bit register moves group is:

<table>
<thead>
<tr>
<th>15</th>
<th>7</th>
<th>5 4</th>
<th>0</th>
<th>15</th>
<th>12</th>
<th>8</th>
<th>7 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>11101110</td>
<td>op0</td>
<td>101</td>
<td></td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The A32 encoding of the Advanced SIMD 32-bit register moves group is:

<table>
<thead>
<tr>
<th>31</th>
<th>27 23</th>
<th>21 20</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>#=1111 1110</td>
<td>op0</td>
<td>101</td>
<td></td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The encodings in this group are identified by:

- \( \text{hw1}[15:12] \) of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - Has the value 0b1110 in the T32 encoding.
  - Can have any value other than 0b1111 in the A32 encoding.
  
  This range of values is required because A32 instructions in this group can be executed conditionally, see Conditional execution on page F1-7229.

- \( \text{hw1}[11:8] \) of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.

- \( \text{hw2}[4] \) of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b1.

\( \text{op0} \) is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

**Floating-point data-processing**

The T32 encoding of the Floating-point data-processing group is:

```
| 15 | 8 | 7 | 4 | 3 | 0 | 15 | 12 | 11 | 10 | 9 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|---|---|---|---|---|----|----|----|----|----|---|---|---|---|---|---|---|
| 11101110 | op0 | 10 | | | | 0 |
```  

The A32 encoding of the Floating-point data-processing group is:

```
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 12 | 11 | 10 | 9 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|
| !=1111 | 1110 | op0 | 10 | | | 0 |
```

The encodings in this group are identified by:

- \( \text{hw1}[15:12] \) of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - In the T32 encoding, \( \text{hw1}[15:13] \) has the value 0b111, and \( \text{hw1}[12] \) is the \( \text{op0} \) parameter used in identifying instruction encodings within this group.
  - In the A32 encoding, is the \( \text{cond} \) field and also implies the value of bit[28] of some A32 instruction encodings within this group, as the following table shows:

<table>
<thead>
<tr>
<th>\text{cond}</th>
<th>\text{Significance of bit}[28] in A32 encodings</th>
</tr>
</thead>
<tbody>
<tr>
<td>!=0b1111</td>
<td>Part of the ( \text{cond} ) field.</td>
</tr>
<tr>
<td>0b1111</td>
<td>Has fixed value of 1.</td>
</tr>
</tbody>
</table>

The range of \( \text{cond} \) values other than 0b1111 is required because A32 instructions in this group can be executed conditionally, see Conditional execution on page F1-7229.

- \( \text{hw1}[11:8] \) of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.

- \( \text{hw2}[4] \) of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b0.
This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

<table>
<thead>
<tr>
<th>T32 encoding</th>
<th>A32 encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td>Bit[28] of the instruction encoding is 1 when cond is 0b1111.</td>
</tr>
<tr>
<td>op1</td>
<td>op0</td>
</tr>
<tr>
<td>op2</td>
<td>op1</td>
</tr>
<tr>
<td>op3</td>
<td>op2</td>
</tr>
</tbody>
</table>

### F1.7.5 The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions

Restrictions on the use of PC or 0b1111 as a register specifier differ between the T32 and the A32 instruction sets, as described in:

- **T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier.**
- **A32 restrictions on the use of PC or 0b1111 as a register specifier** on page F1-7242.

#### T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  ____________ Note ____________
  Arm deprecates use of the PC as the base register in the STC instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.

- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.

- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions.
  - Explicitly by using a register mask, for example LDM instructions.

  The address to branch to can be:
  - A loaded value, for example, RFE.
  - A register value, for example, BX.
  - The result of a calculation, for example, TBB or TBH.
The method of choosing the instruction set used after the branch can be:

- Similar to the LDR case, for example, LDM or BX.
- A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.
- Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.
- Set from the SPSR.T bit, for RFE and SUBS PC, LR, #imm8.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.

- If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the System register are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.

### A32 restrictions on the use of PC or 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are CONSTRAINED UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. Armv8-A constrains the resulting CONSTRAINED UNPREDICTABLE behavior, see Using R15 by instruction on page K1-11563.

**Note**

Arm deprecates use of the PC as the base register in any store instruction.

### F1.7.6 The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions

In the T32 and A32 instruction sets, Arm recommends that the use of 0b1101 as a register specifier specifies the SP.

**Note**

- The recommendation that the register specifier 0b1101 is used only to specify the SP applies to both the T32 and the A32 instruction sets.

- Despite this recommendation, T32 instructions that can access R13, or the SP, behave predictably from the introduction of Armv8.

### F1.7.7 Modified immediate constants in T32 and A32 instructions

The following sections describe the encoding of modified immediate constants:

- Modified immediate constants in T32 instructions.
- Modified immediate constants in A32 instructions.

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

```
<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>imm3</td>
<td>a</td>
<td>b</td>
<td>c</td>
<td>d</td>
<td>e</td>
<td>f</td>
<td>g</td>
<td>h</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

- Modified immediate constants in T32 and A32 Advanced SIMD instructions.
- Modified immediate constants in T32 and A32 floating-point instructions.
Table F1-2 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table F1-2 Encoding of modified immediates in T32 data-processing instructions

<table>
<thead>
<tr>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000x</td>
<td>00000000 00000000 00000000 abcdefgh</td>
</tr>
<tr>
<td>0001x</td>
<td>00000000 abcdefgh 00000000 abcdefgh</td>
</tr>
<tr>
<td>0010x</td>
<td>abcdefgh 00000000 abcdefgh 00000000</td>
</tr>
<tr>
<td>0011x</td>
<td>abcdefgh abcdefgh abcdefgh abcdefgh</td>
</tr>
<tr>
<td>01000</td>
<td>1bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01001</td>
<td>01bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01010</td>
<td>001bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01011</td>
<td>0001bcdefgh 00000000 00000000 00000000</td>
</tr>
</tbody>
</table>

a. This table shows the immediate constant value in binary form, to relate abcdedgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

b. Arm deprecates using a modified immediate with abcdedgh == 00000000, and these cases are CONSTRAINED UNPREDICTABLE, see UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-11566.

c. Not available in A32 instructions if h == 1.

Note

As the footnotes to Table F1-2 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See Modified immediate constants in A32 instructions on page F1-7244 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, T32 instructions

For a T32 data-processing instruction, the T32ExpandImm() pseudocode function returns the value of the 32-bit immediate constant, calling T32ExpandImm_C() to evaluate the constant.
Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

```
rotation | a b c d e f g h
-----------|---------------------
0000      | 00000000 00000000 00000000 00000000
0001      | gh000000 00000000 00000000 00000000
0010      | efg0000 00000000 00000000 00000000
0011      | cdefg00 00000000 00000000 00000000
0100      | abcd0000 00000000 00000000 00000000
0101      | 00000000 00000000 00000000 00000000
0110      | 00000000 00000000 00000000 00000000
0111      | 00000000 00000000 00000000 00000000
```

Table F1-3 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

### Table F1-3 Encoding of modified immediates in A32 processing instructions

</tr>
<tr>
<td>11110000</td>
<td>00000000 00000000 00000000 00000000</td>
</tr>
</tbody>
</table>

Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See Modified immediate constants in T32 instructions on page F1-7242.

### Carry out

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

### Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F1-3. For example, the constant #3 must be encoded with (rotation, abcd0000) == (0b0000, 0b00000001), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).
In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> Is the numeric value of abcdefgh, in the range 0-255.

<rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and Arm deprecates their use.

**Operation of modified immediate constants, A32 instructions**

For an A32 data-processing instruction, the A32ExpandImm() pseudocode function returns the value of the 32-bit immediate constant, calling A32ExpandImm_C() to evaluate the constant.

**Modified immediate constants in T32 and A32 Advanced SIMD instructions**

Table F1-4 on page F1-7245 shows the modified immediate constants available with Advanced SIMD instructions, and how they are encoded.

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x000000000000000A.
Operation of modified immediate constants, Advanced SIMD instructions

For a T32 or A32 Advanced SIMD instruction that uses a modified immediate constant, the operation described by the \texttt{AdvSIMDExpandImm()} pseudocode function returns the value of the 64-bit immediate constant.

Modified immediate constants in T32 and A32 floating-point instructions

Table \texttt{F1-5} on page F1-7246 shows the immediate constants available in the \texttt{VMOV} (immediate) floating-point instruction, and Table \texttt{F1-6} on page F1-7246 shows the resulting floating-point values.

**Operation of modified immediate constants, floating-point instructions**

For a T32 or A32 floating-point instruction that uses a modified immediate constant, the operation described by the `VFPExpandImm()` pseudocode function returns the value of the immediate constant.
F1.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- Pseudocode description of conditional execution on page F1-7230.
- Pseudocode description of instruction-specified shifts and rotates on page F1-7232

The following subsection gives additional pseudocode support functions for some of the instructions described in Alphabetical list of T32 and A32 base instruction set instructions on page F5-7442. See also Pseudocode support for the banked register transfer instructions on page F5-8163.

F1.8.1 Pseudocode description of operations for System register access instructions

The AArch32.SysRegRead() function obtains the word for an MRC instruction from the System register.

The AArch32.SysRegRead64() function obtains the two words for an MRRC instruction from the System register.

—— Note ———

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

—— ———

The AArch32.SysRegWrite() procedure sends the word for an MCR instruction to the System register.

The AArch32.SysRegWrite64() procedure sends the two words for an MCRR instruction to the System register.

—— Note ———

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

F1.8.2 Pseudocode details of system calls

The AArch32.CallSupervisor() pseudocode function generates a Supervisor Call exception. Valid execution of the SVC instruction calls this function.

The AArch32.CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.
F1.9 Additional information about Advanced SIMD and floating-point instructions

The following subsections give additional information about the Advanced SIMD and floating-point instructions:

- Advanced SIMD and floating-point instruction syntax.
- The Advanced SIMD addressing mode.
- Advanced SIMD instruction modifiers on page F1-7250.
- Advanced SIMD operand shapes on page F1-7250.
- Data type specifiers on page F1-7251.
- Register specifiers on page F1-7252.
- Register lists on page F1-7253.
- Register encoding on page F1-7253.
- Advanced SIMD scalars on page F1-7254.

——— Note ————

The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.

F1.9.1 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

\[ V\{<\text{modifier}>\}\text{<operation>}{\langle\text{shape}\rangle}\{<\text{c}>\}{<\text{q}>}\{.<\text{dt}>\}{<\text{dest}>}, \text{<src1>}, \text{<src2>} \]

All Advanced SIMD and floating-point instructions begin with a \( V \). This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the \( \text{<operation>} \) field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The \( \text{<c>} \) and \( \text{<q>} \) fields are standard assembler syntax fields. For details, see Standard assembler syntax fields on page F1-7228.

F1.9.2 The Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

\[ [<Rn>{:<align}>] \]

The address is contained in general-purpose register \( Rn \).

\( Rn \) is not updated by this instruction.

Encoded as \( Rm = \text{0b1111} \).

If \( Rn \) is encoded as \( \text{0b1111} \), the instruction is CONSTRAINED UNPREDICTABLE.

\[ [<Rn>{:<align}>]! \]

The address is contained in general-purpose register \( Rn \).

\( Rn \) is updated by this instruction: \( Rn = Rn + \text{transfer\_size} \)

Encoded as \( Rm = \text{0b1101} \).

\( \text{transfer\_size} \) is the number of bytes transferred by the instruction. This means that, after the instruction is executed, \( Rn \) points to the address in memory immediately following the last address loaded from or stored to.

If \( Rn \) is encoded as \( \text{0b1111} \), the instruction is CONSTRAINED UNPREDICTABLE.

This addressing mode can also be written as:

\[ [<Rn>{:align}], \#<\text{transfer\_size}> \]

However, disassembly produces the \([<Rn>:<align>]!\) form.
The address is contained in general-purpose register \(<Rn>\).

\(Rn\) is updated by this instruction:

\(Rn = Rn + Rm\)

Encoded as \(Rm = Rm\). \(Rm\) must not be encoded as \(0b1111\) or \(0b1101\), the PC or the SP.

If \(Rn\) is encoded as \(0b1111\), the instruction is CONSTRAINED UNPREDICTABLE.

The CONSTRAINED UNPREDICTABLE behavior of encodings where \(Rn\) is \(0b1111\) is described in the section: Using R15 by instruction on page K1-11563.

In all cases, \(<align>\) specifies an alignment, as specified by the individual instruction descriptions.

Previous versions of the manual used the \(@\) character for alignment. So, for example, the first format in this section was shown as \([<Rn>@<align>]\). Both \(@\) and : are supported. However, to ensure portability of code to assemblers that treat \(@\) as a comment character, : is preferred.

### F1.9.3 Advanced SIMD instruction modifiers

The \(<modifier>\) field provides additional variants of some instructions. Table F1-7 on page F1-7250 provides definitions of the modifiers. Modifiers are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;modifier&gt;)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q</td>
<td>The operation uses saturating arithmetic.</td>
</tr>
<tr>
<td>R</td>
<td>The operation performs rounding.</td>
</tr>
<tr>
<td>D</td>
<td>The operation doubles the result (before accumulation, if any).</td>
</tr>
<tr>
<td>H</td>
<td>The operation halves the result.</td>
</tr>
</tbody>
</table>

### F1.9.4 Advanced SIMD operand shapes

The \(<shape>\) field provides additional variants of some instructions. Table F1-8 on page F1-7250 provides definitions of the shapes. Operand shapes are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;shape&gt;)</th>
<th>Meaning</th>
<th>Typical register shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>(none)</td>
<td>The operands and result are all the same width.</td>
<td>Dd, Dn, Dm, Qd, Qn, Qm</td>
</tr>
<tr>
<td>L</td>
<td>Long operation - result is twice the width of both operands</td>
<td>Qd, Dn, Dm</td>
</tr>
<tr>
<td>N</td>
<td>Narrow operation - result is half the width of both operands</td>
<td>Dd, Qn, Dm</td>
</tr>
<tr>
<td>W</td>
<td>Wide operation - result and first operand are twice the width of the second operand</td>
<td>Qd, Qn, Qm</td>
</tr>
</tbody>
</table>

#### Note

- Some assemblers support a Q shape specifier, which requires all operands to be Q registers. An example of using this specifier is \(VADDQ.S32 q0, q1, q2\). This is not standard UAL, and Arm recommends that programmers do not use a Q shape specifier.

- A disassembler must not generate any shape specifier not shown in Table F1-8 on page F1-7250.
F1.9.5 Data type specifiers

The `<dt>` field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the `<dt>` field combined with the instruction shape. For information about data type formats, see *Data types supported by the Advanced SIMD implementation* on page E1-7142.

In the instruction syntax descriptions in Chapter F1 *About the T32 and A32 Instruction Descriptions*, the `<dt>` field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, `<type><size>`.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
  
  ```
  VSUBW.I16.I16.S8 Q3, Q5, D0
  ```

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
  
  ```
  VSUBW.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0
  ```

- Software can specify two data types, specifying the data types of the single operand and the result. For example:
  
  ```
  VMOVN.I16.I32 D0, Q1
  ```

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in *Table F1-9 on page F1-7251*.

- Where an instruction does not require a data type, software can provide one.

- The F32 data type can be abbreviated to F.

- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

<table>
<thead>
<tr>
<th>Specified data type</th>
<th>Permitted more specific data types</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Any</td>
</tr>
<tr>
<td>.I&lt;size&gt;</td>
<td>-</td>
</tr>
<tr>
<td>.S&lt;size&gt;</td>
<td>.U&lt;size&gt;</td>
</tr>
<tr>
<td>.32</td>
<td>.I32 .S32 .U32 - .F32 or .F</td>
</tr>
<tr>
<td>.64</td>
<td>.I64 .S64 .U64 - .F64 or .D</td>
</tr>
</tbody>
</table>
**F1.9.6 Register specifiers**

The `<dest>`, `<src1>`, and `<src2>` fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F1-10 on page F1-7252 shows the register and scalar specifier formats that appear in the instruction descriptions.

If `<dest>` is omitted, it is the same as `<src1>`.

<table>

<td>A general-purpose register, used as a load or store base address.</td>
<td>Both</td>
</tr>
<tr>
<td><code>&lt;Rm&gt;</code></td>
<td>A general-purpose register, used as a post-indexed address source.</td>
<td>Both</td>
</tr>
</tbody>
</table>

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, `<Dn[x]>` is used only in VMOV (scalar to general-purpose register), see *VMOV (scalar to general-purpose register)* on page F6-8554.
**F1.9.7 Register lists**

A register list is a list of register specifiers separated by commas and enclosed in brackets `{` and `}`. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F1-11 on page F1-7253 shows some register list formats, with examples of actual register lists corresponding to those formats.

--- **Note** ---

Register lists must not wrap around the end of the register bank.

**Syntax flexibility**

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example `{D0-D3}` instead of `{D0, D1, D2, D3}`.

- Where a register list contains an even number of consecutive doubleword registers starting with an even-numbered register, it can be written as a list of quadword registers instead, for example `{Q1, Q2}` instead of `{D2-D5}`.

- Where a register list contains only one register, the enclosing braces can be omitted, for example `VLD1.8 D0, [R0]` instead of `VLD1.8 {D0}, [R0]`.

**Table F1-11 Example register lists**

<table>
<thead>
<tr>
<th>Format</th>
<th>Example</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{&lt;Dd&gt;}</code></td>
<td>{D3}</td>
<td>D3</td>
</tr>
<tr>

<td>{D3, D4, D5}</td>
<td>{D3-D5}</td>
</tr>
<tr>
<td><code>{&lt;Dd[x]&gt;, &lt;Dd+2[x]}</code></td>
<td>{D0[3], D2[3]}</td>
<td>-</td>
</tr>
<tr>
<td><code>{&lt;Dd[]&gt;</code></td>
<td>{D7[0]}</td>
<td>D7[0]</td>
</tr>
</tbody>
</table>

**F1.9.8 Register encoding**

An Advanced SIMD register is either:

- **Quadword**, meaning it is 128 bits wide.
- **Doubleword**, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

