D5.3.8  Transaction Start Packet

**Purpose**
Indicates that the PE has started to execute in Transactional state.

**Configurations**
All.

**Packet Layout**

```
  7  6  5  4  3  2  1  0
  0  0  0  1  0  1  0
```

**Figure D5-16 Transaction Start Packet**

**Element sequence**
This packet encodes the following sequence:

**Additional information**
For more information about the decoding of this packet see `TransactionStartPacket()` on page K4-11635.
D5.3.9 Transaction Commit Packet

Purpose
Indicates that the PE has successfully finished an outer transaction and is leaving Transactional state.

Configurations
All.

Packet Layout

0 0 0 0 1 0 1 1

Figure D5-17 Transaction Commit Packet

Element sequence
This packet encodes the following sequence:
1. Transaction Commit element.

Additional information
For more information about the decoding of this packet see TransactionCommitPacket() on page K4-11635.
D5.3.10 Exception Exact Match Address Packet

Purpose
Indicates that an exception has occurred.

Configurations
All.

Packet Layout

Field descriptions

A

Preferred Exception Return address.
Preferred Exception Return address bits[1:0] always have the value 0b00. The address is compressed relative to address history buffer entry 0. The encoding for this field is Bit replacement.

**CONTEXTID**

Context identifier.

When this field is not output, the Context identifier is the same as the most recently output Context identifier.

If Context identifier tracing is disabled, then one of the following must occur:

- This field is not traced.
- This field contains a value of zero.

The encoding for this field is POD.

See *Context identifier tracing on page D4-4835.*

**E**

Identifies the elements that are indicated by this packet.

The encoding for this field is POD.

<table>
<thead>
<tr>

COMMIT
If this field is zero, there is no Commit element. Otherwise, there is a Commit element before the Cycle Count element and this field indicates the number of P0 elements committed by the Commit element.
The encoding for this field is unsigned LE128n.

Element sequence
This packet encodes the following sequence:
1. Commit element.

Additional information
For more information about the decoding of this packet see CycleCountFormat1Packet() on page K4-11636.
D5.3.24 Cycle Count Format 1_1 unknown count Packet

Purpose

Indicates a Cycle Count element.

Configurations

All the following conditions must be met:

- TRCIDR0.COMMOPT == 0b1.
- TRCIDR0.TRCCCI == 0b1.

Packet Layout

![Figure D5-44 Cycle Count Format 1_1 unknown count Packet](image)

Element sequence

This packet encodes the following sequence:

Additional information

For more information about the decoding of this packet see CycleCountFormat1Packet() on page K4-11636.
D5.3.25   Cycle Count Format 1_0 with count Packet

Purpose
Indicates zero or one Commit elements followed by a Cycle Count element.

Configurations
All the following conditions must be met:
- TRCIDR0.COMMOPT == 0b0.
- TRCIDR0.TRCCCI == 0b1.

Packet Layout

Figure D5-45 Cycle Count Format 1_0 with count Packet

Field descriptions

C0
Continuation Bit.
The encoding for this field is Unary code.

C1
Continuation Bit.
The encoding for this field is Unary code.

COMMIT
If this field is zero, there is no Commit element. Otherwise, there is a Commit element before the Cycle Count element and this field indicates the number of P0 elements committed by the Commit element.
The encoding for this field is unsigned LE128n.
COUNT

Indicates the number of PE clock cycles that have occurred between the 2 most recent Commit elements that both had a Cycle Count element associated with them. The cycle count is COUNT+cc_threshold.
The encoding for this field is unsigned LE128n.

Element sequence

This packet encodes the following sequence:

1. Commit element.
2. Cycle Count element.

Additional information

For more information about the decoding of this packet see CycleCountFormat1Packet() on page K4-11636.
D5.3.26 Cycle Count Format 1_1 with count Packet

Purpose
Indicates a Cycle Count element.

Configurations
All the following conditions must be met:
• TRCIDR0.COMMOPT == 0b1.
• TRCIDR0.TRCCCI == 0b1.

Packet Layout

<table>
<thead>

Figure D5-46 Cycle Count Format 1_1 with count Packet

Field descriptions

C0
Continuation Bit.
The encoding for this field is Unary code.

| 0b0 | Last byte in this section. |
| 0b1 | At least one more byte follows in this section. |

COUNT
Indicates the number of PE clock cycles that have occurred between the 2 most recent Commit elements that both had a Cycle Count element associated with them. The cycle count is COUNT+cc_threshold.
The encoding for this field is unsigned LE128n.

Element sequence
This packet encodes the following sequence:

Additional information
For more information about the decoding of this packet see CycleCountFormat1Packet() on page K4-11636.
D5.3.27  Cycle Count Format 2_0 small commit Packet

Purpose

Indicates a Commit element and a Cycle Count element.

Configurations

All the following conditions must be met:
- TRCIDR0.COMMOPT == 0b0.
- TRCIDR0.TRCCCI == 0b1.

Packet Layout

```
0 0 0 0 1 1 0 0

|AAAA|BBBB|
```

Figure D5-47 Cycle Count Format 2_0 small commit Packet

Field descriptions

AAAA

Indicates the number of P0 elements to be resolved indicated by this field + 1.
The encoding for this field is POD.

BBBB

Indicates the cycle value. The cycle count is calculated from \(cc\_threshold + BBBB\).
The encoding for this field is POD.

Element sequence

This packet encodes the following sequence:

1. Commit element.
2. Cycle Count element.

Additional information

For more information about the decoding of this packet see `CycleCountFormat2Packet()` on page K4-11637.
D5.3.28 Cycle Count Format 2_0 large commit Packet

Purpose
Indicates a Commit element and a Cycle Count element.

Configurations
All the following conditions must be met:
- TRCIDR0.COMMOPT == 0b0.
- TRCIDR0.TRCCCI == 0b1.

Packet Layout

<table>
<thead>
<tr>

AAAA
Indicates the number of P0 elements to be resolved indicated by TRCIDR8.MAXSPEC + field - 15.
The number of P0 elements to be resolved must be greater than 0.
If the number of P0 elements to be resolved is less than 17 then it is preferred that a Cycle Count Format 2_0 small commit Packet is used.
The encoding for this field is POD.

BBBB
Indicates the cycle value. The cycle count is calculated from cc_threshold + BBBB.
The encoding for this field is POD.

Element sequence
This packet encodes the following sequence:
1. Commit element.
2. Cycle Count element.

Additional information
For more information about the decoding of this packet see CycleCountFormat2Packet() on page K4-11637.
D5.3.29 Cycle Count Format 2_1 Packet

Purpose
Indicates a Cycle Count element.

Configurations
All the following conditions must be met:
• TRCIDR0.COMMOPT == 0b1.
• TRCIDR0.TRCCCI == 0b1.

Packet Layout

7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
0 & 0 & 0 & 1 & AA & BB \\
\end{array}
\]

Figure D5-50 Cycle Count Format 3_0 Packet

Field descriptions

AA
The number of P0 elements to be resolved indicated by this field + 1.
The encoding for this field is POD.

BB
Indicates the cycle value. The cycle count is calculated from cc_threshold + BB.
The encoding for this field is POD.

Element sequence
This packet encodes the following sequence:
1. Commit element.
2. Cycle Count element.

Additional information
For more information about the decoding of this packet see CycleCountFormat3Packet() on page K4-11637.
### D5.3.31 Cycle Count Format 3_1 Packet

#### Purpose
Indicates a *Cycle Count element.*

#### Configurations
All the following conditions must be met:
- TRCIDR0.COMMOPT == 0b1.
- TRCIDR0.TRCCCI == 0b1.

#### Packet Layout

![Figure D5-51 Cycle Count Format 3_1 Packet](image)

#### Field descriptions
**BB**
Indicates the cycle value. The cycle count is calculated from cc_threshold + BB.
The encoding for this field is POD.

#### Element sequence
This packet encodes the following sequence:
1. *Cycle Count element.*

#### Additional information
For more information about the decoding of this packet see `CycleCountFormat3Packet()` on page K4-11637.
D5.3.32 Commit Packet

Purpose
Indicates a Commit element.

Configurations
TRCIDR8.MAXSPEC > 0.

Packet Layout

VMID
Virtual context identifier. When this field is not output, the Virtual context identifier is the same as the most recently output Virtual context identifier.
If Virtual context identifier tracing is disabled, then one of the following must occur:

- This field is not traced.
- This field contains a value of zero.

The encoding for this field is POD.

See Virtual context identifier tracing on page D4-4837.

**Element sequence**

This packet encodes the following sequence:

1. Target Address element.
2. Context element.

**Additional information**

For more information about the decoding of this packet see Parse_TargetAddressPacket() on page K4-11631.

For more information about the generation of this packet see Address compression on page D4-4839.

For more information about the encoding of this packet see Instruction set encoding on page D5-4874.
D5.3.56 Target Address with Context 64-bit IS1 Packet

Purpose

Indicates a Target Address element and a Context element.

Configurations

All.

ETE Protocol Descriptions
D5.3 Alphabetical list of ETE packets
Chapter D6
The Trace Buffer Extension

This chapter describes the Trace Buffer Extension (TRBE). It contains the following sections:

- About the Trace Buffer Extension on page D6-5004.
- The trace buffer on page D6-5006.
- Trace buffer management on page D6-5018.
- Synchronization and the Trace Buffer Unit on page D6-5026.
- Trace synchronization and memory barriers on page D6-5031.
- Trace of Speculative execution on page D6-5032.
- Trace in Debug state on page D6-5033.
- Detailed synchronization litmus tests on page D6-5034.
- UNPREDICTABLE behavior on page D6-5038.
D6.1 About the Trace Buffer Extension

The Trace Buffer Extension feature is identified as FEAT_TRBE.

When FEAT_TRBE is implemented, the PE includes a Trace Buffer Unit. There is one logical Trace Buffer Unit for each PE in the processor.

When the Trace Buffer Unit is enabled, Program Flow Trace generated by the trace unit is written directly to memory by the Trace Buffer Unit, rather than routing it to a trace fabric. Figure D6-1 shows this.

![Figure D6-1 Logical organization of an Armv9-A PE including a trace unit and a Trace Buffer Unit](image)

In this figure:

- **EIS** is an internal representation of the executed instruction stream.
- The trace unit converts the EIS into formatted trace data.
- **Sink** is described by the section Trace Buffer Unit disabled on page D6-5013.

To allow use by self-hosted software in a platform OS environment, a Trace Buffer Unit or ETR must support a trace buffer that is mapped to a set of non-contiguous physical blocks in memory. The Trace Buffer Unit achieves this by using the PE VMSA-based MMU.

This means that all of the following apply:

- The trace buffer is normally virtually addressed.
- The trace buffer has an owning Exception level and owning Security state that define the translation regime the trace buffer uses.
- FEAT_TRBE provides a synchronization instruction, TSB CSYNC, that is used with a DSB operation to flush trace to the trace buffer.
- For FEAT_TRBE, trace is implicitly prohibited when the owning translation regime is not in context. That is, trace is prohibited if executing at a higher Exception level than the owning Exception level, or not executing in the owning Security state. This is in addition to the behavior in FEAT_ETE and FEAT_TRF for when trace is prohibited.

FEAT_TRBE also allows the trace buffer to be defined using physical addresses. This allows the Trace Buffer Unit to be used for debugging software that changes the virtual address mappings. In this configuration, the buffer must be contiguously mapped in physical memory.
The extent of the trace buffer is defined by a Base pointer and a Limit pointer. The Base pointer and Limit pointer are aligned to the smallest implemented translation granule, meaning that a buffer must be at least one full virtual page.

The Trace Buffer Unit supports the following operational modes:

**Trace buffer mode**
Controls how the Trace Buffer Unit uses the trace buffer.

**Trigger mode**
Controls how the Trace Buffer Unit reacts to a trigger condition signaled by the trace unit.

### D6.1 System events

The trace unit can be configured to react to PE events and events from the CTI. The CTI is for use by external debuggers.

As part of FEAT_TRBE and FEAT_ETE, the PMU and FEAT_ETE event sources are unified into a single event number space. Unless otherwise stated, all architecturally defined common events that can be counted by the PMU are usable as an event at the trace unit.

The following additional architecturally-defined events are provided:

- The CTI_TRIGOUT<\(n\)> events are defined to map the system events from the CTI into the PMU event number space. As well as defining these events for the trace unit, this also provides a standard mechanism for counting *external events passed to the PE*.
- The TRCEXTOUT<\(n\)> events are defined to allow the PMU to count the events that a FEAT_ETE implementation of the trace unit might generate.
- The PMU_OVFS and PMU_HOVFS events are defined to allow the trace unit to trigger directly from a PMU overflow without using the Performance Monitors overflow trigger for PMU counters accessible to EL1 and EL0, and EL2, respectively.
- The TRB_WRAP event is defined to allow the trace unit to trigger when the current write pointer reaches the end of the trace buffer and is wrapped.

### D6.1.2 Interrupts

An interrupt request is raised on a buffer management event, such as an abort or the trace buffer filling. This is the trace buffer management interrupt.

The interrupt request is passed to an interrupt controller, such as a GIC.

Arm recommends this is a PPI.

### D6.1.3 Specification

Other than where stated otherwise, this chapter describes a simple sequential model of the Trace Buffer Unit. That is, one which performs the simple loop of:

1. Collect a single byte of trace data from the trace unit.
2. If required, translate the current write pointer virtual address to a physical address.
3. If permitted, write the byte of trace data to the write address.
4. If collection is not stopped, increment the current write pointer.
5. If necessary, decrement the Trigger Counter.

Trace buffer management events are processed as part of this operation loop. Implementations conform with the architecture conform with the described behavior of the Trace Buffer Unit. Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with this specification is the same as a simple sequential model. Trace appears to be written sequentially by the Trace Buffer Unit.
D6.2 The trace buffer

**R**YCHKJ If and only if all of the following are true, then the Trace Buffer Unit is enabled:

- `SelfHostedTraceEnabled()` is TRUE.
- `TRBLIMITR_EL1.E` is 1.

The pseudocode function `TraceBufferEnabled` shows this.

**R**JYXPM If the Trace Buffer Unit is not enabled, then the Trace Buffer Unit is disabled. See *Trace Buffer Unit disabled* on page D6-5013.

The pseudocode function `TraceBufferEnabled` shows this.

**I**SMTV `SelfHostedTraceEnabled()` is defined by `FEAT_TRF`.

**R**BGLHT If and only if all of the following are true, then the Trace Buffer Unit is *running*:

- The Trace Buffer Unit is enabled.
- `TRBSR_EL1.S` is 0.

The pseudocode function `TraceBufferRunning` shows this.

**R**FRHIXV If and only if all of the following are true, then *collection is stopped*:

- The Trace Buffer Unit is enabled.
- `TRBSR_EL1.S` is 1.

The pseudocode function `TraceBufferRunning` shows this.

**I**YSQZ While the Trace Buffer Unit is enabled, it collects trace data from the trace unit and does one of the following:

- *Accepts* the trace data and writes it to the trace buffer in memory.
- *Discards* the trace data. The trace data is lost.
- *Rejects* the trace data.

**R**YMYYQX When the Trace Buffer Unit is enabled and *running*, and the Trace Buffer Unit is able to accept the trace data, the Trace Buffer Unit *accepts* the trace data from the trace unit and writes it into the trace buffer.

**R**LNTVR When the Trace Buffer Unit is enabled and *running*, and the Trace Buffer Unit is not able to accept the trace data, the Trace Buffer Unit *rejects* the trace data from the trace unit. The trace data might be retained by the trace unit until the Trace Buffer Unit *accepts* the trace data.

**I**SQYCT For example, the Trace Buffer Unit might not be able to accept trace data while its internal buffers are full.

**I**TRCDR If the Trace Buffer Unit *rejects* trace data and the trace unit is not able to retain the trace data, then the trace unit discards it and enters an *Overflow* state. Details of *Overflow* state and how the trace unit recovers from *Overflow* state are defined by the trace unit. See *Trace unit behavior on a trace unit buffer overflow* on page D4-4804.

**R**YMVZL When the Trace Buffer Unit is enabled and *collection is stopped*, the Trace Buffer Unit *discards* trace data from the trace unit. The trace data is lost.

**R**PHSKP When used with a trace unit that implements `FEAT_ETE`, the Trace Buffer Unit ignores the value of the ETE `TRCTRACEIDR` register.

### D6.2.1 The trace buffer pointers

**R**WKBRT The trace buffer is defined by three trace buffer pointer addresses:

- The Base pointer.
- The Limit pointer.
- The current write pointer.

**R**FVPBS The trace buffer starts at the Base pointer and extends to the Limit pointer. The location at the Base pointer is included in the trace buffer. The location at the Limit pointer is not included in the trace buffer.
The Base pointer and Limit pointer must be aligned by software to the smallest implemented translation granule size.

For each byte of trace that the Trace Buffer Unit accepts and writes to the trace buffer at the address in the current write pointer, one of the following applies:

- If the current write pointer is not equal to the Limit pointer minus one, then the current write pointer is incremented by one.
- If the current write pointer is equal to the Limit pointer minus one, then all of the following occur:
  - The current write pointer is wrapped by setting it to the Base pointer.
  - TRBSR_EL1.WRAP is set to 1.
  - The TRB_WRAP event is generated.

The current write pointer is not incremented when collection is stopped.

The required alignment of the current write pointer is IMPLEMENTATION DEFINED.

The Trace Buffer Unit can write trace data to memory in quantized units. The behavior is as if the bytes are written sequentially.

The Base pointer is (TRBBASER_EL1.BASE << 12). Bits [11:0] of the Base pointer are zero.

The Limit pointer is (TRBLIMITR_EL1.LIMIT << 12). Bits [11:0] of the Limit pointer are zero.

The current write pointer is TRBPTR_EL1.PTR[63:0].

The Trigger Counter is TRBTRG_EL1.TRG.

### D6.2.2 Behavior when address translation enabled

If TRBLIMITR_EL1.nVM is 0, then the Base pointer, Limit pointer, and current write pointer are virtual addresses in the stage 1 translation regime of the owning translation regime.

If TRBLIMITR_EL1.nVM is 0, then the stage 1 translation process for translating virtual addresses and checking for MMU faults is identical to that for any other virtual address in the owning translation regime.

If TRBLIMITR_EL1.nVM is 0, then CMDTG means all of the following apply:

- The virtual addresses are translated to stage 1 output addresses by stage 1 translation, and checked for stage 1 MMU faults. The stage 1 output addresses are:
  - Physical address in the owning Security state if the owning translation regime has no stage 2 translation.
  - Intermediate physical addresses (IPAs) in the owning Security state if the owning translation regime has stage 2 translations.
- If stage 1 translation is enabled for the owning translation regime, the memory type and, as applicable, Cacheability, Shareability, and Device type attributes, for stage 1 output addresses are defined by the translation table entries for the virtual address being written to.
- If stage 1 translation is disabled for the owning translation regime, the memory type of the stage 1 output addresses is Device-nGnRnE, unless overridden by stage 2 controls.
- If SCTLR_ELx.C is 0 for the owning translation regime and stage 1 translation is enabled, then all accesses to Normal memory are Non-cacheable.
- TRBPTR_EL1[63:56] are ignored by address translation if the respective TBI bit is 1.

When the Trace Buffer Unit is enabled, the Trace Buffer Unit might prefetch and cache address translations for the translation regime of the owning Exception level, including when the owning Exception level is out-of-context.

RSIFRO means that, when the Trace Buffer Unit is enabled and the owning Exception level is a lower Exception level, then the Trace Buffer Unit might make memory accesses to translation table entries from the translation regime of the owning Exception level, using the settings of the System registers associated with that translation regime.
If the PE is not executing in the owning Security state, or the PE is executing at EL3 and SCR_EL3.NS does not indicate the owning Security state, then the translation regime of the owning Exception level might not be the owning translation regime.

These memory accesses might be observed by other observers, to the extent that those accesses are required to be observed as determined by the Shareability and Cacheability of those translation table entries.

This is an exception to the rules in the section Speculative memory accesses from out-of-context translation regimes on page D8-5087.

See also Context switching on page K4-11673.

D6.2.3 Behavior when address translation disabled

If TRBLIMITR_EL1.nVM is 1, the Base pointer, Limit pointer, and current write pointer are:

- Physical address in the owning Security state if the owning translation regime has no stage 2 translation.
- Intermediate physical addresses (IPAs) in the owning Security state if the owning translation regime has stage 2 translations.

These addresses are output directly by stage 1 without any address translation.

If TRBLIMITR_EL1.nVM is 1, then unless overridden by stage 2 controls, TRBMAR_EL1 defines the memory type, and, as applicable, Cacheability, Shareability, and Device type attributes, for the stage 1 output addresses.

If TRBLIMITR_EL1.nVM is 1, the values of SCTLR_ELx.{C, M} for the owning translation regime are ignored for the purposes of determining the trace buffer Cacheability attributes.

If TRBLIMITR_EL1.nVM is 1 it is possible to generate mismatched attributes for a location from within the same stage 1 translation regime, using TRBMAR_EL1.

Software must be aware of the consequences of and permitted behaviors when accessing a memory location with mismatched attributes. For more information, including a full definition of mismatched attributes and the permitted behaviors, see Mismatched memory attributes on page B2-208.

If TRBLIMITR_EL1.nVM is 1 and TRBPTR_EL1[top:PAmax()] is nonzero, a stage 1 Address Size fault is generated when the Trace Buffer Unit attempts to write to memory, and:

- If FEAT_LPA is implemented, top is 51.
- If FEAT_LPA is not implemented, top is 47.

If TRBLIMITR_EL1.nVM is 1 and TRBPTR_EL1[63:(top+1)] is nonzero when the Trace Buffer Unit attempts to write to the trace buffer, then one of the following occurs, and it is CONSTRAINED UNPREDICTABLE which:

- A stage 1 Address Size fault is generated.
- TRBPTR_EL1[63:(top+1)] are ignored and treated as zero.

The value of top is as defined by RMXRFD.

D6.2.4 Effect of stage 2 translation

If the owning translation regime has stage 2 translations, the stage 2 process of translating the stage 1 output intermediate physical addresses and attributes to a physical address and attributes, and checking for MMU faults, is identical to that for any other intermediate physical address generated by the owning translation regime.

For example:

- The intermediate physical addresses are translated to physical addresses by stage 2 translation, and checked for stage 2 MMU faults.
- The attributes from stage 1 are combined with the attributes from the stage 2 translation to generate the physical memory attributes.
- If the Effective value of HCR_EL2.DC in the owning translation regime is 1, then stage 1 translation is disabled and the memory type produced by stage 1 is Normal Non-shareable, Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate, regardless of the values of SCTLR_EL1.C and TRBMAR_EL1.
If the Effective value of HCR_EL2.MIOCNCE in the owning translation regime is 0, then for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there is no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

### D6.2.5 Accesses to the trace buffer

**RJTVD**

Writes to the trace buffer by the Trace Buffer Unit are privileged writes within the owning translation regime.

**ITTKZQ**

For accesses made by the Trace Buffer Unit, the memory type and, as applicable, Cacheability, Shareability, and Device type attributes are determined by the translation tables or TRBMAP_EL1.

See:
- \( R_{CMDTG} \) and \( R_{GBKYK} \), if translation is enabled.
- \( R_{FKLW} \), if translation is disabled.
- \( R_{JCMKS} \) and \( R_{IZSME} \), if the owning translation regime has stage 2 translations.

**RFBKCC**

Address translations performed by the Trace Buffer Unit manage dirty state and the Access flag. This is discoverable by software from TRBIDR_EL1.F.

**RSFLWLS**

If all of the following apply, the Trace Buffer Unit can speculatively update the translation table descriptor for any Page or Block in the trace buffer before writing data to it:
- Hardware management of dirty state by the Trace Buffer Unit is implemented.
- Hardware management of dirty state is enabled for the owning translation regime.
- The write is otherwise permitted.

This includes the case where a trace buffer management event means the Trace Buffer Unit stops writing data before the Page or Block is written to.

**RBWNRF**

The access granule for writes to the trace buffer by the Trace Buffer Unit is IMPLEMENTATION DEFINED, up to a maximum of 2KB, and might vary from time to time.

**RCMNS**

Writes to any Device memory type by the Trace Buffer Unit occur once.

**RRZTDD**

A memory access from the Trace Buffer Unit that crosses a Page or Block boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:
- Each memory access generated by the Trace Buffer Unit uses the memory type and Shareability attribute associated with its own address.
- The access generates an Alignment fault caused by the memory type:
  - If only the stage 1 translation generated the mismatch, or there is only one stage of translation in the owning translation regime, the resulting trace buffer management event is a stage 1 Data Abort.
  - If only the stage 2 translation generated the mismatch, the resulting trace buffer management event is a stage 2 Data Abort.
  - If both stages of translation generate the mismatch, the resulting trace buffer management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- The trace data is discarded and the current write pointer might not be updated.

**RXRQTN**

A memory access from the Trace Buffer Unit to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:
- Each memory accesses generated by the Trace Buffer Unit is performed as if the boundary has no effect on the memory accesses.
- Each memory accesses generated by the Trace Buffer Unit is performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between it and other memory accesses.
• The access generates an Alignment fault caused by the memory type:
  — If only the stage 1 translation causes the boundary to be crossed, or there is only one stage of
    translation in the owning translation regime, the resulting trace buffer management event is a stage 1
    Data Abort.
  — If only the stage 2 translation causes the boundary to be crossed, the resulting trace buffer management
    event is a stage 2 Data Abort.
  — If both stages of translation cause the boundary to be crossed, the resulting trace buffer management
    event is either a stage 1 Data Abort or a stage 2 Data Abort.
• The trace data is discarded and the current write pointer might not be updated.

Note: The boundary is between two Device memory regions that are both:
• Of the size of the smallest implemented translation granule.
• Aligned to the size of the smallest implemented translation granule.

Although the Trace Buffer Unit behaves as if trace data is written a byte at a time, it is not required to do so.
For example, RWNRF and CMSNE mean that if the memory type for the trace buffer is Device-nGnRnE, then all
of the following apply:
• Writes are not repeated and not reordered.
• A write Completes only after it reaches its endpoint in the memory system.
• The access granule size at the endpoint in the memory system is not defined by the architecture. However, a
  specific implementation might define the granule to permit interoperability with specific devices.
The access granule is not required to be fixed. For example, the Trace Buffer Unit might output a smaller granule
when flushing trace data to the trace buffer.
See also IQQKZF.

D6.2.6 The owning translation regime

The owning translation regime is defined by the owning Security state and the owning Exception level.

When the Trace Buffer Unit is enabled, the owning Security state is:
• Non-secure state if and only if at least one of the following is true:
  — EL3 is not implemented and the PE executes in Non-secure state.
  — MDCR_EL3.NSTB is either 0b10 or 0b11.
• Secure state if and only if at least one of the following is true:
  — EL3 is not implemented and the PE executes in Secure state.
  — MDCR_EL3.NSTB is either 0b00 or 0b01.

When the Trace Buffer Unit is enabled, the owning Exception level is:
• EL1 if and only if at least one of the following is true:
  — EL2 is not implemented in the owning Security state.
  — EL2 is disabled in the owning Security state.
  — MDCR_EL2.E2TB is either 0b10 or 0b11.
• EL2 if and only if all of the following is true:
  — EL2 is implemented and enabled in the owning Security state.
  — MDCR_EL2.E2TB is 0b00.

When the Trace Buffer Unit is enabled and the owning Exception level is EL1, all of the following apply:
• The owning translation regime is EL1&0.
• If TRBLIMITR_EL1.nVM is 0, the trace buffer pointer addresses are virtual addresses in the EL1&0
  translation regime using the current ASID from TTBRx_EL1.
• If TRBLIMITR_EL1.nVM is 1, the trace buffer pointer addresses are intermediate physical addresses.
• Intermediate physical addresses (whether from the output of stage 1, or the pointers, as applicable) are subject to stage 2 translation using the current VMID if EL2 is implemented and enabled and HCR_EL2.VM is 1.

• The following are prohibited trace regions:
  — EL3.
  — EL2.
  — EL0, if EL2 is implemented and enabled and HCR_EL2.TGE is 1.

When the Trace Buffer Unit is enabled and the owning Exception level is EL2, all of the following apply:

• If HCR_EL2.E2H is 0, the owning translation regime is EL2.
• If HCR_EL2.E2H is 1, the owning translation regime is EL2&0.
• If HCR_EL2.E2H is 0 and TRBLIMITR_EL1.nVM is 0, the trace buffer pointer addresses are virtual addresses in the EL2 translation regime.
• If HCR_EL2.E2H is 1 and TRBLIMITR_EL1.nVM is 0, the trace buffer pointer addresses are virtual addresses in the EL2&0 translation regime using the current ASID from TTBRx_EL2.
• If TRBLIMITR_EL1.nVM is 1, the trace buffer pointer addresses are physical addresses.
• EL3 is a prohibited trace region.

The following table summarizes the owning translation regime.

<table>
<thead>
<tr>
<th>Enabled</th>
<th>NSTB</th>
<th>E2TB</th>
<th>EEL2</th>
<th>E2H</th>
<th>Owning translation regime</th>
</tr>
</thead>
<tbody>
<tr>

<td>0b1</td>
<td>Non-secure EL2&amp;0</td>
</tr>
<tr>
<td>TRUE</td>
<td>0b1x</td>
<td>0b1x</td>
<td>x</td>
<td>x</td>
<td>Non-secure EL1&amp;0</td>
</tr>
</tbody>
</table>

When any of the following is true, then the translation of addresses generated by the Trace Buffer Unit is CONstrained UNPREDICTABLE:

• The owning Security state is Secure and SCR_EL3.NS is 1.
• The owning Security state is Non-secure and SCR_EL3.NS is 0.
The PE behaves as if one of the following is true for these translations:

- The owning Security state is Secure and SCR_EL3.NS is 0.
- The owning Security state is Non-secure and SCR_EL3.NS is 1.

Note: The behavior might differ within the same translation.

Secure and Non-secure translation regimes have different behaviors. Non-secure translation regimes only operate on Non-secure addresses, but a Secure stage 1 translation regime can generate both Secure and Non-secure output addresses and a Secure stage 2 translation regime can have both Secure and Non-secure input and output addresses. In addition, stage 2 translation is disabled when EL2 is disabled in the current Security state.

RRRCNN means that if software executing at EL3 changes the value of SCR_EL3.NS before ensuring all trace operations are complete, this might cause CONSTRAINED UNPREDICTABLE behaviors, including any of the following:

- The owning Security state is Non-secure but the PE can generate Secure output addresses at both stage 1 and, if applicable, stage 2.
- The owning Security state is Non-secure EL1&0 but the PE behaves as if stage 2 is disabled because, in this example, Secure EL2 is disabled.
- The owning Security state is Secure but the PE treats Secure output addresses as Non-secure addresses at both stage 1 and, if applicable, stage 2.
- The owning Security state is Secure EL1&0 but the PE behaves as if stage 2 is enabled even if Secure EL2 is disabled.

See also RNSFRO and RMRVFT.

RMFFGX means that when the Trace Buffer Unit is enabled and the owning Security state is Non-secure state, Secure state is a prohibited trace region.

RVGWJN means that when the Trace Buffer Unit is enabled and the owning Security state is Secure state, Non-secure state is a prohibited trace region.

The following table summarizes the Trace Prohibited regions, by Exception level and state, when all of the following apply:

- TraceBufferEnabled() is TRUE.
- EL3, Non-secure EL2, and Secure EL2 are all implemented.
- EL3 is using AArch64.

In this table:

- NS is the Effective value of SCR_EL3.NS.
- STE is the Effective value of MDCR_EL3.STE.
- NSTB is the Effective value of MDCR_EL3.NSTB.
- E2TB is the Effective value of MDCR_EL2.E2TB.
- EEL2 is the Effective value of SCR_EL3.EEL2.
- TGE is the Effective value of HCR_EL2.TGE.

The EL3, EL2, EL1, EL0 columns show which control, if any, enables tracing at the Exception level. In these columns:

- P means tracing is prohibited.
- E2TRE means tracing is allowed if TRFCR_EL2.E2TRE is 1 and prohibited otherwise.
E1TRE
means tracing is allowed if TRFCR_EL1.E1TRE is 1 and prohibited otherwise.

E0HTRE
means tracing is allowed if TRFCR_EL2.E0HTRE is 1 and prohibited otherwise.

E0TRE
means tracing is allowed if TRFCR_EL1.E0TRE is 1 and prohibited otherwise.

The pseudocode function TraceAllowed shows this.

When the Trace Buffer Unit is disabled, the owning translation regime, owning Security state, and owning Exception level are not defined.

D6.2.7 Trace Buffer Unit disabled

When the Trace Buffer Unit is disabled, the Trace Buffer Unit discards trace data from the trace unit.

The Trace Buffer Unit does not prefetch and cache address translations when the Trace Buffer Unit is disabled.

When the Trace Buffer Unit is disabled the trace unit might send trace data to an IMPLEMENTATION DEFINED trace bus.

The trace unit does not send trace data to the IMPLEMENTATION DEFINED trace bus when the Trace Buffer Unit is enabled.

Figure D6-1 on page D6-5004 shows this IMPLEMENTATION DEFINED trace bus as a dotted line to an external trace Sink.
Details of this bus are outside the scope of this architecture, and might require further configuration. For example, if the trace unit implements FEAT_ETE and the trace bus is AMBA ATB, the ATID value is configured through the trace unit external trace registers.

D6.2.8 Restrictions on programming the Trace Buffer Unit

A current write pointer value is out-of-range if any of the following are true:
- The current write pointer is less-than the Base pointer, treating both pointers as unsigned integers.
The current write pointer is greater-than-or-equal-to the Limit pointer, treating both pointers as unsigned integers.

- Bits [63:56] of the current write pointer are not equal to bits [63:56] of the Base pointer.
- Bits [63:56] of the current write pointer are not equal to bits [63:56] of the Limit pointer.

Note: R_MSPSD means the current write pointer is out-of-range if the Base pointer is not less-than the Limit pointer or bits [63:56] of the Base pointer are not equal to bits [63:56] of the Limit pointer.

A current write pointer or Trigger Counter value is misaligned if it is not a multiple of an IMPLEMENTATION DEFINED alignment specified by TRBIDR_EL1.Align.

A current write pointer or Trigger Counter value is a valid restart value if it was previously initialized with a value that was not out-of-range and not misaligned and later read from the applicable register when all of the following are true:

- The Trace Buffer Unit is disabled.
- All trace operations are complete. See R_NSFRQ for the definition of complete.
- No External abort has been reported to the Trace Buffer Unit. TRBSR_EL1.EA is 0.
- No write by the Trace Buffer Unit has generated an Alignment fault.
- No write by the Trace Buffer Unit has generated an asynchronous SError interrupt exception.

A current write pointer or Trigger Counter value is a fault value if it was previously initialized with a value that was not out-of-range and not misaligned or a value that was a valid restart value, and later read from the applicable register when all of the following are true:

- The Trace Buffer Unit is disabled.
- All trace operations are complete. See R_NSFRQ for the definition of complete.
- One of the following is true:
  - An External abort has been reported to the Trace Buffer Unit. TRBSR_EL1.EA is 1.
  - A write by the Trace Buffer Unit has generated an Alignment fault.
  - A write by the Trace Buffer Unit has generated an asynchronous SError interrupt exception.

A fault value is for error handling purposes only. Software must not cause the Trace Buffer Unit to become enabled and running with the current write pointer having a fault value.

If the current write pointer is written by a direct write with a misaligned value that is not a restart value and not a fault value, the value returned by a subsequent direct read of the current write pointer is UNKNOWN.
If the current write pointer has an out-of-range value, or a misaligned value that is not a restart value when the Trace Buffer Unit attempts to write to the trace buffer, then any of the following might occur:

- If the value is out-of-range, the current write pointer might be wrapped before or after the write, and the TRB_WRAP event might be generated.
- If the value is misaligned, the write might generate an Alignment fault.
- The Trace Buffer Unit might write the trace data to any address in memory that is writable by a privileged access in the owning translation regime. These addresses are:
  - Virtual addresses in the owning translation regime if TRBLIMITR_EL1.nVM is 0.
  - Intermediate physical addresses in the owning Security state if TRBLIMITR_EL1.nVM is 1 and the owning translation regime has stage 2 translations.
  - Physical addresses in the owning Security state if TRBLIMITR_EL1.nVM is 1 and the owning translation regime has no stage 2 translation.
- The write might generate a trace buffer management event with an UNKNOWN reason:
  - TRBSR_EL1.S is either set to 1 or unchanged.
  - TRBSR_EL1.WRAP is either set to 1 or unchanged.
  - TRBSR_EL1.EC is set to an UNKNOWN value.
  - TRBSR_EL1.MSS is set to an UNKNOWN value.
  - The TRB_WRAP event might be generated.

If the Trigger Counter is written by a direct write with a misaligned value that is not a restart value, then all of the following apply:

- If the value is not a fault value, the value returned by a subsequent direct read of the Trigger Counter register is UNKNOWN.
- The generation of a Trigger Event while the Trace Buffer Unit remains enabled and running is UNPREDICTABLE.

RXZHH and RCZDM mean an implementation that always keeps the current write pointer and/or Trigger Counter aligned to the IMPLEMENTATION DEFINED alignment specified by TRBIDR_EL1.Align, where TRBIDR_EL1.Align is greater-than-zero (byte alignment), can implement bits [M:0] of the applicable register(s) as RAZ/WI bits, where M is (TRBIDR_EL1.Align-1).

RHZXZZM allows an implementation where an External abort is reported to the Trace Buffer Unit and handled synchronously to implement TRBPTR_EL1[M:N], where N is IMPLEMENTATION SPECIFIC and typically determined by the minimum memory access granule, as read/write bits for the purpose of reporting an External abort fault address, but otherwise ignore the value in these bits. If N>0, bits [(N-1):0] can be implemented as RAZ/WI.

When TRBLIMITR_EL1.E is 1, the PE might ignore a direct write to any of the following registers, other than a direct write to TRBLIMITR_EL1 that modifies TRBLIMITR_EL1.E:

- The current write pointer, TRBPTR_EL1.
- The Base pointer, TRBBASER_EL1.
- The Limit pointer, TRBLIMITR_EL1.
- The Trigger Counter, TRBTRG_EL1.
- TRBSR_EL1.
- TRBMAR_EL1.

Software must use appropriate Context synchronization operations to order a direct write that modifies TRBLIMITR_EL1.E with respect to other direct writes to Trace Buffer Unit registers. This includes a write to enable the Trace Buffer Unit by setting TRBLIMITR_EL1.E to 1.

See also:

- Synchronization and the Trace Buffer Unit on page D6-5026.
- UNPREDICTABLE behavior on page D6-5038.
- Context switching on page K4-11673.
### D6.2.9 Cache and TLB operations

**IWYVXK** Translations used by the Trace Buffer Unit might be cached in a TLB.

**RGQJMC** TLB maintenance operations that affect the TLB of the PE also affect any TLB caching translations for the Trace Buffer Unit of that PE.

**RNPNNM** The PE is permitted, but not required, to cache all translations used by the Trace Buffer Unit in TLB caching structures that combine stage 1 and stage 2 of the translation. This includes when TRBLIMITR_EL1.nVM is 1 and the owning translation regime has stage 2 translations.

**SLSZDR** When TRBLIMITR_EL1.nVM is 1 and the owning translation regime has stage 2 translations, the Trace Buffer Unit uses intermediate physical addresses (IPAs). RNPNNM permits, but does not require, such translations to be cached in a TLB in such a way that an IPAS2 TLB maintenance operation is not sufficient to invalidate the cached copies. In this case, there is no VA for the translation.

If TRBLIMITR_EL1.nVM is 1 and the owning translation regime has stage 2 translations, then the following code executed at EL2 or above is sufficient to invalidate all cached copies of the stage 2 translations used by the Trace Buffer Unit of the IPA held in Xt for the current VMID:

```
TLBI IPAS2E1, Xt
DSB
TLBI VMALLE1
```

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.

Equivalent sequences guaranteed to invalidate all entries invalidated by the above code sequence can be used, such as TLBI ALL or TLBI VMALLS1S2.

**RDNFWB** Cache maintenance operations that affect the caches of the PE also affect data caching by the Trace Buffer Unit of that PE.

**IMZQPT** RGQJMC and RDNFWB mean that the completion of any cache or TLB maintenance instruction includes its completion on all Trace Buffer Units for PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction. See Detailed synchronization litmus tests on page D6-5034 for more information.

### D6.2.10 Effect on the exclusive monitors and transactions

**RDJCVN** If an operation between Load-Exclusive and Store-Exclusive instructions is traced, and the trace data is written to an unrelated address, then the write has no effect on the exclusive monitors.

**RMJDKN** If an operation inside a transaction is traced, and the trace data is written to an unrelated address, then the write has no effect on the transaction.

**RNWSKV** If the Trace Buffer Unit writes to the marked address of an exclusives monitor in the Exclusive Access state, then one of the following occurs, and it is CONSTRAINED UNPREDICTABLE which:

- The write has the same effect on the exclusives monitor as a store by the PE or any other Observer to that address.
- The write has no effect on the exclusives monitor.

**RFVRXJ** If the Trace Buffer Unit writes to the working set of a transaction, then one of the following occurs, and it is CONSTRAINED UNPREDICTABLE which:

- The write has the same effect on the transaction as a store by any other Observer to that address.
- The write has no effect on this transaction.

### D6.2.11 MPAM

**RWXXSYG** If The Memory Partitioning and Monitoring (MPAM) Extension on page A2-126 is implemented, then the MPAM information for accesses made by the Trace Buffer Unit to the trace buffer use the MPAM values of the owning Exception level and owning Security state.
For example, if the owning Exception level is EL2 the trace buffer writes use MPAM2_EL2.PARTID_D and MPAM2_EL2.PMG_D. MPAM_NS is set for the owning Security state.

**D6.2.12 MTE**

If **FEAT_MTE** is implemented, then the Trace Buffer Unit generates an Unchecked access for each access to the trace buffer.

Note: This is the case even when a Tagged Normal memory type is accessed.

See also Chapter D9 *The Memory Tagging Extension*. 
D6.3 Trace buffer management

IGYHBH FEAT_TRBE supports the following trace buffer modes:

Circular Buffer mode
In Circular Buffer mode, when the current write pointer reaches the Limit pointer, it is wrapped by setting it to the Base pointer.

Wrap mode
As Circular Buffer mode, except that an interrupt request is generated when the current write pointer is wrapped.

Fill mode
As Wrap mode, except that trace collection stops when the current write pointer is wrapped.

The trace buffer mode is controlled by TRBLIMITR_EL1.FM.

INFZKS A trace buffer management event occurs:
• On an Alignment fault or MMU fault.
• On an External abort.
• On a Trigger Event, if enabled.
• When the current write pointer is wrapped to the Base pointer and the trace buffer mode is not Circular Buffer mode. This event is known as:
  — A buffer wrap event, if the trace buffer mode is Wrap mode.
  — A buffer full event, if the trace buffer mode is Fill mode.
• On a programming error, when permitted as an UNPREDICTABLE behavior of the PE. For more information, see Restrictions on programming the Trace Buffer Unit on page D6-5013 and UNPREDICTABLE behavior on page D6-5038.
• On an IMPLEMENTATION DEFINED event.

Note: The trace buffer management event behavior differs from that of the SPE Profiling Buffer management event.

RHLKSG On a trace buffer management event, all of the following occurs:
• The interrupt request bit, TRBSR_EL1.IRQ, is set to 1.
• The trace buffer management interrupt signal, TRBIRQ, is asserted.
• Additional syndrome for the event might be written to TRBSR_EL1.MSS.

RLRTBP TRBIRQ is a level triggered interrupt request driven by TRBSR_EL1.IRQ. This means that all of the following apply:
• A direct write that sets TRBSR_EL1.IRQ to 1 causes the interrupt request to be asserted.
• The interrupt request remains asserted until software clears TRBSR_EL1.IRQ to 0.

RTPPCF When a GIC is implemented, TRBIRQ is configured as a PPI. TRBIRQ is signaled by the PE that implements the Trace Buffer Unit.

IHJFLC The PPI number is not defined by the architecture. Arm recommends that the PPI number is discoverable to an Operating System, for example using ACPI or devicetree interfaces.

SXLNJY Software must configure the trace buffer management interrupt to be taken to the correct Exception level.

IHJFLC Buffer full, Alignment fault, and MMU fault trace buffer management events are synchronous. This means that the effect of these trace buffer management events setting TRBSR_EL1.S to 1, collection is stopped, happens before any further trace is collected by the Trace Buffer Unit from the trace unit.

ILZDN When the trigger mode is Stop on Trigger, a Trigger Event initiates a trace unit flush meaning more trace might be written to the trace buffer before any Collection is stopped by the Trigger Event trace buffer management event. This additional trace might cause a second trace buffer management event to be generated before the Trigger Event trace buffer management event.
The TRBIRQ interrupt is always taken asynchronously by the PE, even if the event is reported synchronously to the Trace Buffer Unit.

Following an Alignment fault, MMU fault, or External abort trace buffer management event, TRBPTR_EL1 serves as a Fault Address Register.

For a fault or synchronous External abort trace buffer management event, the frozen TRBPTR_EL1 is the address that generated the fault or External abort.