```
<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Vn</td>
<td>Vd</td>
<td>sz</td>
<td>N</td>
<td>G</td>
<td>M</td>
<td>Vm</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

```
<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Vn</td>
<td>Vd</td>
<td>sz</td>
<td>N</td>
<td>G</td>
<td>M</td>
<td>Vm</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F1-12 on page F1-7254 shows the encodings for the registers.

### Table F1-12 Encoding of register numbers

<td>Floating-point</td>
</tr>
</tbody>
</table>

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.
b. If this bit is 1, the instruction is UNDEFINED.

### F1.9.9 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F1-13 on page F1-7254 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, \( D_m[x] \) in a 32-bit context (\( 0 <= m <= 15, 0 <= x <= 1 \)) is equivalent to \( S[2m + x] \).

Chapter F2
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- Support for instructions in different versions of the Arm architecture on page F2-7256.
- Unified Assembler Language on page F2-7257.
- Branch instructions on page F2-7259.
- Data-processing instructions on page F2-7260.
- PSTATE and banked register access instructions on page F2-7268.
- Load/store instructions on page F2-7269.
- Load/store multiple instructions on page F2-7272.
- Miscellaneous instructions on page F2-7273.
- Exception-generating and exception-handling instructions on page F2-7275.
- System register access instructions on page F2-7277.
- Advanced SIMD and floating-point load/store instructions on page F2-7278.
- Advanced SIMD and floating-point register transfer instructions on page F2-7280.
- Advanced SIMD data-processing instructions on page F2-7281.
- Floating-point data-processing instructions on page F2-7292.
F2.1 Support for instructions in different versions of the Arm architecture

This manual describes the T32 and A32 instruction sets for the architecture. Therefore, it indicates how any options or extensions in the architecture affect the available instructions.
F2.2 Unified Assembler Language

This manual uses the Arm Unified Assembler Language (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier Arm assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier T32 assembly language mnemonics are not supported.

UAL includes instruction selection rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an ADD R0, R1, R2 instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F2.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, Arm recommends that:

- IT instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any IT instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an IT instruction must be written with a condition. These conditions must match the conditions imposed by the IT instruction. For example, an ITTEE EQ instruction imposes the EQ condition on the first two following instructions, and the NE condition on the next two. Those four instructions must be written with EQ, EQ, NE and NE conditions respectively.

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a Condition code field cannot be made conditional by an IT instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a Condition code field.

F2.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the PC or Align(PC, 4) value of the instruction. The PC value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The Align(PC, 4) value of an instruction is its PC value ANDed with 0xFFFFFFFC to force it to be word-aligned. There is no difference between the PC and Align(PC, 4) values for an A32 instruction, but there can be for a T32 instruction.

2. Calculate the offset from the PC or Align(PC, 4) value of the instruction to the address of the labeled instruction or literal data item.

3. Assemble a PC-relative encoding of the instruction, that is, one that reads its PC or Align(PC, 4) value and adds the calculated offset to form the required address.
Note

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- B, BL, and BLX (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.

- CBNZ and CBZ. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.

- LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the Align(PC, 4) value of the instruction. Encodings that subtract 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by [PC, #+/-<imm>], where:

  +/ - Is + or omitted to specify that the immediate offset is to be added to the Align(PC, 4) value, or if it is to be subtracted.

  <imm> Is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the Align(PC, 4) value, and to disassemble them to a syntax that can be re-assembled correctly.

- ADR. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the Align(PC, 4) value of the instruction. The encoding that subtracts 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions ADD <Rd>, PC, #<imm> or subtractions SUB <Rd>, PC, #<imm>. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the Align(PC, 4) value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

Arm recommends that where possible, software avoids using:

- The alternative syntax for the ADR, LDC, LDR, LDRD, LDRH, LDRSB, LDRSH, PLD, PLI, PLDW, and VLDR instructions.

- The encodings of these instructions that subtract 0 from the Align(PC, 4) value.
### Branch instructions

Table F2-1 on page F2-7259 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

<table>
<thead>

<td>0-131070 bytes</td>
<td></td>
</tr>
</tbody>
</table>

\(^a\) These instructions do not exist in the A32 instruction set.

\(^b\) The range is determined by the instruction set of the BLX instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by LDR, LD\# and data-processing instructions. For details, see Load/store instructions on page F2-7269, Load/store multiple instructions on page F2-7272, Standard data-processing instructions on page F2-7260, and Shift instructions on page F2-7262.

In addition to the branch instructions shown in Table F2-1 on page F2-7259:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see Data-processing instructions on page F2-7260.

- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see Load/store instructions on page F2-7269.
F2.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- Standard data-processing instructions.
- Shift instructions on page F2-7262.
- Multiply instructions on page F2-7262.
- Saturating instructions on page F2-7264.
- Saturating addition and subtraction instructions on page F2-7264.
- Packing and unpacking instructions on page F2-7265.
- Parallel addition and subtraction instructions on page F2-7266.
- Divide instructions on page F2-7267.
- Miscellaneous data-processing instructions on page F2-7267.

For related Advanced SIMD and floating-point instructions see Advanced SIMD data-processing instructions on page F2-7281 and Floating-point data-processing instructions on page F2-7292.

F2.4.1 Standard data-processing instructions

These instructions perform basic data-processing operations, and share a common format with some variations.

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A modified immediate constant that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see Modified immediate constants in T32 instructions on page F1-7242 and Modified immediate constants in A32 instructions on page F1-7244.

If the second operand is another register, it can optionally be shifted in any of the following ways:

- LSL: Logical Shift Left by 1-31 bits.
- LSR: Logical Shift Right by 1-32 bits.
- ASR: Arithmetic Shift Right by 1-32 bits.
- ROR: Rotate Right by 1-31 bits.
- RRX: Rotate Right with Extend. For details, see Shift and rotate operations on page E1-7130.

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than CMN, CMP, TEQ, and TST, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the ADD and MOV instructions.

These instructions can optionally set the Condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F2-2 on page F2-7261 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in Chapter F1 About the T32 and A32 Instruction Descriptions, one section for each of the following:

- INSTRUCTION (immediate) where the second operand is a modified immediate constant.
- INSTRUCTION (register) where the second operand is a register, or a register shifted by a constant.
- INSTRUCTION (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

</table>

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F2.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F2-4 on page F2-7262 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
  The least significant 32 bits of the result are used. More significant bits are discarded.
- Table F2-5 on page F2-7263 summarizes the signed multiply instructions.
- Table F2-6 on page F2-7263 summarizes the unsigned multiply instructions.

**F2.4.7 Parallel addition and subtraction instructions**

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:
- *S* Signed arithmetic modulo $2^8$ or $2^{16}$.
- *Q* Signed saturating arithmetic.
- *SH* Signed arithmetic, halving the results.
- *U* Unsigned arithmetic modulo $2^8$ or $2^{16}$.
- *UQ* Unsigned saturating arithmetic.
- *UH* Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

- **ADD16** Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.
- **ASX** Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.
- **SAX** Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.
- **SUB16** Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.
- **ADD8** Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.
- **SUB8** Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F2-10 on page F2-7266 shows.

See also *Advanced SIMD parallel addition and subtraction* on page F2-7282.

F2.4.8 Divide instructions

Signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set.

For descriptions of the instructions see:
• SDIV on page F5-7878.
• UDIV on page F5-8096.

For the SDIV and UDIV instructions, division by zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of 0b0010 indicates they are implemented in both the T32 and A32 instruction sets.

F2.4.9 Miscellaneous data-processing instructions

Table F2-11 on page F2-7267 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

F2.5 PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

F2.5.1 PSTATE access instructions

PSTATE holds process state information, see Process state, PSTATE on page E1-7133. In AArch32 state:

- At EL1 or higher, PSTATE is accessible using the Current Program Status Register (CPSR).
- At EL0, a subset of the CPSR is accessible as the Application Program Status Register (APSR).
- On taking an exception, the contents of the CPSR are copied to the Saved Program Status Register (SPSR) of the mode from which the exception is taken.

The MRS and MSR instructions move the contents of the CPSR, APSR, or the SPSR of the current mode to or from a general-purpose register, see:

- MRS on page F5-7734.
- MSR (immediate) on page F5-7744.
- MSR (register) on page F5-7746.

When executed at EL0, MRS and MSR instructions can only access the APSR.

The PSTATE Condition flags, PSTATE.\{N, Z, C, V\} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the Condition flags explicitly using the MSR instruction, and can read the current state of the Condition flags explicitly using the MRS instruction.

In addition, at EL1 or higher, software can use the CPS instruction to change the PSTATE.M field and the PSTATE.\{A, I, F\} interrupt mask bits, see CPS, CPSID, CPSIE on page F5-7535.

F2.5.2 Banked register access instructions

At EL1 or higher, the MRS (banked register) and MSR (banked register) instructions move the contents of a banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. See:

- MRS (Banked register) on page F5-7736.
- MSR (Banked register) on page F5-7740.
F2.6 Load/store instructions

Table F2-12 on page F2-7269 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- *Load/store multiple instructions* on page F2-7272.
- *Synchronization and semaphores* on page E2-7211, for more information about the Load-Exclusive and Store-Exclusive instructions.
- *Advanced SIMD and floating-point load/store instructions* on page F2-7278.

Load/store instructions have several options for addressing memory. For more information, see *Addressing modes* on page F2-7270.

#### F2.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.

#### F2.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.
F2.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an \texttt{LDRT} instruction executes in exactly the same way as the equivalent \texttt{LDR} instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an \texttt{LDRT} instruction executes in exactly the way that the equivalent \texttt{LDR} instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

--- Note ---

As described in \textit{Security state, Exception levels, and AArch32 execution privilege on page G1-8908}, execution at PL1 describes all of the following:

- Execution at Non-secure EL1 using AArch32.
- Execution at Secure EL1 using AArch32 when EL3 is not implemented.
- Execution at Secure EL1 using AArch32 when EL3 is implemented and is using AArch64.
- Execution at Secure EL3 when EL3 is implemented and is using AArch32.

The Load unprivileged and Store unprivileged instructions are \textbf{CONSTRAINED UNPREDICTABLE} if executed at EL2.

For more information about execution privilege, see \textit{About access permissions on page G5-9192}.

F2.6.4 Load-Exclusive and Store-Exclusive

Load-Exclusive and Store-Exclusive instructions provide shared memory synchronization. For more information, see \textit{Synchronization and semaphores on page E2-7211}.

F2.6.5 Load-Acquire and Store-Release

Load-Acquire and Store-Release instructions provide memory barriers. Load-Acquire Exclusive and Store-Release Exclusive instructions provide memory barriers with shared memory synchronization. For more information, see \textit{Load-Acquire, Store-Release on page E2-7186}.

F2.6.6 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter F1 \textit{About the T32 and A32 Instruction Descriptions} are PC-relative loads.

The offset takes one of three formats:

- **Immediate**: The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets, and input/output registers.

- **Register**: The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

- **Scaled register**: The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

- **Offset**: The offset is added to or subtracted from the base register to form the memory address.
Pre-indexed  The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

Post-indexed  The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

Note  Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F1 About the T32 and A32 Instruction Descriptions for full details for each instruction.
F2.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F2-13 on page F2-7272 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

### Table F2-13 Load/store multiple instructions

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

a. Not available in the T32 instruction set.
b. This instruction is equivalent to an LDM instruction with the SP as base register, and base register updating.
c. This instruction is equivalent to an STMDB instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the LDM and STM instructions load and store User mode registers. Another system level variant of the LDM instruction performs an exception return.

F2.7.1 Loads to the PC

The LDM, LDMDA, LDMDB, LDMIB, and POP instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
F2.8 Miscellaneous instructions

Table F2-14 on page F2-7273 summarizes the miscellaneous instructions in the T32 and A32 instruction sets.

</tr>
</tbody>
</table>

Note

Previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system, in this group. From the introduction of Armv8, this instruction executes as a NOP. Arm deprecates any use of the DBG instruction.

F2.8.1 The Yield instruction

In a Symmetric Multithreading (SMT) design, a thread can use the YIELD instruction to give a hint to the PE that it is running on. The YIELD hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.
The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a `NOP` if there is no implementation benefit.
F2.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-8968.
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see Breakpoint Instruction exceptions on page G2-9051.
- In an implementation that includes EL3 the SMC instruction generates a Secure Monitor Call exception. For more information, see Secure Monitor Call (SMC) exception on page G1-8969.
- In an implementation that includes EL2 the HVC instruction generates a Hypervisor Call exception. For more information, see Hypervisor Call (HVC) exception on page G1-8970.

Debug state on page F2-7276 summarizes the Debug state instructions.

For an exception taken to an EL1 mode:

- The system level variants of the SUBS and LDM instructions can perform a return from an exception.

  Note
  The variants of SUBS include MOV. See the references to Subtract (exception return) on page F2-7275, Move (exception return) on page F2-7275, and Load Multiple (exception return) on page F2-7275 in Table F2-15 on page F2-7275 for more information.

- The SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see Exception return to an Exception level using AArch32 on page G1-8951.

Table F2-15 on page F2-7275 summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

<table>

</tbody>
</table>

Table F2-16 T32 Debug state instructions
F2.10 System register access instructions

The System register encoding space is indexed using the parameters {coproc, opc1, CRn, CRm, opc2}, see The AArch32 System register interface on page G1-8993. This encoding space provides System registers and System instructions. The only permitted values of coproc are 0b1110 and 0b1111, and the following instructions give access to this encoding space:

- Instructions that transfer data between general-purpose registers and System registers. See:
  - MCR on page F5-7707.
  - MCRR on page F5-7709.
  - MRC on page F5-7730.
  - MRRC on page F5-7732.

- Instructions that load or store from memory to a System register. See:
  - LDC (immediate) on page F5-7596.
  - LDC (literal) on page F5-7598.
  - STC on page F5-7952.

Note

The System register encoding space with coproc==0b101x is redefined to provide some of the Advanced SIMD and floating-point functionality. That is, to:

- Initiate a floating-point data-processing operation, see Floating-point data-processing instructions on page F2-7292.
- Transfer data between general-purpose registers and the Advanced SIMD and floating-point registers, see Advanced SIMD and floating-point register transfer instructions on page F2-7280.
- Load or store data to the Advanced SIMD and floating-point registers, see Advanced SIMD and floating-point load/store instructions on page F2-7278.

System register access instructions are part of the instruction stream executed by the PE, and therefore any System register access instruction that cannot be executed by the implementation causes an Undefined Instruction exception. In the A-profile and the R-profile architectures, the instruction encodings in the System register access instruction encoding space are unallocated, and generate Undefined Instruction exceptions, except for:

- The instructions summarized in this section that access the coproc==0b111x encoding space.
- The instructions in the coproc==0b101x encoding space that are redefined to provide Advanced SIMD and floating-point functionality, as summarized in the Note in this section.
F2.11 Advanced SIMD and floating-point load/store instructions

Table F2-17 on page F2-7278 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see *Element and structure load/store instructions*.

### Table F2-17 SIMD and floating-point register file load/store instructions

F2.11.1 Element and structure load/store instructions

Table F2-18 on page F2-7278 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see *Figure F2-1 on page F2-7279* for an example of de-interleaving. Interleaving is the inverse process.

Figure F2-1 shows the de-interleaving of a VLD3.16 (multiple 3-element structures) instruction:

![De-interleaving diagram](image)

**Figure F2-1 De-interleaving an array of 3-element structures**

Figure F2-1 shows the VLD3.16 instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, VLD4 and VST4 instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.
F2.12 Advanced SIMD and floating-point register transfer instructions

Table F2-19 on page F2-7280 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details, see The SIMD and floating-point register file on page E1-7140.

F2.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F2-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

Figure F2-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with 1, 2, 8, or 16 operations performed in parallel instead of 4.

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F2-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F2-4 on page F2-7282 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.
Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the Arm standard floating-point arithmetic defined in Floating-point support on page A1-55.

The following sections summarize the Advanced SIMD data-processing instructions:

- Advanced SIMD parallel addition and subtraction.
- Bitwise Advanced SIMD data-processing instructions on page F2-7283.
- Advanced SIMD comparison instructions on page F2-7284.
- Advanced SIMD shift instructions on page F2-7285.
- Advanced SIMD multiply instructions on page F2-7286.
- Advanced SIMD dot product instructions on page F2-7287.
- Miscellaneous Advanced SIMD data-processing instructions on page F2-7289.
- Advanced SIMD BFloat16 instructions on page F2-7288.
- Advanced SIMD matrix multiply instructions on page F2-7288.
- The Cryptographic Extension in AArch32 state on page F2-7290.

</tbody>
</table>

Advanced SIMD multiply instructions can operate on vectors of:
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over \{0, 1\}. VMUL and VMULL are the only instructions that operate on polynomials. VMULL produces a 16-bit polynomial over \{0, 1\}.
- Single-precision (32-bit) or half-precision (16-bit) floating-point numbers.
They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Half-precision (16-bit) floating-point numbers.
- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

### F2.13.6 Advanced SIMD dot product instructions

**FEAT_DotProd** provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

**Vector form**

The dot product is calculated for each element of the first vector with the corresponding element of the second vector.

**Indexed form**

The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

---

**Note**

That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

Table F2-25 on page F2-7287 shows the Advanced SIMD dot product instructions.

<td>Mixed sign integer dot product by indexed quadruplet(^a)</td>
<td><em>VUSDOT (by element)</em> on page F6-8880</td>
</tr>
</tbody>
</table>

\(^a\) This instruction is only supported when FEAT_AA32I8MM is implemented.

---

### F2.13.7 Advanced SIMD complex number arithmetic instructions

**FEAT_FCMA** provides AArch32 Advanced SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide single-precision versions. If **FEAT_FP16** is implemented they also provide half-precision versions, otherwise the half-precision encodings are **UNDEFINED**.
Table F2-26 on page F2-7288 shows the FEAT_FCMA AArch32 Advanced SIMD instructions.

**Table F2-26 Advanced SIMD complex number arithmetic instructions**

<table>
<thead>

</tr>
<tr>
<td>VCMIL</td>
<td>Floating-point complex multiply accumulate (indexed form)</td>
<td>VCMILA (by element) on page F6-8297</td>
</tr>
</tbody>
</table>

A pair of VCMILA instructions can be used to perform a complex number multiplication. In Complex multiplication on page K12-11746, this is demonstrated for the similar AArch64 instruction FCMLA. The usage of VCMILA in this manner is identical.

### F2.13.8 Advanced SIMD BFloat16 instructions

When FEAT_AA32BF16 is implemented, BFloat16 instructions are available in AArch32 state.

Table F2-27 on page F2-7288 shows the Advanced SIMD BFloat16 instructions.

</tr>
</tbody>
</table>

### F2.13.9 Advanced SIMD matrix multiply instructions

When FEAT_AA32I8MM is implemented, these instructions are available in AArch32 state. They include integer and mixed sign dot product instructions.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. Within each segment:
- The first source vector matrix is organized in row-by-row order.
- The second source vector matrix elements are organized in a column-by-column order.
- The destination vector matrix is organized in row-by-row order.

One matrix multiplication is performed per segment.

Table F2-28 on page F2-7288 shows the Advanced SIMD matrix multiply instructions.

**Table F2-28 Matrix multiply Advanced SIMD instructions**

F2.13.11 The Cryptographic Extension in AArch32 state

The instructions provided by the optional Cryptographic Extension use the Advanced SIMD and floating-point register file. For more information about the functions they provide see:
- Announcing the Advanced Encryption Standard.
- The Galois/Counter Mode of Operation.
- Announcing the Secure Hash Standard.

Table F2-30 on page F2-7290 shows the AArch32 Cryptographic Extension instructions.

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

See *The Armv8 Cryptographic Extension on page A2-80* for information about the permitted implementation options for the Cryptographic Extension.
F2.14 Floating-point data-processing instructions

Table F2-31 on page F2-7292 summarizes the data-processing instructions in the floating-point instruction set. In this table, floating-point register means a register in the SIMD and floating-point register file. The BFloat16 floating-point instructions are provided by FEAT_AA32BF16.

For details of the floating-point arithmetic used by floating-point instructions, see Floating-point support on page A1-55.

The AArch32 Instruction Sets Overview
F2.14 Floating-point data-processing instructions
Chapter F3
T32 Instruction Set Encoding

This chapter describes the encoding of the T32 instruction set. It contains the following sections:

- *T32 instruction set encoding* on page F3-7296.
- *About the T32 Advanced SIMD and floating-point instructions and their encoding* on page F3-7371.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
F3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:
- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

The T32 instruction encoding is:

<table>
<thead>
<tr>
<th>15 13 12</th>
<th>11 10</th>
<th>0 15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td>op1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table F3-1 Main encoding table for the T32 instruction set

<table>
<thead>
<tr>
<th>Decode fields</th>
<th>Decode group or instruction page</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0 op1</td>
<td></td>
</tr>
<tr>
<td>!= 111</td>
<td>16-bit on page F3-7296</td>
</tr>
<tr>
<td>111 00</td>
<td>B- T2 variant</td>
</tr>
<tr>
<td>111 1= 00</td>
<td>32-bit on page F3-7307</td>
</tr>
</tbody>
</table>

F3.1.1 16-bit

This section describes the encoding of the 16-bit group. The encodings in this section are decoded from T32 instruction set encoding.

<table>
<thead>
<tr>
<th>15 10 9</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td></td>
</tr>
</tbody>
</table>

This decode also imposes the constraint:
- op0<5:3> != 111.

Load/store halfword (immediate offset)

This section describes the encoding of the Load/store halfword (immediate offset) instruction class. The encodings in this section are decoded from 16-bit on page F3-7296.