For an asynchronous External abort trace buffer management event, the frozen TRBPTR_EL1 is not guaranteed to be the address that generated the External abort.

### D6.3.1 Prioritization of a trace buffer management event

Where multiple synchronous trace buffer management events occur on writing trace data, the PE prioritizes them from highest to lowest priority, reporting the highest priority event as follows:

1. Synchronous fault.
2. Synchronous External abort.
3. Buffer full event.
4. Buffer wrap event.

Do not confuse the prioritization of trace buffer management events with the prioritization of trace buffer management interrupts by an interrupt controller.

Asynchronous and IMPLEMENTATION DEFINED trace buffer management events are not prioritized relative to synchronous trace buffer management events.

### D6.3.2 Buffer full and buffer wrap events

If the current write pointer is wrapped to the Base pointer and the trace buffer mode is Fill mode, then all of the following occur:

- A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
- TRBSR_EL1.WRAP is set to 1.
- The TRB_WRAP event is generated.
- If TRBSR_EL1.S is 0, then all of the following occur:
  - TRBSR_EL1.S is set to 1, collection is stopped.
  - TRBSR_EL1.EC is set to 0x00, other buffer management event.
  - TRBSR_EL1.BSC is set to 0b000001, buffer filled.
- The other fields in TRBSR_EL1 are unchanged.

After the trace buffer management event, the current write pointer will point to the Base pointer.

If the current write pointer is wrapped to the Base pointer and the trace buffer mode is Wrap mode, then all of the following occur:

- A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
- TRBSR_EL1.WRAP is set to 1.
- The TRB_WRAP event is generated.

Because TRBSR_EL1.S is unchanged, trace continues to be collected and written to the trace buffer.

If the current write pointer is wrapped to the Base pointer and the trace buffer mode is Circular Buffer mode, then all of the following occur:

- TRBSR_EL1.WRAP is set to 1.
- The other fields in TRBSR_EL1 are unchanged.
- The TRB_WRAP event is generated.
If TRBSR_EL1.S is 1, the current write pointer is not updated, meaning the current write pointer is never wrapped when TRBSR_EL1.S is already 1.

Software can configure the PMU to count the TRB_WRAP event and monitor how many times the current write pointer has wrapped, particularly in Circular Buffer mode or Wrap mode.

See also Controlling generation of trace buffer management events on page K4-11675.

D6.3.3 Trigger event

The Trace Buffer Extension supports detection of a trigger condition from the trace unit. A trigger condition is typically used to stop trace capture to ensure trace is captured around a point of interest.

The trace unit defines how software programs the trace unit to generate trigger conditions.

A Detected Trigger is signaled to the Trace Buffer Unit by the trace unit when the trace unit detects a trigger condition. The trace unit defines whether the Detected Trigger is signaled synchronously or asynchronously to the trace data stream.

A Trigger Event occurs when the Trigger Counter has counted the specified number of trace bytes after a Detected Trigger. Software can set the Trigger Counter to zero to skip this step.

The Trigger Counter is a counter used to delay a Trigger Event for a specified number of trace bytes after a Detected Trigger.

Figure D6-2 shows this.

Figure D6-2 Trigger condition to Trigger Event

For a trace unit that implements FEAT_ETE, event 0 is the trigger condition.

When the trigger mode is set to Stop on trigger, software uses the Trigger Counter to control how trace is collected around the Detected Trigger as follows:

• Set the Trigger Counter to zero to trace before the Detected Trigger.
• Set the Trigger Counter to half the size of the trace buffer to trace around the Detected Trigger.
• Set the Trigger Counter to the size of the trace buffer to trace after the Detected Trigger.

Restrictions on programming the Trace Buffer Unit on page D6-5013 defines additional constraints on writing to the Trigger Counter.

If a Detected Trigger occurs while the Trace Buffer Unit is enabled, then all of the following occur:

• TRBSR_EL1.TRG is set to 1.
• The other fields in TRBSR_EL1 are unchanged.

If all of the following are true, then the Trace Buffer Unit decrements the Trigger Counter by 1 for each byte of trace data written to the trace buffer by the Trace Buffer Unit:

• The Trigger Counter is nonzero.
• TRBSR_EL1.TRG is set to 1.

If the write generates an Alignment fault, MMU fault, or External abort, it is UNPREDICTABLE whether the Trigger Counter is decremented.
If a Detected Trigger occurs when the Trigger Counter is nonzero and TRBSR_EL1.TRG is 0, the Trace Buffer Unit might decrement the Trigger Counter by an amount up to the value specified by TRBIDR_EL1.Align without writing any additional trace data to the trace buffer.

An implementation might include an internal buffer that collects bytes of trace data into more convenient units before writing them to memory. For example, the width of the system bus or the length of a cache line. In such an implementation, TRBIDR_EL1.Align specifies the size of this unit, and the Trigger Counter is decremented by the size of this unit when the write occurs, meaning the Trigger Counter is always aligned to the size specified by TRBIDR_EL1.Align.

However, this means that if the Detected Trigger occurs when such an internal buffer is not empty, the Trace Buffer Unit will over-decrement the counter when the internal buffer is written to memory. RQFGNQ permits this.

See also RBWNRf.

A Trigger Event is generated when the Trace Buffer Unit is enabled and one of the following occurs:

- A Detected Trigger occurs when the Trigger Counter is zero and TRBSR_EL1.TRG is 0.
- The Trace Buffer Unit decrements the Trigger Counter to zero.

A Trigger Event is not generated when a Detected Trigger occurs, the Trigger Counter is set to zero, and TRBSR_EL1.TRG is already 1.

A Trigger Event is not generated when the Trace Buffer Unit is disabled.

The Detected Trigger might be generated by a trace operation tT. This might be the trace operation generated by an instruction that also matched the trigger condition, or might be a trace operation generated asynchronously by the trace unit to mark the trigger condition in the trace data. The trace unit defines this relationship for triggers.

A Trigger Event might be generated by a trace operation as follows:

- If the Trigger Event is generated when a Detected Trigger occurs when the Trigger Counter is zero and TRBSR_EL1.TRG is 0, and the Detected Trigger is generated by a trace operation tT then the Trigger Event is generated by the same trace operation tT.
- If the Trigger Event is generated when the Trace Buffer Unit decrements the Trigger Counter to zero, then Trigger Event is generated by the trace operation that generated the trace data that caused the Trigger Counter to decrement to zero.

A Trigger Event is not generated by a specific trace operation if the Trigger Event is generated when a Detected Trigger occurs when the Trigger Counter is zero and TRBSR_EL1.TRG is 0, and the Detected Trigger is not generated by a specific trace operation.

The link between a Trigger Event and a trace operation that generated it affects when the trace operation is Microarchitecturally-finished and the behavior of the TSB CSYNC instruction. See RQJDJD.

FEAT_TRBE supports the following trigger modes:

**Stop on trigger**

Trace collection is stopped and an interrupt request is generated after a Trigger Event.

**IRQ on trigger**

An interrupt request is generated after a Trigger Event.

**Ignore trigger**

The Trace Buffer Unit ignores the trigger condition.

In the Stop on trigger and IRQ on trigger modes, software specifies the amount of trace that is collected after the trigger condition before the Trigger Event.

If a Trigger Event is generated when collection is not stopped and the trigger mode is Stop on trigger, then all of the following occur:

- The Trace Buffer Unit initiates a trace unit flush of the trace unit.
- The TRB_TRIG event is generated.

On completion of the trace unit flush, all of the following occur:

- A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
• If TRBSR_EL1.S is 0, then all of the following occur:
  — TRBSR_EL1.S is set to 1, \textit{collection is stopped}.
  — TRBSR_EL1.EC is set to 0x00, other buffer management event.
  — TRBSR_EL1.BSC is set to 0b000010, Trigger Event.
• The other fields in TRBSR_EL1 are unchanged.

After the trace buffer management event, the current write pointer will point to either the first byte after the last trace byte written to the trace buffer, or, if the last trace byte written to the trace buffer was the last byte in the trace buffer, the Base pointer.

The trace unit defines the behavior and completion of a trace unit flush, including which trace operations, if any, are accepted by the Trace Buffer Unit before the trace unit flush completes.

If the \textit{Detected Trigger} is generated by a trace operation \( t_T \), then the trace unit flush does not complete before the Trace Buffer Unit accepts the trace data for \( t_T \).

Because the Trace Buffer Unit initiates a trace unit flush before stopping this means that, before TRBSR_EL1.S is set to 1:
• More trace might be written to the trace buffer after the \textit{Trigger Event} is detected.
• This might generate other management events that set TRBSR_EL1.S to 1.

If a \textit{Trigger Event} is generated when collection is not stopped and the trigger mode is \textit{IRQ on trigger}, then all of the following occur:
• The Trace Buffer Unit initiates a \textit{trace unit flush} of the trace unit.
• The TRB_TRIG event is generated.

On completion of the trace unit flush, all of the following occur:
• A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
• The other fields in TRBSR_EL1 are unchanged.

Because TRBSR_EL1.S is unchanged, trace continues to be collected and written to the trace buffer.

If a \textit{Trigger Event} is generated and the trigger mode is \textit{Ignore trigger}, then all of the following occur:
• TRBSR_EL1 is unchanged.
• The TRB_TRIG event is generated.

If a \textit{Trigger Event} is generated when \textit{collection is stopped}, then all of the following occur:
• TRBSR_EL1 is unchanged.
• The TRB_TRIG event is generated.

These rules mean that trace might be collected after the \textit{Trigger Event}, but are included to ensure that trace for the instructions that caused the trigger condition is not discarded in common cases.

The trigger mode is controlled by TRBLIMITR_EL1.TM.

See also \textit{Controlling generation of trace buffer management events on page K4-11675}.

### D6.3.4 Faults

A write by the Trace Buffer Unit might generate one or more of the following faults:

**Alignment fault**

If TRBPTR_EL1 is misaligned, the behavior is \textit{UNPREDICTABLE} and a write to the trace buffer by the Trace Buffer Unit might generate an Alignment fault. See also \textit{RMGZWR}.

**Translation fault**

Any access outside the virtual address or intermediate physical address space generates a Translation fault.
The translation of a virtual address or intermediate physical address to a physical address might generate Translation fault.

Writes to the trace buffer are made as privileged writes in the owning translation regime, meaning they are not affected by the TCR_ELx.E0PDy bits for the owning translation regime.

Address Size fault

The translation of a virtual address or intermediate physical address to a physical address, or use of an out-of-range physical address, might generate an Address Size fault.

Permission fault

Writes to the trace buffer are made as privileged writes in the owning translation regime. If the write does not have write permission, a Permission fault is generated. The value of PSTATE.PAN is ignored.

If the Trace Buffer Unit does not manage the dirty state in translation tables, then accesses ignore the Dirty Bit Modifier bit in Page and Block descriptors and as a result, might generate a Permission fault.

Access Flag fault

If the Trace Buffer Unit does not manage the Access flag in translation tables or hardware management of the Access flag state is disabled for the owning translation regime, then any access to a Page or Block with the Access flag bit set to 0 in a descriptor will generate an Access Flag fault.

TLB Conflict fault

IMPLEMENTATION DEFINED.

Unsupported atomic hardware update fault

If hardware update of the translation tables is not guaranteed atomic in regard to other agents that access the memory, the translation of a virtual address to a physical address might generate an Unsupported atomic hardware update fault.

External abort on translation table walk or translation table update

The translation of a virtual address to a physical address might generate an External abort on the translation table walk or translation table update, and be treated as a synchronous MMU fault. See also External aborts on page D6-5024.

MMU fault means any of these faults other than an Alignment fault.

RFYBCG

Writes to the trace buffer by the Trace Buffer Unit never generate watchpoints.

IDTKGB

Faults do not generate an actual Data Abort exception. The ESR and FAR registers are unchanged.

SGTLCY

To avoid MMU faults, Arm recommends:

- Software pins the Pages or Blocks used for the trace buffer. This includes a hypervisor pinning these Pages or Blocks in the stage 2 translation.
- If the Trace Buffer Unit does not manage the Access Flag and dirty state, software marks the Pages or Blocks as accessed and dirty. Software can discover whether address translations performed by the Trace Buffer Unit manage dirty state and the Access flag from TRBIDR_EL1.F.

RFSPBK

If a write by the Trace Buffer Unit generates an Alignment fault or MMU fault, and TRBSR_EL1.S is 0, then all of the following occur:

- A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
- TRBSR_EL1.S is set to 1, collection is stopped.
- TRBSR_EL1.EC is set to the appropriate one of the following values:
  - 0x24, stage 1 Data Abort on write to trace buffer.
  - 0x25, stage 2 Data Abort on write to trace buffer.
- TRBSR_EL1.FSC is set to indicate the type of the fault.
- TRBPTR_EL1 is set to the address that generated the fault.
- The other fields in TRBSR_EL1 are unchanged.

If a write by the Trace Buffer Unit generates an External abort on a translation table walk or translation table update, it is IMPLEMENTATION DEFINED whether TRBSR_EL1.EA is set to 1 or unchanged.
In the case of a stage 2 Data Abort on a write to trace buffer, the PE does not record whether the fault was due to a stage 2 fault on the access, or a stage 2 fault on a stage 1 translation table access.

**D6.3.5 External aborts**

A write to the trace buffer might generate an External abort, including an External abort on a translation table walk or translation table update:

**External abort**

The write might generate a synchronous or asynchronous External abort.

**External abort on translation table walk or translation table update**

The translation of a virtual address or intermediate physical address to a physical address might generate an External abort.

However, an External abort on a translation table walk or translation table update might be treated as a synchronous MMU fault. See *Faults* on page D6-5022.

When a write to the trace buffer generates an External abort, then one of the following occurs, and it is IMPLEMENTATION DEFINED which:

- The External abort is reported to the Trace Buffer Unit and treated as a trace buffer management event.
- The External abort is not reported to the Trace Buffer Unit and generates an asynchronous SError interrupt exception at the PE.

When an External abort is reported to the Trace Buffer Unit, then one of the following occurs, and it is IMPLEMENTATION DEFINED which:

- The External abort is handled synchronously by the Trace Buffer Unit.
- The External abort is handled asynchronously by the Trace Buffer Unit.

If the Trace Buffer Unit handles External aborts asynchronously, then all of the following apply:

- The External abort trace buffer management event might not be generated until after a first trace buffer management event has set TRBSR_EL1.S to 1.
- Writes to the trace buffer might generate a second trace buffer management event after the External abort trace buffer management event has set TRBSR_EL1.S to 1.
- The Trace Buffer Unit might collect further trace data from the trace unit and write it to memory before the External abort trace buffer management event sets TRBSR_EL1.S to 1.

When a write by the Trace Buffer Unit generates an External abort reported to the Trace Buffer Unit, all of the following occur:

- The External abort bit, TRBSR_EL1.EA, is set to 1.
- The Trace Buffer Unit stops writing trace data to the trace buffer.
- If the Trace Buffer Unit handles External aborts synchronously, TRBPTR_EL1 is set to the address that generated the External abort.
- If the Trace Buffer Unit handles External aborts asynchronously, TRBPTR_EL1 is not guaranteed to be set to the address that generated the External abort.
- If TRBSR_EL1.S is 0, then all of the following occur:
  - A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
  - TRBSR_EL1.S is set to 1, *collection is stopped*.
  - TRBSR_EL1.EC is set to the appropriate one of the following values:
    - 0x24, stage 1 Data Abort on write to trace buffer.
    - 0x25, stage 2 Data Abort on write to trace buffer.
  - TRBSR_EL1.FSC is set to indicate the type of External abort.
- The other TRBSR_EL1 fields are unchanged.
Reporting the External abort to the Trace Buffer Unit and generating a trace buffer management event:

- Sets TRBSR_EL1.S to 1 and so discards further trace data.
- Allows error recovery software to isolate the event to the actions of the Trace Buffer Unit.

Not reporting the External abort to the Trace Buffer Unit and generating an asynchronous SError interrupt exception at the PE:

- Means that, while tracing is not prohibited, the trace unit might continue generating trace data that the Trace Buffer Unit accepts. However, the SError interrupt might be taken to an Exception level where tracing is prohibited.
- Might not allow error recovery software to isolate the event and error containment.

**D6.3.6 IMPLEMENTATION DEFINED management events**

When IMPLEMENTATION DEFINED conditions are met all of the following occur:

- A trace buffer management event is generated. This sets TRBSR_EL1.IRQ to 1.
- TRBSR_EL1.S is set to 1, collection is stopped.
- TRBSR_EL1.EC is set to \( 0x1F \), IMPLEMENTATION DEFINED buffer management event.
- TRBSR_EL1.MSS is set to an IMPLEMENTATION DEFINED value.
- The other fields in TRBSR_EL1 are unchanged.

The intent of this event is for cases such as errata workarounds to allow an implementation to report any failure to write data to the buffer that is not covered by other codes. Arm recommends that such mechanisms are disabled on reset.
D6.4 Synchronization and the Trace Buffer Unit

Program Flow Trace data is generated by traced instructions. When an instruction is executed:

1. The PE decides whether to create a trace operation for the instruction.
2. If created, the trace operation generates the Program Flow Trace data.

For some trace unit implementations, Speculative instructions might generate trace operations, as well as architecturally Resolved instructions.

See on page K5-11677 for more information on these terms.

The trace unit might also generate asynchronous trace operations, that are not causally related to an executed instruction. If the trace unit implements the FEAT_ETE then the ETE Resources can generate trace operations that are not causally related to an instruction or Speculative instruction.

The architecture defines a Trace Synchronization event that synchronizes the operation of trace operations with the execution of instructions. Without correct use of the Trace Synchronization event, a trace operation might for instance read a stale value from a System register, causing trace data to be written to the wrong memory location, or the Trace Buffer Unit to otherwise generate UNPREDICTABLE software behavior. See also UNPREDICTABLE behavior on page D6-5038.

Trace operations operate independently of the instructions that are executed on the PE and make indirect reads and indirect writes of System registers as an external agent.

The synchronization requirements for direct reads, direct writes, indirect reads, and indirect writes of System registers made by instructions and external agents are defined in Synchronization requirements for AArch64 System registers on page D17-5547.

Synchronization in self-hosted trace on page D3-4762 defines that indirect reads of the TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE} trace filter controls when determining whether the current Execution stream is part of a prohibited trace region and an instruction \( A \) should generate a trace operation, are treated as indirect reads made by \( A \).

Each System register access made by the trace unit is one of the following, and the trace unit defines which:

- An indirect read or indirect write \( rw_A \) made by an instruction \( A \). For example, to determine whether to generate a trace operation for \( A \).
- An indirect read or indirect write \( rw_{A'} \) made by a trace operation \( A' \). This is in addition to System register accesses defined by this Manual as indirect reads or indirect writes made by the Trace Buffer Unit.
- An other indirect read or indirect write \( rw \), not directly related to either an instruction or trace operation. The trace unit defines the synchronization requirements for these registers.

In addition to the registers listed by RNRLDV, for the ETE, the following ETE System registers are indirectly read by an instruction \( A \) to determine whether \( A \) should generate a trace operation:

- TRCPRTL.R, the Trace unit enable bit in the Programming Control Register.
- TROSLSR.OSLK, the Trace OS Lock Status Register.

This Manual defines which System registers are indirectly read or indirectly written by the Trace Buffer Unit as part of the trace operation \( t_A \) for a traced instruction \( A \). For example:

- Trace Buffer Unit System registers.
- VMSA System registers and SCR_EL3.NS, when translating addresses generated by the Trace Buffer Unit. Other System registers are indirectly read or indirectly written by the trace unit as part of the trace operation \( t_A \) for a traced instruction \( A \). For example:
  - Other ETE System registers.
  - If context tracing is enabled, the applicable Context ID register or registers, CONTEXTIDR_EL1 or CONTEXTIDR_EL2.
  - If trace timestamping is enabled, any applicable counter offset, CNTV_OFF_EL2 or CNTPOFF_EL2.

Some ETE System registers are indirectly read or indirectly written by, for example, the ETE Resources when generating trace operations or updating the ETE Resources, and are made by neither a trace operation of an instruction nor an instruction.
The behavior of the ETE is defined by FEAT_ETE. See also *Trace synchronization and the Trace Unit* on page D6-5028.

The indirect reads and indirect writes to Trace Buffer Unit, VMSA and other System registers made by the Trace Buffer Unit are made by the trace operation tOP.

To synchronize trace operations, software must use the TSB CSYNC instruction to generate a Trace Synchronization event.

In the absence of any explicit synchronization, the trace unit generates the trace data for an instruction and the Trace Buffer Unit accepts, discards, or rejects the trace data in finite time. However:

- If the Trace Buffer Unit accepts the trace data, then the write of the trace data to memory requires explicit synchronization to Complete.
- The indirect writes to System registers made by a trace operation require explicit synchronization to guarantee they are observable.

### D6.4.1 Trace Synchronization event

Executing a TSB CSYNC instruction generates a Trace Synchronization event.

A trace operation tOP is not Microarchitecturally-finished before all of the following are true:

- All indirect reads and indirect writes of System registers made by tOP have been performed.
- If tOP generates a *Trigger Event* that in turn initiates a *trace unit flush*, then all of the following are true:
  - The trace unit flush is complete.
  - All trace operations the Trace Buffer Unit accepts before the trace unit flush completes are Microarchitecturally-finished.
  - All indirect writes to System registers made by the Trace Buffer Unit on completion of the trace unit flush have been performed.

Indirect reads and writes include but are not limited to the following:

- All indirect reads and indirect writes of the Trace Buffer Unit, VMSA System registers, and SCR_EL3.NS made by memory accesses performed by tOP.
- All indirect writes to System registers made by a trace buffer management event generated by tOP.

However, this does explicitly exclude any indirect writes of System registers made in response to an External abort by the access.

A trace operation tOP is complete when it is Microarchitecturally-finished and all memory accesses performed by tOP are Complete and any indirect writes of System registers made in response to an External abort response to the access have been performed.

If, following a Context synchronization event CSE the PE is executing in a Trace Prohibited region, a TSB CSYNC executed in the Trace Prohibited region and Non-debug state in program order after CSE is not Microarchitecturally-finished before all of the following are true:

- All trace operations tA generated by instructions A in program order before CSE are Microarchitecturally-finished.
- All trace operations tS generated by Speculative instructions S that are not in speculative execution order after CSE are Microarchitecturally-finished.
- All trace operations tR generated by the trace unit are Microarchitecturally-finished.
- The trace unit enters a state where the trace unit does not generate further trace operations and does not signal a Detected Trigger. The trace unit remains in this state while the PE is executing in the Trace Prohibited region.
- If a *trace unit flush* is initiated by a *Trigger Event* before the TSB CSYNC is Microarchitecturally-finished, the trace unit flush is complete, all trace operations the Trace Buffer Unit accepts before the trace unit flush completes are Microarchitecturally-finished, and any indirect writes made by the Trace Buffer Unit on completion of the trace unit flush have been performed.
These trace operations are synchronized by the TSB CSYNC.

A direct write \( W_2 \) to a System register made by an instruction \( B \) is Coherence-after an indirect read or indirect write \( rw_1 \) of the same System register made by a trace operation \( t_A \) for a traced instruction \( A \) if all of the following are true:

- Either \( A \) is executed in program order before a Context synchronization event \( CSE \), or \( A \) is \( CSE \).
- \( CSE \) is in program order before a Trace synchronization barrier \( TSB \).
- \( B \) is executed in program order after \( TSB \).
- After executing \( CSE \), the PE is in a Trace Prohibited region and \( TSB \) is executed in Non-debug state in the same Trace Prohibited region.

RZCDDS A direct write \( W_2 \) to a System register made by an instruction \( B \) is Coherence-after an indirect read or indirect write \( rw_1 \) of the same System register made by a trace operation \( t_A \) for a traced instruction \( A \) if all of the following are true:

- Either \( A \) is executed in program order before a Context synchronization event \( CSE \), or \( A \) is \( CSE \).
- \( CSE \) is in program order before a Trace synchronization barrier \( TSB \).
- \( B \) is executed in program order after \( TSB \).
- After executing \( CSE \), the PE is in a Trace Prohibited region and \( TSB \) is executed in Non-debug state in the same Trace Prohibited region.

RZCDDS emerges from the requirement in RMRVPT for the trace operations to be Microarchitecturally-finished by the TSB CSYNC operation.

RZCDDS A direct write \( W_2 \) to a System register made by an instruction \( B \) is Coherence-after an indirect read or indirect write \( rw_1 \) of the same System register made by a trace operation \( t_A \) for a traced instruction \( A \) if all of the following are true:

- Either \( A \) is executed in program order before a Context synchronization event \( CSE \), or \( A \) is \( CSE \).
- \( CSE \) is in program order before a Trace synchronization barrier \( TSB \).
- \( B \) is executed in program order after \( TSB \).
- After executing \( CSE \), the PE is in a Trace Prohibited region and \( TSB \) is executed in Non-debug state in the same Trace Prohibited region.

Self-hosted trace extension synchronization rules on page D6-5029 and Trace in Debug state on page D6-5033 define further rules for the operation of TSB CSYNC.

The PE does not stall indefinitely (or until interrupted) waiting for a TSB CSYNC. For example, the TSB CSYNC must not wait until there is no trace data left to write if the trace unit is capable of producing a constant stream of trace data.

A PE might abandon a TSB CSYNC executed in Non-debug state before it is Microarchitecturally-finished to take an interrupt, so long as the preferred return address is set such that the TSB CSYNC is re-executed when the interrupt handler completes. That is, the TSB CSYNC is only Speculatively executed.

Absent any Context synchronization event or DSB Data synchronization barrier, a TSB CSYNC instruction is not required to execute in program order with respect to other instructions or memory accesses. This means that software must execute additional barriers to guarantee that the trace operations are Microarchitecturally-finished and/or complete.

D6.4.2 Trace synchronization and the Trace Unit

The ETE has Resources that can generate trace operations that are not directly generated by an instruction or Speculative instruction.

The ETE specification defines the following rules:

- The Resources do not generate trace operations in the Paused state.
- If, following a Context synchronization event, the PE is executing in a Trace Prohibited region and the ETE is enabled, the ETE pauses the ETE Resources.
- How software synchronizes indirect writes to System registers made by trace operations generated by Resources.

The behavior of the ETE is defined by FEAT_ETE.

If FEAT_ETE is implemented, further rules are defined for the behavior of the trace unit when a TSB CSYNC instruction is executed.

A trace operation \( t_0 \) generated by ETE Resources inherits the synchronization requirements for a trace operation generated by an instruction \( A \), even if no trace operation is generated by \( A \), provided that one of the following applies:

- The requirement is that \( A \) is executed in program-order after \( CSE \) and tracing was prohibited before \( CSE \) and is allowed after \( CSE \).
- The requirement is that either \( A \) is executed in program-order before \( CSE \) or \( A \) is \( CSE \), and tracing was allowed before \( CSE \) and is prohibited after \( CSE \).

If the trace unit becomes enabled when the PE is executing a Trace Prohibited region, it does not generate any trace operations, including trace operations for Speculative instructions and other trace operations not generated by instructions, until the PE enters a region where tracing is allowed.

The trace unit defines the sequence by which software enables the trace unit.
D6.4.3 Self-hosted trace extension synchronization rules

ICMGRF FEAT_TRF defines further rules for the TSB CSYNC instruction. In particular, how a TSB CSYNC instruction synchronizes direct reads and indirect writes to a System register with respect to indirect reads and indirect writes of the same System register made by trace operations.

These rules restate the synchronization behavior described in Memory barriers on page B2-174 and Synchronization in self-hosted trace on page D3-4762.

RTSPXF is similar to RZCDDS and RXQVZW. However:
- RTSPXF applies whether the TSB CSYNC operation is executed in a trace prohibited or trace allowed region, in both Non-debug state and Debug state. RZCDDS applies only when the TSB CSYNC is executed in a Trace Prohibited region and the PE is in Non-debug state, and RXQVZW applies only when the TSB CSYNC is executed when the trace unit is disabled and the PE is in Debug state.
- RTSPXF applies only to System registers accessed by the trace unit as part of a trace operation. RZCDDS and RXQVZW apply to all System register accesses made by the trace operation and includes indirect reads and indirect writes made by the Trace Buffer Unit.

See RSXXQJ and IDDLVC.

RBFJKD An indirect read r1 of a System register made by a trace operation tA for a traced instruction A Reads-from a direct write W2 to the same System register made by an instruction B if all of the following are true:
- A is executed in program order after a Context synchronization event CSE.
- B is executed in program order before CSE.

See also IFVBPF.

SYPWVJ RBFJKD means that, if the PE enters a region where tracing is allowed by executing a Context synchronization event, such as an ERET instruction when SCTLR_ELx.EOS is 1, then all indirect reads and writes of System registers made by trace operations generated after entering the tracing allowed region will observe the values in those System registers written by direct writes before the Context synchronization event.

RMQXJM An indirect write w1 of a System register made by a trace operation tA for a traced instruction A is Coherence-after a direct write W2 of the same System register made by an instruction B if all of the following are true:
- A is executed in program order after a Context synchronization event CSE.
- B is executed in program order before CSE.

See also IFVBPF.

RTSPXF A direct write W2 to a System register made by an instruction B is Coherence-after an indirect read or indirect write rw1 of the same System register made by the trace unit as part of a trace operation tA for a traced instruction A if all of the following are true:
- Either A is executed in program order before a Context synchronization event CSE, or A is CSE.
- CSE is in program order before a Trace synchronization barrier TSB.
- B is executed in program order after TSB.

See also IMQTRQ.

RVTNCS A direct read R2 of a System register made by an instruction B Reads-from an indirect write w1 to the same System register made by a trace operation tA for a traced instruction A if all of the following are true:
- Either A is executed in program order before a first Context synchronization event CSE1, or A is CSE1.
- CSE1 is in program order before a Trace synchronization barrier TSB.
- TSB is executed in program order before a second Context synchronization event CSE2.
- B is executed in program order after CSE2.

See also ISLWRW.
**RNNRHD**

An instruction A in program-order after a direct write W that modifies one of the trace filter controls, TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE}, Reads-from W when determining whether A should generate a trace operation, if there is no intervening direct write to the same register and any of the following is true:

- A is in program-order after a Context synchronization event CSE and CSE is in program-order after W.
- An instruction B Reads-from W when determining whether B should generate a trace operation, and A is in program-order after B.

**IVKGRM**

RNNRHD means that for the instructions between a direct write to one of the trace filter controls to either enable or disable trace at the current Exception level and a following Context synchronization event, although it is UNPREDICTABLE whether each instruction observes the old or new values of the trace filter controls, once one instruction has observed the new value, all subsequent instructions also observe the new value.

However this might not happen, and all instructions might observe the old values until the Context synchronization event occurs.

This guarantees that trace switches either on and off cleanly, and is required by Program Flow Trace protocols.
D6.5 Trace synchronization and memory barriers

RVLWDM If, following a Context synchronization event CSE, the PE is executing in a Trace Prohibited region, a DSB with required access types of reads and write is executed in program order after a TSB CSYNC operation that is executed in the Trace Prohibited region in program order after CSE, then in addition to the requirements in this Manual, the DSB does not complete until all explicit memory accesses of the required access type made by the trace operations synchronized by the TSB CSYNC are Complete for the set of observers in the required Shareability domain.

See also RMPSXN.

RDFHWV An explicit read, explicit write, translation table walk, cache maintenance operation, or TLB invalidate operation M₁ will be Observed-by a read or a write RW₂ of a Location made by a trace operation tA relating to a traced instruction A if all of the following are true:

- A is executed in program-order after a Context synchronization event CSE.
- CSE is in program order after a Data Synchronization Barrier DSB.
- DSB does not complete before M₁ is complete.

INLHGN In RDFHWV, CSE is required to allow A to be traced as a Speculative instruction before it is Canceled or Resolved. The equivalent rule for SPE does not require CSE as SPE cannot write profiling records to memory until the profiled operation is Canceled or Resolved. See Trace of Speculative execution on page D6-5032.

RJPPZZ For the indirect writes to TRBPTR_EL1 and TRBSR_EL1 that are made as a result of an External abort on a write of trace data to memory, the synchronization rules apply only after the write to memory has completed.
D6.6 Trace of Speculative execution

In the standard model of execution for an instruction, instructions are executed as Speculative operations and then later become one of the following:

- Resolved. These instructions will then proceed to Complete.
- Canceled.
- Transaction-failed, if FEAT_TME is implemented.
- Transaction-canceled, if FEAT_TME is implemented.

A trace unit might generate trace for Speculative instructions before they are Resolved, Canceled, Transaction-failed or Transaction-canceled, and this trace can be written to memory. This means that, as well as indirectly reading System registers or memory, a trace operation $t_S$ for a Speculative instruction $S$ might perform any of the following:

- Indirectly write to System registers.
- Write to memory.

This sets trace operations apart from the normal operation of instructions, as the Arm architecture prohibits, for example, a Canceled instruction from updating a System register or memory. (Performance Monitors and Statistical Profiling can also cause speculative updates of System registers and memory.)

The preceding rules deal with the ordering of trace operations for Resolved (and ultimately Complete) instructions, and the requirements for synchronization based on the position of those instructions in the program order of the Execution stream.

This section extends the rules to cover Speculative instructions that are later Canceled, Transaction-canceled or Transaction-failed, and for trace operations generated by ETE Resources. Because these trace operations are not generated by instructions that Complete, they cannot be determined to be in program order with respect to architecturally Complete instructions.

A Speculative instruction $S$ is in speculative execution-order after an instruction $A$ if $S$ will be in program order after $A$ if $S$ is Resolved, even if $S$ is subsequently Canceled, Transaction-failed, or Transaction-canceled.

For example, a Speculative instruction $S$ is in speculative execution-order after a Resolved instruction $A$ if either of the following are true:

- The branch predictor mispredicted $A$ and, had the prediction been correct, $S$ would be in program order after $A$. Branch predictor means any structure that causes the PE to execute Speculative instructions. This includes, for example, branch history buffers, branch target caches, and instruction trace caches. It is not limited to structures that predict only the direction and/or target of branch instructions.

- $S$ forms part of a Transaction $T$ that was Transaction-canceled or Transaction-failed and $A$ is the Resolved TSTART operation for the outermost Transaction containing $T$.

Speculative execution-order does not provide a complete ordering. A pair of Speculative instructions $A$ and $B$ might not be ordered with respect to each other. For example, if $A$ and $B$ are respectively the result of different incorrect predictions by the branch predictor. However, each Speculative instruction is in speculative execution-order after at least one Resolved instruction.

The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively.

A trace operation $t_S$ generated by a Speculative instruction $S$ that is in speculative execution-order after a Resolved instruction $A$ inherits the synchronization requirements for a trace operation generated by $A$, even if no trace operation is generated by $A$, provided that one of the following applies:

- The requirement is that $A$ is executed in program-order after CSE, and $S$ is in speculative execution-order after CSE.

- The requirement is that either $A$ is executed in program-order before CSE or $A$ is CSE, and $S$ is not in speculative execution-order after CSE.

See also $I_{WLOHQ}$ and $I_{GXWM}$. 
D6.7 Trace in Debug state

If the trace unit is disabled, then a TSB CSYNC executed in Debug state is not Microarchitecturally-finished before all of the following are true:

- All trace operations $t_A$ generated by instructions $A$ in program order before the PE entered Debug state are Microarchitecturally-finished.
- All trace operations $t_S$ generated by Speculative instructions $S$ that are not in speculative execution order after the entry to Debug state are Microarchitecturally-finished.
- All trace operations $t_R$ generated by the trace unit are Microarchitecturally-finished.
- The trace unit enters a state where the trace unit does not generate further trace operations and does not signal a Detected Trigger. The trace unit remains in this state while the PE is in Debug state.
- If a trace unit flush is initiated by a Trigger Event before the TSB CSYNC is Microarchitecturally-finished, the trace unit flush is complete, all trace operations the Trace Buffer Unit accepts before the trace unit flush completes are Microarchitecturally-finished, and any indirect writes made by the Trace Buffer Unit on completion of the trace unit flush have been performed.

These trace operations are synchronized by the TSB CSYNC.

A direct write $W_2$ to a System register made by an instruction $B$ is Coherence-after an indirect read or indirect write $rw_1$ of the same System register made by a trace operation $t_A$ for a traced instruction $A$ if all of the following are true:

- $A$ is executed in program order before the PE entered Debug state.
- $B$ is executed in program order after a Trace synchronization barrier TSB.
- TSB was executed in Debug state when the trace unit was disabled.

IVHGVC RJXQVZW emerges from the requirement in RWYHRT for the trace operations to be Microarchitecturally-finished by the TSB CSYNC operation.

Trace Synchronization event on page D6-5027 and Self-hosted trace extension synchronization rules on page D6-5029 define further rules for the operation of TSB CSYNC.

RMPXXN A DSB with required access types of reads and write is executed after a TSB CSYNC operation executed in Debug state, then in addition to the requirements in this Manual, the DSB does not complete until all explicit memory accesses of the required access type made by the trace operations synchronized by the TSB CSYNC are Complete for the set of observers in the required Shareability domain.
D6.8 Detailed synchronization litmus tests

This section details example synchronization scenarios and litmus tests for TSB CSYNC. These are derived from FEAT_TRF and Trace Synchronization event on page D6-5027.

This section uses the terms program order, Reads-from and Coherence-after to define the ordering of System register and memory accesses made by trace operations. These terms are defined for memory accesses in Definition of the Arm memory model on page B2-159. For the purposes of this section, these terms are used for System registers as well as memory accesses.

The terms external agent, Observer, and Observed-by, also used in this section, are also defined in Definition of the Arm memory model on page B2-159.

This section does not describe the synchronization rules in Debug state defined in Trace in Debug state on page D6-5033. In general, litmus tests for Debug state can be derived by applying the following modifications:

- Where a rule mentions a Context synchronization event (CSE) coming before a TSB CSYNC operation, if the TSB CSYNC is executed in Debug state, then the entry to Debug state can replace that CSE for the rule.
- Where a rule mentions the PE executing instructions in a Trace Prohibited region following the CSE, then executing the instructions in Debug state with the trace unit disabled is sufficient for the rule.

Exit from Debug state is a Context synchronization event.

Figure D6-3 shows RBFJKD and RMJQXM.

![Figure D6-3 Indirect read or indirect write by Trace operation after direct write](image)

Figure D6-4 Direct write after indirect read or indirect write by Trace operation

In RVTNCS, the second Context synchronization event CSE2 is required to ensure the direct read B is not executed before the synchronization barrier TSB. Figure D6-5 on page D6-5035 shows this.
If the trace is not prohibited after the Context synchronization event, further trace operations might be generated that are not guaranteed to be synchronized by the TSB CSYNC. For ISLWRW, this applies to the first Context synchronization event CSE1.

Trace is prohibited at higher Exception levels than the owning Exception level. This means that if the PE takes an exception to a higher Exception level than the owning Exception level then trace is prohibited at by taking the exception.

Figure D6-6 shows RDFHWV for an explicit read or a write M1 of a Location made by an instruction B in program order before DSB.

If all of the following are true, RVILWDM requires that a DSB with required access types of reads and writes does not complete until at least all reads or writes RW made by the Trace Buffer Unit for all trace operations tA relating to a traced instruction A are complete for the set of the observers in the required Shareability domain:

• Either A is executed in program order before a Context synchronization event CSE, or A is CSE.
• The PE is executing in a Trace Prohibited region after CSE.
• CSE is in program order before a Trace synchronization barrier TSB.
• TSB is executed in program order before the DSB.

Figure D6-7 on page D6-5036 shows a read or a write RW1 of a Location made by the Trace Buffer Unit for a trace operation tA relating to a traced instruction A is complete and therefore will be Observed-by a read or a write RW2 of the same Location made by an instruction B executed in program order after a DSB ISH instruction.
RHCVVS defines Trace synchronization for Speculative instructions.

For example, an indirect read \( r_1 \) of a System register made by a trace operation \( t_S \) for a traced Speculative instruction \( S \) from a direct write \( W_2 \) to the same System register made by an instruction \( B \), if all of the following are true:

- \( S \) is executed in speculative execution-order after a Resolved instruction \( A \).
- \( A \) is executed in program order after a Context synchronization event \( CSE \).
- \( B \) is executed in program order before \( CSE \).

Figure D6-8 shows this.

\[
\text{Figure D6-7 Observation of Trace operation memory access}
\]

RHCVVS defines Trace synchronization for Speculative instructions.

For example, if all of the following are true, a DSB with required access types of reads and writes does not complete until at least all reads or writes \( RW \) made by the Trace Buffer Unit for all trace operations \( t_S \) relating to a traced Speculative instructions \( S \) are complete for the required Shareability domain:

- \( S \) is executed in speculative execution-order after a Resolved instruction \( A \).
- \( A \) is executed in program order before a Context synchronization event \( CSE \).
- \( S \) is not in speculative execution-order after \( CSE \).
- \( CSE \) is in program order before a Trace synchronization barrier \( TSB \).
- The PE is executing in a Trace Prohibited region after \( CSE \).
- \( TSB \) is executed in program order before the DSB.

Figure D6-9 on page D6-5037 shows a read or a write \( RW_1 \) of a Location made by the Trace Buffer Unit for a trace operation \( t_S \) relating to a traced Speculative instruction \( S \) is Complete and therefore will be Observed-by a read or a write \( RW_2 \) of the same Location made by an instruction \( B \) executed in program order after a DSB ISH instruction.
Figure D6-9 Observation of Speculative Trace operation memory access
### D6.9 UNPREDICTABLE behavior

In the absence of correct synchronization events, it is UNPREDICTABLE whether an indirect read made by a trace operation of a System register updated by a direct write will return the old or the new values. A trace operation might make multiple indirect reads of a System register, and each might return a different one of the old or the new values.

For example, a trace operation might read MDCR_EL2.E2TB twice, as follows:

1. When the trace operation is first generated, to evaluate TraceAllowed() and determine whether trace is prohibited.
2. When the trace operation is complete and ready to be written to memory, to evaluate TraceBufferOwner() to determine the context for TRBPTR_EL1.

If MDCR_EL2.E2TB is updated without proper synchronization between these two events, both the old and new value might be used.

In the absence of correct synchronization events, it is UNPREDICTABLE whether a direct read of a System register updated by an indirect write made by a trace operation will return the old or the new values.

If an instruction is traced because the Trace Buffer Unit is enabled and running, but a later indirect read of a System register by the trace operation for the instruction determines that the trace data cannot be written to memory, because the Trace Buffer Unit now appears to be disabled, then one of the following occurs, and it is CONSTRAINED UNPREDICTABLE which:

- The trace data is written to memory.
- The trace data is sent to an IMPLEMENTATION DEFINED trace bus.
- The trace data is written to memory and sent to an IMPLEMENTATION DEFINED trace bus.
- The Trace Buffer Unit discards the trace data.

This also includes any trace data that might be flushed by the trace unit, for example due to a TSBSYNC operation.

If the Trace Buffer Unit discards the trace data, a trace buffer management event might be generated:

- TRBSR_EL1.EC is set to a CONSTRAINED UNPREDICTABLE choice of the following values:
  - 0x00, other buffer management event.
  - 0x1F, IMPLEMENTATION DEFINED buffer management event.
- If TRBSR_EL1.EC is set to 0x00, then TRBSR_EL1.BSC is set to 0b000000 to indicate that the trace buffer is not full.

It is also CONSTRAINED UNPREDICTABLE whether any of the following occur, whether or not the trace data is written to memory:

- The current write pointer and, if TRBSR_EL1.TRG is 1, the Trigger Counter are updated for the trace data.
- A trace buffer management event that would have been generated is observed and/or generated.
- A PMU event that would have been generated is generated.

See also **Context switching on page K4-11673**.
Chapter D7
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- About the memory system architecture on page D7-5040.
- Address space on page D7-5041.
- Mixed-endian support on page D7-5042.
- Cache support on page D7-5043.
- External aborts on page D7-5072.
- Memory barrier instructions on page D7-5074.
- Pseudocode description of general memory System instructions on page D7-5075.
D7.1 About the memory system architecture

The Arm architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page B2-184.

If FEAT_MTE2 is implemented, the definitions of the memory model which apply to data accesses and data apply to Allocation Tag accesses and Allocation tags, unless otherwise specified in Chapter D9 The Memory Tagging Extension.

D7.1.1 Form of the memory system architecture

The A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter D8 The AArch64 Virtual Memory System Architecture describes the AArch64 view of the VMSA.

D7.1.2 Memory attributes

Memory types and attributes on page B2-196 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D7-1 on page D7-5040 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

a. Takes additional attributes, see Device memory on page B2-200.
b. See also Cacheability, cache allocation hints, and cache transient hints on page D7-5046.

D7.2 Address space

The architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see Implemented physical address size on page D8-5088.

D7.2.1 Virtual address space overflow

When a PE performs a Simple sequential execution of instructions, it calculates:

\[(address\_of\_current\_instruction) + (size\_of\_executed\_instruction)\]

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows 0xFFFF FFFF FFFF FFFF, the program counter becomes UNKNOWN. Similarly, if the address calculation based on the program counter for the value of the link register or exception link register overflows 0xFFFF FFFF FFFF FFFF, then those registers also become UNKNOWN.

Note

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the 0xFFFF_FFFF_FFFF_FFFF boundary when tagged addresses are not used, or the 0xFFF_FFFF_FFFF_FFFF boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.
D7.3 Mixed-endian support

A control bit, SCTLR_EL1.E0E is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D7-2 on page D7-5042 shows the endianness of explicit data accesses and translation table walks.

--- Note ---

SCTLR_EL1.E0E has no effect on the endianness of the LDTR, LDTRH, LDTRSH, and LDTRSW instructions, or on the endianness of the STTR and STTRH instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR_ELx.EE is RW and SCTLR_EL1.E0E is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR_ELx.EE is RES0 and SCTLR_EL1.E0E is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR_ELx.EE is RES1 and SCTLR_EL1.E0E is RW.
- All Exception levels support only little-endianness:
  - SCTLR_ELx.EE is RES0 and SCTLR_EL1.E0E is RES0.
- All Exception levels support only big-endianness:
  - SCTLR_ELx.EE is RES1 and SCTLR_EL1.E0E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1. PSTATE.E is ignored in AArch64 state.

The BigEndian() function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in Chapter J1 Armv8 Pseudocode.

For more information about endianness in the Arm architecture see Endian support on page B2-192.
D7.4 Cache support

This section describes the cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- General behavior of the caches.
- Cache identification on page D7-5044.
- Cacheability, cache allocation hints, and cache transient hints on page D7-5046.
- Enabling and disabling the caching of memory accesses on page D7-5047.
- Behavior of caches at reset on page D7-5049.
- Non-cacheable accesses and instruction caches on page D7-5049.
- About cache maintenance in AArch64 state on page D7-5050.
- A64 Cache maintenance instructions on page D7-5054.
- Data cache zero instruction on page D7-5068.
- Cache lockdown on page D7-5068.
- System level caches on page D7-5070.
- Branch prediction on page D7-5070.
- Execution, data prediction and prefetching restriction System instructions on page D7-5070.

See also Caches on page D8-5215.

D7.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page D7-5069.
Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

It is guaranteed that no memory location will be allocated into a Data or Unified cache if that location does not have a Normal Cacheable attribute in either:
- The translation regime at the current Exception level.
- The translation regime at any higher Exception level.

For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all Requesters in its shareability domain.

Any memory location is not guaranteed to remain incoherent with the rest of memory.

The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.

The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

Note: The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D7.4.2 Cache identification

The cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

- Affect the entire cache, for example IC IALU.
- Operate by VA, for example IC IVAU.
- Operate by set/way, for example DC ISW.

The cache identification registers are:

- The Cache Type Register, CTR_EL0, that defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instruction.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

Note: It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches on page D7-5070.

- A single Cache Level ID Register, CLIDR_EL1, that defines:
  - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  - The Level of Coherence (LoC) for the caches. See Terms used in describing the cache maintenance instructions on page D7-5050 for the definition of LoC.
— The Level of Unification Uniprocessor (LoUU) for the caches. See Terms used in describing the cache maintenance instructions on page D7-5050 for the definition of LoUU.
— An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.

• A single Cache Size Selection Register, CSSELR_EL1, that selects the cache level and sort of cache (Instruction, Data/Unified/Tag) of the current Cache Size Identification Register.

• For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, CCSIDR_EL1, that defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  — The number of sets, associativity and line length of the cache. See Terms used in describing the cache maintenance instructions on page D7-5050 for a definition of these terms.

----- Note ----- 
From Armv8.3, multiple formats of the Cache Size Identification Register are supported. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   • Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   • Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Register, CCSIDR_EL1

From Armv8.3, the Cache Size Identification Register, CCSIDR_EL1 has two different formats available for defining the number of sets and associativity of the cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions on page D7-5050.

When FEAT_CCIDX is implemented:
   • CCSIDR_EL1 is a 64-bit register.
   • The length of the CCSIDR_EL1.Assoc field is 21 bits. This limits the associativity of the currently selected cache to 2^{21}.
   • The length of the CCSIDR_EL1.NumSets field is 24 bits. This limits the number of sets in the currently selected cache to 2^{24}.

This is the 64-bit format of the Cache Size Identification Register.

When FEAT_CCIDX is not implemented:
   • CCSIDR_EL1 is a 32-bit register.
   • The length of the CCSIDR_EL1.Assoc field is 10 bits. This limits the associativity of the currently selected cache to 2^{10}.
The AArch64 System Level Memory Model

D7.4 Cache support

- The length of the CCSIDR_EL1.NumSets field is 15 bits. This limits the number of sets in the currently selected cache to $2^{15}$.

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

D7.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page B2-196, the memory attributes include a cacheability attribute that is one of:
- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hint is supported the following cache allocation hints can be assigned:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

--- Note ---

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.

- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.

- For VMSAv8-64 translation table walks, the TCR_ELx.{IRGNn, ORGNn} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In Armv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

--- Note ---

The architecture does not specify what is meant by a relatively short period.

The description of the AArch64 MAIR_EL1, MAIR_EL2, and MAIR_EL3 registers, and the AArch32 MAIR0, MAIR1, HMAIR0, and HMAIR1 registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
D7.4 Cache support

D7.4.4 Enabling and disabling the caching of memory accesses

Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the Arm architecture.

The Cacheability control fields and their effects are as follows:

For the EL1&0 translation regime

- When the value of SCTL_EL1.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTL_EL1.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.CD is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of HCR_EL2.ID is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.DC is 1, all stage 1 translations and all accesses to the EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTL_EL1.{I, C}. This applies to translations for both data and instruction accesses.

Note

- The stage 1 and stage 2 cacheability attributes are combined as described in Combining stage 1 and stage 2 Cacheability attributes for Normal memory on page D8-5154.
- The SCTL_EL1.{C, I} and HCR_EL2.DC fields have no effect on the EL2, EL2&0, and EL3 translation regimes.
- The HCR_EL2.{ID, CD} fields affect only stage 2 of the EL1&0 translation regime.
- When EL2 is using AArch64 and EL1 is using AArch32, the HCR_EL2.{ID, CD, DC} controls apply as described here, but the EL1 controls are SCTL_EL1.{C, I}.
- When FEAT_XS is implemented, the SCTL_EL1.{C, I} and HCR_EL2.{ID, CD} fields have no effect on the value of the XS attribute.

For the EL2 translation regime

- When the value of SCTL_EL2.C is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of SCTL_EL2.I is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.
The AArch64 System Level Memory Model
D7.4 Cache support

--- Note ---

- The SCTLR_EL2.{I, C} fields have no effect on the EL1&0 and EL3 translation regimes.
- When FEAT_XS is implemented, the SCTLR_EL2.{I, C} fields have no effect on the value of the XS attribute.

--- For the EL2&0 translation regime ---

- When the value of SCTLR_EL2.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL2&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR_EL2.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.

--- Note ---

When FEAT_XS is implemented, the SCTLR_EL2.{I, C} fields have no effect on the value of the XS attribute.

--- For the EL3 translation regime ---

- When the value of SCTLR_EL3.C is 0:
  - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
  - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of SCTLR_EL3.I is 0:
  - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

--- Note ---

- The SCTLR_EL3{I, C} fields have no effect on the EL1&0, EL2, and EL2&0 translation regimes.
- When FEAT_XS is implemented, the SCTLR_EL3.{I, C} fields have no effect on the value of the XS attribute.

--- In addition ---

- For translation regimes other than the EL1&0 translation regime, if the value of SCTLR_ELx.M is 0, indicating that stage 1 translations are disabled for that translation regime, then:
  - If the value of SCTLR_ELx.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_ELx.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
- For the EL1&0 translation regime, if the value of SCTLR_EL1.M is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of HCR_EL2.DC is 0:
  - If the value of SCTLR_EL1.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_EL1.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of SCTLR_ELx.C, HCR_EL2.DC and HCR_EL2.CD is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.
D7.4 Cache support

D7.4.5 Behavior of caches at reset

The behavior of caches at reset is as follows:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in Enabling and disabling the caching of memory accesses on page D7-5047 reset to values that force all memory locations to be treated as Non-cacheable.

— Note —

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  — Provide a mechanism to ensure the correct initialization of the caches.
  — Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- Arm recommends that whenever an invalidation routine is required, it is based on the cache maintenance instructions.

See also TLB behavior at reset on page D8-5193.

D7.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in Non-cacheable space in a uniprocessor system, the following sequence is required:

; Enter this code with $t0 containing the new 32-bit instruction
; to be held at a location pointed to by $x0 in Normal Non-cacheable memory.
STR $t0, [$x0]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [$x0]; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;
In a multiprocessor system, the IC IVAU for a non-cacheable location is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. This is despite non-cacheable normal memory locations being treated as Outer Shared in other parts of the architecture.

Additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences. See also Concurrent modification and execution of instructions on page B2-156 and Concurrent modification and execution of instructions on page E2-7166.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or a IC IALLUIS for a multiprocessor system.

--- Note ---
This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses on page D7-5047.

## D7.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:
- Terms used in describing the cache maintenance instructions.
- Abstraction of the cache hierarchy on page D7-5053.

The following sections describe the A64 cache maintenance instructions:
- The instruction cache maintenance instruction (IC) on page D7-5056.
- The data cache maintenance instruction (DC) on page D7-5056.

--- Note ---
Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

--- Terms used in describing the cache maintenance instructions ---

Cache maintenance instructions are defined to act on particular memory locations. Instruction scope can be defined:
- By the virtual address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:
- Terminology for cache maintenance instructions operating by set/way on page D7-5051.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D7-5051.

--- Note ---
There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling an address translation stage on page D8-5118.
Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

**Level**

The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR_EL1.

In the Arm architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy on page B2-184.

**Set**

Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the Arm architecture, sets are numbered from 0.

**Way**

The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the Arm architecture, ways are numbered from 0.

--- **Note**

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, Arm expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

---

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

**Clean**

A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

**Invalidate**

A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

--- **Note**

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.
Clean and Invalidate

A cache **clean and invalidate** instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instructions operating by VA, the following conceptual points are defined:

**Point of Coherency (PoC)**

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

--- **Note** ---

The presence of system caches can affect the determination of the point of coherency as described in *System level caches* on page D7-5070.

**Point of Unification (PoU)**

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

**Point of Persistence (PoP)**

*When FEAT_DPB is implemented:*

The point in a memory system, if it exists, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

*When FEAT_DPB and FEAT_DPB2 are implemented:*

The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed.

--- **Note** ---

Such memory is sometimes called non-volatile memory. For example, the Storage-class memory shown in *Figure B2-1 on page B2-185* could be used as target memory for this feature.

**Point of Deep Persistence (PoDP)**

The point in a memory system where any writes that have reached that point are persistent, even in the event of an instantaneous hardware failure of the power system.
The following fields in the CLIDR_EL1 relate to the PoC and PoU:

**LoC, Level of Coherence**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:
- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.
If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.
If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**
This field defines the last level of data cache that must be cleaned, or the last level of instruction cache that must be invalidated, when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.
If the LoUU field value is 0x0, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.
If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**LoUIS, Level of Unification, Inner Shareable**
In any implementation:
- This field defines the last level of data or unified cache that must be cleaned, or the last level of instruction or unified cache that must be invalidated, when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of data or unified cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**Abstraction of the cache hierarchy**
The following subsections describe the abstraction of the cache hierarchy:
- *Cache maintenance instructions that operate by VA.*
- *Cache maintenance instructions that operate by set/way on page D7-5054.*

**Cache maintenance instructions that operate by VA**
The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:
- Performed to the Point of Coherency.
- Performed to the Point of Unification.
- When FEAT_DPB is implemented, performed to the Point of Persistence.

See *Terms used in describing the cache maintenance instructions on page D7-5050* for definitions of these terms, and for more information about possible meanings of VA.

*A64 Cache maintenance instructions on page D7-5054* lists the VA-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:
- The instruction caches.
- The data and unified caches.
These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

**Cache maintenance instructions that operate by set/way**

*AArch64 Cache maintenance instructions* lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

**D7.4.8 A64 Cache maintenance instructions**

The A64 cache maintenance instructions are part of the A64 System instruction class in the register encoding space. For encoding details and other general information on these System instructions, see [System instructions on page C3-250, SYS on page C6-1993](#) and [Cache maintenance instructions, and data cache zero operation on page C5-659](#).

Table D7-3 on page D7-5054 shows the AArch64 System instructions that perform instruction or data cache maintenance. Instructions that take an argument include Xt in the entry in the *System instruction on page D7-5054* column.

<table>

\(^a\) When HCR_EL2.{E2H,TGE} == {1, 1}, the control is from SCTRL_EL2.
\(^b\) Supported only when FEAT_DPB is implemented.
• Effects of instructions that operate by VA to the PoU on page D7-5060.
• Effects of All and set/way maintenance instructions on page D7-5061.
• Effects of virtualization and Security state on the cache maintenance instructions on page D7-5061.
• Boundary conditions for cache maintenance instructions on page D7-5063.
• Ordering and completion of data and instruction cache instructions on page D7-5063.
• Performing cache maintenance instructions on page D7-5066.

The instruction cache maintenance instruction (IC)

System instructions on page C3-250 describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:
• For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H==1, the current ASID.
• The current Security state.
• Whether the instruction was executed at EL1 or EL2.
• For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:
• It is IMPLEMENTATION DEFINED whether the instruction can generate:
  — An Access flag fault.
  — A Translation fault.
• The instruction cannot generate a Permission fault, except for:
  — The possible generation of a Permission fault by the execution of an IC IVAU instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D7-5058.
  — When FEAT_CMOW is implemented, the possible generation of a Permission fault by:
    — The execution of an IC IVAU instruction at EL0 when the specified address has stage 1 read permission, but does not have stage 1 write permission.
    — The execution of an IC IVAU instruction at EL1 or EL0 when the specified address has stage 2 read permission, but does not have stage 2 write permission.
    — The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a cache maintenance instruction that operates by VA see Memory aborts on page D8-5180.

See also Ordering and completion of data and instruction cache instructions on page D7-5063.

The data cache maintenance instruction (DC)

System instructions on page C3-250 describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-11600 or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.
Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H is 1, the current ASID.
- The current Security state.
- Whether the instruction is executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

- The possible generation of a Permission fault by:
  - The execution of a `DC IVAC` instruction when the specified address does not have write permission.
  - The execution of an enabled DC * instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D7-5058.

The description of Permission faults includes possible constraints on the generation of Permission faults on cache maintenance by VA instructions.

- When FEAT_CMOW is implemented, the possible generation of a Permission fault by:
  - The execution of a `DC CIVAC`, `DC CIGVAC`, or `DC CIGDVAC` instruction at EL0 when the specified address has stage 1 read permission, but does not have stage 1 write permission.
  - The execution of a `DC CIVAC`, `DC CIGVAC`, or, `DC CIGDVAC` instruction at EL1 or EL0 when the specified address has stage 2 read permission, but does not have stage 2 write permission.

- The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a VA to PA translation see Memory aborts on page D8-5180.

When executed at EL1, a `DC ISW` instruction performs a clean and invalidate, meaning it performs the same maintenance as a `DC CISW` instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - The value of HCR_EL2.SWIO is 1, forcing a cache clean to perform a clean and invalidate.
  - The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

When executed at EL1, a `DC IVAC` instruction performs a clean and invalidate, meaning it performs the same maintenance as a `DC CIVAC` instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

-- Note --

The forcing of a clean instruction to perform a clean invalidate applies to the AArch32 cache maintenance instructions `DCIWAC` and `DCISW`. See AArch32 data cache maintenance instructions (DC*) on page G4-9125.

-- Note --

When FEAT_DPB is implemented, meaning the `DC CVAP` instruction is implemented, if the memory system does not support the Point of Persistence, a data cache clean to the PoP, `DC CVAP`, behaves as a data cache clean to the PoC, `DC CVAC`.

-- Note --

- Support for the Point of Persistence does not change the definition or behavior of the CLIDR_EL1 System register.
- Because a DSB SYS instruction will not complete until all previous DC CVAP instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:
  ```
  DMB ; Note this can be any DMB that applies to both loads and stores
  DC CVAP , Xt
  DSB SYS
  ```
If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the **DC CVAP** operation causes the Non-cacheable locations to be cleaned from those caches.

If a memory fault that sets the **FAR** for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the **FAR** holds the address specified in the register argument of the instruction.

**Note**

Despite its mnemonic, **DC ZVA** is not a cache maintenance instruction.

See also [EL0 accessibility of cache maintenance instructions](#) and [Ordering and completion of data and instruction cache instructions](#) on page D7-5063.

### EL0 accessibility of cache maintenance instructions

The **SCTLR_EL1.UCI** bit enables EL0 access for the **DC CVAU, DC CVAC, DC CVAP, DC CIVAC, DC CIVAC, DC CIGVAC, DC CIGDVAC**, and **IC IVAU** instructions. When EL0 use of these instructions is disabled because **SCTLR_EL1.UCI** == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using **EC** = 0x18. When **HCR_EL2.{E2H,TGE}** == {1,1}, the control is from **SCTLR_EL2**.

**Note**

**DC CVAP** is implemented only if **FEAT_DPB** is implemented.

For these instructions read access permission is required. When the value of **SCTLR_EL1.UCI** is 1:

- For the **DC CVAU, DC CVAC, DC CVAP, DC CIVAC, DC CIGVAC**, and **DC CIGDVAC**, instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a **Permission fault** might be generated.

- For the **IC IVAU** instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is **IMPLEMENTATION DEFINED** whether a **Permission fault** is generated.

- When **FEAT_CMOW** is implemented, for the **DC CIVAC, DC CIGVAC, DC CIGDVAC**, and **IC IVAU** instructions, both read and write access permission is required:
  - When **SCTLR_EL1.CMOW** is 1, if the instruction executed at EL0 has stage 1 read permission, but does not have stage 1 write permission, a **Permission fault** is generated.
  - When **HCRX_EL2.CMOW** is 1, if the instruction executed at EL0 has stage 2 read permission, but does not have stage 2 write permission, a **Permission fault** is generated.

  **Note**
  
  This stage 2 access permission also applies to the **DCCIMVAC** and **ICIMVAU** AArch32 cache maintenance instructions.

For more information see the description of **Permission faults**, In the case of a **DC */* instruction executed at EL0 when the address specified cannot be read at EL0 the **Permission fault** is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the **CTR_EL0** to discover the stride needed for cache maintenance instructions. The **SCTLR_EL1.UCT** bit enables EL0 access to the **CTR_EL0**. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using **EC** = 0x18.
General requirements for the scope of maintenance instructions

The specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page D7-5043, Behavior of caches at reset on page D7-5049, and Preloading caches on page B2-188.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

Note

Arm recommends that, for best performance, such side-effects are kept to a minimum. Arm strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

If an implementation can overwrite Allocation Tags in memory that have been written by another observer, where the Allocation Tags have not been written by an observer in the Shareability domain of that memory location, then:

- A cache maintenance operation which cleans data from a cache level must also clean the associated Allocation Tags.
- A cache maintenance operation which invalidates, or cleans and invalidates data from a cache level, must also clean and invalidate the associated Allocation Tags.

Effects of instructions that operate by VA to the PoC

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. Table D7-4 on page D7-5059 shows the scope of these Data and unified cache maintenance instructions.

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
</tbody>
</table>

Note

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.
Effects of instructions that operate by VA to the PoP

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. Table D7-5 on page D7-5060 shows the scope of these Data and unified cache maintenance to the PoP instructions.

Table D7-5 PEs affected by cache maintenance instructions to the PoP

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
</tbody>
</table>

Note

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

Effects of instructions that operate by VA to the PoU

For cache maintenance instructions that operate by VA to the PoU, Table D7-6 on page D7-5060 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D7-6 PEs affected by cache maintenance instructions to the PoU

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable or Outer Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>

Note

- The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.
- It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.
Effects of All and set/way maintenance instructions

The \texttt{IC IALLU} and \texttt{DC} set/way instructions apply only to the caches of the PE that performs the instruction.

The \texttt{IC IALLUIS} instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

\begin{note}
- The possible presence of system caches, as described in \textit{System level caches} on page D7-5070, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.
- It is \textsc{IMPLEMENTATION DEFINED} by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.
\end{note}

Effects of virtualization and Security state on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space. \textbf{Table D7-7} on page D7-5061 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the \textit{Specified entries} on page D7-5061 are entries that the architecture requires the instruction to affect.

\begin{note}
The rules described in \textit{General behavior of the caches} on page D7-5043 mean that an instruction might also affect other entries.
\end{note}

\begin{table}[h]
\centering

\hline
\end{tabular}
\caption{Effects of virtualization and security on the maintenance instructions}
\end{table}
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions* on page D7-5069 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, invalidate by set/way instructions can, instead, perform a clean and invalidate by set/way.

- As described in *The data cache maintenance instruction (DC)* on page D7-5056, the AArch64 Data cache invalidate instructions, DC _IVAC and DC _ISW, when executed at EL1 and EL0, and the AArch32 Data cache invalidate instructions DCIMVAC and DCISW, when executed at EL1, can be configured to perform a cache clean as well as a cache invalidation.

- TLB and instruction cache invalidate instructions executed at EL1 are broadcast across the Inner Shareable domain when all of the following is true:
  - When the value of HCR_EL2.FB is 1.
— EL3 is not implemented, or EL3 is implemented and either SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1.

When EL1 is using AArch64, this applies to the IC IALLU instruction. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction IC IALLUIS.

For more information about the cache maintenance instructions, see About cache maintenance in AArch64 state on page D7-5050, A64 Cache maintenance instructions on page D7-5054, and Chapter D8 The AArch64 Virtual Memory System Architecture.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, DC GVA, and DC GZVA that specify an address:

- Execute in program order relative to loads or stores that have all of the following properties:
  — Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  — Use an address with the same cacheability attributes as the address passed to the data cache instruction.
- Can execute in any order relative to loads or stores that have all of the following properties:
  — Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  — Use an address with different cacheability attributes as the address passed to the data cache instruction.
  — Do not have a DMB or DSB executed between the load or store instruction and the data cache instruction.
- Can execute in any order relative to other data cache instructions, other than DC ZVA, DC GVA, and DC GZVA that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
- Can execute in any order relative to other data cache instructions, other than DC ZVA, DC GVA, and DC GZVA that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to other data cache instructions, other than DC ZVA, DC GVA, and DC GZVA that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.
• Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

--- Note ---
Despite their mnemonics, the DC ZVA, DC GVA, and DC GZVA instructions are not data cache maintenance instructions.

--- Note ---
• Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches on page D8-5215.
• Data cache zero instruction on page D7-5068 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:
• Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
• Can execute in any order relative to data cache maintenance instructions that specify an address, other than DC ZVA, DC GVA, and DC GZVA, unless a DMB or DSB is executed between the instructions.
• Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
• Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in Completion and endpoint ordering on page B2-168.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

--- Note ---
These ordering requirements are extended from the requirements in AArch32 state given in:
• Ordering of cache and branch predictor maintenance instructions on page G4-9132.
• AArch32 instruction cache maintenance instructions (IC*) on page G4-9124.

Ordering and completion of Data Cache Clean to Point of Persistence

The update of the persistent memory as a result of Data Cache Clean to the Point of Persistence is guaranteed to have occurred either after:
• The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Persistence.
• The update to persistent memory caused by a different Data Cache Clean to the Point of Persistence that is ordered after a DMB applying to both reads and writes that appears after the original Data Cache Clean to the Point of Persistence.

--- Note ---
This second point is an aspect of the fact that the Data Cache Clean to the Point of Persistence instructions are ordered by DMB, and this controls the order of arrival in persistent memory.
The ordering effect for the Data Cache Clean to the Point of Persistence by DMB applying to both read and writes is not sufficient to ensure that in Example D7-1, observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Persistence has caused an update of persistent memory:

**Example D7-1 The ordering effect for the Data Cache Clean to the Point of Persistence**

; initial condition has [X3]=0.
DC_CVADP, X1
DMB
MOV X2, #1
STR X2, [X3]

However, in Example D7-2, the ordering effects of the DMB instruction will ensure that the location pointed by P0: X1 will reach the Point of Persistence before, or at the same time as, the location pointed by P1:X8.

**Example D7-2 The ordering effect for the Data Cache Clean to the Point of Persistence**

; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of this example
P0
DC_CVAP, X1
DMB
MOV X2, #1
STR X2, [X3]
P1
loop
LDR X2, [X3]
CBZ X2, loop
DMB
DC_CVAP, X8

**Ordering and completion of Data Cache Clean to Point of Deep Persistence**

The update of the deep persistent memory as a result of Data Cache Clean to the Point of Deep Persistence is guaranteed to have occurred either after:

- The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Deep Persistence.
- The update to deep persistent memory caused by a different Data Cache Clean to the Point of Deep Persistence that is ordered after a DMB applying to both reads and writes that appears after the original Data Cache Clean to the Point of Deep Persistence.

**Note**

This second point is an aspect of the fact that the Data Cache Clean to the Point of Deep Persistence instructions are ordered by DMB, and this controls the order of arrival in deep persistent memory.

**Note**

The ordering effect for the Data Cache Clean to the Point of Deep Persistence by DMB applying to both read and writes is not sufficient to ensure that in Example D7-3, observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Deep Persistence has caused an update of deep persistent memory:
Example D7-3 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

; initial conditions has [X3]=0.
DC CVADP, X1
DMB
MOV X2, #1
STR X2, [X3]

However, in Example D7-4, the ordering effects of the DMB instruction will ensure that the location pointed by P0: X1 will reach the Point of Deep Persistence before, or at the same time as, the location pointed by P1: X8.

Example D7-4 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of this example
P0
DC CVADP, X1
DMB
MOV X2, #1
STR X2, [X3]
P1
loop
LDR X2, [X3]
CBZ X2, loop
DMB
DC CVADP, X8

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache Arm strongly recommends that software:

• For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
• For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, Arm strongly discourages the use of set/way
instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set.way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and Arm advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

**System level caches on page D7-5070** refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1 on page D7-5045.

```
MRS     X0, CLIDR_EL1
AND     W3, W0, #0x07000000     // Get 2 x Level of Coherence
LSR     W3, W3, #23
CEZ     W3, Finished
MOV     W10, #0                  // W10 = 2 x cache level
MOV     W8, #1                   // W8 = constant 0b1

Loop1:  ADD     W2, W10, W10, LSR #1    // Calculate 3 x cache level
        LSR     W1, W0, W2              // extract 3-bit cache type for this level
        AND     W1, W1, #0x7            // W1 = constant 0x7
        CMP     W1, #2
        B.LT    Skip                    // No data or unified cache at this level
        MSR     CSSELR_EL1, X10         // Select this cache level
        ISB                             // Synchronize change of CSSELR
        MRS     X1, CCSIDR_EL1          // Read CCSIDR
        AND     W2, W1, #7              // W2 = log2(linelen)-4
        ADD     W2, W2, #4              // W2 = log2(linelen)
        UBFX    W4, W1, #3, #10         // W4 = max way number, right aligned
        CLZ     W5, W4                  // W5 = 32-log2(ways), bit position of way in DC operand
        LSL     W9, W4, W5              // W9 = max way number, aligned to position in DC operand
        LSL     W16, W8, W5             // W16 = amount to decrement way number per iteration

Loop2:  UBFX    W7, W1, #13, #15        // W7 = max set number, right aligned
        LSL     W7, W7, W2              // W7 = max set number, aligned to position in DC operand
        LSL     W17, W8, W2             // W17 = amount to decrement set number per iteration

Loop3:  ORR     W11, W10, W9           // W11 = combine way number and cache number...
        ORR     W11, W11, W7            // ... and set number for DC operand
        DC      CSW, X11                // Do data cache clean by set and way
        B.GE    Loop3
        SUBS    W7, W7, W17             // Decrement set number
        B.GE    Loop2
        SUBS    X9, X9, X16             // Decrement way number

Skip:   ADD     W10, W10, #2          // Increment 2 x cache level
        CMP     W3, W10
        DSB     // Ensure completion of previous cache maintenance instruction
        B.GT    Loop1

Finished:
```

Similar approaches can be used for all cache maintenance instructions.
D7.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, DC ZVA, writes 0x00 to each byte of a block of N bytes, aligned in memory to N bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the DC ZVA instruction. There are no alignment restrictions on this address.

--- Note ---

This means that each byte of the block of memory that includes the supplied address is set to zero.

- The DCZID_EL0 register indicates the block size, N bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See Configurable instruction controls on page D1-4665 and the description of the DC ZVA instruction.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See ISS encoding for an exception from a Data Abort on page D17-5685 for more information about the encoding of the associated ESR_ELx.ISS field.

- If the memory region being zeroed is any type of Device memory, then DC ZVA generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

--- Note ---

The architecture makes no statements about whether or not a DC ZVA instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

Despite its mnemonic, the DC ZVA instruction is not a data cache maintenance instruction.

D7.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, **DC CSW**.
  - Cache invalidate by set/way, **DC ISW**.
  - Cache clean and invalidate by set/way, **DC CISW**.
  - Instruction cache invalidate all, **IC IALLU** and **IC IALLUIS**.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose, see [ISS encoding for an exception from a Data Abort on page D17-5685](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, **DC CVAC**, **DC CVAP**, and **DC CVAU**.
- Cache invalidate by virtual address, **DC IVAC**.
- Cache clean and invalidate by virtual address, **DC CIVAC**.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See [ESR_ELx on page K17-11846](#).

In an implementation that includes EL2 enabled in the current Security state, if **HCR_EL2.TIDCP** is set to 1, any exception relating to lockdown of an entry is routed to EL2.

--- Note ---

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.
Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D16-5542.

D7.4.11 System level caches

The Arm Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR_EL1 and CLIDR_EL1, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the Arm architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

D7.4.12 Branch prediction

The architecture does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.

D7.4.13 Execution, data prediction and prefetching restriction System instructions

When FEAT_SPECRES is implemented, the System instructions listed in A64 System instructions for prediction restriction on page C5-1146 prevent predictions based on information gathered from earlier execution within a particular execution context (CTX), from affecting the later speculative execution within that CTX, to the extent that the speculative execution is observable through side-channels.

The prediction restriction System instructions being used by a particular CTX apply to:

- All control flow prediction resources that predict execution addresses.
- Data value prediction.
- Cache allocation prediction.

For these System instructions, the CTX is defined by:

- The Security state.
- The Exception level.
- When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
- When executing at EL0 when using the EL1&0 translation regime, the ASID and, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0 when using the EL2&0 translation regime, the ASID.

--- Note ---

- The data value prediction applies to all prediction resources that use some form of training to speculate data values as part of an execution.
- The cache allocation applies to all instruction and data caches, and TLB prefetching hardware used by the executing PE that applies to the supplied context.
The context information is passed as a register argument, and is restricted so that:

- Execution of the System instruction at EL0 only applies to the current hardware defined context.
- Execution of the System instruction at EL1 only applies to the current VMID and Security state, and does not apply to EL2 or EL3.
- Execution of the System instruction at EL2 can only apply to the current Security state, and does not apply to EL3.

If the System instruction is specified to apply to Exception levels that are not implemented, or which are higher than the Exception level that the System instruction is executed at, then the System instruction is treated as a NOP.

When the System instruction is complete and synchronized, no predictions of the restricted type for the affected context are influenced by the execution of the program before the System instruction in a manner that can be observed by the use of any side channels.

--- Note ---

- Prediction restriction System instructions do not require the invalidation of prediction structures so long as the behavior described for completion is met by an implementation.
- Prediction restriction System instructions are permitted to invalidate more prediction information than is defined by the supplied execution context.

---

These System instructions are guaranteed to be complete following a DSB that covers both read and write behavior on the same PE that executed the original instruction. A subsequent Context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

In AArch64 state, EL0 access to the System instructions is controlled by:

- When HCR_EL2.{E2H, TGE} is not {1, 1}, SCTLR_EL1.EnRCTX.
- When HCR_EL2.{E2H, TGE} == {1, 1}, SCTLR_EL2.EnRCTX.

--- Note ---

If the SCR_EL3.EEL2 is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated for:

- Secure EL0 for all ASID and VMID values.
- Secure EL1 for all VMID values.
D7.5 External aborts

The Arm architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of the following:
- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception entry terminology on page D1-4638.

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the Arm architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported.

External aborts on data accesses and translation table walks on data accesses can be either synchronous or asynchronous.

When FEAT_DoubleFault is not implemented, External aborts on instruction fetches and translation table walks on instruction fetches can be either synchronous or asynchronous.

When FEAT_DoubleFault is implemented, all External abort exceptions on instruction fetches and translation table walks on instruction fetches must be synchronous.

A synchronous External abort on an instruction fetch, including a translation table walk on an instruction fetch, is taken precisely using the Instruction Abort exception.

A synchronous External abort on a data read or write, including a translation table walk on a data read or write, is taken precisely using the Data Abort exception.

See Synchronous exception types on page D1-4646.

An asynchronous External abort is taken using the SError interrupt exception. See Asynchronous exception types on page D1-4656.

The effect of a failed memory access is described in Definition of a precise exception and imprecise exception on page D1-4638.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running. Arm recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:
- Provision for the classification of External aborts.
- Parity or ECC error reporting, RAS Extension not implemented on page D7-5073.

D7.5.1 Provision for the classification of External aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, ESR_ELx.EA, ISS[9], returns a value of 0.

If the RAS Extension is implemented:
- The ESR_ELx.SET field provides information about the state of the PE following a synchronous External abort.
- The ESR ELx.AET field might contain more information following an asynchronous abort taken as an SError interrupt.
• The implementation might define error record registers.

For more information, see:
• ISS encoding for an exception from an Instruction Abort on page D17-5679.
• ISS encoding for an exception from a Data Abort on page D17-5685.
• ISS encoding for an SError interrupt on page D17-5695.
• Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

D7.5.2 Parity or ECC error reporting, RAS Extension not implemented

The Arm architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors. However, when parity or ECC error reporting is implemented, it is implementation defined whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
D7.6 Memory barrier instructions

Memory barriers on page B2-174 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D7.6.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 enabled in the current Security state and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can modify the required shareability of an instruction that is executed at EL0 or EL1. Table D7-8 on page D7-5074 shows the encoding of this field.

<table>
<thead>
<tr>
<th>HCR_EL2.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1, Table D7-9 on page D7-5074 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

<table>
<thead>
<tr>
<th>Shareability specified by the DMB or DSB argument</th>
<th>HCR_EL2.BSU</th>
<th>Resultant shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full system</td>
<td>Any</td>
<td>Full system</td>

</tbody>
</table>
D7.7 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access.
- Unaligned memory access.
- Exclusives monitors operations.
- Access permission checking on page D7-5076.
- Abort exceptions on page D7-5076.
- Memory barriers on page D7-5077.

D7.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, MemHint_RA, and MemHint_RWA constants.
- Access permissions, defined by the Permissions type.

These types are defined in Chapter J1 Armv8 Pseudocode.

D7.7.2 Basic memory access

The PhysMemRead() and PhysMemWrite() functions perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page B2-196, Ordering relations on page B2-163, and Atomicity in the Arm architecture on page B2-154.

D7.7.3 Aligned memory access

The two MemSingle[] accessors, non-assignment (memory read) AArch64.MemSingle[] and assignment (memory write) AArch64.MemSingle[], make atomic, little-endian accesses of size bytes.

D7.7.4 Unaligned memory access

The two Mem[] accessors, Non-assignment (memory read) Mem[] and Assignment (memory write) Mem[], make accesses of the required type. If an access is not architecturally defined to be atomic, Mem[] synthesizes accesses from multiple calls to AArch64.MemSingle[]. It also reverses the byte order if the access is big-endian.

The AArch64.CheckAlignment() function checks the alignment of memory accesses.

D7.7.5 Exclusives monitors operations

The AArch64.SetExclusiveMonitors() function sets the Exclusives monitors for a block of bytes, the size of which is determined by size, at the virtual address defined by address.
The AArch64.ExclusiveMonitorsPass() function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch64.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by AArch64.ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid for which an address has had a request for an exclusive access.

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least the size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

D7.7.6 Access permission checking

The AArch64.S1HasPermissionsFault() and AArch64.S2HasPermissionsFault() functions are used by the architecture to perform access permission checking based on attributes derived from the Translation Tables descriptors.

The interpretation of access permission is shown in Memory access control on page D8-5132.

D7.7.7 Abort exceptions

The AArch64.Abort() function generates either a Data Abort or an Instruction Abort exception by calling AArch64.DataAbort() or AArch64.InstructionAbort(). It also can generate a debug exception for debug related faults, see Chapter D2 AArch64 Self-hosted Debug.
The `AArch64.DataAbort()` function generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See *ISS encoding for an exception from a Data Abort* on page D17-5685. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.DataAbort()` also sets the FAR to the VA of the abort.

The `AArch64.InstructionAbort()` function generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx, see *ISS encoding for an exception from an Instruction Abort* on page D17-5679. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.InstructionAbort()` also sets the FAR to the VA of the abort.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault.

The function `NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

### D7.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required shareability domains and required access types used as arguments for `DMB` and `DSB` instructions.

The procedures `DataMemoryBarrier`, `DataSynchronizationBarrier`, and `InstructionSynchronizationBarrier` perform the memory barriers.
The AArch64 System Level Memory Model

D7.7 Pseudocode description of general memory System instructions
Chapter D8
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSAv8-64), the memory system architecture of an A-profile implementation that is executing in AArch64 state. It contains the following sections:

- Address translation on page D8-5080
- Translation process on page D8-5093
- Translation table descriptor formats on page D8-5123
- Memory access control on page D8-5132
- Memory region attributes on page D8-5151
- Other descriptor fields on page D8-5158
- Address tagging on page D8-5162
- Pointer authentication on page D8-5164
- Virtualization Host Extensions on page D8-5168
- Nested virtualization on page D8-5173
- Memory aborts on page D8-5180
- Translation Lookaside Buffers on page D8-5193
- TLB maintenance on page D8-5197
- Caches on page D8-5215
- Pseudocode description of VMSAv8-64 address translation on page D8-5217
D8.1 Address translation

If an implementation is executing in AArch64 state, then it is using the Armv8 Virtual Memory System Architecture (VMSA), specifically the 64-bit VMSAv8-64.

Address translation converts the addresses used by instructions to the addresses used by the physical memory system.

When a data address or instruction address is used in an instruction, it is a virtual address (VA). This includes any address stored in one of the following registers:

- Program counter (PC).
- Stack pointers (SP).
- Link register (LR).
- Exception link register (ELR).

When an access is made to the physical memory system, a physical address (PA) is used.

An address translation maps a VA to a PA.

An address translation requires one of the following:

- A single translation stage, stage 1.
- Two sequential translation stages, stage 1 and stage 2.

An address translation stage maps an input address (IA) to an output address (OA).

If one address translation stage is used, then a VA is mapped to a PA using all of the following steps:

1. The VA is input as the IA to the translation stage.
2. The PA is output as the OA from the translation stage.

If two address translation stages are used, then a VA is mapped to a PA using all of the following steps:

1. The VA is input as the IA to the stage 1 translation.
2. The intermediate physical address (IPA) is output as the OA from the stage 1 translation.
3. The IPA is input as the IA to the stage 2 translation.
4. The PA is output as the OA from the stage 2 translation.

If an address translation stage is disabled, then the value of the OA is the same as the IA.

When an IA is translated to an OA, an address translation stage uses a set of memory mapped translation tables that hold all of the following information:

- The OA corresponding to the IA.
- For accesses made from Secure state, whether the OA access is to the Secure or Non-secure address map.
- The OA memory access permissions.
- The OA memory region attributes.

When an IA is translated by an address translation stage, all of the following apply:

- A translation table lookup reads an entry from a translation table.
- A translation table entry resolves a subset of the IA.
- Multiple translation table entries can be required to completely resolve an IA.
- An address translation can require multiple lookups across different lookup levels and multiple translation tables.

When memory is accessed, the Memory Management Unit (MMU) controls address translation, memory access permissions, memory attribute determination, and memory attribute checking.

When the MMU cannot translate the IA, an MMU fault is generated.
When an address translation stage generates an MMU fault, it is one of the following:

- When a stage 1 translation cannot translate an IA, a stage 1 MMU fault is generated.
- When a stage 2 translation cannot translate an IA, a stage 2 MMU fault is generated.

For more information, see:

- Implemented physical address size on page D8-5088.
- Output address size configuration on page D8-5088.
- Supported virtual address ranges on page D8-5089.
- Input address size configuration on page D8-5090.
- Intermediate physical address size configuration on page D8-5091.
- Translation process on page D8-5093.
- The effects of disabling an address translation stage on page D8-5118.
- Memory aborts on page D8-5180

### D8.1.1 Translation granules

The translation granule size determines the number of bits resolved by each lookup level when mapping from an IA to OA, and the maximum size of a single translation table.

The VMSA defines all of the following translation granule sizes:

- 4KB.
- 16KB.
- 64KB.

For each translation granule size, and translation stage, support is IMPLEMENTATION DEFINED.

Each address translation stage can be independently configured to use one of the supported translation granule sizes.

A page is the smallest memory region in which an IA to OA mapping can be specified.

The translation granule determines all of the following:

- The translation process used to resolve an IA to an OA.
- The page size of the address translation stage.
- The number of address bits required to address a page.
- The maximum translation table size of the address translation stage.
- The number of address bits that can be resolved in a single translation table lookup.

For all of the following reasons, a larger translation granule can reduce the number of translation lookup levels:

- The larger granule uses a larger translation table with more entries.
- A single lookup can resolve more IA bits.
- The larger page size means more of the least significant address bits are used to address within a page and do not require translation because those bits are flat-mapped from IA to OA.

Arm recommends separating memory-mapped peripherals by an integer multiple of the largest granule size supported by the PEs in the system, to allow independent management of each peripheral.

If FEAT_GTG is not implemented, then the ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} fields specify the translation granules supported in both stage 1 and stage 2 translations.

If FEAT_GTG is implemented, then support for translation granule sizes are determined by all of the following:

- The ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} fields specify the translation granules supported in stage 1 translations.
• The ID_AA64MMFR0_EL1.{TGran4_2, TGran16_2, TGran64_2} fields specify the translation granules supported in stage 2 translations.

D8.1.2 Translation regimes

A translation regime determines how a VA is mapped to a PA. The translation regime is affected by the current Security state, the current Exception level, the enabled Exception levels, HCR_EL2 settings, and implemented features.

The architecture defines all of the following translation regimes:
- Secure EL1&0 translation regime.
- Non-secure EL1&0 translation regime.
- Secure EL2&0 translation regime.
- Non-secure EL2&0 translation regime.
- Secure EL2 translation regime.
- Non-secure EL2 translation regime.
- Secure EL3 translation regime.

The implemented Exception levels affect the supported translation regimes and translation stages.

If a VA is accessed in Non-secure state, then the VA is mapped to Non-secure PA space.

If a VA is accessed in Secure state, then one of the following can occur:
- The VA is mapped to Non-secure PA space.
- The VA is mapped to Secure PA space.

Only the EL1&0 translation regimes support a stage 2 translation.

If a software agent, such as an operating system, uses or configures stage 1 translations, then that software agent might be unaware of all of the following:
- The stage 2 translation.
- The distinction between IPA and PA.

If the Effective value of HCR_EL2.E2H is 0, then only the EL1&0 translation regime, stage 1, can support two VA ranges.

If the Effective value of HCR_EL2.E2H is 1, then the EL2&0 translation regime, stage 1, can support two VA ranges.

If a stage 1 translation supports two VA ranges, then that translation stage also supports two privilege levels.

Secure EL1&0 translation regime

If all of the following apply, then the Secure EL1&0 translation regime is used to translate addresses:
- The memory accesses occur in Secure state.
- Memory is accessed from EL1 or EL0.
- The Effective value of HCR_EL2.{E2H, TGE} is not \{1, 1\}.

If Secure EL2 is disabled or not implemented, then the Secure EL1&0 translation regime has a single address translation stage, stage 1, that does all the following:
- Maps VAs to PAs.
- Supports two VA ranges and the use of ASIDs.
If Secure EL2 is enabled, then the Secure EL1&0 translation regime, supports all of the following:

- Translation stage 1 that does all the following:
  - Maps VAs to IPAs.
  - Supports two VA ranges and the use of ASIDs.
- Translation stage 2 that does all the following:
  - Maps stage 1 IPAs to PAs.
  - Supports a single Non-secure IPA range and a single Secure IPA range.
- Translation stage 1 and translation stage 2 can be enabled independent of each other.

For more information, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page D8-5194.

**Non-secure EL1&0 translation regime**

If all of the following apply and EL2 is disabled, then the Non-secure EL1&0 translation regime is used to translate addresses:

- The memory accesses occur in Non-secure state.
- Memory is accessed from EL1 or EL0.
- The Effective value of HCR_EL2.{E2H, TGE} is not \( \{1, 1\} \).

If Non-secure EL2 is not implemented, then the Non-secure EL1&0 translation regime has a single address translation stage, stage 1, that does all the following:

- Maps VAs to PAs.
- Supports two VA ranges and the use of ASIDs.