```
| 15 14 13 12| 11 10  6  5  3  2  0 |
| 1 0 0 0 | L | imm5 | Rn | Rt |
```

Load/store (SP-relative)

This section describes the encoding of the Load/store (SP-relative) instruction class. The encodings in this section are decoded from 16-bit on page F3-7296.

```
| 15 14 13 12| 11 10  8  7  0 |
| 1 0 0 1 | L | Rt | imm8 |
```

Add PC/SP (immediate)

This section describes the encoding of the Add PC/SP (immediate) instruction class. The encodings in this section are decoded from 16-bit on page F3-7296.
Load/store multiple

This section describes the encoding of the Load/store multiple instruction class. The encodings in this section are decoded from 16-bit on page F3-7296.

```
<table>
<thead>
<tr>
<th>15 14 13 12</th>
<th>11 10  8  7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 1 0</td>
<td>SP</td>
<td>Rd</td>
</tr>
<tr>

Exception generation

This section describes the encoding of the Exception generation instruction class. The encodings in this section are decoded from Conditional branch, and Supervisor Call.
This section describes the encoding of the 32-bit group. The encodings in this section are decoded from T32 instruction set encoding on page F3-7296.

This decode also imposes the constraint:

- $\text{op0<3:2>} \neq 00$.

F3.1 T32 instruction set encoding

F3.1.8 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, and floating-point on page F3-7313.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-7371

### F3.1.11 Advanced SIMD and System register load/store and 64-bit move

This section describes the encoding of the Advanced SIMD and System register load/store and 64-bit move group. The encodings in this section are decoded from *System register access, Advanced SIMD, and floating-point* on page F3-7313.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see *About the T32 Advanced SIMD and floating-point instructions and their encoding* on page F3-7371.
This section describes the encoding of the Advanced SIMD and floating-point 64-bit move instruction class. The encodings in this section are decoded from Advanced SIMD and System register load/store and 64-bit move on page F3-7323.

### Advanced SIMD and floating-point 64-bit move

This section describes the encoding of the Advanced SIMD and floating-point 64-bit move instruction class. The encodings in this section are decoded from Advanced SIMD and System register load/store and 64-bit move on page F3-7323.

### Floating-point move special register

This section describes the encoding of the Floating-point move special register instruction class. The encodings in this section are decoded from *Advanced SIMD and System register 32-bit move.*
Advanced SIMD 8/16/32-bit element move/duplicate

This section describes the encoding of the Advanced SIMD 8/16/32-bit element move/duplicate instruction class. The encodings in this section are decoded from "Advanced SIMD and System register 32-bit move on page F3-7327."

System register 32-bit move

This section describes the encoding of the System register 32-bit move instruction class. The encodings in this section are decoded from "Advanced SIMD and System register 32-bit move on page F3-7327."
F3.1.13 Floating-point data-processing

This section describes the encoding of the Floating-point data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, and floating-point on page F3-7313.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-7371.

Floating-point data-processing (two registers)

This section describes the encoding of the Floating-point data-processing (two registers) instruction class. The encodings in this section are decoded from Floating-point data-processing.

F3.1.15 Load/store dual, load/store exclusive, load-acquire/store-release, and table branch

This section describes the encoding of the Load/store dual, load/store exclusive, load-acquire/store-release, and table branch group. The encodings in this section are decoded from 32-bit on page F3-7307.

This decode also imposes the constraint:

• op0<1> == 1.

This section describes the encoding of the Move Wide (16-bit immediate) instruction class. The encodings in this section are decoded from Data-processing (plain binary immediate) on page F3-7348.

Saturate, Bitfield

This section describes the encoding of the Saturate, Bitfield instruction class. The encodings in this section are decoded from Data-processing (plain binary immediate) on page F3-7348.
This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from 32-bit on page F3-7307.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding on page F3-7371.

### F3.1.19 Load/store single

This section describes the encoding of the Load/store single group. The encodings in this section are decoded from 32-bit on page F3-7307.

<table>
<thead>
<tr>
<th>L</th>
<th>size</th>
<th>N</th>
<th>Rm</th>
<th>Instruction page</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
<td>11</td>
<td>!= 111</td>
<td>VLD4 (single 4-element structure to one lane)</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>11</td>
<td>1101</td>
<td>VLD4 (single 4-element structure to one lane)</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>11</td>
<td>1111</td>
<td>VLD4 (single 4-element structure to one lane)</td>
</tr>
</tbody>
</table>

This decode also imposes the constraint:

- \( \text{op0<1>:op1 } \neq 10 \).

F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All T32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit T32 instruction decode structure. Table F3-23 shows these instruction groups, and where each group is decoded from the overall T32 decode structure:

<table>

F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding
Chapter F4
A32 Instruction SetEncoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- *A32 instruction set encoding* on page F4-7374.
- *About the A32 Advanced SIMD and floating-point instructions and their encoding* on page F4-7440.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is either a single 32-bit word in that stream.

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the cond field. For more information see The Condition code field in A32 instruction encodings on page F1-7229. This applies to all instructions except those with the cond field equal to 0b111.

The behavior of an attempt to execute an unallocated instruction is described in UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space on page F1-7236.

For more information on A32 instruction encodings see Chapter F1 About the T32 and A32 Instruction Descriptions.

The A32 instruction encoding is:

The behavior of the CONSTRAINED UNPREDICTABLE encodings in this table is described in CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-11574.

### Integer Saturating Arithmetic

This section describes the encoding of the Integer Saturating Arithmetic instruction class. The encodings in this section are decoded from Miscellaneous on page F4-7380.
F4.1.5 Data-processing register (immediate shift)

This section describes the encoding of the Data-processing register (immediate shift) group. The encodings in this section are decoded from Data-processing and miscellaneous instructions on page F4-7374.

```
|31|28|27|26|25|24|23|22|21|20|19|16|15|12|11|10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|≠1111|0|0|0|1|0|opc|0|Rn|Rd|0|0|0|0|0|0|1|0|1|Rm|
```

This decode also imposes the constraint:

- $\text{op0:op1 } \neq 100$.

### Table F4-6 Encoding table for the Data-processing register (immediate shift) group

Integer Test and Compare (two register, register shift)

This section describes the encoding of the Integer Test and Compare (two register, register shift) instruction class. The encodings in this section are decoded from Data-processing register (register shift).
Logical Arithmetic (three register, register shift)

This section describes the encoding of the Logical Arithmetic (three register, register shift) instruction class. The encodings in this section are decoded from *Data-processing register (register shift)* on page F4-7386.

![Instruction Set Encoding Diagram]

F4.1.7  Data-processing immediate

This section describes the encoding of the Data-processing immediate group. The encodings in this section are decoded from *Data-processing and miscellaneous instructions* on page F4-7374.

F4.1.15 Advanced SIMD and System register load/store and 64-bit move

This section describes the encoding of the Advanced SIMD and System register load/store and 64-bit move group. The encodings in this section are decoded from System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-7402.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-7440.

System register load/store

This section describes the encoding of the System register load/store instruction class. The encodings in this section are decoded from *Advanced SIMD and System register load/store and 64-bit move on page F4-7410*.

The encoding for the System register load/store instruction class is:

| !|= 000 | 0 | - | - | !|= 010 | 0 | Unallocated. |
| !|= 000 | 0 | 1 | 1111 | 010 | 0 | LDC (literal) |
| !|= 000 | - | - | - | - | 1 | Unallocated. |
| !|= 000 | 1 | - | - | 010 | 0 | Unallocated. |
| 0x1 | 0 | 0 | - | 010 | 0 | STC - Post-indexed variant |
| 0x1 | 0 | 1 | !|= 1111 | 010 | 0 | LDC (immediate) - Post-indexed variant |
| 010 | 0 | 0 | - | 010 | 0 | STC - Unindexed variant |
| 010 | 0 | 1 | !|= 1111 | 010 | 0 | LDC (immediate) - Unindexed variant |
| 1x0 | 0 | 0 | - | 010 | 0 | STC - Offset variant |
| 1x0 | 0 | 1 | !|= 1111 | 010 | 0 | LDC (immediate) - Offset variant |
| 1x1 | 0 | 0 | - | 010 | 0 | STC - Pre-indexed variant |
| 1x1 | 0 | 1 | !|= 1111 | 010 | 0 | LDC (immediate) - Pre-indexed variant |

F4.1.16 Advanced SIMD and System register 32-bit move

This section describes the encoding of the Advanced SIMD and System register 32-bit move group. The encodings in this section are decoded from *System register access, Advanced SIMD, floating-point, and Supervisor call on page F4-7402*.

The encoding for the Advanced SIMD and System register 32-bit move group is:

| !|= 000 | 0 | - | - | !|= 010 | 0 | Unallocated. |
| !|= 000 | 0 | 1 | 1111 | 010 | 0 | LDC (literal) |
| !|= 000 | - | - | - | - | 1 | Unallocated. |
| !|= 000 | 1 | - | - | 010 | 0 | Unallocated. |

The behavior of the CONSTRAINED UNPREDICTABLE encodings in this table is described in CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-11574.

Change Process State

This section describes the encoding of the Change Process State instruction class. The encodings in this section are decoded from Miscellaneous.
F4.1.20 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from Unconditional instructions on page F4-7420.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-7440.

F4-7422

Advanced SIMD three registers of the same length

This section describes the encoding of the Advanced SIMD three registers of the same length instruction class. The encodings in this section are decoded from Advanced SIMD data-processing.

F4.1.24 Advanced SIMD element or structure load/store

This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from Unconditional instructions on page F4-7420.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the A32 Advanced SIMD and floating-point instructions and their encoding on page F4-7440.

F4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All A32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit A32 instruction decode structure. Table F4-24 shows these instruction groups, and where each group is decoded from the overall A32 decode structure:

Chapter F5
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-7442.
- *Encoding and use of banked register transfer instructions* on page F5-8160.
F5.1  Alphabetic list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see Format of instruction descriptions on page F1-7224.

This section is formatted so that each instruction description starts on a new page.
F5.1.1 ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Decode for all variants of this encoding

```plaintext
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- `<c>`: See *Standard assembler syntax fields on page F1-7228.*
- `<q>`: See *Standard assembler syntax fields on page F1-7228.*
- `<Rd>`: For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.*
  - For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
- `<Rn>`: For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
- `<const>`: For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions on page F1-7244* for the range of values.

Operation for all encodings

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  (result, nzcv) = AddWithCarry(R[n], imm32, PSTATE.C);
  if d == 15 then          // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.<N,Z,C,V> = nzcv;
```
Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.2 ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Decode for this encoding

d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);

T2

ADC, rotate right with extend variant

Applies when \( S == 0 \) \&\& \( \text{imm3} == 000 \) \&\& \( \text{imm2} == 00 \) \&\& \( \text{stype} == 11 \).

ADC<{c}>{q}> {<Rd>,} <Rn>, <Rm>, RRX

ADC, shift or rotate by value variant

Applies when \( S == 0 \) \&\& \( !(\text{imm3} == 000 \) \&\& \( \text{imm2} == 00 \) \&\& \( \text{stype} == 11 \).

ADC.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADCS<{c}>{q}> {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

ADCS, rotate right with extend variant

Applies when \( S == 1 \) \&\& \( \text{imm3} == 000 \) \&\& \( \text{imm2} == 00 \) \&\& \( \text{stype} == 11 \).

ADCS<{c}>{q}> {<Rd>,} <Rn>, <Rm>, RRX

ADCS, shift or rotate by value variant

Applies when \( S == 1 \) \&\& \( !(\text{imm3} == 000 \) \&\& \( \text{imm2} == 00 \) \&\& \( \text{stype} == 11 \).

ADCS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADCS<{c}>{q}> {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR.<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.

- Inside an IT block, if ADC<< <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<< <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
  if d == 15 then          // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
else
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

Flag setting variant

Applies when \( S = 1 \).

\[
\text{ADCS}\{<c>\}{<q>} \{<Rd>,} <Rn>, <Rm>, <\text{shift}> <Rs>
\]

Not flag setting variant

Applies when \( S = 0 \).

\[
\text{ADC}\{<c>\}{<q>} \{<Rd>,} <Rn>, <Rm>, <\text{shift}> <Rs>
\]

Decode for all variants of this encoding

\[
d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ m = \text{UInt}(Rm); \ s = \text{UInt}(Rs);
\setflags = (S == '1'); \ \text{shift}_t = \text{DecodeRegShift}(\text{stype});
\text{if} \ d == 15 || n == 15 || m == 15 || s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings

For more information about the CONstrained UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\)

See Standard assembler syntax fields on page F1-7228.

\(<q>\)

See Standard assembler syntax fields on page F1-7228.

\(<Rd>\)

Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\)

Is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\)

Is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\)

Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>when stype = 00</td>
</tr>
<tr>
<td>LSR</td>
<td>when stype = 01</td>
</tr>
<tr>
<td>ASR</td>
<td>when stype = 10</td>
</tr>
<tr>
<td>ROR</td>
<td>when stype = 11</td>
</tr>
</tbody>
</table>

\(<Rs>\)

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.4 ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Assembler symbols

<\>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rdn>
Is the general-purpose source and destination register, encoded in the "Rdn" field.

<imm8>
Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field.
If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate). If the PC is used, see ADR.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate).

<imm3>
Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<imm12>
Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const>
For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.
For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the ADDW syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.
Operation for all encodings

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
      if setflags then
        ALUExceptionReturn(result);
      else
        ALUWritePC(result);
    else
      R[d] = result;
      if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
  else
    if ConditionPassed() then
      EncodingSpecificOperations();
      (result, nzcv) = AddWithCarry(R[n], imm32, '0');
      R[d] = result;
      if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.5  ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

• The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

• The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  — The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

// Armv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

<
See Standard assembler syntax fields on page F1-7228.

<
See Standard assembler syntax fields on page F1-7228.

<Rdn>
Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rd> and <Rm> are in the range R0 to R7, <Rdn> must be specified so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and:

- If omitted, this register is the same as <Rn>.
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see ADD, ADDS (SP plus register).
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.
For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus register).

<\text{Rm}> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.
For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

<\text{shift}> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when \text{stype} = 00
- LSR when \text{stype} = 01
- ASR when \text{stype} = 10
- ROR when \text{stype} = 11

<\text{amount}> For encoding A1: is the shift amount, in the range 1 to 31 (when <\text{shift}> = LSL or ROR) or 1 to 32 (when <\text{shift}> = LSR or ASR) encoded in the "imm5" field as <\text{amount}> modulo 32.
For encoding T3: is the shift amount, in the range 1 to 31 (when <\text{shift}> = LSL or ROR) or 1 to 32 (when <\text{shift}> = LSR or ASR), encoded in the "imm3:imm2" field as <\text{amount}> modulo 32.

Inside an IT block, if \text{ADD(c)} <\text{Rd}, <\text{Rn}, <\text{Rd}> cannot be assembled using encoding T1, it is assembled using encoding T2 as though \text{ADD(c)} <\text{Rd}, <\text{Rn}> had been written. To prevent this happening, use the .W qualifier.

**Operation for all encodings**

if ConditionPassed() then
   EncodingSpecificOperations();
   shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
   (result, nzcv) = AddWithCarry(R[n], shifted, '0');
   if d == 15 then
      if setflags then
         ALUExceptionReturn(result);
      else
         ALUWritePC(result);
      end
   else
      R[d] = result;
      if setflags then
         PSTATE.<N,Z,C,V> = nzcv;
   end

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.6   ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the
destination register, and can optionally update the condition flags based on the result.

A1

```
|31| 28|27|26|25|24|23|22|21|20|19|16|15| 12| 11|  8|  7|  6|  5|  4|  3|  0|
|1=111| 0| 0| 0| 0| 1| 0| 0| 1| 0| 0| 0| 0| 0| 0| 0| S| Rn| Rd| Rs| 0| stype| 1| Rm|
```

Flag setting variant

Applies when $S == 1$.

ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

Not flag setting variant

Applies when $S == 0$.

ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural
Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- `<c>`   See Standard assembler syntax fields on page F1-7228.
- `<q>`   See Standard assembler syntax fields on page F1-7228.
- `<Rd>`  Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>`  Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`  Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can
  have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>`  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the
  "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.7 ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

SP, is the stack pointer.

<imm7> Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm8> Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   (result, nzcv) = AddWithCarry(R[13], imm32, '0');
   if d == 15 then // Can only occur for A32 encoding
      if setflags then
         ALUExceptionReturn(result);
      else
         ALUWritePC(result);
   else
      R[d] = result;
      if setflags then
         PSTATE.<N,Z,C,V> = nzcv;
}
F5.1.8   ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<current\_mode>\).
  - The PE checks SPSR_\(<current\_mode>\) for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Applies when \(S = 1\) \&\& \(\text{imm}3 = 000\) \&\& \(\text{Rd} = 1111\) \&\& \(\text{imm}2 = 00 \&\& \text{stype} = 11\).

ADDS\{<c>\}{<q>} {<Rd>}, SP, <Rm>, RRX
**ADDS, shift or rotate by value variant**

Applies when $S = 1$ && $(\text{imm3} == 000$ && $\text{imm2} == 00$ && $\text{stype} == 11)$ && $Rd != 1111$.

`ADDS{<c>}{<q>} {<Rd>,} SP, <Rm> {, <shift> #<amount>}`

**Decode for all variants of this encoding**

$$
\begin{align*}
\text{if } Rd == '1111' \&\& S == '1' \text{ then SEE "CMN (register)";} \\
d = \text{UInt}(Rd); \ m = \text{UInt}(Rm); \ setflags = (S == '1'); \\
(\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{stype}, \text{imm3:imm2}); \\
\text{if } (d == 15 \&\& \neg setflags) \text{ || } m == 15 \text{ then UNPREDICTABLE; } // \text{Armv8-A removes UNPREDICTABLE for R13}
\end{align*}
$$

**Notes for all encodings**

For more information about the CONstrained UNPREDICTable behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>`: See Standard assembler syntax fields on page F1-7228.
- `<q>`: See Standard assembler syntax fields on page F1-7228.
- `SP`: Is the stack pointer.
- `<Rdm>`: Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- `<Rd>`: For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
  - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

- `<Rm>`: For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.

- `<shift>`: Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL: when stype = 00
  - LSR: when stype = 01
  - ASR: when stype = 10
  - ROR: when stype = 11

- `<amount>`: For encoding A1: is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR) encoded in the "imm5" field as `<amount>` modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR), encoded in the "imm3:imm2" field as `<amount>` modulo 32.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[13], shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
F5.1.9  ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result

to the destination register. Arm recommends that, where possible, software avoids using this alias

This instruction is a pseudo-instruction of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ADR gives the operational pseudocode for this instruction.

A1

\[
\begin{array}{ccccccccccccccc}
\end{array}
\]

A1 variant

ADD\{<c>\}{<q>} <Rd>, PC, #<const>

is equivalent to

ADR\{<c>\}{<q>} <Rd>, <label>

and is never the preferred disassembly.

\]

T3 variant

ADD\{<c>\}{<q>} <Rd>, PC, #<imm12> // <Rd>, <imm12> can be represented in T1

is equivalent to

ADR\{<c>\}{<q>} <Rd>, <label>

and is never the preferred disassembly.
ADD{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

**Assembler symbols**

- **<c>**  
  See [Standard assembler syntax fields on page F1-7228](#).

- **<q>**  
  See [Standard assembler syntax fields on page F1-7228](#).

- **<Rd>**  
  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133](#).

  For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- **<label>**  
  For encoding A1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

  If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.

  If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

  Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions on page F1-7244](#).

  For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

  For encoding T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

  If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

  If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

  Permitted values of the size of the offset are 0-4095.

- **<imm8>**  
  Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

- **<imm12>**  
  Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

- **<const>**  
  An immediate value. See [Modified immediate constants in A32 instructions on page F1-7244](#) for the range of values.