If Non-secure EL2 is enabled, then the Non-secure EL1&0 translation regime supports all of the following:

- Translation stage 1 that does all the following:
  - Maps VAs to IPAs.
  - Supports two VA ranges and the use of ASIDs.
- Translation stage 2 that does all the following:
  - Maps stage 1 IPAs to PAs.
  - Supports a single IPA range.
- Translation stage 1 and translation stage 2 can be enabled independent of each other.

For more information, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page D8-5194.

Non-secure EL2 is effectively disabled if it is not implemented.

**Secure EL2&0 translation regime**

If all of the following apply, then the Secure EL2&0 translation regime is used to translate addresses:

- The Effective value of SCR_EL3.EEL2 is 1.
- The memory accesses occur in Secure state.
- One of the following applies:
  - The Effective value of HCR_EL2.{E2H, TGE} is \( \{1, 0\} \) and memory accesses are from EL2.
  - The Effective value of HCR_EL2.{E2H, TGE} is \( \{1, 1\} \) and memory accesses are from EL2 or EL0.

For more information, see Virtualization Host Extensions on page D8-5168.

The Secure EL2&0 translation regime has a single address translation stage, stage 1, that does all the following:

- Maps VAs to PAs.
- Supports two VA ranges and the use of ASIDs.

For more information, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page D8-5194.
Non-secure EL2&0 translation regime

If all of the following apply, then the Non-secure EL2&0 translation regime is used to translate addresses:

- The memory accesses occur in Non-secure state.
- One of the following applies:
  - The Effective value of HCR_EL2.{E2H, TGE} is \{1, 0\} and memory accesses are from EL2.
  - The Effective value of HCR_EL2.{E2H, TGE} is \{1, 1\} and memory accesses are from EL2 or EL0.

For more information, see Virtualization Host Extensions on page D8-5168.

Non-secure EL2 translation regime

If all of the following apply, then the Non-secure EL2 translation regime is used to translate addresses:

- The memory accesses occur in Non-secure state.
- The Effective value of HCR_EL2.E2H is 0.
- Memory is accessed from EL2.

The Non-secure EL2 translation regime has a single address translation stage, stage 1, that does all the following:

- Maps VAs to PAs.
- Supports a single VA range.

Secure EL2 translation regime

If all of the following apply, then the Secure EL2 translation regime is used to translate addresses:

- The Effective value of SCR_EL3.EEL2 is 1.
- The memory accesses occur in Secure state.
- The Effective value of HCR_EL2.E2H is 0.
- Memory is accessed from EL2.

The Secure EL2 translation regime has a single address translation stage, stage 1, that does all the following:

- Maps VAs to PAs.
- Supports a single VA range.

Non-secure EL3 translation regime

If memory is accessed from EL3, then the Secure EL3 translation regime is used to translate addresses.

The Secure EL3 translation regime has a single address translation stage, stage 1, that does all the following:

- Maps VAs to PAs.
- Supports a single VA range.

D8.1.3 Relationship between translation regimes and implemented Exception levels

The set of translation regimes that an implementation supports depend on the set of Exception levels that the implementation supports.
If an implementation does not include EL2, then all of the following apply:

- If the implementation does not include EL3, then the MMU provides a single EL1&0 stage 1 translation regime with an IMPLEMENTATION DEFINED Security state.
- If the implementation includes EL3, then the MMU provides an EL1&0 stage 1 translation regime in each Security state.

For each translation stage supported by a translation regime, the following table shows what is required to support that translation stage.

<table>
<thead>
<tr>
<th>Translation stage</th>
<th>Requires</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure EL3 stage 1</td>
<td>EL3 is implemented and EL3 uses AArch64.</td>
</tr>
<tr>
<td>Secure EL2 stage 1</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.EEL2 is 1. The Effective value of SCR_EL3.NS is 0.</td>
</tr>
<tr>
<td>Secure EL2&amp;0 stage 1</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.EEL2 is 1. The Effective value of SCR_EL3.NS is 0. The Effective value of HCR_EL2.E2H is 1.</td>
</tr>
<tr>
<td>Secure EL1&amp;0 stage 2</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.EEL2 is 1. The Effective value of SCR_EL3.NS is 0.</td>
</tr>
<tr>
<td>Secure EL1&amp;0 stage 1</td>
<td>EL1 uses AArch64. EL1 uses AArch64. The Effective value of SCR_EL3.NS is 0.</td>
</tr>
<tr>
<td>Non-secure EL2 stage 1</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.NS is 1.</td>
</tr>
<tr>
<td>Non-secure EL2&amp;0 stage 1</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.NS is 1. The Effective value of SCR_EL3.NS is 1.</td>
</tr>
<tr>
<td>Non-secure EL1&amp;0 stage 2</td>
<td>EL2 is implemented and EL2 uses AArch64. EL2 is implemented and EL2 uses AArch64. The Effective value of SCR_EL3.NS is 1.</td>
</tr>
<tr>
<td>Non-secure EL1&amp;0 stage 1</td>
<td>EL1 uses AArch64. EL1 uses AArch64. The Effective value of SCR_EL3.NS is 1.</td>
</tr>
</tbody>
</table>

For a stage 1 translation, if EL0 uses AArch32 state and one or more of the following applies, then VMSAv8-64 translation is required:

- EL1 uses AArch64 and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- EL2 uses AArch64 and the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

For a stage 2 translation, if either EL1 or EL0 uses AArch32 state and EL2 uses AArch64, then VMSAv8-64 translation is required.

If EL0 uses AArch32, then accesses from EL0 have all of the following properties:

- Accesses use the EL1&0 or EL2&0 translation regime.
- Accesses use the AArch32 application-level memory model.
- Accesses are limited to a 32-bit VA range.

For more information, see Chapter B1 The AArch64 Application Level Programmers’ Model.
### D8.1.4 System registers relevant to MMU operation

If a System register name has a numeric suffix, then the suffix indicates the lowest Exception level that can access the register.

Translation stages are enabled and controlled by the registers specified in the following table.

**Table D8-2 Registers that enable and control translation stages**

<table>
<thead>
<tr>
<th>Translation Stage</th>

</table>

When software that enables or disables an address translation stage uses a PA that differs from the VA, speculative instruction fetching can cause complications. If software controls address translations that apply to the software itself, then when that software enables or disables an address translation stage, Arm recommends that the software uses a PA that is identical to the VA.
D8.1.5 Out-of-context translation regimes

Software is required to consider the effects on registers and translation tables when a context switch is made from one translation regime to another.

Speculative memory accesses from out-of-context translation regimes

If a speculative memory access causes a translation table walk, and the translation table walk is speculative when the lower Exception level was entered, all of the following apply regarding memory accesses caused by speculative translation table walks from the lower Exception level:

- All of the speculative memory accesses are observed as required by the Shareability and Cacheability attributes of the lower Exception level translation table entries.
- If it is impossible to determine that the speculative memory accesses have been observed by the observers, then these speculative memory accesses can still occur.
- No new memory accesses using the lower Exception level translation table entries occur.

If EL2 is enabled, when a switch from one virtual machine to another occurs, software executing at EL0 or EL1 expects register fields controlling or affecting the EL1&0 regime are modified consistently before the next virtual machine starts execution.

If the registers fields controlling or affecting the EL1&0 translation regime are modified when changing a virtual machine, then all of the following apply:

- Software executing at EL2 does the modification.
- The registers are modified out-of-context from software executing at EL1 or EL0.
- When modifying the registers, no synchronization precautions are required until the exception return to EL1 or EL0.
D8.1.6 Implemented physical address size

The implemented PA size is indicated by the value of the ID_AA64MMFR0_EL1.PARange field, as shown in the following table. All other values of the ID_AA64MMFR0_EL1.PARange field are reserved.

<table>
<thead>
<tr>
<th>ID_AA64MMFR0_EL1.PARange</th>
<th>PA memory size</th>
<th>PA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>4GB</td>
<td>32 bits, PA[31:0]</td>
</tr>
<tr>
<td>0b0001</td>
<td>64GB</td>
<td>36 bits, PA[35:0]</td>
</tr>
<tr>
<td>0b0010</td>
<td>1TB</td>
<td>40 bits, PA[39:0]</td>
</tr>
<tr>
<td>0b0011</td>
<td>4TB</td>

<td>52 bits, PA[51:0]</td>
</tr>
</tbody>
</table>

If the implemented PA size is greater than 48 bits, then FEAT_LPA is required.

D8.1.7 Output address size configuration

For a translation stage, the maximum OA size that can be described by translation table entries is one of the following:

- For a translation regime controlled by TCR_ELx, if the 4KB or 16KB translation granule is used, then one of the following:
  - If the Effective value of TCR_ELx.DS is 0, then 48 bits.
  - If the Effective value of TCR_ELx.DS is 1, then 52 bits.
- For any translation regime, if the 64KB translation granule is used, then one of the following:
  - If FEAT_LPA is not implemented, then 48 bits.
  - If FEAT_LPA is implemented, then 52 bits.

The name of the TCR_ELx.{I}PS field is one of the following:

- If the register is TCR_EL1, then the field is TCR_EL1.IPS.
- If the register is TCR_EL2, then one of the following:
  - If the Effective value of HCR_EL2.E2H is 0, then the field is TCR_EL2.PS.
  - If the Effective value of HCR_EL2.E2H is 1, then the field is TCR_EL2.IPS.
- If the register is TCR_EL3, then the field is TCR_EL3.PS.

The OA size from a translation stage is configured by the associated TCR_ELx.{I}PS field, as shown in the following table. All other values of the TCR_ELx.{I}PS field are reserved.

<table>
<thead>
<tr>
<th>TCR_ELx.{I}PS</th>
<th>OA memory size</th>
<th>OA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>4GB</td>
<td>32 bits, OA[31:0]</td>
</tr>
<tr>
<td>0b001</td>
<td>64GB</td>
<td>36 bits, OA[35:0]</td>
</tr>
<tr>
<td>0b010</td>
<td>1TB</td>
<td>40 bits, OA[39:0]</td>
</tr>
<tr>
<td>0b011</td>
<td>4TB</td>
<td>42 bits, OA[41:0]</td>
</tr>
</tbody>
</table>
The TCR_ELx.{I}PS field is three bits and has the same encoding as the three least significant bits of ID_AA64MMFR0_EL1.PARange.

The OA size from a translation stage cannot be larger than the implemented PA size. If the value of TCR_ELx.{I}PS is larger than the implemented PA size, then {I}PS is treated as being the same as the implemented PA size.

Arm strongly recommends that software avoids configuring TCR_ELx.{I}PS to a value greater than the implemented PA size.

If a translation stage is enabled and the translation stage OA size is larger than the implemented PA size, then an Address size fault is generated at the lookup level in the translation stage that generated the OA.

If all of the following apply, then a stage 2 Translation fault is generated:
- Two address translation stages are used.
- Stage 2 address translation is enabled.
- The stage 1 OA size does not generate a stage 1 Address size fault.
- The stage 1 OA size is larger than the specified stage 2 translation IA size.

### Table D8-5 Output address size configuration (continued)

<table>
<thead>
<tr>
<th>TCR_ELx.{I}PS</th>
<th>OA memory size</th>
<th>OA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b100</td>
<td>16TB</td>
<td>44 bits, OA[43:0]</td>
</tr>
<tr>
<td>0b101</td>
<td>256TB</td>
<td>48 bits, OA[47:0]</td>
</tr>
<tr>
<td>0b110</td>
<td>4PB</td>
<td>52 bits, OA[51:0]</td>
</tr>
</tbody>
</table>

Only stage 1 address translation in the EL1&0 and EL2&0 translation regimes support two VA ranges.

If a translation regime supports a single VA range, then the maximum VA range is one of the following:
- If the maximum VA size is 48 bits, then the maximum VA range is 0x0000000000000000 to 0x0000FFFFFFFFFFFF.
- If the maximum VA size is 52 bits, then the maximum VA range is 0x0000000000000000 to 0x000FFFFFFFFFFFFF.

If a translation regime supports two VA ranges, then all of the following apply:
- IA bit[55] determines one of the following VA ranges:
  - If IA bit[55] is 0, the lower VA range is used.
  - If IA bit[55] is 1, the upper VA range is used.
• The maximum lower VA range is one of the following:
  — If the maximum VA size is 48 bits, then the maximum VA range is 0x0000000000000000 to 0xFFFFFFFFFFFF.
  — If the maximum VA size is 52 bits, then the maximum VA range is 0x0000000000000000 to 0xFFFFFFFFFFFF.

• The maximum upper VA range is one of the following:
  — If the maximum VA size is 48 bits, then the maximum VA range is 0xFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.
  — If the maximum VA size is 52 bits, then the maximum VA range is 0xFFF0000000000000 to 0xFFFFFFFFFFFFFFFF.

If the configured size of the upper VA range is less than the maximum, then all of the following apply:
• The range starting address is greater than the address used by the maximum VA size.
• The range ending address is 0xFFFFFFFFFFFFFFFF.

A 48-bit VA range defines an address space of 256TB. A 52-bit VA range defines an address space of 4PB.

D8.1.9 Input address size configuration

If a translation stage supports a single VA range, then TCR_ELx.T0SZ configures the IA size, translated using TTBR0_ELx.

If a translation stage supports two VA ranges, then all of the following TCR_ELx.TnSZ fields specify the IA size:
• TCR_ELx.T0SZ configures the IA size of the lower VA range, translated using TTBR0_ELx.
• TCR_ELx.T1SZ configures the IA size of the upper VA range, translated using TTBR1_ELx.

The stage 1 translation IA size is defined as 64-TCR_ELx.TnSZ.

For all translation stages, the following table shows how the maximum permitted TnSZ value is determined:

<table>
<thead>
<tr>
<th>Translation granule size</th>
<th>FEAT_TTST not implemented</th>
<th>FEAT_TTST implemented</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>39</td>
<td>48</td>
</tr>
<tr>
<td>16KB</td>
<td>39</td>
<td>48</td>
</tr>
<tr>
<td>64KB</td>
<td>39</td>
<td>47</td>
</tr>
</tbody>
</table>

If TCR_ELx.TnSZ configures an IA size that is smaller than the maximum size, then each one-bit reduction in the IA size has one of the following effects on the lookup level that the table walk starts with:
• The translation table size is reduced by one half.
• The table walk starts one level later.

If the value of TnSZ is greater than the maximum permitted value, then any use of the TnSZ value causes one of the following IMPLEMENTATION DEFINED behaviors to occur:
• For all purposes other than reading back the value, the implementation behaves as if the TnSZ field has the maximum permitted value.
• Any use generates a level 0 Translation fault.

For a stage 1 translation, the minimum Effective value of TnSZ is one of the following:
• For the 4KB or 16KB translation granule, one of the following:
  — If the Effective value of TCR_ELx.DS is 0, then the minimum Effective value of TnSZ is 16.
  — If the Effective value of TCR_ELx.DS is 1, then the minimum Effective value of TnSZ is 12.
• For the 64KB translation granule, one of the following:
  — If FEAT_LVA is not implemented, then the minimum Effective value of TnSZ is 16.
  — If FEAT_LVA is implemented, then the minimum Effective value of TnSZ is 12.

If all of the following apply, then a stage 1 level 0 Address size fault is generated:
• Stage 1 translation is disabled.
• The IA size is larger than the implemented PA size.

For an address translation stage, when an attempt is made to translate an address larger than the configured IA size, a level 0 Translation fault at that translation stage is generated.

For a stage 1 address translation, if the value of TnSZ is smaller than the minimum Effective value, then when using the TnSZ value to translate an address, one of the following applies:
• If FEAT_LVA is not implemented, then it is IMPLEMENTATION DEFINED which of the following behaviors occurs:
  — For all uses other than reading back the value, the implementation behaves as if the TnSZ field has a value of 16.
  — When using the TnSZ value to translate an address, a stage 1 level 0 Translation fault is generated.
• If FEAT_LVA is implemented, then when using the TnSZ value to translate an address, a stage 1 level 0 Translation fault is generated.

For more information, see Relationship between translation regimes and implemented Exception levels on page D8-5084.

**D8.1.10 Intermediate physical address size configuration**

When a stage 2 translation occurs, the configured IPA size is specified by one of the following T0SZ values:
• If the IPA is in Non-secure address space, then VTCR_EL2.T0SZ
• If the IPA is in Secure address space, then VSTCR_EL2.T0SZ

The implemented PA size constrains all of the following:
• The maximum IPA size.
• The effective minimum T0SZ value, VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ, used to specify the configured IPA size.
• The stage 2 initial lookup level.

When all of the following apply, the stage 2 translation IPA size check generates a stage 2 level 0 Translation fault:
• Stage 2 translation is enabled.
• The OA size from the stage 1 translation, whether or not stage 1 translation is enabled, is larger than the IA size specified by VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ.

When a stage 2 translation occurs, the effective minimum value of T0SZ is determined by the implemented PA size as shown in the following table:

<table>
<thead>
<tr>
<th>Implemented PA size</th>
<th>Effective minimum T0SZ value</th>
</tr>
</thead>
<tbody>
<tr>
<td>32 bits</td>
<td>32 if EL1 is using AArch64</td>
</tr>
<tr>
<td>32 bits</td>
<td>24 if EL1 is using AArch32</td>
</tr>
<tr>
<td>36 bits</td>
<td>28 if EL1 is using AArch64</td>
</tr>
<tr>
<td>36 bits</td>
<td>24 if EL1 is using AArch32</td>
</tr>
</tbody>
</table>

For more information, see Relationship between translation regimes and implemented Exception levels on page D8-5084.
For a stage 2 address translation, if FEAT_LPA is not implemented and the value of T0SZ is smaller than the effective minimum value, then it is IMPLEMENTATION_DEFINED which of the following behaviors occurs:

- For all purposes other than reading back the value of the field, the implementation treats the T0SZ field as having the effective minimum value.
- The implementation generates a stage 2 level 0 Translation fault.

For a stage 2 address translation, if FEAT_LPA is implemented and the value of the T0SZ field is smaller than the effective minimum value, then a stage 2 level 0 Translation fault is generated.

If the T0SZ field is programmed to a value smaller than the effective minimum value, then a larger address range cannot be supported because an Address size fault is generated due to one of the following reasons:

- For a VMSAv8-64 stage 1 translation, the stage 1 OA is larger than the PA size.
- For a VMSAv8-32 stage 1 translation, the stage 1 OA is larger than 40 bits.

For more information, see:

- Implemented physical address size on page D8-5088.
- Translation table walk on page D8-5093.
- Memory aborts on page D8-5180.

### Table D8-7 Determining the effective minimum T0SZ value for stage 2 translations (continued)

</tr>
</tbody>
</table>
D8.2 Translation process

The translation of a VA to a PA begins with reading the translation table base address register, followed by a walk through the translation tables to read the descriptors associated with the mapping.

D8.2.1 Translation table walk

A translation table walk is the set of translation table lookups that are required to do all of the following:

- For a single stage translation at stage 1, translate a VA to a PA.
- For two translation stages and stage 1 is disabled, translate an IPA to a PA.
- For a two stage translation, all of the following:
  - For a stage 1 translation, translate a VA to an IPA.
  - For a stage 2 translation, translate an IPA to a PA for each of the stage 1 translation table lookups.
  - For a stage 2 translation, translate an IPA to a PA for the stage 1 OA.

When a translation table walk begins, the initial translation table lookup uses the translation table base address stored in the TTBR_ELx register to locate the translation table.

When a translation table lookup occurs, the descriptor held in the translation table entry is read as an 8-byte single-copy atomic access.

For information on the translation table alignment requirements, see Translation table alignment on page D8-5098.

The descriptor type indicates one of the following:

- The translation table walk is complete and the translation table entry is the final entry.
- The translation table walk requires an extra lookup at the next higher lookup level.
- The descriptor is invalid.

When an extra lookup level is required, the descriptor contains all of the following information:

- The translation table walk base address of the next lookup level.
- For stage 1 descriptors, if the Effective value of TCR_ELx.HPD is 0, then the descriptor has hierarchical access permissions that are applied to the final translation.
- If the translation is made in a Secure translation regime, then a stage 1 descriptor indicates whether the base address is in the Secure address space or the Non-secure address space, unless a hierarchical control at a previous lookup level has indicated that it is required to be in the Non-secure address space.

For more information, see Security state of translation table lookups on page D8-5099.

For a translation lookup level, the translation table base address is one of the following:

- For the initial lookup level, the aligned value of the appropriate TTBR_ELx.BADDR field.
- For subsequent lookup levels, the next-level translation table base address returned by the previous lookup level.

When the last lookup level of a translation stage returns a valid descriptor, it contains all of the following:

- The OA from the translation stage.
- The memory region access permissions.
- The memory region attributes.

For more information, see Memory region attributes on page D8-5151 and Memory access control on page D8-5132.

For a translation regime that uses two translation stages, the stage 1 descriptor addresses require stage 2 translation from IPA to PA.

When a translation table walk succeeds, all of the following are returned:

- The OA.
• If the translation table walk is made in a Secure translation regime, then the information returned indicates whether the OA is in the Secure IPA or PA space, or to the Non-secure IPA or PA space.
• The output memory region attributes.
• The output memory region access permissions.

For more information, see Security state of translation table lookups on page D8-5099.

The following figure is a generalized view of a single address translation stage with three lookup levels.

Figure D8-1 Generalized view of a single address translation stage

If all of the following are true, then a translation table entry is permitted to be cached in a Translation Lookaside Buffer (TLB):

- The entry is valid.
- Using the entry does not generate a Translation fault, an Address size fault, or an Access flag fault.

TLB caching can reduce the number of required translation table lookups.

If two address translation stages are used and when a full translation table walk at both stages is required, then all of the following apply:

- \( S1 \) is the number of lookup levels required for a stage 1 translation.
- \( S2 \) is the number of lookup levels required for a stage 2 translation.
- The maximum number of translation table lookups required is \((S1+1)*(S2+1)-1\).

**D8.2.2 Concatenated translation tables**

For the initial lookup of a stage 2 address translation, up to 16 translation tables can be concatenated.

For a stage 2 translation, if the translation table in the initial lookup level would require 16 or fewer entries, then the stage 2 translation can be configured to have all of the following properties:

- The initial lookup of the stage 2 translation starts at the next lookup level.
- A number of translation tables corresponding to the original number of translation table entries at the previously initial lookup level are concatenated at that next lookup level.

For the 16KB translation granule, if the Effective value of VTCR_EL2.DS is 0 and a 48-bit address size is translated by the stage 2 translation, then the initial lookup is required to start at level 1 with two concatenated translation tables.
For the initial lookup in a stage 2 translation, if concatenated translation tables are used, then all of the following apply:

- Up to four additional IA bits are resolved by the initial lookup.
- For each additional $n$ IA bits resolved by the initial lookup, the number of least significant translation table base address bits held in the TTBR_ELx is reduced by $n$ bits.
- For each additional $n$ IA bits resolved by the initial lookup, $2^n$ concatenated translation tables are required at the initial lookup level.

Using a concatenated translation table eliminates the overhead of an extra lookup level.

If concatenated translation tables are used, then software is required to do all of the following:

- Align the base address of the first translation table to the sum of the size of the memory occupied by the concatenated translation tables.
- Program VTTBR_EL2 or VSTTBR_EL2 with the address of the first translation table in the set of concatenated translation tables.
- Program VTCR_EL2 or VSTCR_EL2 with the initial lookup level.

### D8.2.3 Translation table base address register

For a translation stage, the translation table base address register, TTBR_ELx, holds the translation table base address of the initial lookup.

For a translation stage that supports two VA ranges, two translation table base address registers are required.

Software can use TCR_ELx.TnSZ to configure the translation stage IA size to be smaller than the supported size.

If EL2 is disabled or not implemented, then for the stage 1 EL1&0 regime, all of the following apply:

- The translation table base address held in the TTBR_ELx register is a PA.
- The translation table base address returned by a Table descriptor is a PA.

If EL2 is enabled, then for all address translation stages other than stage 1 in EL1&0, all of the following apply:

- The translation table base address held in the TTBR_ELx register is a PA.
- The translation table base address returned by a Table descriptor is a PA.

If EL2 is enabled, then for stage 1 address translations in EL1&0, all of the following apply:

- The stage 1 translation table base address held in the TTBR_ELx register is an IPA.
- The stage 1 translation table base address returned by a Table descriptor is an IPA.
- Accesses to stage 1 translation tables are subject to a stage 2 translation.

For an address translation stage, the translation table base address in TTBR_ELx is defined for the supported OA size of that stage.

The number of OA bits held in TTBR_ELx is determined by the granule size and OA address size. The bits used for each granule size when using the maximum OA address size of 48 bits or 52 bits are shown in the following table. Software might be required to set one or more of the low-order base address bits to zero to align the table to the table size.

<table>
<thead>
<tr>
<th>Granule size</th>
<th>Maximum OA size</th>
<th>Translation table base address</th>
<th>OA bits held in TTBR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB, 16KB, or 64KB</td>
<td>52 bits</td>
<td>TTBR_ELx[5:2]</td>
<td>OA[51:48]</td>
</tr>
</tbody>
</table>
If an address translation stage uses an OA size smaller than the maximum, then the upper bits of the translation table base address in TTBR_ELx corresponding to the upper bits of OA size are required to be set by software to zero.

If TCR_ELx.TnSZ specifies an IA size that is smaller than the maximum size resolved at the initial lookup level, then more low-order TTBR_ELx bits are used to hold the translation table base address.

If an address translation stage uses an OA size smaller than the maximum and if the bits above the configured OA size of the translation table base address in TTBR_ELx are not set to zero, then an Address size fault is generated and reports all of the following:

- A translation level 0 lookup as generating the fault, regardless of whether or not the translation stage starts with a level 0 lookup.
- The translation stage that generated the fault.

For more information, see System registers relevant to MMU operation on page D8-5086.

### Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported

If a stage 1 translation regime supports two VA ranges, then the translation regime TTBR_ELx registers point to all of the following address ranges:

- For the lower VA range that begins at address 0x0000000000000000, TTBR0_ELx points to the translation table for the initial lookup level.
- For the upper VA range that ends at address 0xFFFFFFFFFFFFFFFF, TTBR1_ELx points to the translation table for the initial lookup level.

If a stage 1 translation regime supports two VA ranges, then the TCR_ELx.{T0SZ, T1SZ} fields configure all of the following address range sizes:

- The lower VA range is 0x0000000000000000 to (2^(64-T0SZ) - 1).
- The upper VA range is (2^64 - 2^(64-T1SZ)) to 0xFFFFFFFFFFFFFFFF.

If a stage 1 translation regime supports two VA ranges, when an accessed address is not in the lower VA range or the upper VA range, a stage 1 level 0 Translation fault is generated.

The following figure illustrates the two address ranges translated by the tables the TTBR_ELx registers point to.
If a stage 1 translation regime supports two VA ranges, then all of the following are used to select the TTBR_ELx:

- If VA bit[55] is zero, then TTBR0_ELx is selected.
- If VA bit[55] is one, then TTBR1_ELx is selected.

If a stage 1 translation regime supports two VA ranges and TCR_ELx.EPDn is one, then when a TLB miss occurs based on TTBRn_ELx, a level 0 Translation fault is generated, and no translation table walk is done.

For more information, see Address tagging on page D8-5162.

**Preventing EL0 access to halves of the address map**

All statements in this section require implementation of FEAT_E0PD.

The TCR_ELx.{E0PD0, E0PD1} fields can be used to prevent EL0 access to the addresses translated by the corresponding TTBR0_ELx or TTBR1_ELx.

When the TCR_ELx.{E0PD0, E0PD1} fields prevent EL0 access to an address translated by TTBR0_ELx or TTBR1_ELx, then a level 0 Translation fault is generated.

When the TCR_ELx.{E0PD0, E0PD1} fields generate a level 0 Translation fault, then the time needed to take the fault should be the same whether or not the address accessed is present in a TLB, to mitigate attacks that use fault timing.

When the TCR_ELx.{E0PD0, E0PD1} fields generate a level 0 Translation fault, the fault is not counted as a TLB miss for performance monitoring features.

**D8.2.5 Translation table and translation table lookup properties**

Translation table and translation table lookup properties include the table size, table alignment, table endianness, and memory attributes.

**Translation table size**

The descriptor in a translation table entry is an eight-byte, or 64-bit, object.
The size of a translation table in bytes is determined by multiplying the number of entries by the eight-byte descriptor size.

The maximum number of translation table entries is determined by the translation granule size, which is defined by one of the following:

- For a stage 1 translation that supports one VA range, TCR_ELx.TG0.
- For a stage 1 translation that can support two VA ranges, all of the following:
  - For the lower VA range, TCR_ELx.TG0.
  - For the upper VA range, TCR_ELx.TG1.
- For a stage 2 translation in the Non-secure EL1&0 translation regime, VTCR_EL2.TG0.
- For a stage 2 translation in the Secure EL1&0 translation regime, one of the following:
  - If the stage 2 IA is a Non-secure IPA, then VTCR_EL2.TG0.
  - If the stage 2 IA is a Secure IPA, then VSTCR_EL2.TG0.

Translation table alignment

A translation table is required to be aligned to one of the following:

- If the translation table has eight or more entries, then it is aligned to the translation table size.
- If the translation table has fewer than eight entries, then it is aligned to 64 bytes.

Only when all of the following are true is it possible to have fewer than 8 translation table entries:

- The translation table is at the initial lookup level.
- Concatenated translation tables are not used.

If concatenated translation tables are used, then the concatenated translation tables are required to be aligned to the overall size of the memory occupied by the concatenated translation tables.

Translation table lookup endianness

When a translation table lookup reads a translation table entry, the read is 8-byte single-copy atomic.

The endianness of a translation table lookup is determined by the appropriate SCTLR_ELx.EE bit.

Changing an SCTLR_ELx.EE bit requires synchronization before the change is guaranteed to be visible to subsequent operations.

For more information, see *Synchronization requirements for AArch64 System registers* on page D17-5547.

Arm does not recommend changing an SCTLR_ELx.EE bit unless one or more of the following apply:

- The translation table lookups affected by the modified SCTLR_ELx.EE bit belong to an out-of-context translation regime.
- For any translation stage affected by the modified SCTLR_ELx.EE bit, address translation is disabled.

Translation table lookup memory attributes

For a translation table lookup in an address translation stage, the TCR_ELx and VTCR_EL2 registers determine the memory Cacheability and Shareability attributes that apply.

For a translation table lookup in an address translation stage, the required memory type is Normal memory.

For a two stage translation regime, when a translation table lookup from stage 1 occurs, all of the following apply:

- Arm recommends that the stage 2 translation of the stage 1 translation table lookup does not map to Device memory.
- Software can configure HCR_EL2.PTW to protect stage 2 table walks from mapping stage 1 translation tables to Device memory.
D8.2 Translation process

Stage 2 fault on a stage 1 translation table walk

Mismatched memory attributes

D8.2.6 Translation table walk properties

Ordering of memory accesses from translation table walks

A translation table walk is considered to be a separate observer. An explicit write to the translation tables might be observed by that separate observer for either of the following:
- A translation table walk caused by a different explicit write generated by the same instruction.
- A translation table walk caused by an explicit access generated by any instruction appearing in program order after the instruction doing the explicit write to the translation table.

The explicit write to the translation tables is guaranteed to be observable, to the extent required by the Shareability attributes, only after the execution of a DSB instruction. This DSB instruction and the instruction that performed the explicit write to the translation tables must have been executed by the same PE.

Any writes to the translation tables are not observed by any translation table accesses associated with an explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

If FEAT_ETS is implemented, and a memory access RW1 is Ordered-before a second memory access RW2, then RW1 is also Ordered-before any translation table walk generated by RW2 that generates any of the following:
- A Translation fault.
- An Address size fault.
- An Access flag fault.

For more information, see:
- Ordering relations on page B2-163.
- Ordering constraints on page B2-165.

Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are done to Non-secure IPA or PA space.

When EL2 is enabled, the OA space of the Secure EL1&0 stage 1 translation regime is IPA space. In all other cases, the OA space for a Secure stage 1 translation regime is PA space.

For a stage 1 translation table walk in a Secure translation regime, the OA space of the translation table lookups is determined by all of the following:
- The initial translation table lookup is done to Secure OA space.
- When the Table descriptor lookup is to Secure OA space, the descriptor NSTable bit determines one of the following:
  - If NSTable is zero, the next translation table lookup is made to Secure OA space.
  - If NSTable is one, the next translation table lookup is made to Non-secure OA space.
When the Table descriptor lookup is to Non-secure OA space, the next translation table lookup is made to Non-secure OA space.

For more information, see Hierarchical control of Secure or Non-secure memory accesses on page D8-5135.

For a stage 2 translation in a Secure translation regime, the PA space of translation table lookups is determined by one of the following:

- When translating an address in Secure IPA space, the Effective value of the VSTCR_EL2.SW bit.
- When translating an address in Non-secure IPA space, the Effective value of the VTCR_EL2.NSW bit.

When an IPA from a Secure translation regime is translated by stage 2 translation, the output PA space of the translation is determined by one of the following:

- When translating an address in Secure IPA space, the Effective value of the VSTCR_EL2.SA bit.
- When translating an address in Non-secure IPA space, the Effective value of the VTCR_EL2.NSA bit.

Translation using the 4KB granule

Address translations that use the 4KB granule have a 4KB page size. Depending on the settings and supported features, up to 40 address bits are resolved using up to 5 lookup levels.

Throughout this section, if an address translation stage is not specified, then references to the Effective value of TCR_ELx.DS also apply to VTCR_EL2.DS.

For the 4KB translation granule, the maximum VA and PA supported by a translation regime is one of the following:

- If the Effective value of TCR_ELx.DS is 0, then the maximum VA and PA supported is 48 bits.
- If the Effective value of TCR_ELx.DS is 1, then the maximum VA and PA supported is 52 bits.

For the 4KB translation granule, if the Effective value of TCR_ELx.DS is 0, then OA[51:48] are treated as 0b0000.

For each lookup level supported by the 4KB translation granule, the following table describes the translation table properties at that level.

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Index into translation table</th>
<th>Maximum entries in table</th>
<th>Contents of translation table entries</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>-</td>
<td>-</td>
<td>Lookup level not supported</td>
<td>Effective value of TCR_ELx.DS is 0</td>
</tr>
<tr>

<td>Table descriptors and Block descriptors</td>
<td>-</td>
</tr>
<tr>
<td>3</td>
<td>IA[20:12]</td>
<td>512</td>
<td>Page descriptors</td>
<td>-</td>
</tr>
</tbody>
</table>

For the 4KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

- The page size is 4KB.
- The translation can resolve a page using one of the following maximum address ranges:
  - If the Effective value of TCR_ELx.DS is 0, then IA[47:12].
  - If the Effective value of TCR_ELx.DS is 1, then IA[51:12].
- The page is addressed by one of the following:
  - If the Effective value of TCR_ELx.DS is 0, then OA[47:12].
If the Effective value of TCR_ELx.DS is 1, then OA[51:12].

- IA[11:0] is mapped directly to OA[11:0].

For the 4KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

### Table D8-10 4KB granule block descriptor properties at each lookup level

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Size of memory region addressed by Block descriptor</th>
<th>Bit range that is direct mapped from IA to OA</th>
<th>IA bit range that selects Block descriptor</th>

</table>

For the 4KB translation granule, the following figure shows how the maximum 52-bit IA size is resolved. An IA larger than 48 bits requires that the Effective value of TCR_ELx.DS is 1.

### Figure D8-3 52-bit IA resolved using 4KB translation granule
Stage 1 address translation using the 4KB translation granule

For the 4KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.TnSZ field as shown in the following table.

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ minimum value</th>
<th>Maximum IA bits resolved</th>
<th>TnSZ maximum value</th>
<th>Minimum IA bits resolved</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>12</td>
<td>IA[51:12]</td>
<td>15</td>
<td>IA[48:12]</td>
<td>Effective value of TCR_ELx.DS is 1</td>
</tr>
<tr>
<td>0</td>
<td>16</td>
<td>IA[47:12]</td>
<td>24</td>
<td>IA[39:12]</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>25</td>
<td>IA[38:12]</td>
<td>33</td>
<td>IA[30:12]</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>34</td>
<td>IA[29:12]</td>
<td>39</td>
<td>IA[24:12]</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>40</td>
<td>IA[23:12]</td>
<td>42</td>
<td>IA[21:12]</td>
<td>FEAT_TTST is implemented</td>
</tr>
<tr>
<td>3</td>
<td>43</td>
<td>IA[20:12]</td>
<td>48</td>
<td>IA[15:12]</td>
<td>FEAT_TTST is implemented</td>
</tr>
</tbody>
</table>

For a stage 1 translation in the 4KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 9 bits and all remaining lookup levels are indexed by exactly 9 bits.

For the 4KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 1 address translation. An IA and an OA larger than 48 bits requires that the Effective value of TCR_ELx.DS is 1. The 512GB block size requires that the Effective value of TCR_ELx.DS is 1.

Key:
- D_Table is a Table descriptor.
- D_Block is a Block descriptor.
- D_Page is a Page descriptor.
  - a Indexed by IA[n:48], where IA width is (n+1) bits.
  - b Indexed by IA[47:39].
  - c Indexed by IA[38:30].
  - d Indexed by IA[29:21].
  - e Indexed by IA[20:12].

Figure D8-4 Generalized view of a stage 1 address translation using the 4KB granule
Stage 2 address translation using the 4KB translation granule

For the 4KB translation granule, when a stage 2 translation table walk is started, the initial lookup level is determined by one of the following:

- If the Effective value of VTCR_EL2.DS is 0, then the initial lookup level is determined by one of VTCR_EL2.SL0 or VSTCR_EL2.SL0, and VTCR_EL2.SL2 and VSTCR_EL2.SL2 are RES0.
- If the Effective value of VTCR_EL2.DS is 1, then the initial lookup level is determined by the combination of VTCR_EL2.SL0 and VTCR_EL2.SL2, or VSTCR_EL2.SL0 and VSTCR_EL2.SL2.

For the 4KB translation granule, when a stage 2 translation table walk is started, the following table shows the initial lookup level determined by VTCR_EL2.SL0 or VSTCR_EL2.SL0 and, when the Effective value of VTCR_EL2.DS is 1, the corresponding VTCR_EL2.SL2 or VSTCR_EL2.SL2.

<table>

Key for both diagrams:

D_Table is a Table descriptor.
D_Block is a Block descriptor.
D_Page is a Page descriptor.

- a Indexed by IA[47:39], where IA width is (n+1) bits.
- b1 Indexed by IA[47:39].
- b2 Indexed by IA[39:30], where IA width is (n+1) bits.
- c Indexed by IA[38:30].
- d Indexed by IA[29:21].
- e Indexed by IA[20:12].

For the 4KB translation granule, when a stage 2 translation table walk is started and one of the following is true, a stage 2 level 0 Translation fault is generated:

- If the Effective value of VTCR_EL2.DS is 0, then one or more of the following is true:
  - The VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ value is not consistent with the corresponding VTCR_EL2.SL0 or VSTCR_EL2.SL0 value.
  - VTCR_EL2.SL0 or VSTCR_EL2.SL0 is programmed to a reserved value.

- If the Effective value of VTCR_EL2.DS is 1, then one or more of the following is true:
  - The VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ value is not consistent with the corresponding VTCR_EL2.{SL2, SL0} or VSTCR_EL2.{SL2, SL0} value.
  - VTCR_EL2.{SL2, SL0} or VSTCR_EL2.{SL2, SL0} is programmed to a reserved value.
Finding the descriptor when using the 4KB translation granule

For the 4KB translation granule, the following table shows the algorithm to find the descriptor address at each supported lookup level, using all of the following information:

- The translation table base address, \textit{BaseAddr}.
- The number of bits in the supported PA size, \textit{PAsize}.
- The IA supplied to the translation stage and used as an index into the translation table.
- For each initial lookup level, the permitted range of values for TCR\_ELx.TnSZ.
- For a stage 2 translation, all of the following:
  - The value of VTCR\_EL2.T0SZ or VSTCR\_EL2.T0SZ.
  - The value of VTCR\_EL2.SL0 or VSTCR\_EL2.SL0.
  - If the Effective value of VTCR\_EL2.DS is 1, then the value of VTCR\_EL2.SL2 or VSTCR\_EL2.SL2.

</tr>
</tbody>
</table>

D8.2.8 Translation using the 16KB granule

Address translations that use the 16KB granule have a 16KB page size. Depending on the settings and supported features, up to 38 address bits are resolved using up to 4 lookup levels.
Throughout this section, if an address translation stage is not specified, then references to the Effective value of TCR_ELx.DS also apply to VTCR_EL2.DS.

For the 16KB translation granule, the maximum VA and PA supported by a translation regime is one of the following:

- If the Effective value of TCR_ELx.DS is 0, then the maximum VA and PA supported is 48 bits.
- If the Effective value of TCR_ELx.DS is 1, then the maximum VA and PA supported is 52 bits.

For the 16KB translation granule, if the Effective value of TCR_ELx.DS is 0, then OA[51:48] are treated as 0b0000.

For each lookup level supported by the 16KB translation granule, the following table describes the translation table properties at that level.

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Index into translation table</th>
<th>Maximum entries in table</th>
<th>Contents of translation table entries</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>IA[47]</td>
<td>2</td>
<td>Table descriptors</td>
<td>Effective value of TCR_ELx.DS is 0</td>
</tr>
<tr>
<td></td>
<td>IA[51:47]</td>
<td>32</td>
<td>Table descriptors</td>
<td>Effective value of TCR_ELx.DS is 1</td>
</tr>
<tr>
<td>1</td>
<td>IA[46:36]</td>
<td>2048</td>

<td>Effective value of TCR_ELx.DS is 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Table descriptors and Block descriptors</td>
<td>Effective value of TCR_ELx.DS is 1</td>
</tr>
<tr>
<td>2</td>
<td>IA[35:25]</td>
<td>2048</td>
<td>Table descriptors and Block descriptors</td>
<td>-</td>
</tr>
<tr>
<td>3</td>
<td>IA[24:14]</td>
<td>2048</td>
<td>Page descriptors</td>
<td>-</td>
</tr>
</tbody>
</table>

For the 16KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

- The page size is 16KB.
- The translation can resolve a page using one of the following maximum address ranges:
  - If the Effective value of TCR_ELx.DS is 0, then IA[47:14].
  - If the Effective value of TCR_ELx.DS is 1, then IA[51:14].
- The page is addressed by one of the following:
  - If the Effective value of TCR_ELx.DS is 0, then OA[47:14].
  - If the Effective value of TCR_ELx.DS is 1, then OA[51:14].
- IA[13:0] is mapped directly to OA[13:0].

For the 16KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Size of memory region addressed by Block descriptor</th>
<th>Bit range that is directly mapped from IA to OA</th>
<th>IA bit range that selects Block descriptor</th>
<th>Effective value of TCR_ELx.DS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Not supported</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>64GB</td>
<td>IA[35:0] maps to OA[35:0]</td>
<td>IA[51:36]</td>
<td>1</td>
</tr>
</tbody>
</table>
For the 16KB translation granule, the following figure shows how the maximum 52-bit IA size is resolved. An IA larger than 48 bits requires that the Effective value of TCR_ELx.DS is 1.

![Input address (IA)](image)

**Figure D8-6 52-bit IA resolved using 16KB translation granule**

### Stage 1 address translation using the 16KB translation granule

For the 16KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.TnSZ field as shown in the following table:

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ minimum value</th>
<th>Maximum IA bits resolved</th>
<th>TnSZ maximum value</th>
<th>Minimum IA bits resolved</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>IA[51:14]</td>
<td>15</td>
<td>IA[48:14]</td>
<td>Effective value of TCR_ELx.DS is 1</td>
</tr>
<tr>
<td>0</td>
<td>16</td>
<td>IA[47:14]</td>
<td>16</td>
<td>IA[47:14]</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>17</td>
<td>IA[46:14]</td>
<td>27</td>
<td>IA[36:14]</td>
<td>-</td>
</tr>
<tr>
<td>2</td>
<td>28</td>
<td>IA[35:14]</td>
<td>38</td>
<td>IA[25:14]</td>
<td>-</td>
</tr>
</tbody>
</table>

For a stage 1 translation in the 16KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 11 bits and all remaining lookup levels are indexed by exactly 11 bits.

For the 16KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 1 address translation. An IA and an OA larger than 48 bits requires that the Effective value of TCR_ELx.DS is 1. The 64GB block size requires that the Effective value of TCR_ELx.DS is 1.

![Generalized view](image)
Figure D8-7 Generalized view of a stage 1 address translation using the 16KB granule

### Stage 2 address translation using the 16KB translation granule

For the 16KB translation granule, when a stage 2 translation table walk is started, the initial lookup level is determined by the corresponding VTCR_EL2.SL0 or VSTCR_EL2.SL0 value.