**Operation for all encodings**

The description of ADR gives the operational pseudocode for this instruction.
F5.1.10   ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the pseudo-instructions ADD (immediate, to PC) and SUB (immediate, from PC). The pseudo-instruction is never the preferred disassembly.

</tbody>
</table>

### Assembler symbols

- `<c>` See *Standard assembler syntax fields* on page F1-7228.
- `<q>` See *Standard assembler syntax fields* on page F1-7228.
- `<Rd>` For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.
For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into \(<Rd>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.

If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in Modified immediate constants in A32 instructions on page F1-7244.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into \(<Rd>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into \(<Rd>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```
F5.1.11   **AND, ANDS (immediate)**

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(_{<current\_mode>}\).
  - The PE checks SPSR_\(_{<current\_mode>}\) for an illegal return event. See *Illegal return events from AArch32 state* on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

PSTATE.C = carry;
// PSTATE.V unchanged

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.12   AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.*
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state on page G1-8952.*
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Decode for this encoding

d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);

T2

AND, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && stype == 11.

AND{<c>}{<q>}{<Rd>,} <Rn>, <Rm>, RRX

AND, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11).

AND{<c>}{<q>}{<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

ANDS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11.

ANDS{<c>}{<q>}{<Rd>,} <Rn>, <Rm>, RRX

ANDS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11) && Rd != 1111.

ANDS.W{<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ANDS{<c>}{<q>}{<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

if Rd == '1111' && S == '1' then SEE "TST (register)";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.

- Inside an IT block, if AND<< <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<< <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    if d == 15 then  // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
```c
else
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.13 AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8  | 7  | 6  | 5  | 4  | 3  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| S  | Rn | Rd | Rs | 0  | 0  | 0  | 0  | 1111 |

Flag setting variant

Applies when \( S = 1 \).

\[
\text{ANDS\{<c>\}{<q>} {<Rd>,} <Rn>, <Rm>, <\text{shift}> <Rs>}
\]

Not flag setting variant

Applies when \( S = 0 \).

\[
\text{AND\{<c>\}{<q>} {<Rd>,} <Rn>, <Rm>, <\text{shift}> <Rs>}
\]

Decode for all variants of this encoding

\[
\begin{align*}
d &= \text{UInt}(Rd); \\
n &= \text{UInt}(Rn); \\
m &= \text{UInt}(Rm); \\
s &= \text{UInt}(Rs);
\end{align*}
\]

\[
\text{setflags} = (S == '1'); \\
\text{shift_t} = \text{DecodeRegShift(stype)};
\]

\[
\text{if } d == 15 \text{ || } n == 15 \text{ || } m == 15 \text{ || } s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\)  See Standard assembler syntax fields on page F1-7228.

\(<q>\)  See Standard assembler syntax fields on page F1-7228.

\(<Rd>\)  Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\)  Is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\)  Is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\)  Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

\[
\begin{align*}
\text{LSL} & \quad \text{when stype} = 00 \\
\text{LSR} & \quad \text{when stype} = 01 \\
\text{ASR} & \quad \text{when stype} = 10 \\
\text{ROR} & \quad \text{when stype} = 11
\end{align*}
\]

\(<Rs>\)  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        /* PSTATE.V unchanged */

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.14   ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1

\[
\begin{array}{cccccccccccc}

\text{S} & Rd & imm3 & imm2 & 1 & 0 & Rm & \hline
\end{array}
\]

**MOV, shift or rotate by value variant**

\[
\text{ASR}\{}<c>\text{\{}W\text{\{}<Rd>,} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2}
\]

is equivalent to

\[
\text{MOV}\{}<c>\text{\{}<p>\text{\{}<Rd>,} <Rm>, ASR #<imm>}
\]

and is always the preferred disassembly.

\[
\text{ASR}\{}<c>\text{\{}<p>\text{\{}<Rd>,} <Rm>, #<imm>}
\]
is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

**Assembler symbols**

**<c>** See *Standard assembler syntax fields* on page F1-7228.

**<q>** See *Standard assembler syntax fields* on page F1-7228.

**<Rd>** For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

**<Rm>** For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

**<imm>** For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
F5.1.15 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

**A1**

Not flag setting variant

ASR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

**T1**

Arithmetic shift right variant

ASR{<c>}{<q>} {<Rdm>,} <Rdm>, <Rs> // Inside IT block

is equivalent to

MOV{<c>}{<q>} <Rdm>, <Rdm>, ASR <Rs>

and is the preferred disassembly when InITBlock().

**T2**

Not flag setting variant

ASR{<c>}{<W>} {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
and is always the preferred disassembly.

\[ \text{ASR} \{<c>\} \{<q>\} \{<Rd>,\} \{<Rm>,\} \{<Rs>\} \]

is equivalent to

\[ \text{MOV} \{<c>\} \{<q>\} \{<Rd>,\} \{<Rm>,\} \{\text{ASR} <Rs>\} \]

and is always the preferred disassembly.

**Assembler symbols**

\(<c>\) See [Standard assembler syntax fields on page F1-7228](#).

\(<q>\) See [Standard assembler syntax fields on page F1-7228](#).

\(<Rdm>\) Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.

\(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rm>\) Is the first general-purpose source register, encoded in the "Rm" field.

\(<Rs>\) Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.16 ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Related encodings: Branches and miscellaneous control on page F3-7343.

**Assembler symbols**

**<c>**

For encoding A1, T2 and T4: see Standard assembler syntax fields on page F1-7228.
For encoding T1: see Standard assembler syntax fields on page F1-7228. Must not be AL or omitted.
For encoding T3: see Standard assembler syntax fields on page F1-7228. <c> must not be AL or omitted.

**<q>**

See Standard assembler syntax fields on page F1-7228.

**<label>**

For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the 8 instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the 8 instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the \texttt{B} instruction to this label, then selects an encoding that sets \texttt{imm32} to that offset. Permitted offsets are even numbers in the range –2048 to 2046.

For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the \texttt{B} instruction to this label, then selects an encoding that sets \texttt{imm32} to that offset. Permitted offsets are even numbers in the range –1048576 to 1048574.

For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the \texttt{B} instruction to this label, then selects an encoding that sets \texttt{imm32} to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.

\textbf{Operation for all encodings}

\begin{verbatim}
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32, BranchType_DIR);
\end{verbatim}
F5.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

A1

\[
\begin{array}{cccccccccccc}
| & | & | & | & | & | & | & | & | & | & | \\
|31|28|27|26|25|24|23|22|21|20|15|12|11|10|9|8|7|6|5|4|3|2|1|0| \\

\end{array}
\]

**T1 variant**

\[
BFC\{c\}\{q\} <Rd>, #<lsb>, #<width>
\]

**Decode for this encoding**

\[
d = UInt(Rd); \ms = UInt(msb); \ls = UInt(imm3:imm2);
if \(d = 15\) then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
if \(\ms < \ls\) then UNPREDICTABLE;
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \(\ms < \ls\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \texttt{NOP}.
- The value in the destination register is UNKNOWN.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

Rd
Is the general-purpose destination register, encoded in the "Rd" field.

<lsb>
For encoding A1: is the least significant bit to be cleared, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width>
Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+(<width>-1).

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  R[d]<msb:lsbit> = Replicate('0', (msb-<lsbit>);+1);
  // Other bits of R[d] are unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.20   BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

A1

| [31 28|27 26 25 24|23 22 21 20] | 16|15 | 12|11 | 7 6 5 4 | 3 | 0 |

CONSTRAINED UNPREDICTABLE behavior

If msbit < lsb, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

<
See Standard assembler syntax fields on page F1-7228.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rn>
Is the general-purpose source register, encoded in the "Rn" field.

<lsb>
For encoding A1: is the least significant destination bit, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the least significant destination bit, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width>
Is the number of bits to be copied, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<msbit:lsbit> = R[n]<msbit-1:0>;
    // Other bits of R[d] are unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.21   BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.*
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state on page G1-8952.*
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Assembler symbols

<c>  
See *Standard assembler syntax fields* on page F1-7228.

<q>  
See *Standard assembler syntax fields* on page F1-7228.

<Rdn>  
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>  
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.
- For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>  
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>  
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>  
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL  when stype = 00
- LSR  when stype = 01
- ASR  when stype = 10
- ROR  when stype = 11

<amount>  
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then  // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
        // PSTATE.V unchanged
```
Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.23 **BIC, BICS (register-shifted register)**

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**A1**

```
| 31 28|27 26 25 24|23 22 21 20|19 16|15 12|11  8 | 7 6 5 4 | 3 | 0 |

|   !=1111| 0 0 0 1 | 1 1 |   S | Rn | Rd | Rs | 0 | stype | 1 | Rm |
```

Flag setting variant

Applies when $S = 1$.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when $S = 0$.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

**Decode for all variants of this encoding**

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
  - LSL when stype = 00
  - LSR when stype = 01
  - ASR when stype = 10
  - ROR when stype = 11
- `<Rs>` Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.24   BKPT

Breakpoint causes a Breakpoint Instruction exception.

Breakpoint is always unconditional, even when inside an IT block.

A1

\[
\begin{array}{cccccccccc}
31 & 28 & 27 & 26 & 25 & 24 & 23 & 22 & 21 & 20 & 19 & | & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\

\text{cond} & & & & & & & & & & \end{array}
\]

A1 variant

\[
\text{BKPT}\{<q>\} \{#\}<\text{imm}>
\]

Decode for this encoding

\[
\text{imm16} = \text{imm12:imm4}; \\
\text{if cond} \neq \text{"1110" then UNPREDICTABLE; } // \text{BKPT must be encoded with AL condition}
\]

CONSTRAINED UNPREDICTABLE behavior

If cond \neq \text{"1110"}, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes unconditionally.
• The instruction executes conditionally.

T1

\[
\begin{array}{cccccccccc}
15 & 14 & 13 & 12 & 11 & 10 & 9 & 8 & 7 & | & 0 \\
1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & | \text{imm8} \\
\end{array}
\]

T1 variant

\[
\text{BKPT}\{<q>\} \{#\}<\text{imm}>
\]

Decode for this encoding

\[
\text{imm16} = \text{ZeroExtend(imm8, 16)};
\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\[
<q> \quad \text{See Standard assembler syntax fields on page F1-7228. A BKPT instruction must be unconditional.}
\]
&lt;imm&gt; For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm12:imm4” field. This value:
  • Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
  • Is ignored otherwise.
For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:
  • Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
  • Is ignored otherwise.

**Operation for all encodings**

EncodingSpecificOperations();
AArch32.SoftwareBreakpoint(imm16);
F5.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

For encoding A2: see Standard assembler syntax fields on page F1-7228. <c> must be A1 or omitted.

<q>
See Standard assembler syntax fields on page F1-7228.

<label>
For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –33554432 to 33554430.
For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

**Operation for all encodings**

if ConditionPassed() then

<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**T1 variant**

CLZ{<c>}{<q>} <Rd>, <Rm>

**Decode for this encoding**

\[
d = \text{UInt}(\text{Rd}); \quad m = \text{UInt}(\text{Rm}); \quad n = \text{UInt}(\text{Rn});
\]

\[
\text{if } m != n || d == 15 || m == 15 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( m != n \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: \( m = \text{UInt}(\text{Rn}); \).
- The value in the destination register is UNKNOWN.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F1-7228.
- `<q>` See *Standard assembler syntax fields* on page F1-7228.
<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.32  CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

**Notes for all encodings**

For more information about the CONstrained UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

<\> See Standard assembler syntax fields on page F1-7228.

<\> See Standard assembler syntax fields on page F1-7228.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<\> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<\> For encoding A1: is the shift amount, in the range 1 to 31 (when <\> = LSL or ROR) or 1 to 32 (when <\> = LSR or ASR) encoded in the "imm5" field as <\> modulo 32.
For encoding T2: is the shift amount, in the range 1 to 31 (when <\> = LSL or ROR) or 1 to 32 (when <\> = LSR or ASR), encoded in the "imm3:imm2" field as <\> modulo 32.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, '0');
  PSTATE.<N,Z,C,V> = nzcv;
Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.34 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

### Notes for all encodings

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Appendix K1](#) *Architectural Constraints on UNPREDICTABLE Behaviors*.

### Assembler symbols

- **<c>** See *Standard assembler syntax fields on page F1-7228*.
- **<q>** See *Standard assembler syntax fields on page F1-7228*.
- **<Rn>** For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
  For encoding T1 and T3: is the first general-purpose source register, encoded in the "Rn" field.
  For encoding T2: is the first general-purpose source register, encoded in the "N:Rn" field.
<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1, T2 and T3: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcv;

Operational information
If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.37  CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

\(<Rm>\) Is the second general-purpose source register, encoded in the "Rm" field.
\(<\text{type}>\) Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11
\(<Rs>\) Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
  PSTATE.<N,Z,C,V> = nzcv;
Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.38  CPS, CPSID, CPSIE

Change PE State changes one or more of the PSTATE.{A, I, F} interrupt mask bits and, optionally, the PSTATE.M mode field, without changing any other PSTATE bits.

CPS is treated as NOP if executed in User mode unless it is defined as being CONSTRAINED UNPREDICTABLE elsewhere in this section.

The PE checks whether the value being written to PSTATE.M is legal. See Illegal changes to PSTATE.M on page G1-8925.

affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if InITBlock() then UNPREDICTABLE;
\end{verbatim}
**CONSTRANGED UNPREDICTABLE behavior**

If $A:I:F == '000'$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.

**T2**

```
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 0 | (1)(1)(1)| 1 | 0 | (0) | 0 | (0) | imod | M | A | I | F | mode |
```

**Change mode variant**

Applies when $imod == 00$ && $M == 1$.

`CPS{<q>} #<mode>` // Not permitted in IT block

**Interrupt disable variant**

Applies when $imod == 11$ && $M == 0$.

`CPSID.W <iflags>` // Not permitted in IT block

**Interrupt disable and change mode variant**

Applies when $imod == 11$ && $M == 1$.

`CPSID{<q>} <iflags>, #<mode>` // Not permitted in IT block

**Interrupt enable variant**

Applies when $imod == 10$ && $M == 0$.

`CPSIE.W <iflags>` // Not permitted in IT block

**Interrupt enable and change mode variant**

Applies when $imod == 10$ && $M == 1$.

`CPSIE{<q>} <iflags>, #<mode>` // Not permitted in IT block

**Decode for all variants of this encoding**

if $imod == '00'$ && $M == '0'$ then SEE "Hint instructions";
if mode != '00000' && $M == '0'$ then UNPREDICTABLE;
if (imod<1> == '1' && $A:I:F == '000') || (imod<1> == '0' && $A:I:F != '000') then UNPREDICTABLE;
if imod == '01' || InITBlock() then UNPREDICTABLE;

**CONSTRANGED UNPREDICTABLE behavior**

If $imod == '01'$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.

If mode != '00000' && $M == '0'$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
• The instruction executes as NOP.
• The instruction executes with the additional decode: changemode = TRUE.
• The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If imod<1> == '1' && A:I:F == '000', then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction behaves as if imod<1> == '0'.
• The instruction behaves as if A:I:F has an UNKNOWN nonzero value.

If imod<1> == '0' && A:I:F != '000', then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction behaves as if imod<1> == '1'.
• The instruction behaves as if A:I:F == '000'.

Notes for all encodings

Hint instructions: In encoding T2, if the imod field is 00 and the M bit is 0, a hint instruction is encoded. To determine which hint instruction, see Branches and miscellaneous control on page F3-7343.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<q> See Standard assembler syntax fields on page F1-7228.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:
    a Sets the A bit in the instruction, causing the specified effect on PSTATE.A, the SError interrupt mask bit.
    i Sets the I bit in the instruction, causing the specified effect on PSTATE.I, the IRQ interrupt mask bit.
    f Sets the F bit in the instruction, causing the specified effect on PSTATE.F, the FIQ interrupt mask bit.

<mode> Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.

Operation for all encodings

if CurrentInstrSet() == InstrSet_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then

      // AArch32.WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
      AArch32.WriteModeByInstr(mode);
F5.1.39   CRC32

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes
an input CRC value in the first source operand, performs a CRC on the input value in the second source operand,
and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage,
the bit order of the values is reversed as part of the operation, and the polynomial \(0x04C11DB7\) is used for the CRC
calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all
implementations to implement this instruction.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.41 CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions and instructions that write to the PC appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.\{N,Z,C,V\} predictions of any instructions other than conditional branch instructions and conditional instructions that write to the PC appearing in program order before the CSDB that have not been architecturally resolved.

Note

For purposes of the definition of CSDB, PSTATE.\{N,Z,C,V\} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.\{N,Z,C,V\} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

A1

```
cond  !='1110' then UNPREDICTABLE;      // CSDB must be encoded with AL condition
```

F5.1.43  DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from EL0 or to a specific mode at the current Exception level.

DCPS1 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is implemented, EL2 is implemented and enabled in the current Security state, and any of:
  - EL2 is using AArch32 and HCR.TGE is set to 1.
  - EL2 is using AArch64 and HCR_EL2.TGE is set to 1.

When the PE executes DCPS1 at EL0, EL1 or EL3:

- If EL3 or EL1 is using AArch32, the PE enters SVC mode and LR_svc, SPSR_svc, DLR, and DSPSR become UNKNOWN. If DCPS1 is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL1 is using AArch64, the PE enters EL1 using AArch64, selects SP_EL1, and ELR_EL1, ESR_EL1, SPSR_EL1, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

When the PE executes DCPS1 at EL2 the PE does not change mode, and ELR_hyp, HSR, SPSR_hyp, DLR and DSPSR become UNKNOWN.

For more information on the operation of the DCPS<n> instructions, see DCPS<n> on page H2-10262.

then
    SynchronizeErrors();

UpdateEDSCRFields(); // Update EDSCR PE state flags
F5.1.45   DCPS3

Debug Change PE State to EL3 allows the debugger to move the PE into EL3 from a lower Exception level or to a specific mode at the current Exception level.

DCPS3 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL3 is not implemented.
- EDSCR.SDD is set to 1.

When the PE executes DCPS3:

- If EL3 is using AArch32, the PE enters Monitor mode and LR_mon, SPSR_mon, DLR and DSPSR become UNKNOWN. If DCPS3 is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL3 is using AArch64, the PE enters EL3 using AArch64, selects SP_EL3, and ELR_EL3, ESR_EL3, SPSR_EL3, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

For more information on the operation of the DCPS<n> instructions, see DCPS<n> on page H2-10262.

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F1-7228. Must be AL or omitted.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<option> Specifies an optional limitation on the barrier operation. Values are:

SY Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.

ST Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.

LD Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.
ISH  Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.

ISHST  Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.

ISHLD  Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.

NSH  Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.

NSHST  Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = 0b0110.

NSHLD  Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.

OSH  Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.

OSHST  Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.

OSHLD  Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page E2-7182. All other encodings of option are reserved. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

--- Note ---

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

**Notes for all encodings**

For more information about the *CONSTRAINED UNPREDICTABLE* behavior, see *Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

- `<c>`  For encoding A1: see *Standard assembler syntax fields on page F1-7228*. Must be AL or omitted.
  
  For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

- `<q>`  See *Standard assembler syntax fields on page F1-7228*.

- `<option>`  Specifies an optional limitation on the barrier operation. Values are:
  
  SY  Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.

  ST  Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.
LD  Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.

ISH  Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.

ISHST  Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.

ISHLD  Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.

NSH  Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.

NSHST  Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0110.

NSHLD  Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.

OSH  Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.

OSHST  Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.

OSHLD  Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see Data Synchronization Barrier (DSB) on page E2-7182. All other encodings of option are reserved, other than the values 0b0000 and 0b0100. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

--- Note ---

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- S as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

---

domain = MBReqDomain_FullSystem;
    if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
domain = MBReqDomain_OuterShareable;
    if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
domain = MBReqDomain_InnerShareable;

DataSynchronizationBarrier(domain, types, nXS);
F5.1.48 EOR, EORS (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\[
\text{PSTATE.Z = IsZeroBit(result);}\]
PSTATE.C = carry;
// PSTATE.V unchanged

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.49  **EOR, EORS (register)**

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

// Armv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:
- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:
- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.
To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
EncodingSpecificOperations();
(shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
result = R[n] EOR shifted;
if d == 15 then // Can only occur for A32 encoding
if setflags then
  ALUExceptionReturn(result);
else
  ALUWritePC(result);
else
  R[d] = result;
  if setflags then
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.50   EOR, EORS (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a
register-shifted register value. It writes the result to the destination register, and can optionally update the condition
flags based on the result.

A1

\[
\begin{array}{cccccccc}
| & | & | & | & | & | & | & | \\
\text{cond} & ! & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & S & Rn & Rd & Rs & 0 & stype & 1 & Rm
\end{array}
\]

Flag setting variant

Applies when \( S == 1 \).

\[\text{EORS}\{<c>\}{<q>} \{<Rd>,} \{<Rn>, \langle Rm>, <\text{shift} \rangle <Rs}\]

Not flag setting variant

Applies when \( S == 0 \).

\[\text{EOR}\{<c>\}{<q>} \{<Rd>,} \{<Rn>, \langle Rm>, <\text{shift} \rangle <Rs}\]

Decode for all variants of this encoding

\[
d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ m = \text{UInt}(Rm); \ s = \text{UInt}(Rs);
\text{setflags} = (S == '1'); \ \text{shift}_t = \text{DecodeRegShift}(stype);
\text{if} \ d == 15 || n == 15 || m == 15 || s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings

For more information about the \text{CONSTRAINED UNPREDICTABLE} behavior, see Appendix K1 \text{Architectural Constraints on UNPREDICTABLE Behaviors}.

\text{ROR} \quad \text{when stype} = 11
\(<Rs>\) \quad \text{Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.}
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
**F5.1.51 ERET**

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores PSTATE from SPSR_<current_mode>.

The register holding the preferred return address is:

- ELR_hyp, when executing in Hyp mode.
- LR, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of ERET executes the DRPS operation.

\textbf{Notes for all encodings}

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see \textit{Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors}.

\textbf{Assembler symbols}

\texttt{<q>} See \textit{Standard assembler syntax fields} on page F1-7228. An HLT instruction must be unconditional.
For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

For encoding T1: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

**Operation for all encodings**

```
EncodingSpecificOperations();
boolean is_async = FALSE;
Halt(DebugHalt_HaltInstruction, is_async);
```
F5.1.54   HVC

Hypervisor Call causes a Hypervisor Call exception. For more information, see Hypervisor Call (HVC) exception on page G1-8970. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and using AArch64, and SCR_EL3.HCE is set to 0.
- In Non-secure EL1 modes when EL3 is implemented and using AArch32, and SCR.HCE is set to 0.
- When EL3 is not implemented and either HCR_EL2.HCD is set to 1 or HCR.HCD is set to 1.
- When EL2 is not implemented.
- In Secure state, if EL2 is not enabled in the current Security state.
- In User mode.

The HVC instruction is CONSTRAINED UNPREDICTABLE in Hyp mode when EL3 is implemented and using AArch32, and SCR.HCE is set to 0.

On executing an HVC instruction, the HSR reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see Use of the HSR on page G5-9265.

- `<c>`
  - For encoding A1: see *Standard assembler syntax fields on page F1-7228*. Must be AL or omitted.
  - For encoding T1: see *Standard assembler syntax fields on page F1-7228*.

- `<q>`
  - See *Standard assembler syntax fields on page F1-7228*.

- `<option>`
  - Specifies an optional limitation on the barrier operation. Values are:
    - **SY**
      - Full system barrier operation, encoded as option = 0b1111. Can be omitted.
    - All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
F5.1.56   IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores PSTATE.IT to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

Many uses of the IT instruction are deprecated for performance reasons, and an implementation might include ITD controls that can disable those uses of IT, making them UNDEFINED.

For more information see Conditional execution on page F1-7229 and Conditional instructions on page F2-7257. The first of these sections includes more information about the ITD controls.

T1 variant

IT{<>{<y>{<z>}}}{<q>} <cond>

Decode for this encoding

if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;

CONstrained UNPREDICTABLE behavior

If firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the ITSTATE state machine is progressed in the same way as for any other cond_base value.

Notes for all encodings

For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Related encodings: Miscellaneous 16-bit instructions on page F3-7303.
Assembler symbols

<x> The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000. If present it is encoded in the "mask[3]" field:

\[
\begin{align*}
\top & \text{ firstcond[0]} \\
\bot & \text{ NOT firstcond[0]}
\end{align*}
\]

<y> The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]" field is set to 0b100. If <y> is present it is encoded in the "mask[2]" field:

\[
\begin{align*}
\top & \text{ firstcond[0]} \\
\bot & \text{ NOT firstcond[0]}
\end{align*}
\]

<z> The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]" field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]" field:

\[
\begin{align*}
\top & \text{ firstcond[0]} \\
\bot & \text{ NOT firstcond[0]}
\end{align*}
\]

<q> See Standard assembler syntax fields on page F1-7228.

<cond> The condition for the first instruction in the IT block, encoded in the "firstcond" field. See Table F1-1 on page F1-7229 for the range of conditions available, and the encodings.

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See Conditional instructions on page F2-7257.

Operation

EncodingSpecificOperations();
AArch32.CheckITEnabled(mask);
PSTATE.IT<7:0> = firstcond:mask;
ShouldAdvanceIT = FALSE;

    EncodingSpecificOperations();
    address = R[n];
    R[t] = ZeroExtend(MemO[address, 2], 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### F5.1.64 LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the `DBGDTRTXintSystem` register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

In an implementation that includes EL2, the permitted LDC access to `DBGDTRTXint` can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general Non-secure System register accesses to debug registers on page G1-9027.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

#### Offset variant

Applies when `P == 1 && W == 0`. 
LDC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]  

Post-indexed variant
Applies when P == 0 && W == 1.
LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>  

Pre-indexed variant
Applies when P == 1 && W == 1.
LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>!  

Unindexed variant
Applies when P == 0 && U == 1 && W == 0.
LDC{<c>}{<q>} p14, c5, [<Rn>], <option>  

Decode for all variants of this encoding
if Rn == '1111' then SEE "LDC (literal)";  
if P == '0' && U == '0' && W == '0' then UNDEFINED;  
n = Uint(Rn);  cp = 14;  
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');  

Assembler symbols
<c>          See Standard assembler syntax fields on page F1-7228.
<q>          See Standard assembler syntax fields on page F1-7228.
<Rn>         Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see LDC (literal).
<option>     Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value
              of this field is ignored when executing this instruction.
+/-          Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and
              encoded in the "U" field. It can have the following values:
              - when U == 0
              + when U == 1
<imm>        Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting
              to 0 and encoded in the "imm8" field, as <imm>/4.

Operation for all encodings
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];  

    // System register write to DBGDTRTXint.
    AArch32.SysRegWriteM(cp, ThisInstr(), address);  
    if wback then R[n] = offset_addr;  

Operational information
If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.65  LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the DBGDTRTXintSystem register. For information about memory accesses see Memory accesses on page F1-7233.

In an implementation that includes EL2, the permitted LDC access to DBGDTRXintcan be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general Non-secure System register accesses to debug registers on page G1-9027.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

A1

![A1 variant](image)

**A1 variant**

Applies when !(P == 0 && U == 0 && W == 0).

LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
LDC{<c>}{<q>} p14, c5, [PC], <option>

**Decode for this encoding**

if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1'); add = (U == '1'); cp = 14; imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If W == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

![T1 variant](image)

**T1 variant**

Applies when !(P == 0 && U == 0 && W == 0).

LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
Decode for this encoding

\[
\text{if } P == '0' \&\& U == '0' \&\& W == '0' \text{ then UNDEFINED;} \\
\text{index = (P == '1'); add = (U == '1'); cp = 14; imm32 = ZeroExtend(imm8:'00', 32);} \\
\text{if W == '1' || (P == '0' \&\& CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;} \\
\]

CONSTRANGED UNPREDICTABLE behavior

If W == '1' || P == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes as LDC (immediate) with writeback to the PC. The instruction is handled as described in Using R15 by instruction on page K1-11563.

Assembler symbols

- See Standard assembler syntax fields on page F1-7228.
- See Standard assembler syntax fields on page F1-7228.
- Is an 8-bit immediate, in the range 0 to 255 enclosed in {}, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.
- The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.
- If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1).
- If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).
- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  - when U = 1
- Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm" field, as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

\[
\text{if ConditionPassed()} \text{ then} \\
\quad \text{EncodingSpecificOperations();} \\
\quad \text{offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);} \\
\quad \text{address = if index then offset_addr else Align(PC,4);} \\
\quad // System register write to DBGDTRXint. \\
\quad AArch32.SysRegWriteM(cp, ThisInstr(), address);
\]

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.66   LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133. Related system instructions are LDM (User registers) and LDM (exception return).

This instruction is used by the alias POP (multiple registers). See Alias conditions on page F5-7602 for details of when each alias is preferred.

LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

#### Decode for this encoding

\[ n = \text{UInt}(Rn); \text{ registers } = \text{register_list}; \text{ wback } = (W == '1'); \]
\[ \text{ if } n == 15 \text{ } || \text{ BitCount(registers)} < 1 \text{ then UNPREDICTABLE; } \]
\[ \text{ if wback } \&\& \text{ registers}<n> == '1' \text{ then UNPREDICTABLE; } \]

#### CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If wback \&\& registers<o> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

\]

\[
\text{if registers}<15> == '1' && \text{InITBlock()} && !\text{LastInITBlock()} then UNPREDICTABLE;}
\]

CONSTRINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If $\text{wback} \land \text{registers}<n> == '1'$, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If $\text{BitCount(registers)} == 1$, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction loads a single register using the specified addressing modes.
• The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If $\text{registers}<13> == '1'$, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If $\text{P} == '1' \land \text{M} == '1'$, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Alias conditions

<td>A1</td>
<td>$\text{w} == '1' \land \text{Rn} == '1101' \land \text{BitCount(register_list)} &gt; 1</td>
</tr>
</tbody>
</table>

Assembler symbols

IA
Is an optional suffix for the Increment After form.

<
See Standard assembler syntax fields on page F1-7228.

<
See Standard assembler syntax fields on page F1-7228.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.
For encoding A1 and T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers> For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field.

For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers[i] == '1' then
            R[i] = MemS[address,4];  address = address + 4;
    end
    if registers[15] == '1' then
        LoadWritePC(MemS[address,4]);
    end
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
end
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The SPSR of the current mode is copied to the CPSR. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

The PE checks the encoding that is copied to the CPSR for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.

Load Multiple (exception return) is:

• UNDEFINED in Hyp mode.
• UNPREDICTABLE in debug state, and in User mode and System mode.

A1

A1 variant

LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^

Decode for this encoding

n = UInt(Rn);  registers = register_list;
wbback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wbback && registers<n> == '1' then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If wback && registers<n> == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<amode> is one of:

DA Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
FA Full Ascending. For this instruction, a synonym for DA.
DB Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
Empty Ascending. For this instruction, a synonym for DB.
Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
Full Descending. For this instruction, a synonym for IA.
Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
Empty Descending. For this instruction, a synonym for IB.

See Standard assembler syntax fields on page F1-7228.

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Instructions with similar syntax but without the PC included in the registers list are described in LDM (User registers).

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;       // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address + 4;
        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemS[address,4];  address = address + 4;
                new_pc_value = MemS[address,4];
            if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
            if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
            AArch32.ExceptionReturn(new_pc_value, SPSR[]);

CONstrained UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.68  LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC.

ED Empty Descending. For this instruction, a synonym for IB.

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<registers_without_pc>
Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in LDM (exception return).

Operation
if ConditionPassed() then
   EncodingSpecificOperations();
   if PSTATE.EL == EL2 then UNDEFINED;
   elsif PSTATE.M IN {M32_User, M32_System} then UNPREDICTABLE;
   else
      length = 4*BitCount(registers);
      address = if increment then R[n] else R[n]-length;
      if wordhigher then address = address+4;
      for i = 0 to 14
         if registers<i> == '1' then // Load User mode register
            Rmode[i, M32_User] = MemS[address,4]; address = address + 4;
      endfor
   end

CONstrained UNpredicable behavior
If PSTATE.M IN {M32_User, M32_System}, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Operational information
If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Load Multiple Decrement After (Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133. Related system instructions are LDM (User registers) and LDM (exception return).

A1

```
31 28 27 26 25 24 23 22 21 20 19 16 15  |  |  |  0
1=111 0 0 0 0 0 W 1  Rn  |  register_list
```

**A1 variant**

LDMDA{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Ascending stack

**Decode for this encoding**

```
n = Uint(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.
The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemS[address,4]; address = address + 4;
        if registers<15> == '1' then
            LoadWritePC(MemS[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.70 LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see FEAT_LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133. Related system instructions are LDM (User registers) and LDM (exception return).

\end{align*}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If `wback &\& registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' &\& M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c>  See Standard assembler syntax fields on page F1-7228.

<i>  See Standard assembler syntax fields on page F1-7228.

<Rn>  Is the general-purpose base register, encoded in the "Rn" field.

!  The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers>  For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  address = R[n] - 4*BitCount(registers);
  for i = 0 to 14
    if registers<i> == '1' then
      R[i] = MemS[address,4];  address = address + 4;

Assembler symbols

- See Standard assembler syntax fields on page F1-7228.
- See Standard assembler syntax fields on page F1-7228.
- For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.
- For encoding T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
<Rn> For encoding A1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal).
For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

+- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when $U = 0$
+ when $U = 1$

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.
For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.
For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

**Operation for all encodings**

```c
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
            else
                R[t] = data;
    else
data = MemU[R[n],4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.73   **LDR (literal)**

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses on page F1-7233*.

**A1**

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 12 | 11 | | | 0 |
| 1=1111 | 0 | 1 | 0 | P | U | 0 | W | 1 | 1 | 1 | 1 | Rt | | | imm12 |

**A1 variant**

Applies when !(P == 0 && W == 1).

LDR{<c>}{<q>} <Rt>, <label> // Normal form
LDR{<c>}{<q>} <Rt>, [PC, #{+/-}imm] // Alternative form

**Decode for this encoding**

if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if wback then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDR (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15 by instruction on page K1-11563.

**T1**

| 15 | 14 | 13 | 12 | 11 | 10 | 8 | 7 | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 0 | 1 | Rt | | imm8 |

**T1 variant**

LDR{<c>}{<q>} <Rt>, <label> // Normal form

**Decode for this encoding**

t = UInt(Rt); imm32 = ZeroExtend(imm8:'00', 32); add = TRUE;
T2

|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|15|12|11| | | |0|
|1 |1 |1 |1 |1 |0 |0 |0 |U |1 |0 |1 |1 |1 |1 |Rt | | |imm12|

T2 variant

LDR{<c>}.W <Rt>, <label> // Preferred syntax, and <Rt>, <label> can be represented in T1
LDR{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDR{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax

Decode for this encoding

t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<Rt>
For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

<label>
For encoding A1 and T2: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.
If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.

+/-
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

<imm>
For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For encoding T2: if a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

**Operation for all encodings**

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC, 4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address, 4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.74   LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see Memory accesses on page F1-7233.

The T32 form of LDR (register) does not support register writeback.

A1

<table>
<thead>
<tr>

if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1
Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

**<c>**

See Standard assembler syntax fields on page F1-7228.

**<q>**

See Standard assembler syntax fields on page F1-7228.

**<Rt>**

For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

**<Rn>**

For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

**+-**

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when \( U = 1 \)

+ Specifies the index register is added to the base register.

\(<Rm>\)
Is the general-purpose index register, encoded in the "Rm" field.

\(<\text{shift}>\)
The shift to apply to the value read from \(<Rm>\). If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F1-7231.

\(<\text{imm}>\)
If present, the size of the left shift to apply to the value from \(<Rm>\), in the range 1-3. \(<\text{imm}>\) is encoded in \text{imm}2. If absent, no shift is specified and \text{imm}2 is encoded as 0b00.