For the 16KB translation granule, when a stage 2 translation table walk is started, the following table shows the initial lookup level determined by SL0:

<table>
<thead>
<tr>
<th>SL0</th>
<th>Initial lookup level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Level 3</td>
</tr>
<tr>
<td>0b01</td>
<td>Level 2</td>
</tr>
<tr>
<td>0b10</td>
<td>Level 1</td>
</tr>
<tr>
<td>0b11</td>
<td>Level 0</td>
</tr>
</tbody>
</table>

For the 16KB translation granule, when a stage 2 translation table walk is started and the initial lookup level is 0, the following table shows all of the permitted concatenated translation table configurations and the corresponding VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ value:

<table>
<thead>
<tr>

For the 16KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 2 address translation. An IA larger than 48 bits requires that the Effective value of VTCR_EL2.DS is 1. The 64GB block size requires that the Effective value of VTCR_EL2.DS is 1.
D8.2 Translation process

Figure D8-8 Generalized view of a stage 2 address translation using the 16KB granule

For the 16KB translation granule, when a stage 2 translation table walk is started and one of the following is true, a stage 2 level 0 Translation fault is generated:

- The VTCR_EL2.TOSZ or VSTCR_EL2.TOSZ value is not consistent with the corresponding VTCR_EL2.SL0 or VSTCR_EL2.SL0 value.
- VTCR_EL2.SL0 or VSTCR_EL2.SL0 is programmed to a reserved value.

For more information, see Concatenated translation tables on page D8-5094.

Finding the descriptor when using the 16KB translation granule

For the 16KB translation granule, the following table shows the algorithm to find the descriptor address at each supported lookup level, using all of the following information:

- The translation table base address, BaseAddr.
- The number of bits in the supported PA size, PAsize.
- The IA supplied to the translation stage and used as an index into the translation table.
For each initial lookup level, the permitted range of values for TCR_ELx.TnSZ.

For a stage 2 translation, all of the following:

- The value of VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ.
- The value of VTCR_EL2.SL0 or VSTCR_EL2.SL0.

### D8.2.9 Translation using the 64KB granule

**IVDPWL** Address translations that use the 64KB granule have a 64KB page size. Depending on the settings and supported features, up to 36 address bits are resolved using up to 3 lookup levels.

**ILRFQD** For the 64KB translation granule, the maximum VA size supported by a translation regime is one of the following:

- If FEAT_LVA is not implemented, then the maximum VA supported is 48 bits.
- If FEAT_LVA is implemented, then the maximum VA supported is 52 bits.

**IYZDPC** For the 64KB translation granule, the maximum PA size supported by a translation regime is one of the following:

- If FEAT_LPA is not implemented, then the maximum PA supported is 48 bits.
- If FEAT_LPA is implemented, then the maximum PA supported is 52 bits.

**RNSQXP** For the 64KB translation granule, if FEAT_LPA is not implemented, then OA[51:48] are treated as 0b0000.
For each lookup level supported by the 64KB translation granule, the following table describes the translation table properties at that level.

### Table D8-28 64KB granule translation table properties at each lookup level

<table>
<thead>

<td>IA[28:16]</td>
<td>8192</td>
<td>Page descriptors</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

For the 64KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

- The page size is 64KB.
- For stage 1, the translation can resolve a page using one of the following maximum address ranges:
  - If FEAT_LVA is not implemented, then IA[47:16].
  - If FEAT_LVA is implemented, then IA[51:16].
- For stage 2, the translation can resolve a page using one of the following maximum address ranges:
  - If FEAT_LPA is not implemented, then IA[47:16].
  - If FEAT_LPA is implemented, then IA[51:16].
- For stage 1 and stage 2, the page is addressed by one of the following:
  - If FEAT_LPA is not implemented, then OA[47:16].
  - If FEAT_LPA is implemented, then OA[51:16].
- IA[15:0] is mapped directly to OA[15:0].

For the 64KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

### Table D8-29 64KB granule block descriptor properties at each lookup level

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Size of memory region addressed by Block descriptor</th>
<th>Bit range that is direct mapped from IA to OA</th>
<th>IA bit range that selects Block descriptor</th>
<th>Additional requirements for stage 1</th>
<th>Additional requirements for stage 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

</tbody>
</table>

For the 64KB translation granule, the following figure shows how the maximum 52-bit IA size is resolved. For a stage 1 translation, an IA larger than 48 bits requires the implementation of FEAT_LVA. For a stage 2 translation, an IA larger than 48 bits requires the implementation of FEAT_LPA.
### Figure D8-9 52-bit IA resolved using 64KB translation granule

**Stage 1 address translation using the 64KB translation granule**

For the 64KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.TnSZ field as shown in the following table:

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ minimum value</th>
<th>Maximum IA bits resolved</th>
<th>TnSZ maximum value</th>
<th>Minimum IA bits resolved</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12</td>
<td>IA[51:16]</td>
<td>15</td>
<td>IA[48:16]</td>
<td>FEAT_LVA is implemented</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
<td>IA[47:16]</td>
<td>21</td>
<td>IA[42:16]</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>22</td>
<td>IA[41:16]</td>
<td>34</td>
<td>IA[29:16]</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>40</td>
<td>IA[23:16]</td>
<td>47</td>
<td>IA[16:16]</td>
<td>FEAT_TTST is implemented</td>
</tr>
</tbody>
</table>

For a stage 1 translation in the 64KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 13 bits and all remaining lookup levels are indexed by exactly 13 bits.

For the 64KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 1 address translation. An IA larger than 48 bits requires implementation of FEAT_LVA, and an OA larger than 48 bits requires implementation of FEAT_LPA. The 4TB block size requires implementation of FEAT_LPA.
Stage 2 address translation using the 64KB translation granule

For the 64KB translation granule, when a stage 2 translation table walk is started, the initial lookup level is determined by the corresponding VTCR_EL2.SL0 or VSTCR_EL2.SL0 value.

For the 64KB translation granule, when a stage 2 translation table walk is started, the following table shows the initial lookup level determined by SL0:

<table>
<thead>
<tr>
<th>SL0</th>
<th>Initial lookup level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Level 3</td>
</tr>
<tr>
<td>0b01</td>
<td>Level 2</td>
</tr>
<tr>
<td>0b10</td>
<td>Level 1</td>
</tr>
<tr>
<td>0b11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

For the 64KB translation granule, when a stage 2 translation table walk is started and the initial lookup level is 1, the following table shows all of the permitted concatenated translation table configurations and the corresponding VTCR_EL2.T0SZ or VSTCR_EL2.T0SZ value:

<table>
<thead>
<tr>
<th>Number of concatenated translation tables</th>
<th>IA bits resolved</th>
<th>T0SZ</th>
<th>Additional requirements</th>
</tr>
</thead>
<tbody>

<tr>
<td>2</td>
<td>if $22 \leq TnSZ \leq 34$ then $x = (38 - TnSZ)$ else $x = 16$ BaseAddr[PASize-1:x]:IA[x+25:29]:0b000</td>
<td>if SL0==1 if $18 \leq T0SZ \leq 34$ then $x = (38 - T0SZ)$ else $x = 16$ BaseAddr[PASize-1:x]:IA[x+25:29]:0b000</td>
</tr>
<tr>
<td>3</td>
<td>if $35 \leq TnSZ \leq 47$ then $x = (51 - TnSZ)$ else $x = 16$ BaseAddr[PASize-1:x]:IA[x+12:16]:0b000</td>
<td>if SL0==0 if $31 \leq T0SZ \leq 47$ then $x = (51 - T0SZ)$ else $x = 16$ BaseAddr[PASize-1:x]:IA[x+12:16]:0b000</td>
</tr>
</tbody>
</table>

### D8.2.10 The effects of disabling an address translation stage

#### IXHZJC

Stage 1 and stage 2 translations can be disabled independently, and doing so affects the MMU behavior.

#### Behavior when stage 1 address translation is disabled

If stage 1 address translation is disabled, then all of the following apply to memory accesses that would otherwise be translated at stage 1:

- The stage 1 IA is flat mapped to the OA.
- No Translation faults, Access flag faults, or Permission faults can be generated.
- Address size faults and Alignment faults can be generated.
- No memory is guarded.
- The access is to one of the following IPA or PA spaces:
  - For accesses from the Non-secure state, the access is to the Non-secure IPA or PA space.
  - For accesses from the Secure state, the access is to the Secure IPA or PA space.

#### RWFPZW

If stage 1 address translation is disabled, then the stage 1 translation assigns one of the following attributes to memory accesses:

- For memory accesses using the EL1&0 regime, if the effective value of $\text{HCR}_{\text{EL2}}.DC$ is 1, then all of the following memory attributes are assigned:
  - The Tagged attribute is set according to $\text{HCR}_{\text{EL2}}.DCT$.
  - Normal Inner Write-Back Cacheable Read-Allocate Write-Allocate.
  - Normal Outer Write-Back Cacheable Read-Allocate Write-Allocate.
  - Non-shareable.
  - If $\text{FEAT}_{\text{XS}}$ is implemented, then the XS attribute is set to 0.
• For all other memory accesses, one of the following memory attributes are assigned:
  — For a data access, the Device-nGnRnE memory attribute.
  — For an instruction access, the Normal memory attribute and one of the following:
    — If SCTLR_ELx.I is 0, then the Non-cacheable and Outer Shareable attributes.
    — If SCTLR_ELx.I is 1, then the Cacheable, Inner Write-Through Read-Allocate No
      Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable
      attribute.
    — For data accesses and instruction accesses, if FEAT_XS is implemented, then the XS attribute is set to
      1.

\[\text{R}_{\text{CSDNK}}\]

If all of the following apply, then the stage 1 memory attribute assignments and OA can be modified by the stage 2 translation:

• EL1&0 stage 2 address translation is enabled.
• An access using the EL1&0 translation regime occurs.

\[\text{R}_{\text{LBPTY}}\]

If HCR_EL2.DC is 1, then all of the following apply:

• For all purposes other than reading the value of the bit, the Effective value of SCTLR_EL1.M is 0, disabling
  stage 1 address translation in the EL1&0 translation regime.
• If EL2 is enabled, then for all purposes other than reading the value of the bit, the Effective value of
  HCR_EL2.VM is 1, enabling stage 2 address translation in the EL1&0 translation regime.

**Behavior when stage 2 address translation is disabled**

\[\text{R}_{\text{QVLSD}}\]

If stage 2 address translation is disabled, then all of the following apply to memory accesses that would otherwise be translated at stage 2:

• No stage 2 MMU faults can be generated.
• The IPA is flat mapped to the PA.
• The memory attributes and permissions assigned by the stage 1 translation are assigned to the PA.
• The access is to one of the following PA spaces:
  — For accesses from the Non-secure IPA space, the access is to the Non-secure PA space.
  — For accesses from the Secure IPA space, the access is to the Secure PA space.

**Instruction fetch behavior when all translation stages are disabled**

\[\text{I}_{\text{DLNTB}}\]

If all associated address translation stages are disabled, then software is required to place instructions that will be executed in memory regions where those regions and the memory regions immediately following each have all the following properties:

• The memory region size is equal to the minimum implemented translation granule size.
• The memory region is tolerant to speculative accesses.
• The memory region is naturally aligned.

\[\text{R}_{\text{WLVZN}}\]

If execution is in AArch64 state and all associated address translation stages are disabled, a memory location might be accessed as a result of an instruction fetch, including a speculative instruction fetch, in all of the following cases:

• The memory location is in the same memory region, or in the next contiguous memory region, as an
  instruction that simple sequential program execution either requires to be fetched now or has required to be
  fetched since the last reset.
• The memory location is the target of a direct branch that simple sequential program execution would have
  taken since the most recent of one of the following:
  — The last reset.
  — The last synchronization of instruction cache maintenance targeting the branch instruction address.
If all address translation stages are disabled, then speculative instruction fetches can cause unintended memory location accesses, regardless of whether the fetched instruction is committed to execution.

**Effect of disabling address translation on maintenance and address translation instructions**

- If all address translation stages are disabled, speculative instruction fetches can cause unintended memory location accesses, regardless of whether the fetched instruction is committed to execution.

- Cache maintenance instructions act on the target location regardless of all of the following:
  - Whether or not any address translation stages are disabled.
  - The memory attribute values.

- For an address translation stage that is disabled, cache maintenance instructions use flat address mapping.

- If an address translation stage is disabled, TLB maintenance operations are not affected.

For more information, see:

- *A64 Cache maintenance instructions* on page D7-5054.
- *Address translation instructions*.
- *TLB maintenance instructions* on page D8-5201.

### D8.2.11 Address translation instructions

Address translation instructions return the result of translating an IA using a specified translation stage or regime.

An address translation instruction has all of the following properties:

- An IA is supplied as the argument to the instruction.
- The instruction encoding determines the translation stage and regime used by the translation.
- The PAR_EL1 register is updated with the translation result.
- If an instruction is executed in Non-secure state, the instruction cannot return the result of a Secure address translation stage.
- If an address translation stage is controlled by a higher Exception level than the Exception level at which the address translation instruction is executed, the instruction is UNDEFINED.

If FEAT_MTE2 is enabled, then the results of AT* instructions reflect whether the translation is tagged or untagged. For more information, see *Tagged and Untagged Addresses* on page D9-5224.

The A64 assembly language syntax of an address translation instruction is **AT <operation>, <Xt>**.

- The <operation> in **AT <operation>, <Xt>** is one of the following address translation stages:
  - S1 specifies a stage 1 translation.
  - S12 specifies a stage 1 translation followed by a stage 2 translation.

- The <el> is one of the following Exception levels that apply to the translation:
  - E0 specifies EL0.
  - E1 specifies EL1.
  - E2 specifies EL2.
  - E3 specifies EL3.

- The <read|write> is one of the following:
  - R specifies Read.
  - W specifies Write.
• If FEAT_PAN2 is implemented, then the <pan> component is included and has all of the following properties:
  — P determines whether the PSTATE.PAN value is considered when determining permissions. For more information, see PSTATE.PAN on page D8-5132.
  — The field is optional.
  — If <stages>=S1 and <el>=E1, the field is permitted.
  — If <stages>!=S1 or <el>!=E1, the field is not permitted.

If <el> is higher than the current Exception level, then the address translation instruction is UNDEFINED.

The <Xt> in AT <operation>, <Xt> specifies the 64-bit register holding the address to be translated.

When an address translation instruction applies to a translation regime that is using AArch32, VA[63:32] is RES0.

When an address is translated by an address translation instruction, no alignment restrictions exist and therefore an address translation instruction cannot generate an Alignment fault.

For more information, see MMU faults generated by address translation instructions on page D8-5183.

When an address translation instruction is executed, the specified translation stage and regime determines all of the following:
• The entries in TLB caching structures that are permitted to be used.
• How the translation table walk is done.

When an address translation instruction is executed, it is IMPLEMENTATION DEFINED whether the result can be returned from a TLB, or a translation table walk occurs.

If TLB entries might differ from the underlying translation tables held in memory, such as when waiting for a maintenance or synchronization event to complete after updating the translation tables, Arm recommends not using the address translation instructions.

Address translation instructions, successful address translation

When an address translation instruction successfully translates an address, all of the following are updated in PAR_EL1:
• PAR_EL1.F is set to 0.
• The resulting OA is returned in PAR_EL1.PA, and the resulting attributes are returned in the other fields of PAR_EL1.

The architecture defines a single PAR, PAR_EL1, that is used regardless of all of the following:
• The Exception level at which the address translation instruction was executed.
• The Exception level that controls the address translation stage or stages used by the address translation instruction.

Address translation instructions, effect of translation regime

If EL2 is disabled or not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

If EL3 is implemented and EL2 is disabled or not implemented for the target Security state, then all of the following apply to the AT S1E++ instruction behavior:
• The instruction has the same behavior as the equivalent AT S1E++ instruction.
• The instruction behaves consistently with an implementation that has all of the following characteristics:
  — EL2 is implemented.
  — Stage 2 translation is disabled.

RPXNSR

If SCR_EL3.NS is 0 and Secure EL2 is disabled or not implemented, then executing the following AT instructions at EL3 are is UNDEFINED:
- AT S1E2R.
- AT S1E2W.

IKJDTT

The value of HCR_EL2.DC affects all of the following instructions:
- AT S1E0*.
- AT S1E1*.
- AT S12E0*.
- AT S12E1*.

Address translation instructions, synchronization requirements

IPTYVP

When an address translation instruction is executed, explicit synchronization is required to guarantee the result is visible to subsequent direct reads of PAR_EL1.

For more information, see Synchronization requirements for AArch64 System registers on page D17-5547.

IPCPWC

Requiring explicit synchronization after executing an address translation instruction is consistent with the general requirement that the effect of a write to a System register requires explicit synchronization before the result is guaranteed to be visible to subsequent instructions.
D8.3 Translation table descriptor formats

If an address translation stage is controlled by an Exception level that is using AArch64, then the translation table uses the VMASv8-64 format.

A translation descriptor has one of the following formats:

- An invalid descriptor format.
- A Table descriptor format that points to the next-level translation table.
- A Block descriptor or Page descriptor format that defines the memory access properties.
- A reserved format.

The value of descriptor bit[0] determines one of the following:

- If descriptor bit[0] is 0, then the descriptor is invalid.
- If descriptor bit[0] is 1, then the descriptor is valid.

If descriptor bit[0] is 1, then the value of descriptor bit[1] determines one of the following descriptor types:

- For lookup levels other than lookup level 3, one of the following:
  - If bit[1] is 0, then the descriptor is a Block descriptor.
  - If bit[1] is 1, then the descriptor is a Table descriptor.
- For lookup level 3, one of the following:
  - If bit[1] is 0, then the descriptor is reserved, and treated as invalid.
  - If bit[1] is 1, then the descriptor is a Page descriptor.

D8.3.1 Table descriptor format

Throughout this section, if an address translation stage is not specified, then references to the Effective value of TCR_ELx.DS also apply to VTCR_EL2.DS.

The following figure shows all of following stage 1 and stage 2 Table descriptor formats:

- 4KB, 16KB, and 64KB granules using a 48-bit next-level table address.
- If the Effective value of TCR_ELx.DS is 1, the 4KB and 16KB granules using a 52-bit next-level table address.
- If FEAT_LPA is implemented, the 64KB granule using a 52-bit next-level table address.
The AArch64 Virtual Memory System Architecture
D8.3 Translation table descriptor formats

4KB and 16KB granules, 52-bit OA

| Table | Attributes | RES0 | Next-level table address[51:50] | m-1 | 12 | 11 | 9 | 8 | 7 | 2 | 1 | 0 |
|-------|------------|------|----------------------------------|-----|----|----|---|---|---|---|---|---|---|
| 63    | 59 58 51 50 49 |      |                                  |     |    |    |   |   |   |   |   |   |   |

With the 4KB granule size m is 12 and with the 16KB granule size m is 14.
† When m is 12, the RES0 field shown for bits[(m-1):12] is absent.

64KB granule, 52-bit OA

| Table | Attributes | RES0 | Next-level table address[51:48] | m-1 | 12 | 11 | 9 | 8 | 7 | 2 | 1 | 0 |
|-------|------------|------|----------------------------------|-----|----|----|---|---|---|---|---|---|---|
| 63    | 59 58 51 50 48 47 |      |                                  |     |    |    |   |   |   |   |   |   |   |

† TA[51:48] indicates bits [51:48] of the next-level table address.

4KB, 16KB, and 64KB granules, 48-bit OA

| Table | Attributes | RES0 | Next-level table address[47:48] | m-1 | 12 | 11 | 9 | 8 | 7 | 2 | 1 | 0 |
|-------|------------|------|----------------------------------|-----|----|----|---|---|---|---|---|---|---|
| 63    | 59 58 51 50 47 |      |                                  |     |    |    |   |   |   |   |   |   |   |

With the 4KB granule size m is 12, with the 16KB granule size m is 14, and with the 64KB granule size m is 16.
† When m is 12, the RES0 field shown for bits[(m-1):12] is absent.

**Figure D8-12 Table descriptor formats**

For a stage 1 translation, the following figure shows the next-level attribute fields in a Table descriptor. For a stage 2 translation, bits[63:59] are RES0 and bits[58:51] are IGNORED.

<table>
<thead>
<tr>
<th>63 62 61 60 59 58 51</th>
</tr>
</thead>
<tbody>
<tr>
<td>NTable</td>
</tr>
<tr>
<td>APTable</td>
</tr>
<tr>
<td>UXNTable or XNTable</td>
</tr>
<tr>
<td>PXNTable ‡</td>
</tr>
</tbody>
</table>

‡ UXNTable for a translation regime that supports two VA ranges, XNTable for other regimes.
† Regimes that support two VA ranges only, RES0 in the other regimes.

**Figure D8-13 Stage 1 next-level attribute fields in a Table descriptor**

Table descriptor bit[63] is one of the following:

- For stage 1 translations in Secure state, the NTable field which determines the IPA or PA space used for translation tables in subsequent lookup levels. For more information, see Hierarchical control of Secure or Non-secure memory accesses on page D8-5135.
- For stage 1 translations in Non-secure state, this bit is RES0.
- For stage 2 translations, this bit is RES0.

Table descriptor bits[62:61] are one of the following:

- For stage 1 translations, the APTable[1:0] field which determines the access permissions limit for subsequent lookup levels.
- For stage 2 translations, these bits are RES0.

For more information, see Hierarchical control of data access permissions on page D8-5138.

For EL1&0 stage 1 translations, if the Effective value of HCR_EL2.{NV, NV1} is \{1, 1\}, then APTable[0] is treated as 0 regardless of the actual value.
Table descriptor bit[60] is one of the following:

- For stage 1 translations that support one privilege level, the XNTable field which determines the execute-never limit for subsequent lookup levels.
- For stage 1 translations that support two privilege levels, the UXNTable field which determines the unprivileged execute-never limit for subsequent lookup levels at EL0.
- For EL1&0 stage 1 translations, if the Effective value of HCR_EL2.{NV, NV1} is {1, 1}, then the PXNTable field. For more information, see Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 on page D8-5174.
- For stage 2 translations, this bit is RES0.

For more information, see Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 on page D8-5174.

Table descriptor bit[59] is one of the following:

- For stage 1 translations that support one privilege level, RES0.
- For stage 1 translations that support two privilege levels, the PXNTable field which determines the privileged execute-never limit for subsequent lookup levels.
- For EL1&0 stage 1 translations, if the Effective value of HCR_EL2.{NV, NV1} is {1, 1}, then RES0. For more information, see Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 on page D8-5174.
- For stage 2 translations, this bit is RES0.

For more information, see Hierarchical control of instruction execution permissions on page D8-5141.

Table descriptor bits[58:51] are IGNORED.

Table descriptor bit[50] is RES0.

Table descriptor bits[49:48] are one of the following:

- For the 4KB and 16KB granules, if the Effective value of TCR_ELx.DS is 0, then RES0.
- For the 4KB and 16KB granules, if the Effective value of TCR_ELx.DS is 1, then bits[49:48] of the next-level table address.
- For the 64KB translation granule, RES0.

Table descriptor bits[47:12] are one of the following:

- For the 4KB granule, bits[47:12] of the next-level table address.
- For the 16KB granule, all of the following:
  - Table descriptor bits[47:14] are bits[47:14] of the next-level table address.
  - Table descriptor bits[13:12] are RES0.
- For the 64KB granule, all of the following:
  - Table descriptor bits[47:16] are bits[47:16] of the next-level table address.
  - If FEAT_LPA is not implemented, then Table descriptor bits[15:12] are RES0.
  - If FEAT_LPA is implemented, then Table descriptor bits[15:12] are bits[51:48] of the next-level table address.

Table descriptor bits[11:2] are one of the following:

- For the 4KB and 16KB granules, if the Effective value of TCR_ELx.DS is 0, then the bits are IGNORED.
- For the 4KB and 16KB granules, if the Effective value of TCR_ELx.DS is 1, then all of the following:
  - Table descriptor bits[11:10] are IGNORED.
  - Table descriptor bits[9:8] are bits[51:50] of the next-level table address.
  - Table descriptor bits[7:2] are IGNORED.
- For the 64KB granule, the bits are IGNORED.
For lookup levels other than lookup level 3, to specify a Table descriptor, the value of descriptor bit[1] is required to be 1.

Table descriptor bit[0] is required to be 1 to indicate the descriptor is valid.

The next-level table address is one of the following:
- For a level -1 Table descriptor, the address of a level 0 table.
- For a level 0 Table descriptor, the address of a level 1 table.
- For a level 1 Table descriptor, the address of a level 2 table.
- For a level 2 Table descriptor, the address of a level 3 table.

If EL2 is enabled, the next-level table address is one of the following:
- For translation regimes other than Secure EL1&0 and Non-secure EL1&0, the PA of the target table.
- For the Secure EL1&0 and Non-secure EL1&0 translation regimes, the IPA of the target table.

### D8.3.2 Block descriptor and Page descriptor formats

Throughout this section, if an address translation stage is not specified, then references to the Effective value of TCR_ELx.DS also apply to VTCR_EL2.DS.

The following figure shows all of the following Block descriptor formats:
- 4KB, 16KB, and 64KB granules using a 48-bit OA.
- If the Effective value of TCR_ELx.DS is 1, the 4KB and 16KB granules using a 52-bit OA.
- If FEAT_LPA is supported, the 64KB granule using a 52-bit OA.

For the 4KB granule size, the level 1 descriptor \( n \) is 30, and the level 2 descriptor \( n \) is 21.
For the 16KB granule size, the level 2 descriptor \( n \) is 25.
For the 64KB granule size, the level 2 descriptor \( n \) is 29.

The following figure shows all of the following Page descriptor formats:
- 4KB, 16KB, and 64KB granules using a 48-bit OA.
- If the Effective value of TCR_ELx.DS is 1, the 4KB and 16KB granules using a 52-bit OA.
- If FEAT_LPA is supported, the 64KB granule using a 52-bit OA.

---

**Figure D8-14 Block descriptor formats**
### Figure D8-15 Page descriptor formats

For a stage 1 translation, the following figure shows the attribute fields in Block descriptors and Page descriptors, split into upper attributes and lower attributes.

#### 4KB granule 52-bit OA

<table>
<thead>
<tr>
<th>Page</th>
<th>Upper attributes</th>
<th>Output address[49:12]</th>
<th>Lower attributes</th>
<th>51 50 49</th>

**Figure D8-16 Stage 1 attribute fields in Block and Page descriptors**

- **Upper attributes**
  - 63 62 59 58 55 54 53 52 51 50
  - PBHA
  - IGNORED
  - Reserved for software use
  - UXN or XN
  - PXN
  - Contiguous
  - DBM

- **Lower attributes**
  - 16 15 12 11 10 9 8 7 6 5 4 2
  - nT
  - OA
  - nG
  - AF
  - SH[1:0]
  - AP[2:1]
  - NS
  - AttrIndx[2:0]

- **Notes:**
  - † IGNORED if FEAT_HFDS2 is not implemented.
  - †† UXN for a translation regime that can apply to execution at EL0, otherwise XN.
  - †‡ RES0 for a translation regime that cannot apply to execution at EL0.
  - * RES0 if FEAT_HAFDBS is not implemented.
  - ‡ RES0 if FEAT_LPA is not implemented.
  - # OA[51:50] if the Effective value of TCR_Elx.DS is 1.
For a stage 2 translation, the following figure shows the attribute fields in Block descriptors and Page descriptors, split into upper attributes and lower attributes.

![Figure D8-17 Stage 2 attribute fields in Block and Page descriptors](image)

- **Upper attributes**:
  - Bits [63:51] are reserved for use by a System MMU.
  - Bits [50:22] are reserved for software use.
  - Bit [21] is `CONTIGUOUS`.
  - Bit [20] is `DBM`.
  - Bits [19:16] are reserved for System MMU.

- **Lower attributes**:
  - Bits [11:2] are `OA[51:50]` if the Effective value of VTCR_EL2.DS is 1.
  - Bit [1] is `X[1:0]`.
  - Bit [0] is `AF`.

**Notes**:
- Bit [53] is `RES0` if FEAT_XNX is not implemented.
- Bits [62:60] are reserved for use by System MMU if FEAT_HPDS2 is not implemented.
- Bit [59] is `IGNORED` if FEAT_HPDS2 is not implemented.
- *RES0* if FEAT_HAFDBS is not implemented.
- §RES0 if FEAT_LPA is not implemented.
- #OA[51:50] if the Effective value of VTCR_EL2.DS is 1.

---

**Notes**:
- Bit [53] is `RES0` if FEAT_XNX is not implemented.
- Bits [62:60] are reserved for use by System MMU if FEAT_HPDS2 is not implemented.
- Bit [59] is `IGNORED` if FEAT_HPDS2 is not implemented.
- *RES0* if FEAT_HAFDBS is not implemented.
- §RES0 if FEAT_LPA is not implemented.
- #OA[51:50] if the Effective value of VTCR_EL2.DS is 1.
• For stage 1 translations, bit[53] is one of the following:
  — If the translation regime supports only one privilege level, then RES0.
  — If the translation regime can support two privilege levels, then the Privileged execute-never field (PXN).
  — For EL1&0 translations, if the Effective value of HCR_EL2.NV, NV1 is \{1, 1\}, then RES0.
• For stage 2 translations, bits[54:53] are one of the following:
  — If FEAT_XNX is not implemented, then bit[54] is the Execute-never field (XN) and bit[53] is RES0.
  — If FEAT_XNX is implemented, then bits[54:53] are the Execute-never field (XN[1:0]).
For more information, see Instruction execution permissions on page D8-5138 and Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 on page D8-5174.

RKMTMJ
Block descriptor and Page descriptor bit[52] is the Contiguous bit.
For more information, see The Contiguous bit on page D8-5158.

RNJYJS
Block descriptor and Page descriptor bit[51] is the Dirty Bit Modifier (DBM).
For more information, see Hardware management of the dirty state on page D8-5145.

RKHPCD
Block descriptor and Page descriptor bit[50] is one of the following:
- If FEAT_BTI is not implemented, then Block descriptor and Page descriptor bit[50] is RES0.
- If FEAT_BTI is implemented, then one of the following:
  — For stage 1 translations, the Block descriptor and Page descriptor bit[50] is Guarded Page field (GP).
  — For stage 2 translations, the Block descriptor and Page descriptor bit[50] is RES0.

RCYLDW
Block descriptor and Page descriptor bits[49:48] are one of the following:
- For the 4KB and 16KB granules, one of the following:
  — If the Effective value of TCR_ELx.DS is 0, then RES0.
  — If the Effective value of TCR_ELx.DS is 1, then bits[49:48] of the OA.
- For the 64KB granule, RES0.

RBHRKX
Block descriptor bits[47:17] are one of the following:
- For the 4KB granule, if the Effective value of TCR_ELx.DS is 1, then all of the following in a level 0 Block descriptor:
  — Block descriptor bits[47:39] are bits[47:39] of the OA.
  — Block descriptor bits[38:17] are RES0.
- For the 4KB granule, all of the following in a level 1 Block descriptor:
  — Block descriptor bits[47:30] are bits[47:30] of the OA.
  — Block descriptor bits[29:17] are RES0.
- For the 4KB granule, all of the following in a level 2 Block descriptor:
  — Block descriptor bits[47:21] are bits[47:21] of the OA.
  — Block descriptor bits[20:17] are RES0.
- For the 16KB granule, if the Effective value of TCR_ELx.DS is 1, then all of the following in a level 1 Block descriptor:
  — Block descriptor bits[47:36] are bits[47:36] of the OA.
  — Block descriptor bits[35:17] are RES0.
- For the 16KB granule, all of the following in a level 2 Block descriptor:
  — Block descriptor bits[47:25] are bits[47:25] of the OA.
  — Block descriptor bits[24:17] are RES0.
• For the 64KB granule, if FEAT_LPA is implemented, then all of the following in a level 1 Block descriptor:
  — Block descriptor bits[47:42] are bits[47:42] of the OA.
  — Block descriptor bits[41:17] are RES0.
• For the 64KB granule, all of the following in a level 2 Block descriptor:
  — Block descriptor bits[47:29] are bits[47:29] of the OA.
  — Block descriptor bits[28:17] are RES0.

BBHXV
Block descriptor bit[16] is one of the following:
• If FEAT_BBM is not implemented, then Block descriptor bit[16] is RES0.
• If FEAT_BBM is not implemented, then Block descriptor bit[16] is the nT field.
For more information, see Block translation entry on page D8-5160.

VZRKS
Block descriptor bits[15:12] are one of the following:
• If FEAT_LPA is not implemented, then Block descriptor bits[15:12] are RES0.
• If FEAT_LPA is implemented, then one of the following:
  — For the 4KB and 16KB granules, then Block descriptor bits[15:12] are RES0.
  — For the 64KB granule, then Block descriptor bits[15:12] are bits[51:48] of the OA.

QNVFN
Page descriptor bits[47:12] are one of the following:
• For the 4KB granule, bits[47:12] of the OA.
• For the 16KB granule, all of the following:
  — Page descriptor bits[47:14] are bits[47:14] of the OA.
  — Page descriptor bits[13:12] are RES0.
• For the 64KB granule, all of the following:
  — Page descriptor bits[47:16] are bits[47:16] of the OA.
  — If FEAT_LPA is not implemented, then Page descriptor bits[15:12] are RES0.
  — If FEAT_LPA is implemented, then Page descriptor bits[15:12] are bits[51:48] of the OA.

DFNPW
Block descriptor and Page descriptor bit[11] is one of the following:
• For stage 1 translations that support a single privilege level, Block descriptor and Page descriptor bit[11] is RES0.
• For stage 1 translations that support two privilege levels, Block descriptor and Page descriptor bit[11] is the not global bit (nG). For more information, see Global and process-specific translation table entries on page D8-5194.
• For stage 2 translations, one of the following:
  — If FEAT_XS is not implemented, then Block descriptor and Page descriptor bit[11] is RES0.
  — If FEAT_XS is implemented, then Block descriptor and Page descriptor bit[11] is FnXS. For more information, see XS attribute modifier on page D8-5160.

XBPJZ
Block descriptor and Page descriptor bit[10] is the Access flag (AF).
For more information, see The Access flag on page D8-5143.

MIZBIW
Block descriptor and Page descriptor bits[9:8] are one of the following:
• For the 4KB and 16KB granules, one of the following:
  — If the Effective value of TCR_ELx.DS is 0, then the Shareability field (SH[1:0]).
  — If the Effective value of TCR_ELx.DS is 1, then bits[51:50] of the OA.
• For the 64KB translation granule, the Shareability field (SH[1:0]).
For more information, see Stage 1 Shareability attributes on page D8-5152 and Stage 2 Shareability attributes on page D8-5156.
Block descriptor and Page descriptor bits[7:6] are one of the following:

- For stage 1 translations that support a single privilege level, all of the following:
  - Bit[7] is the data Access Permissions bit (AP[2]).
- For EL1 stage 1 translations, if the Effective value of HCR_EL2.{NV, NV1} is {1, 1}, then all of the following:
  - Bit[7] is the data Access Permissions bit (AP[2]).
  - Bit[6] is treated as 0 regardless of the actual value.
- For stage 1 translations that support two privilege levels, the data Access Permissions bits (AP[2:1]).
- For stage 2 translations, the stage 2 data Access Permissions field (S2AP[1:0]).

For more information, see Data access permissions for stage 1 translations on page D8-5136, Data access permissions for stage 2 translations on page D8-5137, and Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1 on page D8-5174.

The Armv8 Block descriptor and Page descriptor format defines the data Access Permissions bits, AP[2:1], and does not define an AP[0] bit.

Block descriptor and Page descriptor bits[5:2] are one of the following:

- For stage 1 translations bit[5] is one of the following:
  - When the access is from Secure state, the Non-secure bit (NS). For more information, see Control of Secure or Non-secure memory access on page D8-5135.
  - When the access is from Non-secure state, the bit is res0.
- For stage 1 translations, bits[4:2] are the stage 1 memory attributes index field for the MAIR_ELx (AttrIndx[2:0]). For more information, see Stage 1 memory type and Cacheability attributes on page D8-5151.
- For stage 2 translations, if the Effective value of HCR_EL2.FWB is 0, then bits[5:2] are the stage 2 memory attributes (MemAttr[3:0]). For more information, see Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is disabled on page D8-5153.
- For stage 2 translations, if the Effective value of HCR_EL2.FWB is 1, then all of the following:
  - Bit[5] is res0.
  - Bits[4:2] are the stage 2 memory attributes (MemAttr[2:0]). For more information, see Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled on page D8-5155.

Descriptor bit[1] is one of the following:

- For lookup levels other than lookup level 3, to specify a Block descriptor, the value of descriptor bit[1] is required to be 0.
- For lookup level 3, to specify a Page descriptor, the value of descriptor bit[1] is required to be 1.

Block descriptor and Page descriptor bit[0] is required to be 1 to indicate the descriptor is valid.

For more information, see:

- Effect of PSTATE on access permission on page D8-5132.
- Hardware updates to the translation tables on page D8-5148.
D8.4 Memory access control

Fields in the descriptors and in PSTATE provide ways to control access to memory and instruction execution.

D8.4.1 Effect of PSTATE on access permission

PSTATE.PAN affects memory access permissions decoded from memory access control fields in the descriptors. PSTATE.UAO affects the privilege level of a memory access. The PSTATE.BTYPE field is part of the determination of whether a branch access to a guarded memory region generates a Branch Target exception.

For more information on PSTATE, see Process state, PSTATE on page D1-4670.

PSTATE.PAN

PSTATE.PAN is used to prevent privileged data accesses to virtual memory addresses that are accessible from EL0.

All statements in this section require implementation of FEAT_PAN.

For a translation regime, if one or more of the following apply, then the PSTATE.PAN bit has no effect in that regime:

- Stage 1 translation is disabled.
- Stage 1 translation supports a single privilege level.

If the Effective value of PSTATE.PAN is 1, then a privileged data access from any of the following Exception levels to a virtual memory address that is accessible to data accesses at EL0 generates a stage 1 Permission fault:

- A privileged data access from EL1.
- If HCR_EL2.E2H is 1, then a privileged data access from EL2.

If the value of PSTATE.PAN is 0, then a privileged data access is permitted from the corresponding privileged Exception level to a virtual memory address that is accessible at EL0.

When taking an exception from an EL in AArch64 state to an ELx, PSTATE.PAN is saved to and restored from SPSR_ELx.PAN.

When taking an exception from an EL in AArch32 state to an ELx in AArch64 state, CPSR.PAN is saved to and restored from SPSR_ELx.PAN.

When entering and exiting Debug state, PSTATE.PAN is saved to and restored from DSPSR_EL0.PAN.

When an exception occurs, one of the following determines whether PSTATE.PAN is set to 1 or the value of PSTATE.PAN is unchanged:

- When taking an exception to EL1, SCTLR_EL1.SPAN.
- When taking an exception to EL2, SCTLR_EL2.SPAN.

If FEAT_PAN3 is implemented, PSTATE.PAN is 1, and unprivileged instruction execution is permitted to a VA, then all of the following prevent privileged data accesses to that VA:

- For a data access from EL1, when SCTLR_EL1.EPAN is 1, a Permission fault is generated.
- For a data access from EL2, when HCR_EL2.E2H is 1 and SCTLR_EL2.EPAN is 1, a Permission fault is generated.

For the purpose of PAN, if FEAT_PAN3 is implemented, then it is IMPLEMENTATION DEFINED whether SCR_EL3.SIF is used to determine instruction execution permission.

If FEAT_PAN3 is implemented, then the SCTLR_EL1.EPAN and SCTLR_EL2.EPAN bits affect the AT S1E1RP and AT S1E1WP instructions, consistent with those instructions using PSTATE.PAN to determine whether the memory access generates a Permission fault.

The PSTATE.PAN bit has no effect on all of the following:

- Instruction fetches.
• Data cache instructions, except DC ZVA.
• If FEAT_PAN2 is not implemented, then address translation instructions.
• If FEAT_PAN2 is implemented, then the address translation instructions other than AT S1E1RP and AT S1E1WP.

If the current Exception level is EL1 and HCR_EL2.{NV, NV1} is \{1, 1\}, then PSTATE.PAN is treated as 0 for all purposes except reading the bit value.

Software can access PSTATE.PAN using all of the following instructions:
• Software can use MSR (immediate) PAN, #Imm4 to modify PSTATE.PAN.
• Software can use MSR (register) PAN, Xt to modify PSTATE.PAN.
• Software can use MRS Xt, PAN to read PSTATE.PAN.

If the PE is in Debug state, then a debugger can use the DRPS instruction to modify PSTATE.PAN.

PSTATE.UAO

PSTATE.UAO is used to cause unprivileged load/store register instructions to behave as if they are load/store register instructions.

All statements in this section require implementation of FEAT_UAO.

If the value of PSTATE.UAO is 1, then a load/store unprivileged instruction executed at any of the following Exception levels is subject to the same access permissions as the corresponding load/store register instruction:
• EL1.
• If the Effective value of HCR_EL2.{E2H, TGE} is \{1, 1\}, EL2.

If the value of PSTATE.UAO is 0, then load/store unprivileged instructions are not affected.

When an exception occurs, all of the following apply to PSTATE.UAO:
• When taking an exception to ELx, PSTATE.UAO is saved to SPSR_ELx.UAO and then set to 0.
• When returning from an exception at ELx, PSTATE.UAO is restored from SPSR_ELx.UAO.

If the PE is in AArch32 state, then when an exception occurs and the exception is taken to AArch64 state, all of the following occur:
• PSTATE.UAO is set to 0.
• The corresponding SPSR_ELx.UAO is set to 0.

When entering and exiting Debug state, PSTATE.UAO is saved to and restored from DSPSR_EL0.UAO.

Software can access PSTATE.UAO using all of the following instructions:
• Software can use MSR (immediate) UAO, #Imm4 to modify PSTATE.UAO.
• Software can use MSR (register) UAO, Xt to modify PSTATE.UAO.
• Software can use MRS Xt, UAO to read PSTATE.UAO.

If the PE is in Debug state, a debugger can use the DRPS instruction to modify PSTATE.UAO.

PSTATE.BTYPE

PSTATE.BTYPE is part of a mechanism used to guard memory pages against executing instructions that are not the intended target of a branch.

All statements in this section require implementation of FEAT_BTI.

When an instruction completes execution, the value of the PSTATE.BTYPE field is determined by all of the following, as shown in the following table:
• The instruction that was executed.
• Whether or not the memory region is guarded.
• The register accessed by the instruction.

### Table D8-36 Values taken by \texttt{PSTATE.BTYPE} on execution of an instruction

<table>
<thead>
<tr>
<th>Instruction executed</th>
<th>Memory region</th>
<th>Register accessed</th>
<th>PSTATE.BTYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>BR, BRAA, BRAAZ, BRAB, BRABZ</td>
<td>Guarded</td>
<td>Any register except X16 or X17</td>
<td>0b11</td>
</tr>
<tr>
<td>BLR, BLRAA, BLRAAZ, BLRAB, BLRABZ</td>
<td>Any</td>
<td>Any register</td>
<td>0b10</td>
</tr>
<tr>
<td>BR, BRAA, BRAAZ, BRAB, BRABZ</td>
<td>Guarded</td>
<td>X16 or X17</td>
<td>0b01</td>
</tr>
<tr>
<td>BR, BRAA, BRAAZ, BRAB, BRABZ</td>
<td>Non-guarded</td>
<td>Any register</td>
<td>0b01</td>
</tr>
<tr>
<td>Any instruction except BR, BRAA, BRAAZ, BRAB, BRABZ, BLR, BLRAA, BLRAAZ, BLRAB, BLRABZ</td>
<td>Any</td>
<td>Any register</td>
<td>0b00</td>
</tr>
</tbody>
</table>

When the BTI instruction is executed, the \texttt{<targets>} operand determines the compatibility between the BTI instruction and different \texttt{PSTATE.BTYPE} values as shown in the following table:

### Table D8-37 Compatibility of BTI instruction to different \texttt{PSTATE.BTYPE} values

<table>
<thead>
<tr>
<th>\texttt{&lt;targets&gt;}</th>
<th>\texttt{PSTATE.BTYPE} value</th>
<th>0b00</th>
<th>0b01</th>
<th>0b10</th>
<th>0b11</th>
</tr>
</thead>
<tbody>
<tr>
<td>(omitted)</td>
<td>N/A</td>
<td>Not compatible</td>
<td>Not compatible</td>
<td>Not compatible</td>
<td></td>
</tr>
<tr>
<td>c</td>
<td>N/A</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Not compatible</td>

<tr>
<td>j</td>
<td>N/A</td>
<td>Compatible</td>
<td>Not compatible</td>
<td>Compatible</td>
<td></td>
</tr>
<tr>
<td>jc</td>
<td>N/A</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
<td></td>
</tr>
</tbody>
</table>

If stage 1 translation is enabled, the GP bit in Block and Page descriptors indicates whether the memory region is guarded. For more information, see \texttt{FEAT_BTI}.

If stage 1 translation is disabled, no memory regions are guarded. For more information, see \textit{Behavior when stage 1 address translation is disabled} on page D8-5118.

If the \texttt{PSTATE.BTYPE} field is not 0b00 and an attempt is made to execute an instruction within a guarded page, a Branch Target exception is generated unless the instruction is one of the following:

- A BTI instruction that is compatible with the \texttt{PSTATE.BTYPE} field.
- A PACIASP or PACIBSP instruction, and the \texttt{PSTATE.BTYPE} is consistent with implicit BTI behavior of these instructions.
- A Breakpoint Instruction exception.
- A Halt Instruction debug event.

When a Branch Target exception occurs, it is taken to one of the following:

- When executing at EL0 and HCR_EL2.TGE is 0, the Branch Target exception is taken to EL1.
- When executing at EL0 and HCR_EL2.TGE is 1, the Branch Target exception is taken to EL2.
- When executing at ELx, where x is 1, 2, or 3, the Branch Target exception is taken to ELx.