### Operation for all encodings

      else
        \( R[t] = \) data;
```

### Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.75  LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

A1

Offset variant
Applies when \( P = 1 \) \&\& \( W = 0 \).
LDRB\{<c>\}<q> \{<Rt>, \[<Rn> {, #{+/-}<imm>}\]

Post-indexed variant
Applies when \( P = 0 \) \&\& \( W = 0 \).
LDRB\{<c>\}<q> \{<Rt>, \[<Rn>\], #{+/-}<imm>

Pre-indexed variant
Applies when \( P = 1 \) \&\& \( W = 1 \).
LDRB\{<c>\}<q> \{<Rt>, \[<Rn>, {#+/-}imm\]

Decode for all variants of this encoding

If \( \text{Rn} = '1111' \) then SEE "LDRB (literal)";
if \( P = '0' \) \&\& \( W = '1' \) then SEE "LDRBT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback \&\& n == t) then UNPREDICTABLE;

CONstrained UNPREDICTABLE behavior
If wback \&\& n == t, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

\[
\begin{array}{cccc|cc|c}
\hline
0 & 1 & 0 & P & U & 1 & W & 1 & 1 & 1 & 1 & Rt & \text{imm12} \hline
\end{array}
\]

\text{cond}

A1 variant

Applies when \(! (P == 0 \&\& W == 1)\).

LDRB\{<c>\}{<q>} <Rt>, <label> // Normal form
LDRB\{<c>\}{<q>} <Rt>, [PC, \#{+/-}\text{imm}] // Alternative form

Decode for this encoding

\[
\begin{align*}
\text{if } P &= '0' \&\& W == '1' \text{ then see "LDRBT";} \\
\text{t} &= \text{UInt}(Rt); \text{ imm32} = \text{ZeroExtend}(\text{imm12}, 32); \\
\text{add} &= (U == '1'); \text{ wback} = (P == '0') || (W == '1'); \\
\text{if } t &= 15 \text{ } \text{ } \text{ wback then UNPREDICTABLE;}
\end{align*}
\]

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRB (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15 by instruction on page K1-11563.

T1

&\text{ // Armv8-A removes UNPREDICTABLE for R13}
\end{align*}
\]
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<> See Standard assembler syntax fields on page F1-7228.
<q> See Standard assembler syntax fields on page F1-7228.
<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.
    If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.
    If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.
+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
    - when U = 0
    + when U = 1
<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
    For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC, 4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.77 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see Memory accesses on page F1-7233.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
  For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- `+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - `-` when U = 0
  - `+` when U = 1
- `<Rm>` Is the general-purpose index register, encoded in the "Rm" field.
- `<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F1-7231.
- `<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 000.
Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
   offset_addr = if add then (R[n] + offset) else (R[n] - offset);
   address = if index then offset_addr else R[n];
   R[t] = ZeroExtend(MemU[address,1],32);
   if wback then R[n] = offset_addr;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.78   LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F1-7233.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

A1 variant

LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;

CONstrained UNpredictable behavior

If n == 15, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15 by instruction on page K1-11563.
• The instruction uses immediate offset addressing with the base register as PC, without writeback.

If n == t && n != 15, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.
A2

LDRBT{<c>}{<q>} <Rt>, [<Rn>], {+-}<Rm>{, <shift>}

Decode for this encoding

\[ t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm); \quad \text{postindex} = \text{TRUE}; \quad \text{add} = (U == '1'); \]

\[ \text{register\_form} = \text{TRUE}; \quad (\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(stype, \text{imm5}); \]

\[ \text{if } t == 15 \| n == 15 \| n == t \| m == 15 \text{ then UNPREDICTABLE}; \]

### CONSTRAINED UNPREDICTABLE behavior

If \( n == t \&\& \text{!} n != 15 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]

Decode for this encoding

\[ \text{if } Rn == '1111' \text{ then SEE "LDRB (literal)";} \]

\[ t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \quad \text{postindex} = \text{FALSE}; \quad \text{add} = \text{TRUE}; \]

t = UInt(Rt);  t2 = UInt(Rt2);
imm32 = ZeroExtend(imm8:'00', 32);  add = (U == '1');
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if W == '1' then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If t == t2, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The load instruction executes but the destination register takes an UNKNOWN value.

If W == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes without writeback of the base address.
• The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15 by instruction on page K1-11563.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

See Standard assembler syntax fields on page F1-7228.
See Standard assembler syntax fields on page F1-7228.

For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.
For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>
For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.
If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.
If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.
+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when \( U = 0 \)
+ when \( U = 1 \)

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
For encoding T1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian(AccType_ATOMIC) then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.81 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F1-7233.

A1

**Offset variant**

Applies when $P == 1 \land W == 0$.

$LDRD\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]$

**Post-indexed variant**

Applies when $P == 0 \land W == 0$.

$LDRD\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>$

**Pre-indexed variant**

Applies when $P == 1 \land W == 1$.

$LDRD\{<c>\}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]$!

**Decode for all variants of this encoding**

if $Rt<0> == '1'$ then UNPREDICTABLE;

$t = \text{UInt}(Rt);  \ t2 = t+1;  \ n = \text{UInt}(Rn);  \ m = \text{UInt}(Rm);$

$\text{index} = (P == '1');  \ \text{add} = (U == '1');  \ \text{wback} = (P == '0') \ || \ (W == '1');$

if $P == '0' \land W == '1'$ then UNPREDICTABLE;

if $t2 == 15 \ || \ m == 15 \ || \ m == t \ || \ m = t2$ then UNPREDICTABLE;

if wback $\land (n == t \ || \ n == t2)$ then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If $wback \land (n == t \ || \ n == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If $P == '0' \land W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If $m == t \ || \ m == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
The instruction loads register Rm with an \textit{UNKNOWN} value.

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is \textit{UNDEFINED}.
- The instruction executes as \texttt{NOP}.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

**Notes for all encodings**

For more information about the \textit{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see Appendix K1 \textit{Architectural Constraints on UNPREDICTABLE Behaviors}.

**Assembler symbols**

\(<c>\) See \textit{Standard assembler syntax fields} on page F1-7228.

\(<d>\) See \textit{Standard assembler syntax fields} on page F1-7228.

\(<Rt>\) Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

\(<Rt2>\) Is the second general-purpose register to be transferred. This register must be <R(t+1)>.

\(<Rn>\) Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

\(+/-\) Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
- + when U = 1

\(<Rm>\) Is the general-purpose index register, encoded in the "Rm" field.

\]

\[
\text{R[t2] = MemA[address+4,4];}
\]

\[
\text{if wback then R[n] = offset_addr;}
\]
Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.82  LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see Synchronization and semaphores on page E2-7211. For information about memory accesses see Memory accesses on page F1-7233.

A1 variant

LDREX{<c>}{<q>} <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

t = UInt(Rt);  n = UInt(Rn);  imm32 = Zeros(32); // Zero offset
if t == 15 || n == 15 then UNPREDICTABLE;

T1 variant

LDREX{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]

Decode for this encoding

t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
if t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- <>  See Standard assembler syntax fields on page F1-7228.
- <>  See Standard assembler syntax fields on page F1-7228.
- <Rt>  Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn>  Is the general-purpose base register, encoded in the "Rn" field.
For encoding A1: the immediate offset added to the value of \(<Rn>\) to calculate the address. \(<imm>\) can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of \(<Rn>\) to calculate the address. \(<imm>\) can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    AArch32.SetExclusiveMonitors(address,4);
    R[t] = MemA[address,4];
```

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see Synchronization and semaphores on page E2-7211. For information about memory accesses see Memory accesses on page F1-7233.

**A1 variant**

LDREXB{<c>}{<q>} <Rt>, [<Rn>]

**Decode for this encoding**

\[ t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \]
\[ \text{if } t == 15 \text{ or } n == 15 \text{ then UNPREDICTABLE; } \]

**T1 variant**

LDREXB{<c>}{<q>} <Rt>, [<Rn>]

**Decode for this encoding**

\[ t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \]
\[ \text{if } t == 15 \text{ or } n == 15 \text{ then UNPREDICTABLE; } // \text{Armv8-A removes UNPREDICTABLE for R13} \]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,1);
    R[t] = ZeroExtend(MemA[address,1], 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.84 LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see Synchronization and semaphores on page E2-7211. For information about memory accesses see Memory accesses on page F1-7233.

A1

if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
**CONSTRAINED UNPREDICTABLE behavior**

If \( w_{back} \land n = t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

**Notes for all encodings**

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see Appendix K1 Architectural Constraints on **UNPREDICTABLE** Behaviors.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F1-7228.
- `<q>` See *Standard assembler syntax fields* on page F1-7228.
- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rn>` For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRH (literal).
  
  For encoding T1: is the general-purpose base register, encoded in the "Rn" field.
  
  +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  
  - when \( U = 0 \)
  - when \( U = 1 \)
  - when \( U = 1 \)

- `<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
  
  For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as \(<\text{imm}>/2\).
  
  For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
  
  For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

**Operation for all encodings**

```assembly
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
  else
    if ConditionPassed() then
      EncodingSpecificOperations();
      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
      address = if index then offset_addr else R[n];
      data = MemU[address,2];
```
if wback then R[n] = offset_addr;
R[t] = ZeroExtend(data, 12);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.87  LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F1-7233.

A1

LDRH{<c>}{<q>} <Rt>, <label> // Normal form
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}imm] // Alternative form

Decode for this encoding
if P == '0' && W == '1' then SEE "LDRHT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;

CONSTRUANCED UNPREDICTABLE behavior
If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRH (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15 by instruction on page K1-11563.

T1

LDRH{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}imm] // Alternative syntax

Decode for this encoding
if Rt == '1111' then SEE "PLD (literal)";
t = UInt(Rt);  imm32 = ZeroExtend(imm22, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
  + when U = 1

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  base = Align(PC,4);
  address = if add then (base + imm32) else (base - imm32);
  data = MemU[address,2];
  R[t] = ZeroExtend(data, 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**5.1.88 LDRH (register)**

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses on page F1-7233*.

**Offset variant**
Applies when $P == 1 \&\& W == 0$.

$LDRH\{<c>\}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]$

**Post-indexed variant**
Applies when $P == 0 \&\& W == 0$.

$LDRH\{<c>\}{<q>} <Rt>, [<Rn>], {+/-}<Rm>$

**Pre-indexed variant**
Applies when $P == 1 \&\& W == 1$.

$LDRH\{<c>\}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]$

**Decode for all variants of this encoding**

```
if P == '0' \&\& W == '1' then SEE "LDRHT";
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') \|| (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If $wback \&\& n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

```

Notes for all encodings

For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<Rt>
Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn>
For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/
Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

+ Specifies the index register is added to the base register.

<Rm>
Is the general-purpose index register, encoded in the "Rm" field.

<imm>
If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.89 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F1-7233.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

A1 variant

LDRHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

\[ t = \text{UInt}(Rt); \quad n = \text{UInt}(Rn); \quad \text{postindex} = \text{TRUE}; \quad \text{add} = (U == '1'); \]
\[ \text{register} = \text{FALSE}; \quad \text{imm32} = \text{ZeroExtend}(\text{imm4H:imm4L}, 32); \]
\[ \text{if } t == 15 || n == 15 || n == t \text{ then UNPREDICTABLE; } \]

CONstrained UNPREDICTABLE behavior

If \( n = 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15 by instruction on page K1-11563.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If \( n == t \) \&\& \( n != 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.
A2

LDRHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;

CONSTRANGED UNPREDICTABLE behavior

If n == t && n != 15, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

<q>  See Standard assembler syntax fields on page F1-7228.

<Rt>  Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label>  For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, \( \text{imm32} \) is equal to the offset and \( add = \text{TRUE} \), encoded as \( U = 1 \). If the offset is negative, \( \text{imm32} \) is equal to minus the offset and \( add = \text{FALSE} \), encoded as \( U = 0 \).

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, \( \text{imm32} \) is equal to the offset and \( add = \text{TRUE} \), encoded as \( U = 1 \).

If the offset is negative, \( \text{imm32} \) is equal to minus the offset and \( add = \text{FALSE} \), encoded as \( U = 0 \).

+-  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

-  when \( U = 0 \)

+  when \( U = 1 \)

<imm>  For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  base = Align(PC,4);
  address = if add then (base + imm32) else (base - imm32);
  R[t] = SignExtend(MemU[address,1], 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.92 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F1-7233.

A1

| 31 28 26 25 24 23 22 21 20 19 16 15 12 11 10 9 8 7 6 5 4 3 0 |
|-----------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| !=1111 | 0 0 0 | P | U | 0 | W | 1 | Rn | 1 | Rt | 0 0 0 | 0 1 0 1 | 1 | 0 | 1 | Rm |

cond

Offset variant

Applies when P == 1 && W == 0.
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when P == 0 && W == 0.
LDRSB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when P == 1 && W == 1.
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Decode for all variants of this encoding

if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Assembler symbols

<{}> See Standard assembler syntax fields on page F1-7228.

<{}> See Standard assembler syntax fields on page F1-7228.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/− Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
+ when \( U = 1 \)

+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address, 1], 32);
    if wback then R[n] = offset_addr;

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.93   LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F1-7233.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

A1 variant

LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

\[ t = \text{UInt}(Rt); \ n = \text{UInt}(Rn); \ \text{postindex} = \text{TRUE}; \ \text{add} = (U == '1'); \ \text{register}._{\text{form}} = \text{FALSE}; \ \text{imm32} = \text{ZeroExtend}(\text{imm4H:imm4L}, 32); \text{if } t == 15 \ || \ n == 15 \ || \ n == t \text{ then UNPREDICTABLE; } \]

CONSTRARED UNPREDICTABLE behavior

If \( n == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15 by instruction on page K1-11563.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If \( n == t \ && \ n != 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.
A2

LDRSBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If n == t && n != 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

LDRSBT{<c>}{<q>} <Rt>, [Rn] {, #<imm>}

Decode for this encoding

Related instructions: Load, signed (literal) on page F3-7363.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

\<Rt>\>
Is the general-purpose register to be transferred, encoded in the "Rt" field.

\<label>\>
For encoding A1: the label of the literal data item that is to be loaded into \<Rt>. The assembler calculates the required value of the offset from the Align(\PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into \<Rt>. The assembler calculates the required value of the offset from the Align(\PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

\+-\>
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
  + when U = 1

\<imm>\>
For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  base = Align(\PC, 4);
  address = if add then (base + imm32) else (base - imm32);
  data = MemU[address, 2];
  \R[t]\ = SignExtend(data, 32);

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F1-7233.

Offset variant
Applies when P == 1 && W == 0.

\[
\text{LDRSH}\{<c>\}{<q>} \text{ <Rt>}, [\text{<Rn>}, \{+/-\}<Rm>]

t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRTtype_LSL, 0);

T2

T2 variant

LDRSH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

if Rn == '1111' then SEE "LDRSH (literal)";
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRTtype_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1
Architectural Constraints on UNPREDICTABLE Behaviors.

Related instructions: Load/store, signed (register offset) on page F3-7360.

Assembler symbols

<< See Standard assembler syntax fields on page F1-7228.

<< See Standard assembler syntax fields on page F1-7228.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used
in the offset variant.
For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

/+ Specify the index register is added to or subtracted from the base register, defaulting to + if omitted
and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.
<imm>     If present, the size of the left shift to apply to the value from \( R_m \), in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

**Operation for all encodings**

\[
\text{if } \text{ConditionPassed()} \text{ then}
\quad \text{EncodingSpecificOperations();}
\quad \text{offset} = \text{Shift}(R[m], \text{shift}_t, \text{shift}_n, \text{PSTATE.C});
\quad \text{offset_addr} = \text{if add then } (R[n] + \text{offset}) \text{ else } (R[n] - \text{offset});
\quad \text{address} = \text{if index then } \text{offset_addr} \text{ else } R[n];
\quad \text{data} = \text{MemU}[\text{address}, 2];
\quad \text{if wback then } R[n] = \text{offset_addr};
\quad R[t] = \text{SignExtend(data, } 32);\
\]

**Operational information**

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
F5.1.97 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F1-7233.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');

register_form = FALSE; imm32 = ZeroExtend(imm4H:imm4L, 32);

if t == 15 || n == 15 || n == t then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15 by instruction on page K1-11563.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If n == t & n != 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.
A2

LDRSHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

- `<Rm>`: Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>`: Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.101  LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**Assembler symbols**

<

See *Standard assembler syntax fields on page F1-7228.*

<

See *Standard assembler syntax fields on page F1-7228.*

<Rd>

For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores PSTATE from SPSR_{current_mode}.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm>

For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

<imm>

For encoding A1: is the shift amount, in the range 0 to 31, encoded in the "imm5" field as <imm> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31, encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31, encoded in the "imm3:imm2" field as <imm> modulo 32.

**Operation for all encodings**

The description of MOV, MOVs (register) gives the operational pseudocode for this instruction.
F5.1.102  LSLS (register)

Logical Shift Left, setting flags (register) shifts a register value left by a variable number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVs (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVs (register-shifted register).
- The description of MOV, MOVs (register-shifted register) gives the operational pseudocode for this instruction.

**Assembler symbols**

<{}> See *Standard assembler syntax fields on page F1-7228.*

<q> See *Standard assembler syntax fields on page F1-7228.*

<Rdm> Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the first general-purpose source register, encoded in the "Rm" field.

<Rs> Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.105   LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<current\_mode>\).
- The PE checks SPSR_\(<current\_mode>\) for an illegal return event. See **Illegal return events from AArch32 state** on page G1-8952.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

\textbf{Operation for all encodings}

The description of \texttt{MOV, MOVS} (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.107 MCR

Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see About the AArch32 System register interface on page E1-7158 and General behavior of System registers on page G8-9322.

In an implementation that includes EL2, MCR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2 configurable controls on page G1-9010.

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<c> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:
  p14 when coproc<0> = 0
  p15 when coproc<0> = 1

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc1" field.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

<opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc2" field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  AArch32.SysRegWrite(cp, ThisInstr(), t);
F5.1.108 MCRR

Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see About the AArch32 System register interface on page E1-7158 and General behavior of System registers on page G8-9322.

In an implementation that includes EL2, MCRR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2 configurable controls on page G1-9010.

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<<c>> See Standard assembler syntax fields on page F1-7228.

<<q>> See Standard assembler syntax fields on page F1-7228.

<coproce> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:
 p14 when coproc<0> = 0
 p15 when coproc<0> = 1

<opc1e> Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

<Re> Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

<Rt2e> Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

<CRme> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of {<coproc>, <opc1>, <CRm>} encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   AArch32.SysRegWrite64(cp, ThisInstr(), t, t2);
F5.1.109  MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

### Flag setting variant
Applies when \( S = 1 \).

\[
\text{MLAS}\{<c>\}\{<q>\} <Rd>, <Rn>, <Rm>, <Ra>
\]

### Not flag setting variant
Applies when \( S = 0 \).

\[
\text{MLA}\{<c>\}\{<q>\} <Rd>, <Rn>, <Rm>, <Ra>
\]

#### Decode for all variants of this encoding
\[
d = \text{UInt}(Rd); n = \text{UInt}(Rn); m = \text{UInt}(Rm); a = \text{UInt}(Ra); \text{setflags} = (S == '1');
\]

\[
\text{if } d == 15 || n == 15 || m == 15 || a == 15 \text{ then UNPREDICTABLE;}
\]

### T1

#### T1 variant
\[
\text{MLA}\{<c>\}\{<q>\} <Rd>, <Rn>, <Rm>, <Ra>
\]

#### Decode for this encoding
\[
\text{if } Ra == '1111' \text{ then SEE "MUL";}
\]

\[
d = \text{UInt}(Rd); n = \text{UInt}(Rn); m = \text{UInt}(Rm); a = \text{UInt}(Ra); \text{setflags} = \text{FALSE};
\]

\[
\text{if } d == 15 || n == 15 || m == 15 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\]

#### Notes for all encodings
For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

#### Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.
<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.110   MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

  Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

- `<Rm>`  
  Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

- `<Ra>`  
  Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.111  MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<current\_mode>\).
  — The PE checks SPSR_\(<current\_mode>\) for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

### Decode for this encoding

\[
d = \text{UInt}(Rd); \text{ setflags} = \text{FALSE}; \text{ imm32} = \text{ZeroExtend}(\text{imm4:i:imm3:imm8}, 32);\]
\[
\text{if } d == 15 \text{ then UNPREDICTABLE; } // \text{Armv8-A removes UNPREDICTABLE for R13}
\]
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

>
See Standard assembler syntax fields on page F1-7228.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:
- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding A2, T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<imm8>
Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<imm16>
For encoding A2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T3: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

<const>
For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  result = imm32;
  if d == 15 then          // Can only occur for encoding A1
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.112 MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases ASRS (immediate), ASR (immediate), LSLS (immediate), LSL (immediate), LSRS (immediate), LSR (immediate), RORS (immediate), ROR (immediate), RRXS, and RRX. See Alias conditions on page F5-7721 for details of when each alias is preferred.

\end{array} \]

**MOV, rotate right with extend variant**

Applies when \( S = 0 \text{ } \&\& \text{imm}3 = 000 \text{ } \&\& \text{imm}2 = 00 \text{ } \&\& \text{stype} = 11. \)

`MOV{<c>}{<q>} <Rd>, <Rm}, RRX`
MOV, shift or rotate by value variant

Applies when \( S = 0 \) \&\& \((\text{imm3} = 000 \&\& \text{imm2} = 00 \&\& \text{stype} = 11)\).

\[
\text{MOV}(<c>).W <Rd>, <Rm> \{, \text{LSL} #0\} // <Rd>, <Rm> \text{ can be represented in T1}
\]

\[
\text{MOV}(<c>).W <Rd>, <Rm> \{, <\text{shift}> #<\text{amount}>\} // \text{Inside IT block, and <Rd>, <Rm>, <\text{shift}>, <\text{amount}> \text{ can be represented in T2}
\]

\[
\text{MOV}(<c>)\{<q>\} <Rd>, <Rm> \{, <\text{shift}> #<\text{amount}>\}
\]

MOV, rotate right with extend variant

Applies when \( S = 1 \) \&\& \text{imm3} = 000 \&\& \text{imm2} = 00 \&\& \text{stype} = 11.

\[
\text{MOVS}(<c>)\{<q>\} <Rd>, <Rm>, \text{RRX}
\]

MOV, shift or rotate by value variant

Applies when \( S = 1 \) \&\& \((\text{imm3} = 000 \&\& \text{imm2} = 00 \&\& \text{stype} = 11)\).

\[
\text{MOVS}.W <Rd>, <Rm> \{, <\text{shift}> #<\text{amount}>\} // \text{Outside IT block, and <Rd>, <Rm>, <\text{shift}>, <\text{amount}> \text{ can be represented in T1 or T2}
\]

\[
\text{MOVS}<c>{<q>} <Rd>, <Rm> \{, <\text{shift}> #<\text{amount}>\}
\]

Decode for all variants of this encoding

\[
d = \text{UInt}(\text{Rd}); \ m = \text{UInt}(\text{Rm}); \ \text{setflags} = (S = '1');
\]

\[
(\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{stype}, \text{imm3:imm2});
\]

\[
\text{if} \ d = 15 || m = 15 \text{ then UNPREDICTABLE}; \ // \text{Armv8-A removes UNPREDICTABLE for R13}
\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

</table>

See **Standard assembler syntax fields** on page F1-7228.