When a Branch Target exception occurs, ESR_ELx.EC is 0xD.

For more information, see \textit{ISS encoding for an exception from Branch Target Identification instruction} on page D17-5700.
When PACIASP and PACIBSP instructions access a guarded memory region, the instructions have an implicit branch target identification instruction that is compatible with one of the following:

- The PSTATE.BTYPE value is \(0b10\) or \(0b01\).  
- When the associated SCTLR_ELx.\{BT0, BT1, BT\} bits are 0, the PSTATE.BTYPE value is \(0b11\).

The implicit branch target identification property of PACIASP and PACIBSP is independent of the setting of the SCTLR_ELx.\{EnIA, EnIB\} bits.

The BTI instruction is a NOP in a non-guarded page.

There is no mechanism for direct reads or direct writes of the PSTATE.BTYPE field.

### D8.4.2 Control of Secure or Non-secure memory access

The Non-secure, NS, bit in Block descriptors and Page descriptors, and the Non-secure table, NSTable, bit in Table descriptors are used to provide control over accesses from Secure state to Secure and Non-secure memory.

In this section and subsections, IPA or PA space refers to the OA space of stage 1 translations.

For a Secure translation regime, if the translation table entry is in Secure IPA or PA space, then the Block descriptor and Page descriptor NS determines all of the following:

- If NS is 0, an access to the OA specified by the descriptor is to Secure IPA or PA space.
- If NS is 1, an access to the OA specified by the descriptor is to Non-secure IPA or PA space.

For a Non-secure translation regime, the NS and NSTable bits are RES0 and the OA or next-level table base address is in Non-secure IPA or PA space.

For a Secure translation regime, when the descriptor is fetched from Non-secure IPA or PA space, all of the following apply to the descriptor:

- The descriptor NS and NSTable bits exist but they are SBZ instead of RES0.
- The OA or next-level table base address specified by the descriptor is in Non-secure IPA or PA space.

Hierarchical control of Secure or Non-secure memory accesses

For a Secure translation regime, when a Table descriptor is accessed from a stage 1 translation table in Secure IPA or PA space, the NSTable field determines all of the following:

- If NSTable is 0, the next-level translation table address in the Table descriptor is in Secure IPA or PA space.
- If NSTable is 1, the next-level translation table address in the Table descriptor is in Non-secure IPA or PA space.

If the next-level translation table address in the Table descriptor is in Non-secure IPA or PA space, then the address specified by a descriptor in the next lookup-level translation table is in Non-secure IPA or PA space.

If stage 2 translation is enabled, the VSTCR_EL2.SA, VTCR_EL2.NSA, VSTCR_EL2.SW, and VTCR_EL2.NSW fields can map an IPA space to a PA space not matching the Security of the IPA space.

If all of the following apply, then a stage 1 translation is treated as non-global, meaning the Effective value of nG is 1, regardless of the actual value of the Block descriptor or Page descriptor nG bit:

- The stage 1 translation supports two privilege levels.
- The PE is in Secure state.
- NSTable is 1 at any level of the translation table walk.

For more information, see Global and process-specific translation table entries on page D8-5194.

The descriptor NSTable field affects all subsequent lookup levels and the translation IPA or PA space. When an NSTable field is changed, software is required to use a break-before-make sequence, including TLB maintenance for all lookup levels for the VA range translated by the descriptor.
For more information, see *TLB maintenance* on page D8-5197 and *Using break-before-make when updating translation table entries* on page D8-5198.

### D8.4.3 Data access permissions

The descriptors contain fields used to control data access permissions in stage 1 and stage 2 translations.

#### Data access permissions for stage 1 translations

For a stage 1 translation that supports two Exception levels, the AP[2:1] bits control all of the following stage 1 data access permissions:

- AP[2] selects between read-only and read/write access.
- AP[1] selects between Application level control at EL0 and the privileged Exception level control.

For a stage 1 translation that supports one Exception level, AP[1] is RES1.

For a stage 1 translation that supports two Exception levels, the AP[1] descriptor bit determines all of the following:

- If AP[1] is 0, data accesses are not permitted at EL0.
- If AP[1] is 1, data accesses at EL0 use the data access permission defined by AP[2].

For a stage 1 translation that supports one Exception level, the following table shows the possible data access permissions at the current Exception level.

<table>
<thead>
<tr>
<th></th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write</td>
</tr>
<tr>
<td>1</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

For a stage 1 translation that supports two Exception levels, the following table shows the possible data access permissions at EL0 and the corresponding higher Exception level.

<table>
<thead>
<tr>
<th></th>
<th>Access from higher Exception level</th>
<th>Access from EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Read/write</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read/write</td>
<td>Read/write</td>
</tr>
<tr>
<td>10</td>
<td>Read-only</td>
<td>None</td>
</tr>
<tr>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

If a data access to memory is attempted that is not permitted by the value of one of the following, then in the absence of a higher-priority MMU fault, a stage 1 Permission fault is generated:

- For a stage 1 translation that supports one Exception level, the AP[2] bit.
- For a stage 1 translation that supports two Exception levels, the AP[2:1] bits.

For more information, see *MMU fault prioritization from a single address translation stage* on page D8-5190.

For the EL1&0 translation regime in the current Security state, if the Effective value of HCR_EL2.{NV, NV1} is \{1, 1\}, then AP[1] is treated as 0 regardless of the actual value.

For more information, see *Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1* on page D8-5174.

If hardware management of dirty state is enabled at stage 1, then the AP[2] bit can be cleared by hardware in some situations.
For more information, see *Hardware management of the dirty state on page D8-5145.*

**Data access permissions for stage 2 translations**

For the EL1&0 translation regime, if stage 2 translation is enabled, then the S2AP descriptor field determines the stage 2 data access permissions.

The following table shows encoding of the S2AP descriptor field:

<table>
<thead>
<tr>
<th>S2AP[1:0]</th>
<th>Access permission from EL1&amp;0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No access</td>
</tr>
<tr>
<td>01</td>
<td>Read-only</td>
</tr>
<tr>
<td>10</td>
<td>Write-only</td>
</tr>
<tr>
<td>11</td>
<td>Read/Write</td>
</tr>
</tbody>
</table>

The S2AP data access permissions do not distinguish between EL1 accesses and EL0 accesses.

If an attempt is made to access memory that is not permitted by the value of the S2AP field, then a stage 2 Permission fault is generated.

If hardware management of dirty state is enabled at stage 2, then the S2AP[1] bit can be set to 1 by hardware in some situations.

The combination of both the stage 1 and stage 2 permissions determine the final data access permissions.

If EL2 is enabled, then all of the following apply to the EL1&0 translation regime:

- For enabled stage 1 translations, all of the following apply:
  - The stage 1 translation is configured and controlled from EL1.
  - Stage 1 MMU faults are taken to EL1.
- For enabled stage 2 translations, all of the following apply:
  - The stage 2 translation is configured and controlled from EL2.
  - The stage 2 data access permissions do not differentiate between accesses at EL1 or EL0.
  - Software executing at EL2 can assign a write-only permission to a memory region.
  - Stage 2 MMU faults are taken to EL2.

Stage 1 Permission faults are reported with a higher priority than stage 2 Permission faults.

For a virtualization implementation, a hypervisor can define the stage 2 translation permissions to be more restrictive than the stage 1 translation permissions defined by a Guest OS. The final access permissions are the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of combining access permissions defined by the hypervisor are expected to be functionally transparent to the Guest OS.

For more information, see *MMU fault prioritization from a single address translation stage on page D8-5190.*
Hierarchical control of data access permissions

Translation table entries at a given lookup level can limit data access permissions at subsequent lookup levels.

For a stage 1 translation, the Table descriptor APTable[1:0] field limits the data access permission of subsequent stage 1 translation lookup levels, regardless of the permissions in subsequent lookup levels, as shown in the following table:

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect at subsequent lookup levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions.</td>
</tr>
<tr>
<td>01</td>
<td>Unprivileged access not permitted.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted.</td>
</tr>
<tr>
<td>11</td>
<td>Write access not permitted.</td>
</tr>
</tbody>
</table>

Unprivileged read access not permitted.

For a Permission fault, the level of the Block descriptor or Page descriptor is reported regardless of whether the lack of permission was caused by configuration of the APTable or AP fields.

For translation regimes that support one Exception level, APTable[0] is RES0.

The APTable[1:0] settings are combined with the descriptor access permissions in subsequent lookup levels. They do not change the values entered in those descriptors, nor restrict what values can be entered.

For the translation regime controlled by a TCR_ELx, one or more of the following can be used to disable the Table descriptor APTable[1:0] field so that it is IGNORED by the PE and the behavior is as if the value is 0:

- If the Effective value of TCR_ELx.HPD{0} is 1, hierarchical data access permission control is disabled in the translation tables pointed to by TTBR0_ELx.
- If the Effective value of TCR_ELx.HPD1 is 1, hierarchical data access permission control is disabled in the translation tables pointed to by TTBR1_ELx.

The descriptor APTable field affects all subsequent lookup levels. When an APTable field is changed, software is required to use a break-before-make sequence, including TLB maintenance for all lookup levels for the VA range translated by the descriptor.

D8.4.4 Instruction execution permissions

The descriptors contain fields used to control instruction execution permissions in stage 1 and stage 2 translations.

If instruction execution is not permitted by an execute-never field in a translation table entry at any level and stage of translation, then the memory region is execute-never.

If a memory region is execute-never at the current Exception level, then speculative instruction fetch from that memory region is prohibited.

If a memory region is execute-never at the current Exception level, then when an attempt to execute from that memory region occurs, a Permission fault is generated at the translation stage that determines the region is execute-never.

If Device memory is not execute-never, then speculative instruction fetch from that memory region is permitted.

For all Exception levels from which a read-sensitive memory region can be accessed, to avoid the possibility of a speculative fetch affecting that memory region, software is expected to define that memory region as execute-never.

Except for the purposes of PSTATE.PAN, the descriptor execute-never fields do not prevent data accesses to the memory region translated by the descriptor.
Summary of instruction access and execution permissions for stage 1 translations

If a translation regime applies to EL0 and a higher Exception level, then the following table shows the possible stage 1 memory access permissions, using all of the following notations:

- **Executable.** Executing instructions in the memory location is not prevented.
- **Not Executable.** Executing instructions in the memory location is not permitted.
- **R.** Reading from the memory location is permitted.
- **W.** Writing to the memory location is permitted.
- **WXN** is in the SCTLR_ELx register at the higher Exception level to which the translation regime applies.
- **AP[2:1]** is the effective value of AP[2:1] after the effects of APTable are applied.
- If hardware update of dirty state is enabled, then AP[2] is considered to be 0 for the purposes of computing execute permission in some situations.

</tbody>
</table>

For a memory location, if a translation regime applies to a single Exception level, then the following table shows the stage 1 access permissions, using all of the following notations:

- **Executable.** Executing instructions in the memory location is permitted.
• Not Executable. Executing instructions in the memory location is not permitted.
• R. Reading from the memory location is permitted.
• W. Writing to the memory location is permitted.
• WXN is in the SCTLR_ELx register at the higher Exception level to which the translation regime applies.
• AP[2] is the effective value of AP[2] after the effects of APTable are applied.
• If hardware update of dirty state is enabled, then AP[2] is considered to be 0 for the purposes of computing execute permission in some situations.

For more information, see Implications of enabling the dirty state management mechanism on page D8-5147.

Instruction execution permissions for stage 1 translations

The instruction Execute-never, Unprivileged execute-never, and Privileged execute-never fields in a Block descriptor and Page descriptor are used to control instruction execution permissions by a stage 1 translation.

For a stage 1 translation that supports one Exception level, the XN field in the Block descriptor and Page descriptor has all of the following properties:
• If the Effective value of XN is 0, then instruction execution is not prevented by this bit.
• If the Effective value of XN is 1, then instruction execution is not permitted.

For a stage 1 translation that supports two Exception levels, the UXN field in the Block descriptor and Page descriptor has all of the following properties:
• If the Effective value of UXN is 0, then instruction execution is not prevented by this bit at EL0.
• If the Effective value of UXN is 1, then instruction execution is not permitted at EL0.

For a stage 1 translation that supports two Exception levels, the PXN field in the Block descriptor and Page descriptor has all of the following properties:
• If the Effective value of PXN is 0, then instruction execution is not prevented by this bit at the privileged Exception level.
• If the Effective value of PXN is 1, then instruction execution is not permitted at the privileged Exception level.

For stage 1 translations that support two Exception levels, if the value of the AP[2:1] descriptor field is 0b01, then the PXN descriptor field is treated as if it has the value 1, regardless of the actual value.

For translation regimes supporting EL0, instruction execution at a privileged Exception level is not permitted from unprivileged writable memory.

Instruction execution permissions for stage 2 translations

The instruction Execute-never field in a Block descriptor and Page descriptor is used to control instruction execution permissions by a stage 2 translation.
For a stage 2 translation, if FEAT_XNX is not implemented, then the XN field in the Block descriptor and Page descriptor controls instruction execution permissions as shown in the following table:

<table>
<thead>
<tr>
<th>XN</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The stage 2 control does not forbid execution at EL1 and EL0.</td>
</tr>
<tr>
<td>1</td>
<td>The stage 2 control does not permit execution at EL1 or EL0.</td>
</tr>
</tbody>
</table>

For a stage 2 translation, if FEAT_XNX is implemented, then the XN[1:0] field in the Block descriptor and Page descriptor controls instruction execution permissions as shown in the following table:

<table>
<thead>
<tr>
<th>XN[1]</th>
<th>XN[0]</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The stage 2 control does not forbid execution at EL1 and EL0.</td>
</tr>
<tr>
<td>0</td>

**Effect of both stage 1 and stage 2 on instruction access permissions**

Both the stage 1 and stage 2 permissions determine the final instruction access permissions.

If both stage 1 and stage 2 translations are enabled, then in the absence of other higher-priority MMU faults, the instruction execution permissions are combined in one of the following ways:

1. If instruction execution is not permitted by the stage 1 permissions, then a stage 1 Permission fault is generated, regardless of the stage 2 permissions.
2. If instruction execution is permitted by the stage 1 permissions, but is not permitted by the stage 2 permissions, then a stage 2 Permission fault is generated.
3. If instruction execution is permitted by both the stage 1 permissions and the stage 2 permissions, then a Permission fault is not generated.

For more information, see [MMU fault prioritization from a single address translation stage on page D8-5190](#).

### Hierarchical control of instruction execution permissions

Stage 1 translation table entries at a given lookup level can limit instruction execution permissions at subsequent lookup levels.

For a stage 1 translation, the value of the XNTable Table descriptor field has one of the following effects:

- If the **effective value** of the XNTable field is 0, then the field has no effect.
- If the effective value of the XNTable field is 1, then all of the following apply:
  - The XNTable field is treated as 1 in all Table descriptors in subsequent lookup levels, regardless of the actual value of XNTable.
  - The XN field in Block descriptors and Page descriptors is treated as 1 in subsequent lookup levels, regardless of the actual value of XN.
  - The value and interpretation of the XNTable and XN fields in all subsequent lookup levels are otherwise unaffected.

For a stage 1 translation, the value of the UXNTable Table descriptor field has one of the following effects:

- If the **effective value** of the UXNTable field is 0, then the field has no effect.
If the Effective value of the UXNTable field is 1, then all of the following apply:

— The UXNTable field is treated as 1 in all Table descriptors in subsequent lookup levels, regardless of the actual value of UXNTable.
— The UXN field in Block descriptors and Page descriptors is treated as 1 in subsequent lookup levels, regardless of the actual value of UXN.
— The value and interpretation of the UXNTable and UXN fields in all subsequent lookup levels are otherwise unaffected.

For a stage 1 translation, the value of the PXNTable Table descriptor field has one of the following effects:

• If the Effective value of the PXNTable field is 0, then the field has no effect.
• If the Effective value of the PXNTable field is 1, then all of the following apply:
  — The PXNTable field is treated as 1 in all Table descriptors in subsequent lookup levels, regardless of the actual value of PXNTable.
  — The PXN field in Block descriptors and Page descriptors is treated as 1 in subsequent lookup levels, regardless of the actual value of PXN.
  — The value and interpretation of the PXNTable and PXN fields all subsequent lookup levels are otherwise unaffected.

The UXNTable, XNTable, and PXNTable Table descriptor fields control stage 1 translations. The corresponding bit positions are RES0 in the stage 2 Table descriptors.

For the translation regime controlled by a TCR_ELx, one or more of the following can be used to disable the Table descriptor XNTable, UXNTable, and PXNTable fields so they are ignored by the PE and the system behavior is as if the values are zero:

• If the Effective value of TCR_ELx.HPD{0} is 1, then hierarchical instruction execution permission control is disabled in the translation tables pointed to by TTBR0_ELx.
• If the Effective value of TCR_ELx.HPD1 is 1, then hierarchical instruction execution permission control is disabled in the translation tables pointed to by TTBR1_ELx.

The Table descriptor UXNTable, XNTable, and PXNTable fields affect all subsequent lookup levels, including stage 1 translation output. When a UXNTable, XNTable, or PXNTable field is changed, software is required to use a break-before-make sequence, including TLB maintenance for all lookup levels for the VA range translated by the descriptor.

Preventing execution from writable locations

There are register control fields that can be used to force writable memory to be treated as XN, PXN, or UXN, regardless of the value of the corresponding descriptor fields.

For a stage 1 translation in a translation regime that supports two Exception levels, the corresponding SCTLR_ELx.WXN field does all of the following:

• If the value is 0, then there is no effect on access permissions.
• If the value is 1, then all of the following apply:
  — If the memory region is writable from EL0, then it is treated as Unprivileged execute-never, regardless of the value of the Block descriptor or Page descriptor UXN field.
  — If the memory region is writable from the higher Exception level, ELx, then it is treated as Privileged execute-never, regardless of the value of the Block descriptor or Page descriptor PXN field.

For a stage 1 translation in a translation regime that applies to a single Exception level, the corresponding SCTLR_ELx.WXN field does all of the following:

• If the value is 0, then there is no effect on access permissions.
• If the value is 1 and if the memory region is writable, then it is treated as Execute-never, regardless of the value of the Block descriptor or Page descriptor XN field.
The SCTLR_ELx.WXN field reduces the memory footprint available for code injection attacks by introducing an invariant that writable memory regions are not executable.

For the lifetime of a given virtual machine, Arm expects the SCTLR_ELx.WXN field to remain static in normal operation.

SCTRL_ELx.WXN is permitted to be cached in a TLB.

**Restriction on Secure instruction fetch**

The SCR_EL3.SIF bit can be used to prevent instruction execution from Non-secure memory at stage 1 when the PE is executing in Secure state.

If all of the following apply, then an attempt to execute an instruction fetched from memory defined by the stage 1 translation as Non-secure generates a Permission fault:

- The Effective value of SCR_EL3.SIF is 1.
- Execution is in Secure state.

SCR_EL3.SIF does not prevent speculative instruction fetch. If Secure software wants to prevent speculative instruction fetch from a memory region, including Non-secure mappings of that region, then that software needs to define the region as Device, XN.

SCR_EL3.SIF is permitted to be cached in a TLB.

TLB entries might reflect the value of SCR_EL3.SIF, therefore any change to the value of that bit requires synchronization and TLB invalidation.

For an implementation that does not implement EL3, the Effective value of SCR_EL3.SIF is 0.

**D8.4.5 The Access flag**

The AF in a Block descriptor and Page descriptor indicates one of the following:

- If the value is 0, then the memory region has not been accessed since the value of AF was last set to 0.
- If the value is 1, then the memory region has been accessed since the value of AF was last set to 0.

Descriptors with AF set to zero can never be cached in a TLB.

For more information about when translation table entries are permitted to be cached in a TLB, see *Translation Lookaside Buffers on page D8-5193.*

**Software management of the Access flag**

If the AF is not managed by hardware, software management of the AF is required.

For an implementation that does not manage the AF in hardware, when an attempt is made to translate an address using a descriptor with an AF of 0, an Access flag fault is generated.

For an implementation that does not manage the AF in hardware, when an Access flag fault is generated, software is expected to set the AF to 1 in the descriptor that generated the fault.

Setting the AF to 1 prevents the Access flag fault from being generated the next time an attempt is made to translate an address using that descriptor.

When software sets the AF to 1, there is no requirement to perform TLB invalidation after setting the flag because entries with an AF set to 0 are never held in a TLB.

If a system incorporates components that can autonomously update translation table entries that are shared with the PE, then any changes by system software to translation table entries with an AF of 0 should avoid the possibility of simultaneous updates. This excludes changes to the AF value. For example, this can be done by using use a Load-Exclusive/Store-Exclusive loop or an atomic compare-and-swap operation.
Hardware management of the Access flag

All statements in this section require implementation of the optional feature, FEAT_HAFDBS.

When the PE performs a hardware update of the AF, it sets the AF to 1 in the corresponding descriptor in memory, in a coherent manner, using an atomic read-modify-write of that descriptor.

For a translation stage, if the value of the corresponding TCR_ELx.HA is 1, then AF hardware management is enabled.

For each translation stage, AF hardware management can be enabled independently.

If AF hardware management is enabled, then hardware updates the AF when a memory access is made using a Block descriptor or Page descriptor and all of the following apply:
- The access does not generate an Alignment fault based on the memory type, or a Permission fault.
- If AF hardware management was disabled or not implemented, the access would have generated an Access flag fault.

If AF hardware management is enabled, then it is constrained unpredictable whether hardware updates the AF when a memory access is made using a Block descriptor or Page descriptor and all of the following apply:
- The access generates an Alignment fault based on the memory type or a Permission fault.
- If AF hardware management were disabled or not implemented, the access would have generated an Access flag fault.

If hardware does not update the AF from 0 to 1, then the descriptor is not permitted to be cached in a TLB.

If AF hardware management is enabled in one or both translation stages, then when a memory access occurs, one or more of the following can be updated:
- The stage 1 AF.
- Each of the stage 2 AFS used to translate accesses to the stage 1 translation table walk and the OA.

For stage 1 translations, if AF hardware management is enabled, then when stage 2 translation does not permit access to the OA returned by the stage 1 translation, it is permitted, but not required, for the stage 1 AF to be updated.

For stage 2 translations, if AF hardware management is enabled, then when stage 1 translation does not permit access, it is permitted, but not required, for the stage 2 AF to be updated.

If AF hardware management is enabled and a speculative access is successfully translated, then it is permitted, but not required, for hardware to update the AF.

When a speculative access occurs, the rules determining the AF hardware update apply.

When the translation of an architecturally executed memory access occurs, the architecture requires that AF is set to 1.

When a translation occurs, the AF is permitted to be set to 1 even in the case where no architecturally executed memory access occurs. This could be due to a speculative memory access.

For an address translation stage, if AF hardware management is enabled, then when an address translation instruction is executed, all of the following apply:
- Hardware is permitted, but not required, to update the AF.
- If hardware attempts to update the AF and the update generates a fault, it is implementation defined whether this is reported as a Data Abort or not.
- If a Data Abort does not occur, then the instruction reports a result in the PAR as if the descriptors used to translate the address have an AF value of 1.

For more information, see Using break-before-make when updating translation table entries on page D8-5198.
D8.4.6 Hardware management of the dirty state

RQRTKG All statements in this section require implementation of the OPTIONAL feature, FEAT_HAFDBS, which supports both hardware update of the Access flag and hardware update of the dirty state.

IHJTWZ The dirty state is used to indicate a memory block or page has been modified. When hardware update of the dirty state is enabled, the descriptor DBM field indicates whether the descriptor is a candidate for hardware updates of the dirty state.

RPZFOC If the DBM field in a Block descriptor or Page descriptor is 0, then all of the following apply:

- For write accesses translated by the descriptor, the generation of Permission faults are unaffected by FEAT_HAFDBS.
- Hardware does not update the dirty state.

IFLYZP For a translation stage, if all of the following apply, then dirty state hardware management is enabled:

- The value of the corresponding TCR_ELx.HD is 1.
- The value of the corresponding TCR_ELx.HA is 1.

RLRMSH For the purpose of FEAT_HAFDBS, a Block descriptor or Page descriptor can be described as having one of the following states:

- Non-writeable.
- Writeable-clean.
- Writeable-dirty.

RXSTDV If all of the following apply, then a Block descriptor or Page descriptor is described as non-writeable:

- The AP or S2AP descriptor fields do not grant write access.
- One or more of the following apply:
  - The descriptor DBM field is 0.
  - For the appropriate translation stage, dirty state hardware update is disabled.

RXZFDQH For each translation stage, if all of the following apply, then a Block descriptor or Page descriptor is described as writeable-clean:

- Dirty state hardware update is enabled at that translation stage.
- The descriptor DBM field is 1.
- For a descriptor used by stage 1 translation, the AP[2] field is 1 and this is the only reason that a Permission fault would be generated due to a write access if dirty state hardware management were disabled.
- For a descriptor used by stage 2 translation, the S2AP[1] field is 0 and this is the only reason that a Permission fault would be generated due to a write access if dirty state hardware management were disabled.

RBFQG For each translation stage, if all of the following apply, then a Block descriptor or Page descriptor is described as writeable-dirty:

- Dirty state hardware update is enabled at that translation stage.
- The descriptor DBM field is 1.
- For a stage 1 translation, the AP[2] field is 0.
- For a stage 2 translation, the S2AP[1] field is 1.

IBFDYL Only if a descriptor is writeable-clean, then hardware can update the dirty state.

RPQJHR For a translation stage, when the dirty state is updated by hardware, the PE updates the corresponding descriptor in memory, in a coherent manner, using an atomic read-modify-write of that descriptor to change the descriptor from writeable-clean to writeable-dirty.

RPRJRK If the requirements to update both the Access flag and dirty state by hardware are met, the PE is permitted to update the Access flag to 1 as part of the same atomic read-modify-write of the descriptor that performs the dirty state update.
For a translation stage, Access flag faults are reported with higher priority than Permission faults. Therefore, it is not permitted for hardware to update the dirty state so that a descriptor is writeable-dirty but has the Access flag clear.

When the dirty state is updated by hardware, the PE is required to check that any copy of the descriptor cached in a TLB is not stale with regard to the descriptor in memory.

If the descriptor has changed, then the PE is required to use the new information from the descriptor in memory, regardless of whether the modified descriptor has a different OA, different attributes, or generates a fault.

For performance purposes, when the dirty state is updated by hardware, the PE should update or invalidate any TLB entry that contains a previously-cached copy of the descriptor. This is to prevent multiple writes by the PE from causing multiple updates to the descriptor.

Arm expects many PEs to cause a translation table walk to occur when dirty state hardware management causes an update of a translation table descriptor.

If a write access translated by a writeable-clean descriptor is performed architecturally, then hardware updates the dirty state of that descriptor.

Arm expects many PEs to cause a translation table walk to occur when dirty state hardware management causes an update of a translation table descriptor.

If a write access translated by a writeable-clean descriptor is not performed architecturally, then unless specified here hardware does not update the dirty state of that descriptor. In all of the following cases, hardware is permitted to update the dirty state while attempting to translate the explicit write access:

- The translation generates an MMU fault that is reported with lower priority than a Permission fault at that translation stage.
- The access is non-speculative and the translation generates an Alignment fault only because the memory type indicated by the descriptor is Device, and the hardware update would have occurred if the Alignment fault was not generated.
- The descriptor is for a stage 1 translation, the access is non-speculative, and the stage 2 translation of the OA from stage 1 generates a stage 2 MMU fault.
- The descriptor is used to translate accesses from the Statistical Profiling Buffer. For more information, see The Profiling Buffer on page D13-5458.

If both translation stages are enabled, and the conditions to update a stage 1 descriptor by hardware are met, then the stage 2 translation of the location holding that stage 1 descriptor results in one of the following:

- The stage 2 translation grants write permissions and the stage 1 hardware update occurs, including both of the following cases:
  - The stage 2 translation already grants write permission and does not need to be updated.
  - The stage 2 translation is writeable-clean and is successfully updated to writeable-dirty.
- The stage 2 translation generates a Permission fault due to lack of write access and the stage 1 hardware update does not occur. If the access that caused the stage 1 hardware update was non-speculative, then the stage 2 MMU fault is taken as a Data Abort or Instruction Abort exception.

If a speculative update of a stage 1 Access flag would otherwise be permitted, but the stage 2 translation of the stage 1 descriptor is read-only, then the speculative update of the stage 1 Access flag does not occur.

If all of the following apply, hardware can update the dirty state of a stage 2 descriptor even if the stage 1 descriptor is not updated, including the case where the stage 1 descriptor is not a Block descriptor or Page descriptor:

- Stage 1 hardware updates of the Access flag or dirty state are enabled.
- The stage 2 translation of a stage 1 translation table walk uses a writeable-clean descriptor.

The dirty state hardware update mechanism does not affect the fault reporting priority except in all of the following cases:

- If all of the following stage 2 MMU faults are generated due to a non-speculative access that causes a stage 1 hardware update, then either fault is permitted to be reported:
  - That stage 1 hardware update generates a stage 2 MMU fault.
  - The stage 2 translation of the stage 1 OA generates a stage 2 MMU fault.
• If a hardware update is permitted, that update is permitted to generate a synchronous External abort or an IMPLEMENTATION DEFINED abort caused by a memory type not supporting an atomic read-modify-write.

If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then all of the following apply:
• All accesses that do not fault are permitted to cause hardware updates of the dirty state.
• For faulting accesses that meet the requirements for hardware updates of the dirty state, those accesses are also permitted to cause hardware updates of the dirty state.

For more information, see:
• MMU fault prioritization from a single address translation stage on page D8-5190.
• Faults and watchpoints on page D13-5464

Implications of enabling the dirty state management mechanism

All statements in this section require implementation of the OPTIONAL feature, FEAT_HAFDBS, which supports both hardware update of the Access flag and hardware update of the dirty state.

For stage 1 translations, translations using a descriptor in the writeable-clean state are considered writeable for the purposes of the corresponding SCTLR_ELx.WXN control.

For stage 1 translations, if the corresponding SCTLR_ELx.WXN is 1, then all of the following apply:
• For a translation regime that supports a single privilege level, translations using a writeable-clean descriptor are treated as execute-never.
• For a translation regime that supports two privilege levels, translations using a privileged writable-clean descriptor are treated as privileged execute-never.
• For a translation regime that supports two privilege levels, translations using a writeable-clean descriptor are treated as unprivileged execute-never.

For a translation regime that supports two privilege levels, translations using an unprivileged writable-clean descriptor are treated as privileged execute-never.

Cache invalidation instructions and address translation instructions never cause a dirty state hardware update of either:
• The stage 1 Block descriptor or Page descriptor translating the address specified in the instruction.
• The stage 2 Block descriptor or Page descriptor translating the OA from the stage 1 translation.

For the following instructions that require write permission, if the address specified in the instruction is translated by a writeable-clean descriptor, then the descriptor is considered to grant write access:
• Data cache invalidation instruction, DC IVAC.
• Address translation instructions, AT S12E0W, AT S12E1W, AT S1E0W, AT S1E1W, AT S1E2W, AT S1E3W.

For all of the following cases, if the stage 1 descriptor is writeable-clean, then it is IMPLEMENTATION DEFINED whether hardware updates the dirty state:
• A Store-Exclusive instruction to the memory location fails because the Exclusives monitor is not in the exclusive state.
• A synchronous External abort occurs on a write to the memory location.
• A Watchpoint exception occurs on a write to the memory location.

For all of the following cases, if the stage 2 descriptor is writeable-clean, then it is IMPLEMENTATION DEFINED whether hardware updates the dirty state:
• A Store-Exclusive instruction to the memory location fails because the Exclusives monitor is not in the exclusive state.
• A synchronous External abort occurs on a write to the memory location.
• A Watchpoint exception occurs on a write to the memory location.

A hardware update of the dirty state performed by one PE does not require invalidation of any corresponding TLB entries in other PEs.

For a CAS or CASP instruction to an address translated by a writeable-clean descriptor, if the comparison fails and the location is therefore not updated, then it is constrained unpredictable whether hardware updates the dirty state.

For a stage 2 writeable-clean descriptor with the S2AP[1:0] bits set to 0b00, if an atomic instruction to the address translated by the descriptor generates a stage 2 Permission fault as a result of not having read permission, then it is constrained unpredictable whether hardware updates the dirty state.

D8.4.7 Hardware updates to the translation tables

Hardware updates to the translation tables are subject to memory ordering requirements and restrictions on the memory types.

Ordering of hardware updates to the translation tables

A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the Shareability attributes:

• Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.

• Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load.

• Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.

• Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction that caused the update to the translation table entry and the subsequent cache maintenance instruction.

An update to the translation table that is caused by a load is not ordered with respect to the load itself.

An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the Shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

Restriction on memory types for hardware updates to translation tables

A translation table can be placed in Normal memory with any Cacheability.

If hardware update of translation table entries is enabled, software is required to ensure that the translation table is located in memory that supports atomic read-modify-write updates in a coherent manner.

Atomicity properties can only be met at the system level, and some system implementations might not support this functionality in all memory regions, including all of the following:

• Any system memory type that does not support hardware cache coherency.
The AArch64 Virtual Memory System Architecture

D8.4 Memory access control

The system implementation determines which memory type is treated as Non-cacheable.

The following Conventional memory types architecturally guarantee that hardware updates of the translation tables are atomic:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with read allocation hints and write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with read allocation hints and write allocation hints and not transient.

If a translation table hardware update is not atomic as observed by other agents that can access memory, then the update can have one or more of the following effects:

- A synchronous External abort on the translation table walk is generated.
- The instruction generates an SError interrupt.
- An MMU fault is generated, reported as an Unsupported atomic hardware update using one of the following Fault status codes:
  - For Data Abort exceptions, ESR_ELx.DFSC = 0b110001.
  - For Instruction Abort exceptions, ESR_ELx.IFSC = 0b110001.
  - For an abort on a write to the Statistical Profiling buffer, PMBSR_EL1.FSC = 0b110001.
- The hardware updates occur and all of the following apply:
  - There is no guarantee that the memory accesses are done atomically in regard to accesses to memory by other agents.
  - The instruction might also generate an SError interrupt.

If a translation table hardware update is not atomic as observed by other agents that can access memory, and the update generates an MMU fault, all of the following apply:

- If EL2 is implemented and enabled in the current Security state, then for the EL1&0 translation regime, one of the following:
  - If the atomic hardware update is not supported in the stage 1 translation due to the defined memory type, or if the stage 2 translation is not enabled, then this exception is a stage 1 abort and is taken to EL1.
  - In all other cases, the exception is a stage 2 abort and is taken to EL2.
- For a translation stage, the MMU fault priority is at an IMPLEMENTATION DEFINED point between all of the following:
  - Immediately before the priority of an Access flag fault that is generated at the same translation stage.
  - Immediately after the priority of a Permission fault that is generated at the same translation stage.

If translation table hardware updates are not atomic as observed by other agents that can access memory, then in all of the following cases, the architecture permits, but does not require, an address translation instruction to generate an MMU fault, reported as an Unsupported atomic hardware update using PAR_EL1.FST = 0b110001:

- For a stage 1 translation at EL1, stage 1 translation table hardware updates are enabled.
- For EL2 or EL3, translation table hardware updates are enabled.

For more information, see Possible implementation restrictions on using atomic instructions on page B2-157.

Use of the Contiguous bit with hardware updates to the translation tables

When hardware updates any of the AF, AP[2] or S2AP[1] bits, then the update applies to a single translation table entry.

If hardware updates a translation table entry, and if the Contiguous bit in that entry is 1, then the members in a group of contiguous translation table entries can have different AF, AP[2], and S2AP[1] values.

For more information, see Possible implementation restrictions on using atomic instructions on page B2-157.
If all of the following apply, then the architecture does not require a hardware update of the AF:

- An access is to a location translated by an entry that has the Contiguous bit set to 1.
- At least one descriptor in the set of contiguous translation table entries has AF set to 1.

If all of the following apply, then the architecture does not require a hardware update of the AP[2] or S2AP[1] bit:

- A write is done to a location translated by a descriptor that has the Contiguous bit set to 1.
- The corresponding AP[2] or S2AP[1] bit in at least one descriptor in the set of contiguous translation table entries indicates that the entry is dirty.

The Contiguous bit permits, but does not require, hardware to hold a single entry in a TLB for the set of translation table entries in the group, and to have updated only one or more of the AF and the AP[2] bit or S2AP[1] bit in the single translation table entry that resulted in the TLB entry.

Software is required to combine the AF values and AP[2] or S2AP[1] values across all translation table entries in a contiguous group to determine whether any of the entries have been accessed or are dirty.

For more information on the Contiguous bit, see *The Contiguous bit* on page D8-5158.
D8.5 Memory region attributes

The memory region attributes in a descriptor define the memory type, Cacheability, and whether the memory region is Shareable. For translation regimes that support two translation stages, the stage 1 and stage 2 memory region attributes are combined to produce a resultant memory type and Cacheability, and Shareability.

All of the following apply to the memory region attributes:

- The stage 1 OA attributes are derived from a combination of the Block descriptor and Page descriptor AttrIndx[2:0] field, and the MAIR_ELx register fields.
- The stage 1 translation table walk attributes are derived from the TCR_ELx.{IRGN_n, ORGN_n, SHn} fields.
- The SCTLR_ELx.{C, I} fields might override stage 1 attributes.
- The HCR_EL2.PTW field might override stage 2 translation attributes of a stage 1 translation table walk.
- If EL2 is enabled, then for the EL1&0 translation regime the HCR_EL2.{CD, DC} fields might override stage 1 and stage 2 attributes.
- All of the following HCR_EL2.FWB values affect the stage 2 attributes:
  - When the Effective value of HCR_EL2.FWB is 0, stage 2 attributes are derived from the stage 2 MemAttr[3:2] descriptor bits, then combined with stage 1 attributes.
  - When the Effective value of HCR_EL2.FWB is 1, stage 2 attributes are derived from the stage 2 MemAttr[2:0] descriptor bits.
- For Device memory and Normal Non-cacheable mappings from stage 1, normalization of the Shareability that is input to stage 2 is IMPLEMENTATION DEFINED.
- For Device memory and Normal Non-cacheable mappings from stage 2, Shareability is always normalized to Outer Shareable.

For a virtualization implementation, combining memory attributes from stage 1 and stage 2 translations support all of the following functions that are useful to a hypervisor executing at EL2:

- Reduce or increase the permitted Cacheability of a region.
- Increase the required Shareability of a region.

The effects of combining memory attributes defined by the hypervisor are expected to be functionally transparent to the Guest OS.

If all of the following apply, memory locations are treated as Tagged:

- The combined effects of stage 1 and stage 2 translations define the memory attributes as all of the following:
  - Normal memory.
  - Inner, and Outer Write-Back Non-Transient Read-Allocate Write-Allocate.
- The stage 1 translation is treated as Tagged.

For more information, see Tagged and Untagged Addresses on page D9-5224.

D8.5.1 Stage 1 memory type and Cacheability attributes

For a stage 1 translation, the Block descriptor and Page descriptor AttrIndx[2:0] field holds the value $n$ used to select the 8-bit field MAIR_ELx.Attr$<n>$ that specifies the memory region attributes of the descriptor OA.

For the memory region specified by a Block descriptor and Page descriptor, the MAIR_ELx.Attr$<n>$ field selected by the descriptor AttrIndx[2:0] field defines all of the following:

- The Device or Normal memory type.
- For Device memory, all of the following:
  - One of the Device-nGnRnE, Device-nGnRE, Device-nGRE, or Device-GRE Device memory types.
  - If FEAT_XS is implemented, then the XS attribute.
For Normal memory, all of the following:

- For both inner and outer Cacheability, one of the Non-cacheable, Write-Through, or Write-Back attributes.
- For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate hints, each of which is Allocate or No Allocate, and the Transient allocation hints.
- If FEAT_MTE2 is implemented, then the Tagged attribute.
- If FEAT_XS is implemented, then the XS attribute.

For more information, see XS attribute modifier on page D8-5160 and Tagged and Untagged Addresses on page D9-5224.

For some translation regimes, the memory region attributes determined from translation tables and MAIR_ELx values might be overridden by the configuration of SCTLR_ELx.[C, I] and HCR_EL2.DC.

### D8.5.2 Stage 1 Shareability attributes

For Normal Cacheable memory, if the Effective value of TCR_ELx.DS is 0, then the SH[1:0] field in a stage 1 translation Block descriptor and Page descriptor encodes the Shareability attributes of the descriptor OA, as shown in the following table:

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINT UNPREDICTABLE as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-11583.</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

If a region is mapped as Device memory or Normal Non-cacheable memory after all enabled translation stages, then the region has an effective Shareability attribute of Outer Shareable.

If stage 2 translation is enabled and stage 1 maps a region as Device memory or Normal Non-cacheable memory, then it is IMPLEMENTATION DEFINED whether:

- The Shareability attribute configured for stage 1 is input into stage 2 translation.
- An effective Outer Shareable attribute is input into stage 2 translation.

If the Effective value of TCR_ELx.DS is 1, then the stage 1 translation descriptor bits[9:8] are OA[51:50] instead of SH[1:0].

For Normal Cacheable memory, if the Effective value of TCR_ELx.DS is 1, then the stage 1 translation Shareability is treated as being mapped by one of the following:

- For the EL3 translation regime, TCR_EL3.SH0.
- For the EL2 translation regime, if HCR_EL2.E2H is 0, then TCR_EL2.SH0.
- For the EL2 and EL2&0 translation regimes, if HCR_EL2.E2H is 1 and the VA is an address that is translated using tables pointed to by TTBR0_EL2, then TCR_EL2.SH0.
- For the EL2 and EL2&0 translation regimes, if HCR_EL2.E2H is 1 and the VA is an address that is translated using tables pointed to by TTBR1_EL2, then TCR_EL2.SH1.
- For the EL1&0 translation regime, if the VA is an address that is translated using tables pointed to by TTBR0_EL1, then TCR_EL1.SH0.
- For the EL1&0 translation regime, if the VA is an address that is translated using tables pointed to by TTBR1_EL1, then TCR_EL1.SH1.
D8.5.3 Stage 2 memory type and Cacheability attributes

For any stage 2 translation, if the final memory type any is Normal Cacheable type, then all of the following apply:

- If the output of stage 1 specifies a Cacheable memory type, then the final cache allocation hints are the stage 1 cache allocation hints.
- If the output of stage 1 does not specify a Cacheable memory type, then the final cache allocation hints are Read Allocate, Write Allocate.

Stage 2 translation configuration does not assign cache allocation hints.

If the memory type from a stage 2 translation causes a stage 1 translation table walk to a Device memory type, then one of the following occurs:

- If HCR_EL2.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory, and the walk can be done speculatively.
- If HCR_EL2.PTW is 1, then the memory access generates a stage 2 Permission fault.

D8.5.4 Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is disabled

All statements in this section and subsections require that the Effective value of HCR_EL2.FWB is 0.

If the Effective value of HCR_EL2.FWB is 0, then the stage 1 and stage 2 memory type and Cacheability attributes are combined.

For stage 2 translations, the MemAttr[3:0] field in a Block descriptor and Page descriptor encodes the memory type and Cacheability of the memory region addressed by the descriptor OA.

For stage 2 translations, the MemAttr[3:2] descriptor bits encode the memory type and, for Normal memory, the Outer Cacheability, of the descriptor OA as shown in the following table:

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Outer Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Normal</td>
<td>Outer Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Normal</td>
<td>Outer Write-Back Cacheable</td>
</tr>
</tbody>
</table>

For stage 2 translations, if the MemAttr[3:2] descriptor bits are 0b00, indicating Device memory, then the MemAttr[1:0] descriptor bits encode the Device memory type as shown in the following table:

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Encoding if MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>
For stage 2 translations, if the MemAttr[3:2] descriptor bits are not 0b00, indicating Normal memory, then the MemAttr[1:0] descriptor bits encode the Normal memory Inner Cacheability as shown in the following table:

<table>
<thead>
<tr>
<th>MemAttr[1:0] Encoding if MemAttr[3:2] != 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
</tr>
<tr>
<td>01</td>
</tr>
<tr>
<td>10</td>
</tr>
<tr>
<td>11</td>
</tr>
</tbody>
</table>

For more information, see:

- *Combining stage 1 and stage 2 memory type attributes*.

**Combining stage 1 and stage 2 memory type attributes**

If the Effective value of HCR_EL2.FWB is 0, then the stage 1 and stage 2 memory type attributes are combined as shown in the following table:

<table>
<thead>
<tr>
<th>Rule</th>
<th>If either translation stage assigns:</th>
<th>Resultant memory type is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device has precedence over Normal</td>
<td>Any Device memory type</td>
<td>Any Device memory type</td>
</tr>
<tr>
<td>non-Gathering has precedence over Gathering</td>
<td>A Device-nGxx memory type</td>
<td>A Device-nGxx memory type</td>
</tr>
<tr>
<td>non-Reordering has precedence over Reordering</td>
<td>A Device-nGnRx memory type</td>
<td>A Device-nGnRx memory type</td>
</tr>
<tr>
<td>No Early write acknowledge has precedence over Early write acknowledge</td>
<td>The Device-nGnRnE memory type</td>
<td>The Device-nGnRnE memory type</td>
</tr>
</tbody>
</table>

**Combining stage 1 and stage 2 Cacheability attributes for Normal memory**

If the Effective value of HCR_EL2.FWB is 0, then the stage 1 and stage 2 Inner Cacheability and Outer Cacheability attributes are combined as shown in the following table:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>
<td>Non-cacheable</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Write-Through Cacheable</td>
<td>Write-Through Cacheable</td>
<td>Write-Through Cacheable</td>
</tr>
</tbody>
</table>
For stage 2 translations, if the Effective value of HCR_EL2.FWB is 0 and the stage 2 MemAttr[3:0] field is 0b1111, then the combined memory type and Cacheability attributes are the output memory type and Cacheability attributes from stage 1.

### D8.5.5 Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled

All statements in this section and subsections require that the Effective value of HCR_EL2.FWB is 1.

For stage 2 translations, FEAT_S2FWB has all of the following effects on the MemAttr[3:2] bits:

- MemAttr[3] is RES0.

For stage 2 translations, if MemAttr[2] is 0, then the MemAttr[1:0] bits define Device memory attributes as shown in the following table:

<table>
<thead>
<tr>
<th>Stage 2 MemAttr[1:0]</th>
<th>Device Memory Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td>01</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td>10</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td>11</td>
<td>Device-GRE</td>
</tr>
</tbody>
</table>

For stage 2 translations, if MemAttr[2] is 1, then the MemAttr[1:0] bits affect the memory type and Cacheability as shown in the following table:

<table>
<thead>
<tr>
<th>Stage 1 memory type and Cacheability attribute</th>
<th>Stage 2 MemAttr[1:0]</th>
<th>Resultant memory type and Cacheability attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal Write-Back</td>
<td>11</td>
<td>Normal Write-Back</td>
</tr>
<tr>
<td>Normal Write-Through</td>
<td>11</td>
<td>Normal Write-Through</td>
</tr>
<tr>
<td>Normal Non-cacheable</td>
<td>11</td>
<td>Normal Non-cacheable</td>
</tr>
<tr>
<td>Device</td>
<td>11</td>
<td>Device</td>
</tr>
<tr>
<td>Normal Write-Back</td>
<td>10</td>
<td>Normal Write-Back</td>
</tr>
<tr>
<td>Normal Write-Through</td>
<td>10</td>
<td>Normal Write-Back</td>
</tr>
<tr>
<td>Normal Non-cacheable</td>
<td>10</td>
<td>Normal Write-Back</td>
</tr>
<tr>
<td>Device</td>
<td>10</td>
<td>Normal Write-Back</td>
</tr>
<tr>
<td>Normal Write-Back</td>
<td>01</td>
<td>Normal Non-cacheable</td>
</tr>
</tbody>
</table>
RRMTWN  If the stage 1 translation specifies a Device memory type, and the stage 2 descriptor MemAttr[2:0] field is \(0b110\), then all of the following apply:

- If an atomic memory access occurs, then it is IMPLEMENTATION DEFINED whether it is supported in the same way as accesses to memory locations with a resultant Device memory type.
- If an exclusive access occurs, then it is IMPLEMENTATION DEFINED whether it is supported in the same way as accesses to memory locations with a resultant Device memory type.
- If a misaligned access occurs, then it is CONSTRAINED UNPREDICTABLE whether the resultant stage 1 memory type generates a stage 1 Alignment fault.
- For a DC ZVA, DC GZVA, or DC GVA instruction, it is CONSTRAINED UNPREDICTABLE whether the resultant stage 1 memory type generates a stage 1 Alignment fault.

RRDBK  The architecture requires that CLIDR_EL1.{LoUU, LoIUS} are \(\{0, 0\}\) so that no data cache levels need to be cleaned to manage coherency with instruction fetches.

RDPDXS  If the stage 1 translation specifies a Normal memory type with Cacheability other than Write-Back Cacheable, and the stage 2 descriptor MemAttr[2:0] field is \(0b110\), then it is IMPLEMENTATION DEFINED whether atomic memory accesses or exclusives are supported, in the same way as accesses to a Normal memory type with Cacheability other than Write-Back Cacheable.

LRWWR  For more information, see:
- XS attribute modifier on page D8-5160.
- Reserved values in System and memory-mapped registers and translation table entries on page K1-11600.

### D8.5.6  Stage 2 Shareability attributes

ICBHV  The stage 2 Shareability attributes are not affected by the Effective value of HCR_EL2.FWB.

DNZIQ  For Normal Cacheable memory, if the Effective value of VTCR_EL2.DS is 0, then the SH[1:0] field in a stage 2 translation Block descriptor and Page descriptor encodes the Shareability attributes of the descriptor OA, as shown in the following table:

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

HTSGQ  For Normal Cacheable memory, if the Effective value of VTCR_EL2.DS is 1, then the stage 2 translation Shareability is determined by VTCR_EL2.SH0.
For Device memory and Normal Non-cacheable memory, the Shareability attributes of the stage 2 translation descriptor OA are treated as Outer Shareable.

If the Effective value of VTCR_EL2.DS is 1, then the stage 2 translation descriptor bits[9:8] are OA[51:50] instead of SH[1:0].

For more information, see Reserved values in System and memory-mapped registers and translation table entries on page K1-11600.

Combining the stage 1 and stage 2 Shareability attributes for Normal memory

The value of HCR_EL2.FWB does not affect how Shareability attributes from stage 1 and stage 2 are combined.

If the resultant memory type from a stage 1 and stage 2 translation is one of the following, the memory region is treated as Outer Shareable:

- Any Device memory type.
- Normal Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type of Normal that is not Inner Non-cacheable, Outer Non-cacheable, the stage 1 and stage 2 Shareability attributes can be combined as shown in the following table:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer Shareable</td>
<td>Any</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Non-shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>
D8.6 Other descriptor fields

D8.6.1 The Contiguous bit

The Contiguous bit identifies a descriptor as belonging to a group of adjacent translation table entries that point to a contiguous OA range.

If the Effective value of the Contiguous bit in a Block descriptor or Page descriptor is 1, and the descriptor would otherwise be permitted to be cached in a TLB, then all of the following apply:

- The entry is permitted to be cached in a TLB as though it is one of a number of adjacent translation table entries that point to a contiguous OA range with consistent attributes and permissions.
- Software is required to ensure that all of the adjacent translation table entries for the contiguous region point to a contiguous OA range with consistent attributes and permissions.

The Contiguous bit is \texttt{RES0} and has an Effective value of 0 in all of the following Block descriptors:

- For the 4KB translation granule, if the Effective value of TCR\_ELx.DS or VTCR\_EL2.DS is 1, then the Contiguous bit is \texttt{RES0} in the level 0 Block descriptor of that translation regime.
- For the 16KB translation granule, if the Effective value of TCR\_ELx.DS or VTCR\_EL2.DS is 1, then the Contiguous bit is \texttt{RES0} in the level 1 Block descriptor of that translation regime.
- For the 64KB translation granules, if FEAT\_LPA is implemented, then the Contiguous bit is \texttt{RES0} in a level 1 Block descriptor.

For a lookup level in a translation granule, if the Effective value of the Contiguous bit is 1, then the entry is permitted to be cached in a TLB as though all of the properties shown in the following table apply:

<table>
<thead>
<tr>
<th>Translation granule</th>
<th>Block or Page lookup level</th>
<th>Number of adjacent translation table entries</th>
<th>Alignment boundary of adjacent translation table entries within the translation table</th>
<th>Alignment of contiguous OA range</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>Any</td>
<td>16</td>
<td>128 bytes</td>
<td>Multiple of 16 of the block or page size at that lookup level</td>
</tr>
<tr>
<td>16KB</td>
<td>2</td>
<td>32</td>
<td>256 bytes</td>
<td>1GB</td>
</tr>
<tr>
<td>16KB</td>
<td>3</td>
<td>128</td>
<td>1KB</td>
<td>2MB</td>
</tr>
<tr>
<td>64KB</td>
<td>Any</td>
<td>32</td>
<td>256 bytes</td>
<td>Multiple of 32 of the block or page size at that lookup level</td>
</tr>
</tbody>
</table>

The architecture does not require descriptors with the Contiguous bit set to 1 to be cached as a single TLB entry for the contiguous region. To avoid TLB coherency issues, software is required to perform TLB maintenance on the entire address region that results from using the Contiguous bit.

If the Effective value of the Contiguous bit is 1, then hardware updates to the AF and dirty state can cause members in a group of contiguous translation table entries to have different AF, AP[2], and S2AP[1] values.

For more information, see *Use of the Contiguous bit with hardware updates to the translation tables* on page D8-5149.

**Misprogramming the Contiguous bit**

For all descriptors within the range indicated by one or more descriptors that have the Contiguous bit set to 1, if one or more of the following translation table programming errors is made, then a TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
• One or more of the contiguous translation table entries holds an OA that is not consistent with all of the
entries pointing to the same aligned contiguous address range.
• The attributes and permissions of the contiguous entries are not the same.

For a TLB lookup in a contiguous region mapped by translation table entries that are misprogrammed, that TLB
lookup is permitted to produce one of the following:
• An OA, access permissions, and memory attributes that are consistent with any of the programmed
translation table values.
• If BBM support levels 1 and 2 are not implemented, then an OA, access permissions, or memory attributes
that are inconsistent with any of the programmed translation table values. For more information, see Support
levels for changing block size on page D8-5199.
• A TLB conflict abort.

Architectural guarantees when the Contiguous bit is misprogrammed

If the Contiguous bit is misprogrammed, then the architecture guarantees all of the following:
• If physical memory regions are inaccessible through translation tables programmed at EL1 when the
Contiguous bit is not misprogrammed, then they remain inaccessible to software executing at EL1 or EL0.
• If memory attributes and permissions are unattainable through translation tables programmed at EL1 when
the Contiguous bit is not misprogrammed, then they remain unattainable to software executing at EL1 or
EL0.
• Software executing in Non-secure state cannot access Secure physical memory.

The PE is required to generate an Address Size fault on accesses to addresses above the configured OA size, even
in the case where the Contiguous bit is used to mark a set of Block descriptors as contiguous, such that the OA region
translated by that contiguous set of descriptors exceeds the configured OA size.

An implementation is permitted to ignore the Contiguous bit to ensure that OA range checking is done.

Implementation options when the Contiguous bit is misprogrammed

If software does all of the following, it is considered a programming error:
• The Contiguous bit is used to mark a set of translation table entries as contiguous.
• The address range translated by the set of translation table entries is larger than the IA size configured for the
translation stage as determined by the TCR_ELx.TxSZ field.

If the Contiguous bit is used to mark a set of translation table entries as contiguous and if the address range translated
by the translation table entries is larger than the IA size supported by the translation stage, as defined by the
TCR_ELx.TxSZ field, then an implementation is permitted, but not required to, do one or more of the following:
• Generate a Translation fault.
• When all of the following apply, an implementation is permitted to not generate a Translation fault:
  — A translation table entry within a contiguous set of translation table entries is accessed.
  — The translation table entry is valid.

D8.6.2 Page Based Hardware attributes

The PBHA bits can be used for IMPLEMENTATION DEFINED purposes.

All statements in this section require implementation of FEAT_HPDS2.

For a stage 1 translation that uses TTBR0_ELx, if all of the following apply, then hardware can use the PBHA bit
in the corresponding Block descriptor or Page descriptor bit[nn] for IMPLEMENTATION DEFINED purposes:
• The corresponding TCR_ELx.HWU0nn bit, HWU62, HWU61, HWU60, or HWU59, is 1.
• TCR_ELx.HPD0 is 1.
For a stage 1 translation that uses TTBR1_ELx, if all of the following apply, then hardware can use the PBHA bit in the corresponding Block descriptor or Page descriptor bit[nn] for IMPLEMENTATION DEFINED purposes:

- The corresponding TCR_ELx.HWU{nn} bit, HWU162, HWU161, HWU160, or HWU159, is 1.
- TCR_ELx.HPD1 is 1.

For a stage 2 translation, if the value of VTCR_EL2.HWU{nn} is 1, then hardware can use the PBHA bit in the corresponding Block descriptor or Page descriptor bit[nn] for IMPLEMENTATION DEFINED purposes.

If the PBHA bit is used for IMPLEMENTATION DEFINED purposes, then setting the PBHA bit to 0 has the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.

If the Effective value of TCR_ELx.HWU{0, 1}nn is 0, then the PBHA bit in the corresponding Block descriptor or Page descriptor bit[nn] is IGNORED.

### D8.6.3 Block translation entry

Setting the nT bit in a Block descriptor guarantees that, when changing block size, accesses translated by the translation table entry do not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors.

All statements in this section require implementation of FEAT_BBM.

If the implementation meets either level 1 or level 2 support requirements for changing block size, then when using a Block descriptor with the nT bit set, the PE is permitted to do one of the following:

- Generate a Translation fault and not cache the entry in a TLB.
- If an entry that does not have the nT bit set is cached within a TLB and translates the same address to the same output address with consistent memory attributes and permissions, then the PE guarantees that accesses translated by the translation table entry with the nT bit set does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors.

For more information, see Support levels for changing block size on page D8-5199.

If the nT bit in a Block descriptor is set, then the translation performance can be significantly impacted.

### D8.6.4 XS attribute modifier

The XS attribute indicates that an access to the memory region could take a long time to complete. Variants of DSB instructions and TLB maintenance instructions that do not depend on the completion of memory accesses with the XS attribute set to 1 are defined.

All statements in this section require implementation of FEAT_XS.

For a stage 2 translation, the FnXS bit in a Block descriptor and Page descriptor has all of the following properties:

- If the FnXS bit is 0, then the XS attribute of the resultant memory translation is not modified.
- If the FnXS bit is 1, then the XS attribute of the resultant memory translation is set to 0.

For stage 2 translations, if the resultant memory attributes are Normal Inner Write-back, Outer Write-back Cacheable, then the XS attribute is set to 0 on the resultant memory translation.

If FEAT_XS is implemented and the stage 1 memory type defined by the MAIR_ELx or TCR_ELx registers is one of the following, then the XS attribute is set to 0, otherwise the XS attribute is set to 1:

- Device memory types that use the MAIR_ELx.Attr<n> encoding `0b0000dd01`.
- For Normal memory, one of the following:
  - Inner Write-Back Cacheable, Outer Write-back Cacheable memory types defined in the MAIR_ELx or TCR_ELx registers, including any memory types that are treated as Write-Back Cacheable as a result of IMPLEMENTATION DEFINED choices in the architecture.
  - Inner Write-through Cacheable and Outer Write-through Cacheable memory types that use the MAIR_ELx.Attr<n> encoding `0b10100000`. 

For more information, see Support levels for changing block size on page D8-5199.
Inner Non-cacheable, Outer Non-cacheable memory types that use the MAIR_ELx.Attr<\text{n}> encoding 0b01000000.

The stage 2 impact of the FnXS bit applies for stage 1 translations in the EL1&0 translation regime from AArch32 or AArch64.

For more information, see:

- *Enabling and disabling the caching of memory accesses* on page D7-5047.
- *Stage 1 memory type and Cacheability attributes* on page D8-5151.
- *Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled* on page D8-5155.

### D8.6.5 IGNORED fields

For stage 1 and stage 2 Table descriptors, bits[58:51] and bits[11:2] are IGNORED, and the architecture guarantees that a PE does not use the bits. See Figure D8-16 on page D8-5127 and Figure D8-17 on page D8-5128.

For stage 1 and stage 2 Block descriptors and Page descriptors, all of the following bits are IGNORED, and the architecture guarantees that a PE does not use the bits:

- If FEAT_HPDS2 is not implemented, then descriptor bits[63:55].
- If FEAT_HPDS2 is implemented, then descriptor bit[63] and bits[58:55].

If FEAT_HPDS2 is not implemented, then in the stage 2 Block descriptor and Page descriptor, bits[63:59] are reserved for a System MMU.

If FEAT_HPDS2 is implemented, then in the stage 2 Block descriptor and Page descriptor, bit[63] is reserved for a System MMU.

In the stage 1 and stage 2 Block descriptor and Page descriptor, bits[58:55] have all of the following properties:

- The field is for software use.
- The architecture guarantees that hardware does not use the field.
- If the bits in the field are changed, there is no need to invalidate a TLB.
D8.7 Address tagging

When address tagging is enabled, the top eight bits of the VA are ignored for the purposes of address translation and they are instead described as an address tag. An address tag might be used for software purposes, an MTE Logical Address Tag, or both.

If address tagging is enabled in a translation regime, then the top eight bits of the VA, bits[63:56], have all of the following properties:

- Bits[63:56] are the address tag.
- The bits are ignored during address translation.
- If the translation system is enabled, then the bits are ignored when determining whether the address is out of range and therefore generates a Translation fault.
- If the translation system is not enabled, then the bits are ignored when determining whether the address is out of range and therefore generates an Address size fault.

D8.7.1 Address tag control

Address tagging is controlled using the Top Byte Ignore (TBI) field in the TCR_ELx register.

For a stage 1 translation that supports a single VA range, TCR_ELx.TBI{0} determines whether address tagging is enabled.

For a stage 1 translation that supports two VA ranges, all of the following determine whether address tagging is enabled:

- TCR_ELx.TBI0 determines whether the lower address range uses address tags.
- TCR_ELx.TBI1 determines whether the upper address range uses address tags.

The TCR_ELx.TBI{\(n\)} bit controls address tagging whether or not the corresponding stage 1 translation is enabled.

If FEAT_PAuth is implemented and a TCR_ELx.TBI{\(n\)} bit enables address tagging, then the corresponding TCR_ELx.TBID{\(n\)} bit determines whether address tagging applies to both instruction addresses and data addresses, or just data addresses. For more information, see Pointer authentication on page D8-5164.

D8.7.2 Effect of address tagging on the PC

This section describes how the top byte of an address is considered when address tagging is enabled and an address is propagated to the PC for a branch, procedure return, exception, or exception return occurs.

For a stage 1 translation that supports a single VA range, if address tagging for instruction accesses is enabled in an Exception level, ELx, then bits[63:56] of the address loaded into the PC are forced to 0x00 in all of the following cases:

- A branch or procedure return within ELx.
- An exception is taken to ELx.
- When an exception return does not generate an Illegal exception return, any exception return to ELx.
- Exiting from Debug state to ELx.

For a stage 1 translation that supports two VA ranges, if address tagging for instruction accesses is enabled in an Exception level, ELx, then bits[63:56] of the address loaded into the PC are a sign-extension of address bit[55] in all of the following cases:

- A branch or procedure return within ELx.
- An exception is taken to ELx.
- When an exception return does not generate an Illegal exception return, any exception return to ELx.
- Exiting from Debug state to ELx.

If the value of the SPSR_ELx.M[4] bit of the saved process state is 1 when an Illegal exception return occurs, indicating a return to AArch32 state, then PC bits[63:32] are UNKNOWN.
When address tagging is enabled and an address causes a Data Abort or a *Watchpoint exception*, the address tag is included in the VA returned in the FAR.
D8.8 Pointer authentication

AArch64 state supports authenticating the contents of a register before that register is used as the target of an indirect branch, or as a load.

All statements in this section and subsections require implementation of FEAT_PAuth.

Pointer authentication is supported only in AArch64 state.

The pointer authentication mechanism treats the upper bits of a pointer stored in a register in one of the following ways:

- If FEAT_PAuth2 is not implemented, then the pointer authentication mechanism replaces the upper bits of a pointer stored in a register with a pointer authentication code (PAC).
- If FEAT_PAuth2 is implemented, then the pointer authentication mechanism exclusive-ORs the upper bits of a pointer stored in a register with a PAC.
- If FEAT_EPAC is implemented, then when performing a PAC operation on a non-canonical address, the pointer authentication mechanism sets the PAC field to 0.

If FEAT_CONSTPACFIELD is implemented, then an implementation is permitted to use the value in Xn[55] to determine the size of the PAC field, even when address tagging is not used.

If the value of one or more of the ID_AA64ISAR1_EL1.{GPI, GPA, API, APA} or ID_AA64ISAR2_EL1.{GPA3, APA3} fields is non-zero, then pointer authentication is implemented.

Pointer authentication functionality is the same whether address translation is enabled or disabled, but is useful only when address translation is enabled.

D8.8.1 PAC field

The TCR_ELx.{T0SZ, T1SZ} fields are used to configure the size and location of the PAC field.

When a 64-bit register, Xn, holds an address with a PAC field, the location of the PAC field is determined by all of the following:

- The bottom_PAC_bit is 64-TCR_ELx.TnSZ.
- If FEAT_CONSTPACFIELD is implemented, or address tagging is used, then the value of Xn[55] is the value of n used in TnSZ.
- If FEAT_CONSTPACFIELD is not implemented and address tagging is not used, then the value of Xn[55] is the value of n used in TnSZ.
- If address tagging is used, the PAC field is Xn[54:bottom_PAC_bit].
- If address tagging is not used, the PAC field is Xn[63:56, 54:bottom_PAC_bit].

For more information, see Address tagging on page D8-5162.

Xn[55] always determines whether Xn[63:56] is part of the PAC field, and it is IMPLEMENTATION DEFINED whether Xn[55] or Xn[63] determines which of TCR_ELx.{T0SZ, T1SZ} are used to determine the value of bottom_PAC_bit.

If the TCR_ELx.TBID{r} bit is used to restrict address tagging to data addresses, then instruction addresses can use Xn[63:56] bits to produce larger pointer authentication code fields.

For all of the following reasons, if FEAT_PAuth2 is implemented, FEAT_FPAC is not implemented, and stage 1 translation is disabled, then Arm recommends not setting the TCR_ELx.TnSZ values to indicate an address range that is smaller than the PA size:

- For some PAC values, if TCR_ELx.TnSZ is set to indicate an address range that is smaller than the PA size, the address generated by a failed PAC authentication might be an address within the PA size because the upper address bits, those between the PA size and the size indicated by the TCR_ELx.TnSZ field, are taken from the result of the authentication process.
- Accessing memory using such an address that has failed PAC authentication does not generate an Address size fault.
• The memory access is done using upper address bits, those between the PA size and the size indicated by the TCR_ELx.TnSZ field, taken from the result of the authentication process.

If the value in TCR_ELx.TnSZ is outside the permitted range, then one of the following constrained unpredictable results occur:
• The TCR_ELx.TnSZ value configures the bottom_PAC_bit value.
• The minimum permitted TCR_ELx.TnSZ value configures the bottom_PAC_bit value.
• The maximum permitted TCR_ELx.TnSZ value configures the bottom_PAC_bit value.

If a PE treats an out of range TCR_ELx.TnSZ value as the maximum permitted field value or the minimum permitted field value for all purposes except reading the field value, then that behavior also applies to determining bottom_PAC_bit.

D8.8.2 PAC generation and verification keys

For pointer authentication, all of the following 128-bit PAC keys are provided:
• Instruction address PAC key A, APIAKey_EL1, is the concatenation of the register values APIAKeyHi_EL1:APIAKeyLo_EL1.
• Instruction address PAC key B, APIBKey_EL1, is the concatenation of the register values APIBKeyHi_EL1:APIBKeyLo_EL1.
• Data address PAC key A, APDAKey_EL1, is the concatenation of the register values APDAKeyHi_EL1:APDAKeyLo_EL1.
• Data address PAC key B, APDBKey_EL1, is the concatenation of the register values APDBKeyHi_EL1:APDBKeyLo_EL1.
• Generic authentication PAC key A, APGAKey_EL1, is the concatenation of the register values APGAKeyHi_EL1:APGAKeyLo_EL1.

For an Exception level, all of the following bits in the SCTLR_ELx registers are used to enable PAC generation and validation:
• SCTLR_ELx.EnIA enables instruction address pointer authentication using the APIAKey_EL1 key.
• SCTLR_ELx.EnIB enables instruction address pointer authentication using the APIBKey_EL1 key.
• SCTLR_ELx.EnDA enables data address pointer authentication using the APDAKey_EL1 key.
• SCTLR_ELx.EnDB enables data address pointer authentication using the APDBKey_EL1 key.

All Exception levels use the same set of registers to hold PAC keys.

When switching between Exception levels, software is expected to apply all of the following:
• Software is expected to switch the PAC keys between Exception levels.
• Software is expected to not leave the values of the current keys present in memory, typically done by zeroing those locations after switching.

D8.8.3 PAC instructions

When a register is used as the target of an indirect branch instruction or a load instruction, all of the following instructions can be used to authenticate the register contents and prepare the register to be used:
• Instructions that insert a PAC field into the upper bits of the register.
• Instructions that extract the PAC field from the upper register bits and check that the value is correct.
• Instructions that remove the PAC field in the register and replace it with the extension bits, without verification.

An instruction that inserts a PAC into the upper bits of a register does all of the following:
• The bits used are the extension bits that do not hold valid address bits.
• The inserted PAC value is calculated from the value of the register and one other 64-bit value.
IKBGF An instruction that extracts the PAC from the upper register bits and checks that the value is correct does all of the following:

- The check is based on the value of the register and one other 64-bit value.
- When the value is correct, the PAC is replaced with the extension bits.
- When the value is incorrect, all of the following occur:
  - The PAC is replaced with the extension bits.
  - Two extension bits are set to a unique, fixed value.
  - When the register is used as an indirect branch target, a Translation fault is generated because the VA is not mapped.

IRZFZG Multiple versions of pointer authentication instructions support different use cases. Some instructions combine a pointer authentication operation with another operation.

RWNKCJ If PAC generation and validation is disabled, then the PACGA and XPAC* instructions are not affected and are always enabled.

RWDYDC If PAC generation and validation is disabled, then all of the following apply:

- Instructions that insert a PAC into the address in a register execute as NOPs.
- Instructions that authenticate a PAC execute as NOPs.
- If an instruction combines pointer authentication with another operation, then all of the following apply:
  - The pointer authentication does not occur.
  - The combined operation behaves the same as the equivalent instruction that does not do pointer authentication.

IRHMIV If PAC generation and validation is disabled, all of the following are examples of the behavior of instructions that combine pointer authentication with another operation:

- A RETAA instruction operates as a RET instruction.
- A LDRAA Xt, [Xn, #<simm10>! instruction operates as a LDR Xt, [Xn, #<simm10>:000]! instruction.

IZVGYK The PACGA instruction generates a 32-bit PAC from two 64-bit values and a generic key.

IZPGRZ The PACGA instruction can be used to protect small memory blocks. PACGA instructions can be chained to protect an arbitrary-sized memory block.

IPXWQC For pointer authentication instructions other than the PACGA instruction, the PAC is generated using one of the following IMPLEMENTATION DEFINED methods:

- If FEAT_PACQARMA5 is implemented, then ID_AA64ISAR1_EL1.APA is non-zero and the QARMA5 block cipher algorithm is used.
- If FEAT_PACIMP is implemented, then ID_AA64ISAR1_EL1.API is non-zero and an IMPLEMENTATION DEFINED algorithm is used.
- If FEAT_PACQARMA3 is implemented, then ID_AA64ISAR2_EL1.APA3 is non-zero and the QARMA3 block cipher algorithm is used.

IWXMCQ For the PACGA instruction, the PAC is generated using one of the following IMPLEMENTATION DEFINED methods:

- If FEAT_PACQARMA5 is implemented, then ID_AA64ISAR1_EL1.GPA is non-zero and the QARMA5 block cipher algorithm is used.
- If FEAT_PACIMP is implemented, then ID_AA64ISAR1_EL1.GPI is non-zero and an IMPLEMENTATION DEFINED algorithm is used.
- If FEAT_PACQARMA3 is implemented, then ID_AA64ISAR2_EL1.GPA3 is non-zero and the QARMA3 block cipher algorithm is used.

RZYPJV For the PACGA instruction, if the PAC is generated using an IMPLEMENTATION DEFINED algorithm, then all of the following are required:

- The IMPLEMENTATION DEFINED algorithm uses the same arguments as the ComputePAC() pseudocode function.
The AArch64 Virtual Memory System Architecture

D8.8 Pointer authentication

For a set of arguments passed to the IMPLEMENTATION DEFINED algorithm, the same result is produced by all PEs that an execution thread could migrate between.

For more information, see aarch64/functions/pac/computepac/ComputePAC on page J1-11116.

D8.8.4 Faulting on pointer authentication

All statements in this section require implementation of FEAT_FPAC.

If an instruction only authenticates a PAC, then when the PAC is incorrect, a Translation fault is generated.

If an instruction is a combined instruction that includes pointer authentication, then when the PAC is incorrect, one of the following IMPLEMENTATION DEFINED behaviors occur:

- A Translation fault is generated due to the authentication failure.
- The address is modified in a way that generates a Translation fault when the address is accessed.

If an instruction is a combined instruction that includes pointer authentication and FEAT_FPACCOMBINE is implemented, then when the PAC is incorrect, a Translation fault is generated due to the authentication failure.

When an authentication failure occurs at EL0, the exception is taken at one of the following:

- If HCR_EL2.TGE is 0, the exception is taken at EL1.
- If HCR_EL2.TGE is 1, the exception is taken at EL2.

If the current Exception level is not EL0, then when an authentication failure occurs, the exception is taken at the current Exception level.

When an exception is generated due to an authentication failure, the ESR_ELx.EC code is set to 0x1C.
D8.9 Virtualization Host Extensions

Virtualization Host Extensions provide enhanced support for a Type 2 virtualization solution, where there is a Host OS that is either more privileged than the hypervisor or is the hypervisor.

All statements in this chapter require implementation of FEAT_VHE.

If and only if an implementation includes EL2 using AArch64, then Virtualization Host Extensions, FEAT_VHE, can apply.

FEAT_VHE adds all of the following state:

- The HCR_EL2.E2H configuration bit.
- The CONTEXTIDR_EL2 register, which has the same format and contents as the CONTEXTIDR_EL1 register.
- The TTBR1_EL2 register, which has the same format and contents as the TTBR1_EL1 register.
- The CNTHV_CTL_EL2, CNTHV_CVAL_EL2, and CNTHV_TVAL_EL2 registers, which have the same format and contents as the CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 registers, respectively.
- An EL2 virtual timer with all of the following properties:
  - It is accessed using the CNTHV_CTL_EL2, CNTHV_CVAL_EL2, and CNTHV_TVAL_EL2 registers.
  - The virtual offset is treated as 0.

D8.9.1 Behavior of HCR_EL2.E2H

HCR_EL2.E2H enables a configuration where a host operating system is running in EL2, and the host operating system applications are running in EL0. The host operating system might also manage guest virtual machines that run EL1&0, with stage 2 translation enabled and controlled by the host operating system.

If HCR_EL2.E2H is 0, then all of the following apply:

- Execution at EL2 uses the EL2 translation regime.
- All of the following effects apply to the contents of TTBR1_EL2:
  - The contents can be read by an MRS instruction and written by an MSR instruction.
  - For all other hardware operations, the contents are ignored.
- The Context ID matching breakpoint has all of the following properties:
  - It is disabled at EL2.
  - It uses the value of CONTEXTIDR_EL1 at EL0 and EL1.

If HCR_EL2.E2H is 1, then the translation regime controlled by TCR_EL2 is the EL2&0 translation regime.

All of the following are properties of the EL2&0 translation regime:

- The EL2&0 translation regime behaves the same as stage 1 in the EL1&0 translation regime and uses an upper address range translated by tables pointed to by TTBR1_EL2.
- TTBR0_EL2 translates the lower address range of the EL2&0 translation regime and is extended to have the same format and contents as TTBR0_EL1.
- The Privileged Access Never mechanism applies to data accesses from EL2.
- When CNTVCT_EL0 is read from EL2, the virtual offset is reported as 0.
- All of the following registers are redefined:
  - CNTHCTL_EL2.
  - CPTR_EL2.
  - TCR_EL2.
If the value of \texttt{HCR\_EL2}.E2H is 1, then all of the following effects to the Context ID apply:

- When executing at EL2, a Context ID matching breakpoint uses \texttt{CONTEXTIDR\_EL2}.
- Both VMID and VMID plus Context ID matching breakpoints do not match at EL2.

If \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 0\}, then accesses from EL1 and EL0 use the EL1&0 translation regime.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then when executing at EL0, all of the following apply:

- The EL2&0 translation regime is used and accesses are treated as unprivileged.
- A Context ID matching breakpoint uses \texttt{CONTEXTIDR\_EL2}.
- The following timer registers, and their equivalent AArch32 registers, are redefined to access the associated EL2 register, rather than accessing the EL0 register:
  - \texttt{CNTP\_CTL\_EL0}.
  - \texttt{CNTP\_CVAL\_EL0}.
  - \texttt{CNTP\_TVAL\_EL0}.
  - \texttt{CNTV\_CTL\_EL0}.
  - \texttt{CNTV\_CVAL\_EL0}.
  - \texttt{CNTV\_TVAL\_EL0}.
- Both VMID and VMID plus Context ID matching breakpoints do not match at EL0.

If \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then when executing at EL2, all of the following apply:

- The EL2&0 translation regime is used.
- For permission and watchpoint checking, if the unprivileged instructions \texttt{LDTR}, \texttt{LDTRB}, \texttt{LDTRH}, \texttt{LDTRSB}, \texttt{LDTRSH}, \texttt{LDTRSW}, \texttt{STTR}, \texttt{STTRB}, and \texttt{STTRH} are executed, then the behavior is the same as executing at EL0.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then all of the following register effects apply:

- Except for the purpose of reading the value held in the register, some fields in \texttt{HCR\_EL2} and all fields in \texttt{HSTR\_EL2} are treated as effectively having a specific value.
- \texttt{SCTLR\_EL2} is redefined in all of the following ways:
  - Additional fields from \texttt{SCTLR\_EL1} are included.
  - The register applies to execution at EL0.
- When \texttt{CNTVCT\_EL0} is read from EL0 or EL2, the virtual offset is treated as 0.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then when an exception is taken from EL0 to EL2, the value of the \texttt{HCR\_EL2}.RW bit is ignored when determining the exception vector offset to use.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then the TLB maintenance and address translation instructions that apply to the EL1&0 translation regime are redefined to apply to the EL2&0 translation regime.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then when executing at EL2 or EL0, any physical interrupt that is configured to be taken at EL2 is subject to the \texttt{PSTATE}.\{D, A, I, F\} interrupt masks.

For more information, see \textit{The PSTATE debug mask bit, D} on page D1-4681 and \textit{Asynchronous exception masking} on page D1-4659.

If the value of \texttt{HCR\_EL2}.\{E2H, TGE\} is \{1, 1\}, then all of the following apply to EL1:

- Access from EL1 is not possible.
- \texttt{CPACR\_EL1} does not cause any instructions to be trapped to EL1.
- \texttt{CNTKCTL\_EL1} does not cause any instructions to be trapped to EL1, and the event stream caused by \texttt{CNTKCTL\_EL1} is disabled.

### D8.9.2 System and Special-purpose register redirection

If all of the conditions in the following list are true, then the System register mapping in the following table applies:

- The PE is executing at EL2.
• HCR_EL2.E2H is 1.

Table D8-57 System register redirection

<table>

For more information, see **System and Special-purpose register redirection on page D8-5169.**
D8.10 Nested virtualization

Nested virtualization is an OPTIONAL feature that enables a Host hypervisor executing at EL2 to run a Guest hypervisor at EL1.

All statements in this section and subsections require implementation of FEAT_NV.

Nested virtualization adds the HCR_EL2.{NV, NV1, AT} fields.

An implementation is permitted to cache the HCR_EL2.{NV, NV1} fields in a TLB.

If a Guest hypervisor is run with HCR_EL2.E2H set to 0, then the Host hypervisor is required to set HCR_EL2.TVM to 1 and CPTER_EL2.TCPAC to 1 to trap any Guest hypervisor accesses to the EL1 System registers that would be accessed from any Guest OS running under the Guest hypervisor.

Nested virtualization does not modify either self-hosted debug or the Performance Monitors Extension.

Arm assumes that the Host hypervisor traps accesses to the Breakpoint registers and Performance Monitors registers to EL2, so that it can process any accesses to these registers made by a Guest hypervisor or by a Guest OS running under the Guest hypervisor.

D8.10.1 Behavior when HCR_EL2.NV is 1

If HCR_EL2.NV is 1 and the current Exception level is EL1, then all of the following apply:

- If a read access or write access from EL1 to one of the following System registers or Special-purpose registers occurs and that access is permitted at EL2, then that access is trapped to EL2 and reported using EC syndrome value 0x18 in ESR_EL2:
  - Any System register accessed using MRS or MSR named *_EL2, except SP_EL2.
  - Any System register accessed using MRS or MSR named *_EL12.
  - Any System register accessed using MRS or MSR named *_EL02.
  - Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und, and SPSR_fiq, accessed using MRS or MSR.
  - Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.

- If one of the following instructions is executed from EL1, then the instruction is trapped to EL2 and reported using EC syndrome value 0x18 in ESR_EL2:
  - Address Translation instructions that are accessible only from EL2 and above.
  - TLB maintenance instructions that are accessible only from EL2 and above.

- If the ERET, ERETAA, or ERETAB instruction is executed from EL1, then the instruction is trapped to EL2 and reported using EC syndrome value 0x1a in ESR_EL2.

- If EL3 is not implemented and the Effective value of HCR_EL2.TSC is 1, then when an SMC instruction is executed at EL1, all of the following apply:
  - The SMC instruction is trapped to EL2.
  - The exception is reported using EC syndrome value 0x17 in ESR_EL2.

If HCR_EL2.NV is 1 and the current Exception level is EL1, then EL1 read accesses to the CurrentEL register return a value of 0x2 in bits[3:2].

D8.10.2 Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 0

If HCR_EL2.{NV, NV1} is {1, 0} and the current Exception level is EL1, then any exception taken from EL1 to EL1 causes SPSR_EL1.M[3:2] to be set to 0b10 and not 0b01.
D8.10.3 Additional behavior when HCR_EL2.NV is 1 and HCR_EL2.NV1 is 1

If HCR_EL2.{NV, NV1} is {1, 1} and the current Exception level is EL1, then all of the following apply:

- If an access to one of the following registers occurs, then the access is trapped to EL2 and reported using EC syndrome value 0x18 in ESR_EL2:
  - An access to VBAR_EL1.
  - An access to ELR_EL1.
  - An access to SPSR_EL1.
  - If implemented, then an access from EL1 to SCXTNUM_EL1.
- For Block descriptors and Page descriptors in the EL1&0 translation regime, all of the following apply:
  - Block descriptor and Page descriptor bit[54] holds PXN, not UXN.
  - Block descriptor and Page descriptor bit[53] is RES0.
  - Block descriptor and Page descriptor bit[6], AP[1], is treated as 0 regardless of the actual value.
- For Table descriptors in the EL1&0 translation regime, if hierarchical permissions are enabled, then all of the following apply:
  - Table descriptor bit[61], APTable[0], is treated as 0 regardless of the actual value.
  - Table descriptor bit[60] holds PXNTable, not UXNTable.
  - Table descriptor bit[59] is RES0.
- PSTATE.PAN is treated as 0 for all purposes except reading the value of the bit.
- If the LDTR* or the STTR* instructions are executed, then all of the following apply:
  - The LDTR* instructions behave the same as the corresponding LDR* instructions.
  - The STTR* instructions behave the same as the corresponding STR* instructions.

Arm expects software to clear the HCR_EL2.NV1 bit to 0 before permitting execution at EL0.

D8.10.4 Behavior when HCR_EL2.NV is 0 and HCR_EL2.NV1 is 1

If HCR_EL2.{NV, NV1} is {0, 1} and the current Exception level is EL1, then one of the following constrained unpredictable behaviors apply:

- For all purposes other than reading back the value of the HCR_EL2.NV bit, the implementation behaves as if HCR_EL2.{NV, NV1} is {1, 1}.
- For all purposes other than reading back the value of the HCR_EL2.NV1 bit, the implementation behaves as if HCR_EL2.{NV, NV1} is {0, 0}.
- The implementation behaves as defined when HCR_EL2.NV is 0, with HCR_EL2.NV1 set to 1 having the effect of causing accesses to VBAR_EL1, ELR_EL1, and SPSR_EL1 from EL1 to be trapped to EL2.

D8.10.5 Effect of HCR_EL2.AT

If HCR_EL2.AT is 1, then all of the following are trapped to EL2 and reported using EC syndrome value 0x18 in ESR_EL2:

- Executing AT S1E0R from EL1.
- Executing AT S1E0M from EL1.
- Executing AT S1E1R from EL1.
- Executing AT S1E1M from EL1.
- Executing AT S1E1RP from EL1.
- Executing AT S1E1WP from EL1.
Enhanced support for nested virtualization

Enhanced support for nested virtualization provides a mechanism for hardware to transform reads and writes from System registers into reads and writes from memory.

All statements in this section and subsections require implementation of FEAT_NV2.

If HCR_EL2.NV2 is 1 and the current Exception level is EL1, then all of the following apply:

- Accesses to EL2 registers are redirected to EL1 registers.
- Accesses to System registers are transformed to memory accesses.

If HCR_EL2.NV2 is 0, then the behavior of HCR_EL2.{NV, NV1} is unchanged.

Redirection of register accesses from EL2 to EL1

If HCR_EL2.{NV, NV2} is {1, 1} and the current Exception level is EL1, then accesses to all of the following EL2 Special-purpose registers are redirected to the corresponding EL1 register:

- An access from EL1 to SPSR_EL2 is redirected to SPSR_EL1.
- An access from EL1 to ELR_EL2 is redirected to ELR_EL1.

If HCR_EL2.{NV, NV2} is {1, 1} and the current Exception level is EL1, then accesses to all of the following EL2 System registers are redirected to the corresponding EL1 register:

- An access from EL1 to ESR_EL2 is redirected to ESR_EL1.
- An access from EL1 to FAR_EL2 is redirected to FAR_EL1.

For more information, see:

- \textit{op0==0b11, Moves to and from Special-purpose registers on page C5-668.}
- \textit{Instructions for accessing non-debug System registers on page D16-5523.}

Loads and stores generated by transforming register accesses

If HCR_EL2.{NV, NV2} is {1, 1} and the current Exception level is EL1, then when an MRS or MSR instruction is executed to access certain registers, all of the following apply:

- The instruction is treated as an instruction executed at EL1.
- The register accesses do not generate an exception to EL2.
- The register accesses are transformed to memory accesses.
- The memory accesses are treated as EL2 accesses.

When register accesses are transformed to memory accesses, all of the following information is used to form the memory address:

- A base address that is stored in the VNCR_EL2 register.
- For a register that is redirected to memory, a unique memory offset value.
- The memory address is a combination of the base address and the memory offset according to the formula \( \text{SignExtend}(\text{VNCR_EL2.BADDR} : \text{Offset<11:0>}, 64) \).
When register accesses are transformed to memory accesses, the following table shows the unique memory offset that is assigned to the register.

</table>
Unallocated memory offset values up to but not including \(0x1000\) are reserved.

When a register access instruction targets a register that is not implemented, the PE treats access to that register as unallocated.

When a System register access instruction is trapped by either or both of HCR_EL2.\{NV, NV1\}, then the instruction is transformed into a memory access instruction instead of creating a trap.

When a System register access instruction is not trapped by either or both of HCR_EL2.\{NV, NV1\}, then the trap is subject to the exception prioritization rules.

Accesses to all of the following registers that affect hypervisor execution by controlling the event stream are not transformed into memory accesses:

- \(\text{CNTHCTL}_\text{EL2}\).
- If HCR_EL2.NV1 is 0, then CNTKCTL_EL12.
- If HCR_EL2.NV1 is 1, then CNTKCTL_EL1.

When a System register access is transformed into a memory access, the memory access has all of the following properties:

- The memory access is translated by one of the following:
  - If HCR_EL2.E2H is 0, then the EL2 translation regime.
  - If HCR_EL2.E2H is 1, then the EL2&0 translation regime.
- The endianness of the memory access is defined by SCTLR_EL2.EE.
- The memory access is 64-bit single-copy atomic aligned to 64 bits.
- The memory access does not have Acquire or Release semantics.
- If there is no context synchronizing operation between the register access and a load or store instruction accessing the address of the transformed memory access, then the transformed memory access can be reordered with respect to any reads or writes at EL1 caused by load or store instructions to the same address.
- The memory access behaves as if PSTATE.PAN is 0.
- For fields in a transformed System register that are defined to be RES0 or RES1, the memory access does not check that the fields are set correctly, nor are they forced to their dedicated value.

For more information, see Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.

Exceptions from transformed register accesses

If HCR_EL2.\{NV, NV2\} is \{1, 1\}, then any exception taken from EL1 and taken to EL1 causes the SPSR_EL1.M[3:2] to be set to \(0b10\) and not \(0b01\).

If a System register access is transformed to a memory access, then when the memory access generates a Data Abort, the resulting fault has all of the following properties:

- The fault is taken to EL2, using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current Exception level with the ESR_EL2.EC code \(0x25\).
- FAR_EL2 is updated to hold the faulting address.

If a System register access is transformed to a memory access, then when the memory access generates a synchronous External abort and External aborts are not configured to be taken to EL3, the resulting fault has all of the following properties:

- The fault is taken to EL2, using the standard vector offset for exceptions from EL1 to EL2.
- The fault is reported as a Data Abort from the current Exception level with the ESR_EL2.EC code \(0x25\).

The VNCR field in ESR_EL2 and ESR_EL3 identifies whether the fault came from use of VNCR_EL2 by EL1.