For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133. Arm deprecates use of the instruction if $<Rn>$ is the PC.

- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_{current_mode}. Arm deprecates use of the instruction if $<Rn>$ is not the LR, or if the optional shift or RRX argument is specified.

For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-7133.

- The instruction must either be outside an IT block or the last instruction of an IT block.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. Arm deprecates use of the instruction if $<Rd>$ is the PC.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

For encoding A1 and T3: is the type of shift to be applied to the source register, encoded in the "stype" field. It can have the following values:

- **LSL** when stype = 00
- **LSR** when stype = 01
- **ASR** when stype = 10
- **ROR** when stype = 11
For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values:

- **LSL** when \( \text{op} = 00 \)
- **LSR** when \( \text{op} = 01 \)
- **ASR** when \( \text{op} = 10 \)

For encoding A1: is the shift amount, in the range 0 to 31 (when \(<\text{shift}>\) = LSL), or 1 to 31 (when \(<\text{shift}>\) = ROR) or 1 to 32 (when \(<\text{shift}>\) = LSR or ASR), encoded in the "imm5" field as \(<\text{amount}>\) modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when \(<\text{shift}>\) = LSL or ROR) or 1 to 32 (when \(<\text{shift}>\) = LSR or ASR), encoded in the "imm5" field as \(<\text{amount}>\) modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31 (when \(<\text{shift}>\) = LSL) or 1 to 31 (when \(<\text{shift}>\) = ROR), or 1 to 32 (when \(<\text{shift}>\) = LSR or ASR), encoded in the "imm3:imm2" field as \(<\text{amount}>\) modulo 32.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = shifted;
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

**Operational information**

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.113  MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases ASRS (register), ASR (register), LSLS (register), LSL (register), LSRS (register), LSR (register), RORS (register), and ROR (register). See Alias conditions on page F5-7726 for details of when each alias is preferred.

Flag setting variant
Applies when $S == 1$.

MOVS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

Not flag setting variant
Applies when $S == 0$.

MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;

Arithmetic shift right variant
Applies when op == 0100.

MOV{<c>}{<q>} <Rdm>, <Rdm>, ASR <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs> // Outside IT block

Logical shift left variant
Applies when op == 0010.

MOV{<c>}{<q>} <Rdm>, <Rdm>, LSL <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs> // Outside IT block

Logical shift right variant
Applies when op == 0011.

MOV{<c>}{<q>} <Rdm>, <Rdm>, LSR <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSR <Rs> // Outside IT block
**Rotate right variant**

Applies when `op == 0111`.

\[
\text{MOV<c>{<q}> <Rdm>, <Rdm>, ROR <Rs> // Inside IT block} \\
\text{MOVS{<q}> <Rdm>, <Rdm>, ROR <Rs> // Outside IT block}
\]

**Decode for all variants of this encoding**

\[
\text{if (!op IN ('0010', '0011', '0100', '0111')) then SEE "Related encodings";}
\text{d = UInt(Rdm); m = UInt(Rdm); s = UInt(Rs);}
\text{setflags = !InITBlock(); shift_t = DecodeRegShift(op<2>:op<0>);}
\]

**T2**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|---|---|---|---|---|---|---|---|---|
| 1  | 1  | 1  | 1  | 0  | 1  | 0  | 0  | |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|     |     |     |     |     |     |     |     | |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

**Flag setting variant**

Applies when `S == 1`.

\[
\text{MOVS.W <Rd>, <Rm>, <shift> <Rs> // Outside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1} \\
\text{MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>}
\]

**Not flag setting variant**

Applies when `S == 0`.

\[
\text{MOV{<c>}.W <Rd>, <Rm>, <shift> <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1} \\
\text{MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>}
\]

**Decode for all variants of this encoding**

\[
d = \text{UInt(Rd)}; m = \text{UInt(Rm)}; s = \text{UInt(Rs)};
\text{setflags = (S == '1'); shift_t = DecodeRegShift(stype);}
\text{if d == 15 || m == 15 || s == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\]

**Notes for all encodings**

Related encodings: In encoding T1, for an `op` field value that is not described above, see *Data-processing (two low registers)* on page F3-7297.

For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see *Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.*

### Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rdm>` Is the general-purpose source register and the destination register, encoded in the "Rdm" field.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<rm>` Is the general-purpose source register, encoded in the "Rm" field.
<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (result, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- **The execution time of this instruction is independent of:**
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- **The response of this instruction to asynchronous exceptions does not vary based on:**
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F5.1.114 MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

#### A1

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

#### A1 variant

MOVT{<c>}{<q>} <Rd>, #<imm16>

**Decode for this encoding**

\[
\begin{align*}
\text{d} &= \text{UInt}(\text{Rd}); \\
\text{imm16} &= \text{imm4:imm12}; \\
\text{if } d &= 15 \text{ then UNPREDICTABLE;}
\end{align*}
\]

#### T1

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

#### T1 variant

MOVT{<c>}{<q>} <Rd>, #<imm16>

**Decode for this encoding**

\[
\begin{align*}
\text{d} &= \text{UInt}(\text{Rd}); \\
\text{imm16} &= \text{imm4:i:imm3:imm8}; \\
\text{if } d &= 15 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\end{align*}
\]

#### Notes for all encodings

For more information about the CONSTRUANED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

#### Assembler symbols

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<imm16>` For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.
  - For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.
Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.115  MRC

Move to general-purpose register from System register. This instruction copies the value of a System register to a
general-purpose register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For
more information see About the AArch32 System register interface on page E1-7158and General behavior of System
registers on page G8-9322.

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode,
meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be
permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2
configurable controls on page G1-9010.

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

A1

\[
\begin{array}{ccccccccccccccccccc}
\text{cond} & 31 & 28 & 27 & 26 & 25 & 24 & 23 & 21 & 20 & 19 & 16 & 15 & 12 & 11 & 9 & 8 & 7 & 5 & 4 & 3 & 0 \\
1=1111 & 1 & 1 & 1 & 0 & \text{opc1} & 1 & \text{CRn} & \text{Rt} & 1 & 1 & 1 & \text{opc2} & 1 & \text{CRm} \\

\text{Assembler symbols}

\text{<c> See Standard assembler syntax fields on page F1-7228.}

\text{<q> See Standard assembler syntax fields on page F1-7228.}
<coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

- p14 when coproc<0> = 0
- p15 when coproc<0> = 1

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc1" field.

<Rt> Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the PSTATE condition flags.

<CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

<opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc2" field.

The possible values of \{<coproc>, <opc1>, <CRn>, <CRm>, <opc2>\} encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

**Operation for all encodings**

if ConditionPassed() then
   EncodingSpecificOperations();

   if t != 15 || AArch32.SysRegReadWriteAPSR(cp, ThisInstr()) then
      AArch32.SysRegReadWrite(cp, ThisInstr(), t);
   else
      UNPREDICTABLE;
F5.1.116   MRRC

Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see About the AArch32 System register interface on page E1-7158 and General behavior of System registers on page G8-9322.

In an implementation that includes EL2, MRRC accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2 configurable controls on page G1-9010.

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

A1

```
\[31\quad 28\|27\quad 26\quad 25\quad 24\|23\quad 22\quad 21\quad 20\|19\quad 16\|15\quad 12\|11\quad 9\|8\|7\|4\|3\|0\]

\hline
\end{array}
```

T1 variant

MRRC{<c>}{<q>} <coproc>, {@opc1}, <Rt>, <Rt2>, <CRm>
**Decode for this encoding**

\[ t = \text{UInt}(Rt); \quad t2 = \text{UInt}(Rt2); \quad cp = \text{if coproc<0> == '0' then 14 else 15}; \]
\[ \text{if } t == 15 || t2 == 15 || t == t2 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13} \]

**CONSTRAINED UNPREDICTABLE behavior**

If \( t == t2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<coproc>` Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:
  - p14 when coproc<0> = 0
  - p15 when coproc<0> = 1
- `<opc1>` Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.
- `<Rt>` Is the first general-purpose register that is transferred into, encoded in the "Rt" field.
- `<Rt2>` Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.
- `<CRm>` Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of \{ <coproc>, <opc1>, <CRm> \} encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <t2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

**Operation for all encodings**

\[
\text{if ConditionPassed() then}
\text{EncodingSpecificOperations();}
\text{AArch32.SysRegRead64(cp, ThisInstr(), t, t2);}\]
F5.1.117 MRS

Move Special register to general-purpose register moves the value of the The Application Program Status Register, APSR on page E1-7135, CPSR, or SPSR_{<current_mode>} into a general-purpose register.

Arm recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-7135.

An MRS that accesses the SPSR is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the CPSR returns an UNKNOWN value for the CPSR. {E, A, I, F, M} fields.

Decode for this encoding

d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<c>     See Standard assembler syntax fields on page F1-7228.

<q>     See Standard assembler syntax fields on page F1-7228.

<Rd>    Is the general-purpose destination register, encoded in the "Rd" field.
<spec_reg> Is the special register to be accessed, encoded in the "R" field. It can have the following values:

- CPSR|APSR when R = 0
- SPSR when R = 1

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
if read_spsr then
    if PSTATE.M IN {M32_User, M32_System} then
        UNPREDICTABLE;
    else
        R[d] = SPSR[];
else
    // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
    bits(32) mask = '11110000 11101111 00000011 11011111';
    psr_val = GetPSRFromPSTATE(AArch32_NonDebugState, 32) AND mask;
    if PSTATE.EL == EL0 then
        // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
        // and for the M field, bits<4:0>
        psr_val<22> = bits(1) UNKNOWN;
        psr_val<9:6> = bits(4) UNKNOWN;
        psr_val<4:0> = bits(5) UNKNOWN;
        R[d] = psr_val;
```

**CONSTRAINED UNPREDICTABLE behavior**

If PSTATE.M IN (M32_User, M32_System) && read_spsr, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
F5.1.118   MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of ELR_hyp on page G1-8920, to a general-purpose register.

\textit{MRS} (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an \textit{MRS} (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR\textsubscript{mon}, SP\textsubscript{mon}, or LR\textsubscript{mon}, it is trapped to EL3.

The effect of using an \textit{MRS} (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see Usage restrictions on the banked register transfer instructions on page F5-8161.

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL0, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
F5.1.120  MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the Application Program Status Register, APSR on page E1-7135, CPSR, or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to APSR_nzcvq (CPSR_f).

If an MSR (immediate) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See Illegal changes to PSTATE.M on page G1-8925.

An MSR (immediate) executed in User mode:

- Is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher.

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. Arm deprecates using this to change its value.

<td></td>
</tr>
<tr>
<td>cond</td>
<td>imm12</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A1 variant

Applies when !(R == 0 & mask == 0000).

MSR<spec_reg>, #<imm>

Decode for this encoding

\[
\text{if mask} = '0000' \&\& R = '0' \text{ then SEE "Related encodings";}
\]

\[
\text{imm32} = \text{A32ExpandImm}(\text{imm12}); \quad \text{write_spsr} = (R = '1');
\]

\[
\text{if mask} = '0000' \text{ then UNPREDICTABLE;}
\]

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000' & R == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Related encodings: Move Special Register and Hints (immediate) on page F4-7389.

Assembler symbols

<>

See Standard assembler syntax fields on page F1-7228.

<q>

See Standard assembler syntax fields on page F1-7228.

<spec_reg>

Is one of:

- APSR_bbits.
• CPSR_<fields>.
• SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:
- c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
- f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:
- APSR_nzcvq is the same as CPSR_f (mask== '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-7135.

<imm> Is an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
if write_spsr then
    if PSTATE.M IN {M32_User, M32_System} then
        UNPREDICTABLE;
    else
        SPSRWriteByInstr(imm32, mask);
else
    // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
    CPSRWriteByInstr(imm32, mask);

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System} && write_spsr, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as NOP.
F5.1.121  MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the The Application Program Status Register, APSR on page E1-7135, CPSR or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the MSR instruction is being used at Application level and its destination is not APSR_nzcvq (CPSR_f).

If an MSR (register) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See Illegal changes to PSTATE.M on page G1-8925.

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. Arm deprecates using this to change its value.

cond

A1 variant

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
n = UInt(Rn);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T1

```
|15 14 13 12|11 10 |9 8 |7 6 5 4 |3 0 |
|---|---|---|---|---|---|
|1 1 1 1 |0 0 1 0 |R |1 0 |
mask |0 |0 |0 |0 |0 |0 |
```

T1 variant

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
n = UInt(Rn);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```
CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as NOP.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-7135.

<Rn>
Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
if write_spsr then
    if PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else
        SPSRWriteByInstr(R[n], mask);
else
    // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
    CPSRWriteByInstr(R[n], mask);

CONSTRAINED UNPREDICTABLE behavior

If write_spsr & PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
• The instruction executes as NOP.
F5.1.122 MUL, MULS

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

A1

Flag setting variant

Applies when $S = 1$.

MULS{<q>} <Rd>, <Rn>{, <Rm>}

Not flag setting variant

Applies when $S = 0$.

MUL{<q>} <Rd>, <Rn>{, <Rm>}

Decode for all variants of this encoding

\[

\(\text{// PSTATE.C, PSTATE.V unchanged}\)

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.123 MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Assembler symbols

<c>
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- For the MVNS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field.

<Rm>
For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the source register, encoded in the "stype" field. It can have the following values:

- **LSL** when stype = 00
- **LSR** when stype = 01
- **ASR** when stype = 10
- **ROR** when stype = 11

<amount>
For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
        // PSTATE.V unchanged
```
F5.1.125 MVN, MVNS (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

A1

```
[31 28 27 26 25 24 23 22 21 20 19 18 17 16 15 12 11 8 7 6 5 4 3 2 1 0]
  !=1111 0 0 0 1 1 1 1 S(0)(0)(0) Rd Rs 0 stype 1 Rm
  cond
```

Flag setting variant

Applies when $S == 1$.

$MVNS{<c>}{<q}> <Rd>, <Rm>, <shift> <Rs>$

Not flag setting variant

Applies when $S == 0$.

$MVN{<c>}{<q}> <Rd>, <Rm>, <shift> <Rs>$

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = ($S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

$<c>$ See Standard assembler syntax fields on page F1-7228.

$<q>$ See Standard assembler syntax fields on page F1-7228.

$<Rd>$ Is the general-purpose destination register, encoded in the "Rd" field.

$<Rm>$ Is the general-purpose source register, encoded in the "Rm" field.

$<shift>$ Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Type of Shift</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>when stype = 00</td>
</tr>
<tr>
<td>LSR</td>

<tr>
<td>ASR</td>
<td>when stype = 10</td>
</tr>
<tr>
<td>ROR</td>
<td>when stype = 11</td>
</tr>
</tbody>
</table>

$<Rs>$ Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
```
(shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
result = NOT(shifted);
R[d] = result;
if setflags then
  PSTATE.N = result<31>;
PSTATE.Z = IsZeroBit(result);
PSTATE.C = carry;
// PSTATE.V unchanged
F5.1.126   NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

See Standard assembler syntax fields on page F1-7228.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  // Do nothing

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.127  ORN, ORNS (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

T1

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 12 | 11 | 8 | 7 | 0 |

      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.129   ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\[
PSTATE.N = \text{result} <31>;
\]

\[
PSTATE.Z = \text{IsZeroBit(result);}\]
PSTATE.C = carry;
// PSTATE.V unchanged

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### F5.1.130 ORR, ORRS (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133](#).
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_{<current_mode>}`.
  - The PE checks `SPSR_{<current_mode>}` for an illegal return event. See [Illegal return events from AArch32 state on page G1-8952](#).
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Related encodings: Data-processing (shifted register) on page F3-7308

Assembler symbols

<<> See Standard assembler syntax fields on page F1-7228.

<<q> See Standard assembler syntax fields on page F1-7228.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:
   • For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
   • For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:
   LSL when stype = 00
   LSR when stype = 01
   ASR when stype = 10
   ROR when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:
   • Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
   • Inside an IT block, if ORR<< <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<< <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[n], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
ALUExceptionReturn(result);
else
    ALUWritePC(result);
else
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
F5.1.131 ORR, ORRS (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

```
| 31 28|27 26 25 24|23 22 21 20|19 16|15 12|11 8 7 6 5 4 3 0 |
|---|---|---|---|---|---|---|---|---|---|
| !|=1111 0 0 0 1 1 0 0 S | Rn | Rd | Rs 0 | stype | 1 | Rm |
```

Flag setting variant

Applies when $S = 1$.

```
ORRS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when $S = 0$.

```
ORR{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

F5.1.132  PKHBT, PKHTB

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

A1

PKHBT variant

Applies when \( \text{tb} = 0 \).

\[
\text{PKHBT}\{\langle c\rangle\}{\langle q\rangle}\ {\langle R_{\text{d}},\rangle} {\langle R_{\text{n}}, \langle R_{\text{m}}\rangle}, {\langle \text{LSL #imm}\rangle}}
\]

PKHTB variant

Applies when \( \text{tb} = 1 \).

\[
\text{PKHTB}\{\langle c\rangle\}{\langle q\rangle} {\langle R_{\text{d}},\rangle} {\langle R_{\text{n}}, \langle R_{\text{m}}\rangle}, {\langle \text{ASR #imm}\rangle}}
\]

Decode for all variants of this encoding

\[
d = \text{UInt}(\text{Rd}); \ n = \text{UInt}(\text{Rn}); \ m = \text{UInt}(\text{Rm}); \ \text{tbform} = (\text{tb} == '1');
\]

\[
(\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{tb}:'0', \text{imm5});
\]

\[
\text{if } d == 15 || n == 15 || m == 15 \text{ then UNPREDICTABLE;}
\]

T1

PKHBT variant

Applies when \( \text{tb} = 0 \).

\[
\text{PKHBT}\{\langle c\rangle\}{\langle q\rangle} {\langle R_{\text{d}},\rangle} {\langle R_{\text{n}}, \langle R_{\text{m}}\rangle}, {\langle \text{LSL #imm}\rangle}} \quad \text{\textbackslash{}text{tbform} == \text{FALSE}}
\]

PKHTB variant

Applies when \( \text{tb} = 1 \).

\[
\text{PKHTB}\{\langle c\rangle\}{\langle q\rangle} {\langle R_{\text{d}},\rangle} {\langle R_{\text{n}}, \langle R_{\text{m}}\rangle}, {\langle \text{ASR #imm}\rangle}} \quad \text{\textbackslash{}text{tbform} == \text{TRUE}}
\]

Decode for all variants of this encoding

\[
\text{if } S == '1' || T == '1' \text{ then UNDEFINED;}
\]

\[
d = \text{UInt}(\text{Rd}); \ n = \text{UInt}(\text{Rn}); \ m = \text{UInt}(\text{Rm}); \ \text{tbform} = (\text{tb} == '1');
\]

\[
(\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{tb}:'0', \text{imm3:imm2});
\]

\[
\text{if } d == 15 || n == 15 || m == 15 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\]

Notes for all encodings

For more information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F1-7228.

<q>
See Standard assembler syntax fields on page F1-7228.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rn>
Is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
Is the second general-purpose source register, encoded in the "Rm" field.

<imm>
For encoding A1: the shift to apply to the value read from <Rm>, encoded in the "imm5" field.
For PKHBT, it is one of:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Encoded Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>omitted</td>
<td>0b00000</td>
</tr>
<tr>
<td>1-31</td>
<td>Left shift by specified number of bits, encoded as a binary number.</td>
</tr>
</tbody>
</table>

For PKHTB, it is one of:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Encoded Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>omitted</td>
<td>Instruction is a pseudo-instruction and is assembled as though PKHTB{&lt;c&gt;}{&lt;q&gt;} &lt;Rd&gt;, &lt;Rm&gt;, &lt;Rn&gt; had been written.</td>
</tr>
<tr>
<td>1-32</td>
<td>Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b000000. Other shift amounts are encoded as binary numbers.</td>
</tr>
</tbody>
</table>

--- Note ---
An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  operand2 = Shift(R[m], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
  R[d]<15:0> = if tbform then operand2<15:0> else R[n]<15:0>;
  R[d]<31:16> = if tbform then R[n]<31:16> else operand2<31:16>;

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
F5.1.133 PLD, PLDW (immediate)

Preload Data (immediate) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see Preloading caches on page E2-7191.

if Rn == '1111' then SEE "PLD (literal)";
n = UInt(Rn); imm32 = ZeroExtend(imm8, 32); add = FALSE; is_pldw = (W == '1');

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

{<c>}
For encoding A1: see Standard assembler syntax fields on page F1-7228. Must be AL or omitted.
For encoding T1 and T2: see Standard assembler syntax fields on page F1-7228.

{<q>}
See Standard assembler syntax fields on page F1-7228.

{<Rn>}
Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see PLD (literal).

{+-}
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

{+}
Specifies the offset is added to the base register.

{<imm>}
For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings
if ConditionPassed() then
   EncodingSpecificOperations();
   address = if add then (R[n] + imm32) else (R[n] - imm32);
   if is_pldw then
      Hint_PreloadDataForWrite(address);
else
  Hint_PreloadData(address);
F5.1.134  PLD (literal)

Preload Data (literal) signals the memory system that data memory accesses from a specified address are likely in
the near future. The memory system can respond by taking actions that are expected to speed up the memory
accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see Preloading caches on
page E2-7191.

A1

A1 variant

PLD{<c>}{<q>} <label> // Normal form
PLD{<c>}{<q>} [PC, #{+/-}<imm>] // Alternative form

Decode for this encoding

\[ imm32 = \text{ZeroExtend}(imm12, 32); \text{ add } = (U == \text{'1'}); \]

T1

T1 variant

PLD{<c>}{<q>} <label> // Preferred syntax
PLD{<c>}{<q>} [PC, #{+/-}<imm>] // Alternative syntax

Decode for this encoding

\[ imm32 = \text{ZeroExtend}(imm12, 32); \text{ add } = (U == \text{'1'}); \]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1
Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<c>\)  
For encoding A1: see Standard assembler syntax fields on page F1-7228. Must be AL or omitted.
For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(<q>\)  
See Standard assembler syntax fields on page F1-7228.

\(<label>\)  
The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095.
If the offset is zero or positive, \(imm32\) is equal to the offset and \(add\) == TRUE.
If the offset is negative, \(imm32\) is equal to minus the offset and \(add\) == FALSE.
+/-  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
-  when U = 0
+  when U = 1

<imm>  For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.
        For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    Hint_PreloadData(address);
```
F5.1.135  PLD, PLDW (register)

Preload Data (register) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see Preloading caches on page E2-7191.

A1

\[

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

\(<\text{c}>\) For encoding A1: see Standard assembler syntax fields on page F1-7228. \(<\text{c}>\) must be \text{AT} or omitted.

For encoding T1: see Standard assembler syntax fields on page F1-7228.

\(<\text{q}>\) See Standard assembler syntax fields on page F1-7228.

\(<\text{Rn}>\) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

\(+/-\) Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- \( \text{when } U == 0 \)
- \( \text{when } U == 1 \)

\(+\) Specifies the index register is added to the base register.

\(<\text{Rm}>\) Is the general-purpose index register, encoded in the "Rm" field.

\(<\text{shift}>\) Is the type of shift to be applied to the index register, encoded in the "stype" field. It can have the following values:

- \( \text{LSL when } \text{stype} == \text{00} \)
- \( \text{LSR when } \text{stype} == \text{01} \)
- \( \text{ASR when } \text{stype} == \text{10} \)
- \( \text{ROR when } \text{stype} == \text{11} \)

\(<\text{amount}>\) For encoding A1: is the shift amount, in the range 1 to 31 (when \(<\text{shift}> == \text{LSL or ROR}\) or 1 to 32 (when \(<\text{shift}> == \text{LSR or ASR}\) encoded in the "imm5" field as \(<\text{amount}> \mod 32\).

For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);

**T3 variant**

PLI{<c>}{<q>} <label> // Preferred syntax
PLI{<c>}{<q>} [PC, #<+/-><imm>] // Alternative syntax

**Decode for this encoding**

\[ n = 15; \text{imm32} = \text{ZeroExtend}(\text{imm12}, 32); \text{add} = (U == '1'); \]

**Notes for all encodings**

For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

\(<c>\) For encoding A1: see Standard assembler syntax fields on page F1-7228. Must be At or omitted.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F1-7228.

\(<q>\) See Standard assembler syntax fields on page F1-7228.

\(<label>\) The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the A1ign(PC, 4) value of the instruction to this label. The offset must be in the range -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

\(<Rn>\) Is the general-purpose base register, encoded in the "Rn" field.

\(+/-\) Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
+ when \( U = 1 \)

\(+\) Specifies the offset is added to the base register.

\(<imm>\) For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

For encoding T3: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F2-7257.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);

<> 
See Standard assembler syntax fields on page F1-7228.

<\n> 
Is the general-purpose base register, encoded in the "Rn" field.

+/- 
Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

+ 
Specifies the index register is added to the base register.

<\m> 
Is the general-purpose index register, encoded in the "Rm" field.

<\shift> 
Is the type of shift to be applied to the index register, encoded in the "stype" field. It can have the following values:
- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<\amount> 
For encoding A1: is the shift amount, in the range 1 to 31 (when <\shift> = LSL or ROR) or 1 to 32 (when <\shift> = LSR or ASR) encoded in the "imm5" field as <\amount> modulo 32.
For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
F5.1.138 POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

T1 variant

POP{<c>}{<q>} <registers> // Preferred syntax
LDM{<c>}{<q>} SP!, <registers> // Alternate syntax

Decode for this encoding

register = P:"0000000":register_list; UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<i> See Standard assembler syntax fields on page F1-7228.

<q> See Standard assembler syntax fields on page F1-7228.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0.

If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[13];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
        if registers<15> == '1' then
            if UnalignedAllowed then
                if address<1:0> == '00' then
                    LoadWritePC(MemU[address,4]);
                else
                    UNPREDICTABLE;
            else
                LoadWritePC(MemA[address,4]);
            if registers<13> == '0' then R[13] = R[13] + 4\BitCount(registers);
            if registers<13> == '1' then R[13] = bits(32) UNKNOWN;
F5.1.139   POP (multiple registers)

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

This instruction is an alias of the LDM, LDMIA, LDMFD instruction. This means that:

- The encodings in this description are named to match the encodings of LDM, LDMIA, LDMFD.

- The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.

**A1**

![A1 encoding](image)

**A1 variant**

`POP{<c>}{<q>} <registers>`

is equivalent to

`LDM{<c>}{<q>} SP!, <registers>`

and is the preferred disassembly when `BitCount(register_list) > 1`.

**T2**

![T2 encoding](image)

**T2 variant**

`POP{<c>}W <registers>` // All registers in R0-R7, PC

is equivalent to

`LDM{<c>}SP!, <registers>`

and is the preferred disassembly when `BitCount(P:M:register_list) > 1`.

**Assembler symbols**

- `<c>`  
  See *Standard assembler syntax fields* on page F1-7228.

- `<q>`  
  See *Standard assembler syntax fields* on page F1-7228.

- `<registers>`  
  For encoding A1: is a list of two or more registers to be loaded, separated by commas and surrounded by `{ and }`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F1-7234.

  If the SP is in the list, the value of the SP after such an instruction is UNKNOWN.
The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

Arm deprecates the use of this instruction with both the LR and the PC in the list.

For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

**Operation for all encodings**

The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.
F5.1.140   POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data.

This instruction is an alias of the LDR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of LDR (immediate).
- The description of LDR (immediate) gives the operational pseudocode for this instruction.

### A1

| 31 28|27 26 25 24|23 22 21 20|19 16|15 12|11 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |

**Post-indexed variant**

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F1-7228.*
- `<q>` See *Standard assembler syntax fields on page F1-7228.*
- `<single_register_list>`
  
  Is the general-purpose register `<Rt>` to be loaded surrounded by `{` and `}`.
- `<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.*
For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.

**Operation for all encodings**

The description of LDR (immediate) gives the operational pseudocode for this instruction.
F5.1.141  PSSBB

Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

PUSH{<c>}{<q>} <registers> // Preferred syntax
STMDB{<c>}{<q>} SP!, <registers> // Alternate syntax

Decode for this encoding

registers = '0':M:'000000':register_list; UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

<>{<q>} See Standard assembler syntax fields on page F1-7228.

<>{<q>} See Standard assembler syntax fields on page F1-7228.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[13] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
MemA[address,4] = bits(32) UNKNOWN;
else
  if UnalignedAllowed then
    MemU[address,4] = R[i];
  else
    MemA[address,4] = R[i];
  address = address + 4;
if registers<15> == '1' then  // Only possible for encoding A1 or A2
  if UnalignedAllowed then
    MemU[address,4] = PCStoreValue();
  else
    MemA[address,4] = PCStoreValue();
F5.1.143  **PUSH (multiple registers)**

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

This instruction is an alias of the STMDB, STMFD instruction. This means that:

- The encodings in this description are named to match the encodings of STMDB, STMFD.
- The description of STMDB, STMFD gives the operational pseudocode for this instruction.

and is the preferred disassembly when BitCount(M:register_list) > 1.

PUSH{<c>}{<q>} <registers>

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(M:register_list) > 1.

**Assembler symbols**

- **<c>**  See *Standard assembler syntax fields* on page F1-7228.
- **<q>**  See *Standard assembler syntax fields* on page F1-7228.
- **<registers>**  For encoding A1: is a list of two or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F1-7234.
The SP and PC can be in the list. However:

- Arm deprecates the use of instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F1-7234.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

**Operation for all encodings**

The description of STMDB, STMFD gives the operational pseudocode for this instruction.
F5.1.144   PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below
the address in SP, and updates SP to point to the start of the stored data

This instruction is an alias of the STR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of STR (immediate).
- The description of STR (immediate) gives the operational pseudocode for this instruction.

Decode for this encoding

d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13

CONSTRUINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: m = UInt(Rn);
- The instruction executes with the additional decode: m = UInt(Rm);
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRUINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols

- See Standard assembler syntax fields on page F1-7228.
<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    for i = 0 to 31
        result<31-i> = R[m]<i>;
    R[d] = result;
```

**Operational information**

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.158  REVSH

Byte-Reverse Signed Halfword reverses the byte order in the lower 16-bit halfword of a 32-bit register, and sign-extends the result to 32 bits.

A1

A1 variant

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

\[
d = \text{UInt}(Rd); \quad m = \text{UInt}(Rm);
\]
\[
\text{if } d == 15 \text{ || } m == 15 \text{ then UNPREDICTABLE;}
\]

T1

T1 variant

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

\[
d = \text{UInt}(Rd); \quad m = \text{UInt}(Rm);
\]

T2

T2 variant

REVSH{<c>}{<q>} <Rd>, <Rm> // <Rd>, <Rm> can be represented in T1

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

\[
d = \text{UInt}(Rd); \quad m = \text{UInt}(Rm); \quad n = \text{UInt}(Rn);
\]
\[
\text{if } m != n \text{ || } d == 15 \text{ || } m == 15 \text{ then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13}
\]

CONSTRAINED UNPREDICTABLE behavior

If \( m != n \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes with the additional decode: m = UInt(Rn);
• The instruction executes with the additional decode: m = UInt(Rm);
• The value in the destination register is UNKNOWN.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1
Architectural Constraints on UNPREDICTABLE Behaviors.

Assembler symbols
<e> See Standard assembler syntax fields on page F1-7228.
<q> See Standard assembler syntax fields on page F1-7228.
<Rd> Is the general-purpose destination register, encoded in the "Rd" field.
<Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be
encoded with an identical value in the "Rn" field.

Operation for all encodings
if ConditionPassed() then
  EncodingSpecificOperations();
  bits(32) result;
  result<31:8> = SignExtend(R[m]<7:0>, 24);
  result<7:0> = R[m]<15:8>;
  R[d] = result;

Operational information
If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source
or destination:
• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.159  **RFE, RFEDA, RFEDB, RFEIA, RFEIB**

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore PSTATE. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See *Illegal return events from AArch32 state* on page G1-8952.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

A1

**T1 variant**

RFEDB{<c>}{<q>} <Rn>{!} // Outside or last in IT block, preferred syntax  
RFEFA{<c>}{<q>} <Rn>{!} // Outside or last in IT block, alternate syntax, Full Ascending stack

**Decode for this encoding**

```plaintext
n = UInt(Rn);  wback = (W == '1');  increment = FALSE;  wordhigher = FALSE;  
if n == 15 then UNPREDICTABLE;  
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

**T2**

```
|15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  0|15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
| 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | W | 1 | Rn | (1)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0)| (0) |
```

**T2 variant**

RFE{IA}{<c>}{<q>} <Rn>{!} // Outside or last in IT block, preferred syntax  
RFEFD{<c>}{<q>} <Rn>{!} // Outside or last in IT block, alternate syntax, Full Descending stack

**Decode for this encoding**

```plaintext
n = UInt(Rn);  wback = (W == '1');  increment = TRUE;  wordhigher = FALSE;  
if n == 15 then UNPREDICTABLE;  
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

**Notes for all encodings**

For more information about the **CONstrained UNPREDICTABLE** behavior of this instruction, see Appendix K1, *Architectural Constraints on UNPREDICTABLE Behaviors*.

**Assembler symbols**

IA  
For encoding A1: is an optional suffix to indicate the Increment After variant.  
For encoding T2: is an optional suffix for the Increment After form.

{<c>}  
For encoding A1: see *Standard assembler syntax fields* on page F1-7228.  
{<c>} must be AL or omitted.  
For encoding T1 and T2: see *Standard assembler syntax fields* on page F1-7228.

{<q>}  
See *Standard assembler syntax fields* on page F1-7228.

{<Rn>}  
Is the general-purpose base register, encoded in the "Rn" field.

!  
The address adjusted by the size of the data loaded is written back to the base register.  
If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

RFEFA, RFEEA, RFEDD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

**Operation for all encodings**

```plaintext
if ConditionPassed() then  
    EncodingSpecificOperations();  
    if PSTATE.EL == EL2 then  
        UNDEFINED;  
    elsif PSTATE.EL == EL0 then  
        UNPREDICTABLE;  // UNDEFINED or NOP
```
else
    address = if increment then $R[n]$ else $R[n]$-8;
    if wordhigher then address = address+4;
    new_pc_value = MemA[address,4];
    spsr = MemA[address+4,4];
    if wback then $R[n]$ = if increment then $R[n]$+8 else $R[n]$-8;
    AArch32.ExceptionReturn(new_pc_value, spsr);

CONSTRAINED UNPREDICTABLE behavior

If $PSTATE_EL == EL0$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
F5.1.160  ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**A1**

```
MOV, shift or rotate by value variant

ROR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>
```

and is always the preferred disassembly.

**T3**

```
MOV, shift or rotate by value variant

Apply when !(imm3 == 000 && imm2 == 00).

ROR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>
```

and is always the preferred disassembly.

**Assembler symbols**

- `<>`  See Standard assembler syntax fields on page F1-7228.
- `<q>`  See Standard assembler syntax fields on page F1-7228.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133. For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T3: is the general-purpose source register, encoded in the "Rm" field.
For encoding A1: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.
For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
F5.1.161  ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

A1

ROR<>{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOV<>{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

T1

ROR<>{<c>}{<q>} {<Rdm>,} <Rdm>, <Rs>

is equivalent to

MOV<>{<c>}{<q>} <Rdm>, <Rdm>, ROR <Rs>

and is the preferred disassembly when InITBlock().

T2

Not flag setting variant

ROR<>{<c>}{<q>} W {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1

is equivalent to

MOV<>{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

Not flag setting variant

ROR<>{<c>}{<q>} {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1

is equivalent to

MOV<>{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>
and is always the preferred disassembly.

\[ \text{ROR} \{<c>\} \{<q>\} \{<Rd>,\} \ <Rm>, \ <Rs> \]

is equivalent to

\[ \text{MOV} \{<c>\} \{<q>\} \ <Rd>, \ <Rm>, \ \text{ROR} \ <Rs> \]

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F1-7228.
- `<q>` See *Standard assembler syntax fields* on page F1-7228.
- `<Rdm>` Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>` Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>` Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.162   RORS (immediate)

Rotate Right, setting flags (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

and is always the preferred disassembly.

RORS{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F1-7228*.
- `<q>` See *Standard assembler syntax fields on page F1-7228*.
- `<Rdm>` Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>` Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>` Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.164 RRX

Rotate Right with Extend provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**MOV, rotate right with extend variant**

RRX{<c>}{<q>} {<Rd>,} <Rm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, RRX

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F1-7228*.
- `<q>` See *Standard assembler syntax fields on page F1-7228*.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
  For encoding T3: is the general-purpose destination register, encoded in the "Rm" field.
- `<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
  For encoding T3: is the general-purpose source register, encoded in the "Rm" field.
**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
### F5.1.165 RRXS

Rotate Right with Extend, setting flags provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

If the destination register is not the PC, this instruction updates the condition flags based on the result, and bit[0] is shifted into the Carry flag.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

### MOVES, rotate right with extend variant

RRXS{<c>}{<q>}{<Rd>,}<Rm>

is equivalent to

MOVS{<c>}{<q>}{<Rd>,}<Rm>, RRX

and is always the preferred disassembly.

### Assembler symbols

<

See Standard assembler syntax fields on page F1-7228.
See *Standard assembler syntax fields* on page F1-7228.

<\texttt{Rd}>

For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores \texttt{PSTATE} from \texttt{SPSR_{<current\_mode>}}.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

<\texttt{Rm}>

For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

**Operation for all encodings**

The description of \texttt{MOV, MOVS (register)} gives the operational pseudocode for this instruction.
F5.1.166 RSB, RSBS (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_{current_mode}.
  - The PE checks SPSR_{current_mode} for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

**RSBS variant**

Applies when \( S = 1 \).

\[
\text{RSBS}\{<c>\}{<q>} \{<Rd>,\} <Rn>, #<const>
\]

**Decode for all variants of this encoding**

\[
d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ \text{setflags} = (S == '1'); \ \text{imm32} = \text{T32ExpandImm}(i;imm3;imm8);
\]

if \( d == 15 \) || \( n == 15 \) then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F1-7228.
- `<q>` See Standard assembler syntax fields on page F1-7228.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:
  - For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
  - For the RSBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
- `<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
- `<const>` For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F1-7244 for the range of values.

For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F1-7242 for the range of values.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    \( (\text{result}, \text{ncsv}) = \text{AddWithCarry}(\text{NOT}(R[n]), \text{imm32}, '1'); \)
    if \( d == 15 \) then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        \( R[d] = \text{result}; \)
        if setflags then
            PSTATE.<N,Z,C,V> = ncsv;

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
F5.1.167 RSB, RSBS (register)

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-7133.
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-8952.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

RSB, rotate right with extend variant

Applies when S == 0 && imm5 == 00000 && stype == 11.

RSB{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX

RSB, shift or rotate by value variant

Applies when S == 0 && !(imm5 == 00000 && stype == 11).

RSB{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

RSBS, rotate right with extend variant

Applies when S == 1 && imm5 == 00000 && stype == 11.

RSBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX

RSBS, shift or rotate by value variant

Applies when S == 1 && !(imm5 == 00000 && stype == 11).

RSBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

\[ d = \text{UInt}(Rd); \] \[ n = \text{UInt}(Rn); \] \[ m = \text{UInt}(Rm); \] \[ \text{setflags} = (S == '1'); \] \[ (\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{stype}, \text{imm5}); \]