For more information, see ISS encoding for an exception from a Data Abort on page D17-5685.
Interaction with self-hosted and External debug

When a System register access is transformed into a memory access, all of the following operations treat the instruction as being executed at EL1:

- PMU events filtered by Exception level.
- For trace or Statistical Profiling, instructions filtered by Exception level.
- Checking the instruction address against breakpoint registers or trace resources.

When a System register access is transformed into a memory access, all of the following operations treat the memory access as being executed at EL2:

- The memory access is checked against the watchpoint registers.
- The memory address is recorded in a Statistical Profiling record.

If all of the following apply, then it is CONSTRANDED UNPREDICTABLE whether there is a watchpoint match:

- A System register access is transformed into a memory access.
- The memory access matches an EL2 access in the watchpoint registers.
- A watchpoint is linked to a context-aware breakpoint that is programmed to match the value held in CONTEXTIDR_EL1 or VMID.

If all of the following apply, then a watchpoint match generates a Watchpoint debug event:

- A System register access is transformed into a memory access.
- EDSCR.HDE is 1.
- Halting is enabled.

If all of the following apply, then a watchpoint match generates a Watchpoint exception:

- A System register access is transformed into a memory access.
- EDSCR.HDE is 0.
- Debug exceptions are enabled at EL2.

If a System register access is transformed to a memory access, then when a watchpoint match generates a Watchpoint exception, the resulting exception has all of the following properties:

- The exception is taken to EL2.
- The fault is reported as a Watchpoint from the current Exception level with the ESR_EL2.EC code 0x35.
- FAR_EL2 is updated to hold the cachepointed address.

If a System register access is transformed to a memory access, then when a Watchpoint exception is generated, the VCNCR field in ESR_EL2 identifies whether the Watchpoint exception came from use of VNCR_EL2 by EL1.

If a System register access is transformed to a memory access, then the resulting loads and stores are treated by the Performance Monitors as Memory-read operations and Memory-write operations.

If a System register access is transformed to a memory access, then when the Statistical Profiling Unit selects the instruction generating the memory access for profiling, it records the operation as a Load/Store operation.

If a System register access is transformed to a memory access, then when the Statistical Profiling Unit selects the instruction generating the memory access for profiling and Statistical Profiling is disabled at EL2, the VA for the memory access is not recorded.
D8.11 Memory aborts

**D8.11 Memory aborts**

For a VMSAv8-64 implementation, all of the following abort mechanisms can cause the PE to take an exception due to a failed memory access:

- A *Debug exception* generated by the self-hosted debug system. For more information, see Chapter D2 AArch64 Self-hosted Debug.
- An *Alignment fault* generated by a memory access that is not aligned as required by the operation. For more information, see Alignment support on page B2-189.
- An *MMU fault* generated by the fault checking sequence in the appropriate translation regime. For more information, see MMU fault types.
- An *External abort* generated by the memory system and not by self-hosted debug, alignment checking, or MMU checking. For more information, see External aborts on page D7-5072.

For AArch64 state, MMU faults are synchronous exceptions that are reported as one of the following:

- Data Aborts due to data memory access faults.
- Instruction Aborts due to instruction fetch faults.

For more information, see Synchronous exception types on page D1-4646.

In some cases, an MMU fault generated as part of an instruction execution is reported in PAR_EL1 rather than as a synchronous abort.

When an MMU fault is generated and reported as an Instruction Abort or Data Abort, the Exception level that the exception is taken to depends on the translation regime and translation stage that caused the fault.

When a memory access abort generates an exception, all of the following registers are used to record context information:

- A Fault Address Register, FAR_ELx.
- An Exception Syndrome Register, ESR_ELx.

When an MMU fault is generated, the fault context saved in the ESR_ELx at the Exception level that the fault is taken to depends on all of the following:

- Whether the fault is reported as an Instruction Abort or as a Data Abort.
- Whether the exception is taken from the same or a lower Exception level.

For an Instruction Abort, only the following two exceptions have a higher priority in the exception priority hierarchy:

- Software Step exception.
- PC alignment fault exception.

For a Data Abort, only Watchpoint exceptions have a lower priority in the exception priority hierarchy.

### D8.11.1 MMU fault types

All of the following MMU fault types are supported, and there are no other MMU fault types:

- Alignment fault on a data access. For more information, see Alignment support on page B2-189.
- Translation fault.
- Address size fault.
- Synchronous External abort on a translation table walk.
- Access flag fault.
- Permission fault.
- TLB conflict abort.

When an attempt to access Device memory generates an MMU fault, no memory access occurs.
RTQDJS If the memory attributes cannot be determined and the resultant memory region could be Device memory, then when an attempt to access that region generates an MMU fault, no memory access occurs.

**Translation fault**

RDYNQ If descriptor bit[0] is 0 in any translation table entry, the descriptor is invalid. When a translation table lookup returns an invalid descriptor, a Translation fault is generated and descriptor bits[63:1] are ignored.

RKMJZ If descriptor bit[1] is 0 at a lookup level that does not support Block descriptors, then the descriptor encoding is reserved. When a translation table lookup returns that descriptor, a Translation fault is generated.

RFDQJL If FEAT_BBM is implemented and supported at level 1 or higher, and the Block descriptor has the nT bit set, then the implementation is permitted to generate a Translation fault.

IRSSLQ For any translation lookup level, when a Translation fault is generated, the reported fault code indicates the lookup level.

RVZZSZ When one or more of the following apply, a level 0 Translation fault is generated on the relevant translation stage:
- The IA does not map onto a TTBR_ELx address range.
- If the IA maps onto the TTBR0_ELx address range and the IA contains any one bits above the configured IA size as determined by TCR_ELx.T0SZ.
- If the IA maps onto the TTBR1_ELx address range and the IA contains any zero bits above the configured IA size as determined by TCR_ELx.T1SZ.
- When a TLB miss occurs, the corresponding TCR_ELx.EPDn field prevents a translation table walk using TTBRn_ELx.
- When FEAT_E0PD is implemented, the corresponding TCR_ELx.E0PDn field prevents unprivileged access to an address translated by TTBRn_ELx.
- When FEAT_SVE is implemented, the corresponding TCR_ELx.NFDy field prevents non-faulting unprivileged accesses to an address translated by TTBRy_ELx.

RMLNTS When a Translation fault is generated, the translation table entry causing the fault is not cached in a TLB.

IXFTPJ When a Translation fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

IPXJFV For more information, see *MMU faults generated by cache maintenance operations* on page D8-5185.

**Address size fault**

RCVSBH For a translation stage, if an address in one of the following has nonzero address bits above the configured OA size, then an Address size fault is generated:
- The TTBR_ELx used in the translation.
- A translation table entry.
- The translation OA.

RFTZHB An Address size fault can be generated at any translation lookup level.

RWDZFC For the 64KB translation granule, if FEAT_LPA is implemented and the implementation does not support 52-bit PAs, then all of the following apply:
- It is IMPLEMENTATION DEFINED whether nonzero address bits above the OA size generate an Address size fault.
- For this case, it is deprecated to not generate an Address size fault.

RBFHQH When an Address size fault is generated, the reported fault code indicates one of the following:
- If the fault was generated due to the TTBR_ELx used in the translation having nonzero address bits above the OA size, then a fault at level 0.
• If the fault was not generated due to the TTBR_ELx used in the translation, then the lookup level at which the fault occurred.

When an Address size fault is generated, the translation table entry causing the fault is not cached in a TLB.

When an Address size fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

An implementation is required to ensure that the Contiguous bit does not prevent generation of Address size faults. For more information, see Architectural guarantees when the Contiguous bit is misprogrammed on page D8-5159.

For more information, see:
• MMU faults generated by cache maintenance operations on page D8-5185.
• Output address size configuration on page D8-5088.

External abort on a translation table walk

If an External abort on a translation table walk is generated, then it is reported in one of the following ways:
• If the External abort is synchronous, then it is reported as one of the following:
  — If the translation table walk is due to an instruction fetch, then a synchronous Instruction Abort exception.
  — If the translation table walk is due to a data access, an address translation instruction, or a cache maintenance instruction operating by VA, then a synchronous Data Abort exception.
• If the External abort is asynchronous, then it is reported using the SError interrupt exception.

A TLB or intermediate TLB caching structure might support:
• An arbitrary number of translation table lookup levels.
• One or more translation stages that might not correspond to an address translation lookup stage.

If a synchronous External abort is generated due to a TLB or intermediate TLB caching structure, including parity or ECC errors, then all of the following are permitted:
• If the PE cannot precisely determine the translation stage at which the error occurred, then it is reported and prioritized as a stage 1 fault.
• If the PE cannot precisely determine the lookup level at which the error occurred, then the lookup level is reported and prioritized as one of the following:
  — The lowest-numbered lookup level that could have caused the error.
  — If the PE cannot determine any information about the lookup level, then level 0.

Access flag fault

For an implementation that does not manage the AF in hardware, when and only when a non-speculative access is made to an address and an attempt is made to translate that address using a descriptor with an AF of 0, an Access flag fault is generated.

For a translation lookup of a Block descriptor or Page descriptor, when an Access flag fault is generated, the reported fault code indicates the lookup level.

When an Access flag fault is generated, the translation table entry causing the fault is not cached in a TLB.

When an Access flag fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

For more information, see:
• MMU faults generated by cache maintenance operations on page D8-5185.
• Software management of the Access flag on page D8-5143.
Permission fault

When a Permission fault is generated, the reported fault code indicates the lookup level of the Block or Page descriptor used in the translation, even if the lack of permission was caused by hierarchical permission controls.

A translation table entry that generates a Permission fault is permitted to be cached in a TLB.

If software updates a stage 1 or stage 2 translation table due to a Permission fault, then the software is required to invalidate the appropriate TLB entry to prevent stale information in a TLB from being used by a subsequent memory access.

For more information, see:
- MMU faults generated by cache maintenance operations on page D8-5185.
- Memory access control on page D8-5132.
- Stage 2 fault on a stage 1 translation table walk on page D8-5189.

TLB conflict abort

When a TLB has not been properly invalidated, such as when architecturally required TLB invalidation is not done, an address lookup might hit multiple TLB entries.

When a lookup address hits multiple TLB entries, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

When a TLB conflict abort is generated, it is reported as one of the following:
- On an instruction fetch it is reported as an Instruction Abort.
- On a data access or a cache management instruction, it is reported as a Data Abort.
- For an AT S1E0* or AT S1E1* instruction executed from EL1, when a TLB conflict abort is generated on a stage 2 translation, it is reported as a Data Abort.

For an AT instruction other than an AT S1E0* or AT S1E1* instruction executed from EL1, a TLB conflict does not generate an abort.

When a TLB conflict abort is generated, it is IMPLEMENTATION DEFINED whether it is a stage 1 abort or a stage 2 abort.

If EL2 is enabled and stage 2 of the EL1&0 translation regime is disabled, then a stage 2 abort cannot be generated.

When a TLB conflict abort is generated, all of the following are reported:
- A 0b110000 Fault status code.
- The lookup address that caused the fault.

If an address matches multiple entries in a TLB and does not generate a TLB conflict abort, then all of the following apply:
- The resulting behavior is CONSTRAINED UNPREDICTABLE.
- The CONSTRAINED UNPREDICTABLE behavior cannot permit access to memory regions with permissions or attributes that would not be possible in the current Security state at the current Exception level.

For more information, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-11585.

D8.11.2 MMU faults generated by address translation instructions

An address translation instruction uses the translation system and can generate all of the following faults:
- Translation fault.
- Address size fault.
- Synchronous External abort on a translation table walk.
- Access flag fault.
- Permission fault.
- TLB conflict abort.
- When translating using the AArch32 translation systems, a domain fault.

When an address translation instruction generates a fault and when none of the following generated the fault, the fault is not taken as a synchronous exception, and PAR_EL1 is populated with PAR_EL1.F == 1 and the fault syndrome information:
- A synchronous External abort during a translation table walk.
- An AT S1E0* or AT S1E1* instruction executed from EL1 generates a stage 2 fault on a memory access during a translation table walk.

For more information, see Exceptions to reporting the fault in PAR_EL1.

If an address translation instruction requires two address translation stages, then a fault can be generated from either stage 1 or stage 2.

If an address translation instruction requires two address translation stages in the EL1&0 translation regime, then a fault can be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk.

For more information, see Stage 2 fault on a stage 1 translation table walk on page D8-5189.

If FEAT_PAN2 is implemented, then the <pan> component of the AT instruction <operation> determines whether the PSTATE.PAN value is considered when determining permissions.

Exceptions to reporting the fault in PAR_EL1

For an address translation instruction executed at a particular Exception level, ELx, if a synchronous External abort is generated on a stage 1 translation table walk, then the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 1 translation table walk for a memory access from ELx would be taken.

When an address translation instruction executed at EL3 generates a synchronous External abort on a stage 2 translation table walk, a Data Abort exception is taken to EL3.

For an address translation instruction executed at the EL2 or EL1 Exception level, if a synchronous External abort is generated on a stage 2 translation table walk, then the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 2 translation table walk for a memory access from that same EL2 or EL1 Exception level would be taken.

When an address translation instruction causes a synchronous External abort that is reported as an exception, all of the following apply:
- PAR_EL1 is UNKNOWN.
- The ESR_ELx of the target Exception level indicates that the fault was generated by a translation table walk due to a cache maintenance operation or address translation instruction.
- The FAR_ELx of the target Exception level holds the VA supplied to the address translation instruction.

When an AT S1E0* or AT S1E1* instruction is executed, all of the following can generate a stage 2 fault on a memory access during a translation table walk:
- Stage 2 Translation fault.
- Stage 2 Address size fault.
- Synchronous External abort on a stage 2 translation table walk.
- Stage 2 Access fault.
- Stage 2 Permission fault.
- A TLB conflict abort that takes an IMPLEMENTATION DEFINED choice of reporting as a stage 2 abort.
When an AT \texttt{S1E0} or AT \texttt{S1E1} instruction executed from EL1 generates a stage 2 fault on a memory access during a translation table walk, one of the following occurs:

- If the fault is a synchronous External abort on a stage 2 translation table walk and \texttt{SCR_EL3.EA} is 1, then a synchronous External abort on a stage 2 translation table walk is taken to EL3.
- The fault is taken as an exception to EL2 and all of the following apply:
  - \texttt{PAR_EL1} is \texttt{UNKNOWN}.
  - \texttt{ESR_EL2} indicates that a cache maintenance instruction faulted during a translation table walk.
  - \texttt{HPFAR_EL2} holds the IPA that faulted.
  - \texttt{FAR_EL2} holds the VA supplied to the address translation instruction.

For more information, see \textit{Stage 2 fault on a stage 1 translation table walk} on page D8-5189.

### D8.11.3 MMU faults generated by cache maintenance operations

There are no alignment requirements in cache maintenance instructions and execution of these instructions cannot generate an Alignment fault.

If the Point of Coherency is before any cache level, then it is \texttt{IMPLEMENTATION DEFINED} whether the execution of any cache clean instruction, or clean and invalidate instruction, that operates by VA to the Point of Coherency, can generate any MMU fault.

If the Point of Unification is before any data cache level, then it is \texttt{IMPLEMENTATION DEFINED} whether the execution of any data or unified cache clean instruction, or clean and invalidate instruction, that operates by VA to the Point of Unification, can generate any MMU fault.

It is \texttt{IMPLEMENTATION DEFINED} whether the execution of any cache maintenance instruction by VA can generate an Access flag fault.

If \texttt{SCTLR_ELx.UCI} is 1, enabling EL0 execution of the data cache maintenance instructions that operate by VA, then when the instruction is executed at EL0 to a location that does not have read permission at EL0, a Permission fault can be generated.

If \texttt{SCTLR_ELx.UCI} is 1, enabling EL0 execution of the \texttt{IC IVAU} instruction, and if the instruction is executed at EL0 to a location that does not have read permission at EL0, then it is \texttt{IMPLEMENTATION DEFINED} whether a Permission fault is generated.

If the Effective value of \texttt{SCTLR_EL1.CMOV} is 1, then when executing a \texttt{IC IVAU}, \texttt{DC CVAC}, \texttt{DC CIGVAC}, or \texttt{DC CIGDVAC} instruction at EL0 that has stage 1 read permission, but does not have stage 1 write permission, a stage 1 Permission fault is generated.

If the Effective value of \texttt{HCRX_EL2.CMOV} is 1, then when executing a \texttt{IC IVAU}, \texttt{DC CVAC}, \texttt{DC CIGVAC}, or \texttt{DC CIGDVAC} instruction at EL1 and EL0 that has stage 2 read permission, but does have stage 2 write permission, a stage 2 Permission fault is generated.

If an \texttt{IC IVAU}, \texttt{DC CVAC}, \texttt{DC CIGVAC}, or \texttt{DC CIGDVAC} instruction is implemented as a NOP, then it is \texttt{IMPLEMENTATION DEFINED} whether the instruction generates a stage 1 or stage 2 Permission fault when it does not have read and write permission.

When an implementation can generate MMU faults on execution of cache maintenance operations, Permission faults are generated according to the type of cache maintenance operation and system register configuration.

If a stage 2 translation of a stage 1 translation table walk is done as part of a cache maintenance instruction, then a stage 2 Permission fault can be generated.

If a \texttt{DC IVAC} does not have write permission to the location it invalidates, then a Permission fault can be generated.

\texttt{DC ZVA} is not a cache maintenance instruction.
For more information, see:

- Data and unified caches on page D8-5215.
- Instruction caches on page D8-5215.
- Memory aborts on page D8-5180.
- Permission fault on page D8-5183.
- A64 Cache maintenance instructions on page D7-5054.

## D8.11.4 MMU fault-checking sequence

For a translation stage, when an IA is translated to an OA, the fault checking sequence is done using all of the following steps:

1. If the IA is subject to an alignment check, then check the alignment and do one of the following:
   - If the IA is not aligned, then an Alignment fault is generated.
   - If the IA is aligned, then continue to the next step.

2. Check that the IA maps to a translation table base address register, TTBR, and do one of the following:
   - If the IA does not map to a TTBR, then a Translation fault is generated.
   - If the IA maps to a TTBR and translation using that TTBR is disabled, then a Translation fault is generated.
   - If the IA maps to a TTBR, then get the translation table base address and continue to the next step.

3. Check that the translation table base address size is valid and do one of the following:
   - If the translation table base address size is not valid, then an Address size fault is generated.
   - If the translation table base address size is valid, then continue to the next step.

4. Fetch the descriptor, using all of the following steps:
   - If the descriptor address is an IPA from a stage 1 translation, then all of the following are done:
     - The fault checking sequence is done on the stage 2 translation, using the IPA as an IA to the stage 2 translation.
     - The OA from the stage 2 translation is the descriptor PA.
   - If the descriptor address is not an IPA from a stage 1 translation, then the descriptor address is the descriptor PA.
   - The descriptor fetch is initiated using the descriptor PA, and one of the following occurs:
     - A Synchronous External abort is generated.
     - The descriptor is returned.

5. Check that the descriptor is valid and do one of the following:
   - If the descriptor is not valid, then a Translation fault is generated.
   - If the descriptor is valid, then continue to the next step.

6. Check that the descriptor address size is valid and do one of the following:
   - If the descriptor address size is not valid, then an Address size fault is generated.
   - If the descriptor address size is valid, then continue to the next step.

7. Check the descriptor type and do one of the following:
   - For a Table descriptor, get the descriptor address, get the hierarchical permissions and attributes that apply to subsequent lookup levels, and go back to step 4 to fetch the next descriptor.
   - For a Block descriptor or Page descriptor, continue to the next step.

8. If FEAT_BBM is implemented and supported at level 1 or higher, and the fetched descriptor is a block descriptor with the nT bit set, then the implementation can generate a Translation fault.
9. If AF hardware management is disabled or not implemented, check the descriptor AF bit and do one of the following:
   • If AF is 0, then an Access flag fault is generated.
   • If AF is 1, then continue to the next step.
10. If AF hardware management is enabled, then the hardware attempts to update the AF and that might result in a Permission fault at stage 2, or a Synchronous External abort.
11. Get the OA and OA space from the Block descriptor or Page descriptor returned by the translation table walk.
12. Check the alignment required for the output memory type and do one of the following:
   • If the OA alignment is not valid, then an Alignment fault is generated.
   • If the OA alignment is valid, then continue to the next step.
13. Check the OA space access permissions and do one of the following:
   • If the OA space access is not permitted, then a Permission fault is generated.
   • If the OA space access is permitted, then continue to the next step.
14. If dirty state hardware management is enabled, then the hardware attempts to update the dirty state and that might result in a Permission fault at stage 2, or a Synchronous External abort.
15. The translation stage returns the OA and region attributes.

For a translation stage, the following figure illustrates the MMU fault checking sequence.
For a translation stage, the following figure illustrates the steps taken to fetch a descriptor during a translation table walk.
Stage 2 fault on a stage 1 translation table walk

For a translation regime that uses two translation stages, the memory access made as part of a stage 1 translation table lookup can generate one or more of the following during a stage 2 translation:

- A Translation fault, Address size fault, Access flag fault, or Permission fault.
- A synchronous External abort on the stage 2 descriptor access.
- A synchronous External abort on the memory access.

If an Address size fault, Translation fault, Access flag fault, or Permission fault is generated on a stage 2 translation of a stage 1 translation table walk, then all of the following apply:

- The exception is taken to EL2.
- ESR_EL2.ISS[7] is 1 to indicate a stage 2 fault during a stage 1 translation table walk.
- The part of the ISS field that might contain details of the instruction is invalid.

If a synchronous External abort is generated on a stage 2 translation of a stage 1 translation table walk, then all of the following apply:

- If SCR_EL3.EA is 0, then all of the following apply:
  - The exception is taken to EL2.
  - ESR_EL2.ISS[7] is 1 to indicate a stage 2 fault during a stage 1 translation table walk.
- If SCR_EL3.EA is 1, then all of the following apply:
  - The exception is taken to EL3.
— ESR_EL3.ISS[7] is 1 to indicate a stage 2 fault during a stage 1 translation table walk.

- The part of the ISS field that might contain details of the instruction is invalid.

IZGDIIH
If the stage 2 translation of a stage 1 translation table walk returns a Device memory type, then the value of HCR_EL2.PTW determines all of the following:

- If the value is 0, the translation table walk access is permitted and treated as an access to Normal, Non-cacheable memory.
- If the value is 1, the translation table walk access generates a stage 2 Permission fault.

IVXKVL
If the stage 2 translation of a stage 1 translation table lookup maps to Device memory, it likely indicates a Guest OS error where the stage 1 translation table is corrupted, and it is appropriate to trap this access to the hypervisor.

ILWGSL
If software updates HCR_EL2.PTW without changing the current VMID, then the software is required to invalidate the TLBs because they might hold entries that depend on the effect of HCR_EL2.PTW.

IHPGQN
For more information, see Permission fault on page D8-5183.

The lookup level associated with MMU faults

IXCCCM
For MMU faults, the Data Fault Status Code (DFSC) and Instruction Fault Status Code (IFSC) in the ESR_ELx report the translation lookup level associated with a given MMU fault type.

ICRKPZ
When an MMU fault is generated, all of the following determine the lookup level associated with the fault:

- For a fault generated by a translation table walk, the lookup level at which the fault occurred.
- For a Translation fault, one of the following:
  — The lookup level at which the fault occurred.
  — If a fault is generated because translation table walks are disabled by TCR_ELx.EPD[n], the IA is outside the range specified by the associated TTBR_ELx, or FEAT_E0PD is enabled and prevents access to addresses translated by TTBRn_ELx, then the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level at which the fault occurred.
- For a Permission fault, including a Permission fault generated by hierarchical permissions, the final lookup level that returned the Block descriptor or Page descriptor.

ICIZVP
For more information, see Permission fault on page D8-5183.

D8.11.5 MMU fault prioritization from a single address translation stage

RXCHFJ
For a single translation stage in a VMSA8-64 translation regime, the following numbered list shows the possible MMU faults on a memory access, from highest priority to lowest priority, and includes where stage 2 faults that are generated within a stage 1 translation table walk are prioritized:

1. For a stage 1 translation, an Alignment fault not caused by memory type.
2. If one or more of the following is true, then a Translation fault:
   - The IA out of the translated address range.
   - For a stage 1 translation, the IA requiring a TTBR_ELx that is disabled.
   - For a stage 2 translation, VTCR_EL2.SL0 is inconsistent with VTCR_EL2.T0SZ.
   - For a stage 2 translation, VSTCR_EL2.SL0 is inconsistent with VSTCR_EL2.T0SZ.
   - For a stage 2 translation, SL0 is programmed to a reserved value.
   - For a stage 2 translation, the Effective value of VTCR_EL2.DS is 1 and VTCR_EL2.{SL2, SL0} is inconsistent with VTCR_EL2.T0SZ.
   - For a stage 2 translation, the Effective value of VTCR_EL2.DS is 1 and VSTCR_EL2.{SL2, SL0} is inconsistent with VSTCR_EL2.T0SZ.
   - For a stage 2 translation, the Effective value of VTCR_EL2.DS is 1 and {SL2, SL0} is programmed to a reserved value.
3. If one or more of the following is true, an Address size fault on the address in TTBR_ELx:
   • The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The programmed address is outside the implemented range.
4. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level -1 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
5. A synchronous parity or ECC error on a level -1 lookup of a translation table walk.
6. A synchronous External abort on a level -1 lookup of a translation table walk.
7. Translation fault on a level -1 translation entry.
8. If one or more of the following is true, an Address size fault on the address in a level -1 lookup translation table entry:
   • The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The OA is out of the implemented range.
9. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level 0 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
10. A synchronous parity or ECC error on a level 0 lookup of a translation table walk.
11. A synchronous External abort on a level 0 lookup of a translation table walk.
12. Translation fault on a level 0 translation table entry.
13. If one or more of the following is true, an Address size fault on the address in a level 0 lookup translation table entry:
   • The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The OA is out of the implemented range.
14. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level 1 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
15. A synchronous parity or ECC error on a level 1 lookup of a translation table walk.
16. A synchronous External abort on a level 1 lookup of a translation table walk.
17. Translation fault on a level 1 translation table entry.
18. If one or more of the following is true, an Address size fault on the address in a level 1 lookup translation table entry:
   • The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The OA is out of the implemented range.
19. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level 2 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
20. A synchronous parity or ECC error on a level 2 lookup of a translation table walk.
22. Translation fault on a level 2 translation table entry.
23. If one or more of the following is true, an Address size fault on the address in a level 2 lookup translation table entry:
   • The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The OA is out of the implemented range.
24. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level 3 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
25. A synchronous parity or ECC error on a level 3 lookup of a translation table walk.
27. Translation fault on a level 3 translation table entry.
28. If one or more of the following is true, an Address size fault on the address in a level 3 lookup translation table entry:
   • The address size check on TCR_EL1.IPS, TCR_EL2.(I)PS, TCR_EL3.PS, or VTCR_EL2.PS fails.
   • The OA is out of the implemented range.
30. Alignment fault caused by the memory type.
31. Permission fault.
32. If stage 2 address translation is enabled, then a stage 2 fault on the memory access, including an Address size fault caused by a PA outside the implemented range.
33. Synchronous parity or ECC error on the memory access.
34. Synchronous External abort on the memory access.

If all the following apply, the prioritization between the stage 2 Permission fault on the stage 1 translation table walk and the stage 1 abort caused by the stage 1 Block descriptor or Page descriptor is IMPLEMENTATION DEFINED:
   • Hardware management of the stage 1 access flag or dirty state is enabled.
   • The access flag or dirty state in a stage 1 Block descriptor or Page descriptor needs to be updated.
   • For the location of the stage 1 Block descriptor or Page descriptor, the stage 2 translation has read permission but not write permission.
   • The stage 1 Block descriptor or Page descriptor generates an abort, which can be due to an Address size fault, an Alignment fault caused by memory type, or a Permission fault.

For more information, see Hardware management of the dirty state on page D8-5145.

For a TLB conflict abort, all of the following apply:
   • The priority of the abort is IMPLEMENTATION DEFINED.
   • The priority of the abort is required to be higher than any abort that depends on a value held in a TLB.

The cause of a TLB conflict abort depends on the TLB implementation.

For an IMPLEMENTATION DEFINED MMU fault caused by a Load-Exclusive or Store-Exclusive to an unsupported memory type, the priority is IMPLEMENTATION DEFINED.

For an MMU fault at a translation stage caused by an unsupported atomic hardware update, the priority of this fault lies at an IMPLEMENTATION DEFINED point between all of the following:
   • A priority immediately higher than an Access flag fault generated by the same translation stage as this MMU fault.
   • A priority immediately lower than a Permission fault generated by the same translation stage as this MMU fault.
## D8.12 Translation Lookaside Buffers

The Arm architecture does not specify any structure of *Translation Lookaside Buffers* (TLBs), and permits any structure that complies with the requirements described in this section.

**Translation table entries that generate a Translation fault, an Address size fault, or an Access flag fault are never cached in a TLB.**

When address translation is enabled, a translation table entry for an in-context translation regime that does not cause a Translation fault, an Address size fault, or an Access flag fault is permitted to be cached in a TLB or intermediate TLB caching structure as the result of an explicit or speculative access.

When address translation is enabled, if a translation table entry meets all of the following requirements, then that translation table entry is permitted to be cached in a TLB or intermediate TLB caching structure at any time:

- The translation table entry itself does not generate a Translation fault, an Address size fault, or an Access flag fault.
- The translation table entry is not from a translation regime configured by an Exception level that is lower than the current Exception level.

The Arm architecture permits TLBs to cache certain information from System control registers, including when any or all translation stages are disabled. The individual register descriptions specify System control register fields are permitted to be cached in a TLB.

For more information, see Chapter D17 *AArch64 System Register Descriptions*.

The TLB entries in all of the following translation regimes are out-of-context:

- When executing at EL3 or EL2, the TLB entries associated with the EL1&0 translation regime are out-of-context.
- When executing at EL3, the TLB entries associated with the EL2 or EL2&0 translation regime are out-of-context.

The VMSA provides TLB maintenance instructions for the management of TLB contents.

When a translation stage is disabled and then re-enabled, TLB entries are not corrupted.

### D8.12.1 TLB behavior at reset

When a reset occurs, an implementation is not required to automatically invalidate a TLB.

When a reset occurs, a TLB is affected in all of the following ways:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- It is IMPLEMENTATION DEFINED whether a specific TLB invalidation routine is required to invalidate a TLB before translation is enabled after a reset.

For the ELx reset is taken to, when a reset occurs, SCTLR_ELx.M is reset to 0. For the translation regime controlled by that SCTLR_ELx.M bit, when SCTLR_ELx.M is 0, TLB contents have no effect on address translation.

If an implementation requires a specific TLB invalidation routine, then all of the following apply:

- The routine is IMPLEMENTATION DEFINED.
- The implementation documentation is required to clearly document the routine.
- Arm recommends that the routine is based on the TLB maintenance instructions.

On a Cold reset or Warm reset, an implementation might require TLBs to maintain their contents from before the reset, including one or more of the following reasons:

- Power management.
- Debug requirements.

For more information on the TLB maintenance instructions used in a TLB invalidation routine, see *TLB maintenance instructions* on page D8-5201.
D8.12.2 TLB lockdown

TLB lockdown support is IMPLEMENTATION DEFINED.

If an implementation supports TLB lockdown, then all of the following apply:

- The lockdown mechanism is IMPLEMENTATION DEFINED.
- The implementation documentation is required to clearly document the interaction of the TLB lockdown mechanism with the architecture.
- A locked TLB entry is guaranteed to remain in the TLB, unless the locked TLB entry is affected by a TLBI operation.
- An unlocked TLB entry is not guaranteed to remain in the TLB.
- If a translation table entry is modified, then it is not guaranteed that a locked TLB entry remains coherent with the modified translation table entry.

If a translation table entry is modified, then it is not guaranteed that a locked TLB entry remains incoherent with the modified translation table entry because the lockdown mechanism might permit a TLB maintenance instruction to trigger an update of the locked TLB entry.

For more information, see The interaction of TLB lockdown with TLB maintenance instructions on page D8-5200.

The implementation is permitted to use the reserved IMPLEMENTATION DEFINED register encodings to implement TLB lockdown functions.

TLB lockdown functions might include, but are not limited to, all of the following:

- Unlock all locked TLB entries.
- Preload a translation table entry into a specific TLB level.

If an implementation supports TLB lockdown and EL2 is enabled, then when executing at EL1 or EL0, an exception due to TLB lockdown can be routed to one of the following:

- EL1, as a Data Abort exception.
- EL2, as a Hyp Trap exception.

D8.12.3 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

TLB maintenance can be reduced during context switches by associating the translation table lookups from some translation regimes with an address space identifier (ASID), virtual machine identifier (VMID), or both.

Global and process-specific translation table entries

For translation regimes that use an ASID, it is possible to mark translations as global or non-global.

A TLB entry associated with a specific ASID value, or a specific ASID and a VMID value, can only be used to translate a VA in a context that is associated with the same ASID value, or ASID and VMID value.

For stage 1 of a translation regime that supports two privilege levels, non-global TLB entries are associated with a specific ASID.

For stage 1 of a translation regime that can support two privilege levels, Arm expects that software configures translations specific to a process to be associated with a specific ASID.

For all of the following, the translation does not support association of a translation with an ASID, and all translations are treated as global:

- A stage 1 translation that supports a single privilege level
- The stage 2 component of a two stage translation.

The ASID permits software to switch between process-specific translation table mappings without removing previous mappings cached for another ASID from a TLB.
For stage 1 of a translation regime that can support two privilege levels, each TTBR0_ELx and TTBR1_ELx has an ASID field.

All the following values of TCR_ELx.A1 determine the ASID value that is used by the translations of both the lower VA range and upper VA range:
- If the value is 0, then the TTBR0_ELx.ASID is used.
- If the value is 1, then the TTBR1_ELx.ASID is used.

The nG bit in a Block descriptor and Page descriptor indicates one of the following:
- If the value is 0, the translation is global and the TLB entry applies to all ASID values.
- If the value is 1, the translation is non-global and the TLB entry applies to only the current ASID value.

For a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final lookup level are treated as non-global, regardless of the value of the nG bit in the final lookup level.

For a translation in Secure state, if the NSTable bit in a Table descriptor is 1 at any level of the translation table walk, then the resulting translation is treated as non-global, regardless of the nG bit value in the Block descriptor or Page descriptor for the translation.

If EL2 is enabled, then for the EL1&0 translation regime, TLB entries created for the regime are associated with the current VMID.

If EL2 is enabled, then for the EL1&0 translation regime, TLB entries are associated with the current VMID in all cases, and include all of the following:
- For both global and non-global translations of any ASID value, and regardless of whether stage 2 translation is disabled, TLB entries containing information from stage 1 translation.
- For both stage 1 translation table walks and stage 1 OA, and regardless of whether stage 1 translation is disabled, TLB entries containing information from stage 2 translations.

If EL2 is enabled, then for the EL1&0 translation regime, TLB entries associated with a VMID are associated with a specific virtual machine.

The VMID permits software to switch between virtual machines that have different VMIDs without removing previous translation table mappings from a TLB.

VTTBR_EL2.VMID holds the current VMID.

ASID size

The ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

The maximum supported ASID size is indicated by ID_AA64MMFR0_EL1.ASIDBits.

For an implementation that supports 16-bit ASIDs, all of the following values of TCR_ELx.AS specify whether TTBR0_ELx.ASID[15:8] are used:
- If TCR_ELx.AS is 0, then TTBR0_ELx.ASID[15:8] are not used and are treated in all of the following ways:
  - For every purpose other than direct reads of TTBR0_ELx.ASID and TTBR1_ELx.ASID, the bits are ignored by hardware.
  - When used for allocating and matching entries in a TLB, the bits are treated as if they are all zeros.
- If TCR_ELx.AS is 1, then TTBR0_ELx.ASID[15:8] are used for allocating and matching entries in a TLB.

Bits[15:8] of the ASID field in TLBI instructions are considered by hardware regardless of the value of TCR_ELx.AS.

For a translation using VMSAv8-32, if the implementation supports 16-bit ASIDs, then the 8-bit ASID used is zero-extended to 16 bits.

The AArch32 ASID size is 8 bits.
VMID size

The VMID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

The maximum supported VMID size is specified by ID_AA64MMFR1_EL1.VMIDBits.

If and only if EL2 is using AArch64, then use of a 16-bit VMID is permitted.

For an implementation that supports a 16-bit VMID, all of the following values of VTCR_EL2.VS specify whether VTTBR_EL2.VMID[15:8] are used:

- If VTCR_EL2.VS is 0, then VTTBR_EL2.VMID[15:8] are not used and are treated in all of the following ways:
  - For every purpose other than direct reads of VTTBR_EL2.VMID, the bits are ignored by hardware.
  - When used for allocating and matching entries in a TLB, the bits are treated as if they are all zeros.
- If VTCR_EL2.VS is 1, then VTTBR_EL2.VMID[15:8] are used.

Common not private translations

FEAT_TTCNP allows multiple PEs in the same Inner Shareable domain and operating in the same translation regime to use the same translation table entries in a given translation stage.

If all of the following conditions are met, translation table entries pointed to by TTBR_ELx are shared with all other PEs in the Inner Shareable domain, and are referred to as common not private translation tables:

- For the PEs that share the translation tables, the Effective value of the corresponding TTBR_ELx.CnP is 1.
- For the PEs that share the translation tables, the same translation regime in the same Security state applies to the corresponding TTBR_ELx.
- If an ASID applies to the corresponding translation stage, then all of the PEs that share non-global translation table entries are required to have the same current ASID.
- If a VMID applies to the corresponding translation stage, then all of the PEs that share translation table entries are required to have the same current VMID.

For a common not private translation table, if a System register field with all of the following characteristics is set by a particular PE to a value that is different than the value set by the other PEs, then it is CONSTRAINED UNPREDICTABLE whether the System register field is interpreted using the value of the particular PE or the value of one of the other PEs that are sharing the translation table entry:

- The register field applies to the translation stage.
- The register field is permitted to be cached in a TLB.

For a translation regime with both stage 1 and stage 2 translations, a TLB entry can be shared between different PEs in one or more of the following cases only if the value of the TTBR_ELx.CnP bit is 1 for both stages of translation:

- The TLB entry holds information from stage 1 translation only.
- The TLB entry combines information from stage 1 and stage 2 translations.

The TTBR_ELx.CnP bit is permitted to be cached in a TLB.

For a common not private translation table, if a TTBR_ELx does not point to the same translation table as the other TTBR_ELx registers, then the system is misconfigured and an address translation using that TTBR_ELx causes one of the following to occur:

- Multiple hits in a TLB, which is permitted to generate a TLB conflict abort.
- A CONSTRAINED UNPREDICTABLE result due to caching of control or data values.

For more information, see TLB conflict abort on page D8-5183 and CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-11585.
D8.13 TLB maintenance

For the purpose of TLB maintenance, a TLB entry is any structure that holds a translation table entry, including intermediate TLB caching structures and temporary working registers in translation table walk hardware.

When a translation table walk occurs, translation table entries that are permitted to be cached in a TLB might be held in TLB caching structures.

Entries held in a TLB are distinguished by all of the following context information:

- The Security state and translation regime.
- If applicable to the translation regime, then the VMID.
- If applicable to the translation regime, then whether the translation is global or non-global.
- If the translation is non-global, then the ASID.

TLBs, or TLB caching structures, are not guaranteed to remain coherent with changes to translation table entries, and are therefore distinct from data caches.

Indexing an intermediate TLB structure by the IA is permitted.

If FEAT_nTLBPA is not implemented, then indexing an intermediate TLB structure by all of the following is also permitted:

- The PA of the location holding the translation table entry.
- For stage 1 translations, the IPA of the location holding the translation table entry.

If FEAT_nTLBPA is not implemented, any TLB maintenance instruction that applies to a PE with the context information that is relevant to the translation table entry ensures cached copies of translation table entries are invalidated for that PE in all of the following implementations of intermediate TLB structures:

- Indexing the TLB using the PA of the location holding the translation table entry.
- For stage 1 translations, indexing the TLB using the IPA of the location holding the translation table entry.

FEAT_nTLBPA permits software to determine the existence of intermediate TLB caching structures that are indexed by PA or IPA and perform TLB maintenance accordingly when it would otherwise not be required.

When a TLB maintenance instruction targets only stage 1 entries, all of the following apply:

- The maintenance applies to any entries in caching structures that include stage 1 information used to translate the address or range of addresses being invalidated.
- If the TLB maintenance targets a specific ASID, then entries in caching structures that are not tagged with the specific ASID are not invalidated.
- If the stage 1 translation information contained in a single block or page has been collectively cached in multiple TLB entries, then all entries containing that stage 1 information are invalidated, regardless of whether the entry would be used to translate the address being invalidated.

When a TLB maintenance instruction applies only to stage 2 entries, all of the following apply:

- The maintenance applies to any entries in caching structures that include only stage 2 information used to translate the address or range of addresses being invalidated.
- If the stage 2 translation information contained in a single block or page has been collectively cached in multiple TLB entries, then all entries containing that stage 1 information are invalidated, regardless of whether the entry would be used to translate the address being invalidated.
- The maintenance is not required to apply to structures combining stage 1 and stage 2 information used to translate the address or range of addresses being invalidated.

When a TLB maintenance instruction applies to both stage 1 and stage 2 entries, all of the following apply:

- The maintenance applies to any entries in caching structures that include stage 1 information used to translate the address or range of addresses being invalidated.
- The maintenance applies to any entries in caching structures that include stage 2 information used to translate the address or range of addresses being invalidated.
• The maintenance applies to structures combining stage 1 and stage 2 information used to translate the address or range of addresses being invalidated.

When a translation table entry associated with a specific VMID or ASID is modified, software is required to invalidate the corresponding TLB entry to ensure that the modified translation table entry is visible to subsequent execution, including speculative execution.

When a System register field is modified and that field is permitted to be cached in a TLB, software is required to invalidate all TLB entries that might be affected by the field, at any address translation stage in the translation regime even if the translation stage is disabled, using the appropriate VMID and ASID, after any required System register synchronization.

For more information, see Synchronization requirements for AArch64 System registers on page D17-5547.

When a translation table entry that generates a Translation fault, Address size fault, or Access flag fault is changed to one that does not fault, all of the following apply to software:

• TLB invalidation is not required because an entry that generates one of the listed faults is never cached in a TLB.

• A Context synchronization event is required to ensure that the completed change to the translation table entry affects subsequent instruction fetches.

D8.13.1 Using break-before-make when updating translation table entries

If multiple execution threads use the same translation tables, then when a translation table entry is modified in one or more of the following ways, the architecture requires software to use a break-before-make sequence:

• A change to the memory type, Shareability or Cacheability.

• The translation OA is changed and one or more of the following apply:
  — Either or both of the old and new translations grant write permission, including cases where the DBM bit is set and hardware updates of the dirty state is enabled.
  — The memory contents at the new OA do not match the memory contents at the previous OA.

• If the requirements enabled by FEAT_BBM level 1 or above cannot be followed, all of the following changes to the block size used by the translation system:
  — Changing from a smaller size to a larger size, such as when a stage 2 Table descriptor is replaced with a Block descriptor.
  — Changing from a larger size to a smaller size, such as when a stage 2 Block descriptor is replaced with a Table descriptor.

• A global entry is created that might overlap with non-global entries in a TLB.

A change to the translation OA space is considered a change to the translation OA.

Use of a break-before-make sequence to ensure that old and new translation table entries are never simultaneously visible to different execution threads is guaranteed to prevent all of the following problems:

• Creating multiple TLB entries that apply to the same address.

• The effects of TLB caching breaking coherency.

• The effects of TLB caching breaking single-copy atomicity properties.

• The effects of TLB caching breaking ordering guarantees or uniprocessor semantics.

• The effects of TLB caching causing a failure to clear the Exclusives monitors.

A break-before-make sequence requires all of the following steps:

1. Replace the old translation table entry with an invalid entry.
2. Execute a DSB instruction to ensure the invalid entry is visible.
3. Invalidate TLB entries based on the translation table entry with a broadcast TLB invalidation instruction.
4. Execute a DSB instruction to ensure the invalidation completes.
5. Write the new translation table entry.
6. Execute a DSB instruction to ensure the new entry is visible.

For a translation stage with AF hardware management enabled, if a translation table entry is modified and the break-before-make sequence is not followed, then all of the following failures associated with AF hardware updates can occur:

- When a memory location associated with that translation table entry is accessed, the AF is not set.
- When hardware updates to that translation table entry are followed by stores appearing later in program order, the ordering required is not followed.

For a translation stage with dirty state hardware management enabled, if a translation table entry is modified and the break-before-make sequence is not followed, then all of the following failures associated with dirty state hardware updates can occur:

- When a memory location associated with that translation table entry is not written, hardware modifies the AP[2] or S2AP[1] descriptor bit.
- When a memory location associated with that translation table entry is written, hardware does not modify the AP[2] or S2AP[1] descriptor bit.
- When hardware updates to that translation table entry are followed by stores appearing later in program order, the ordering required is not followed.

### D8.13.2 Support levels for changing block size

All statements in this section require implementation of FEAT_BBM.

When a translation table entry is modified to change the block size, the hardware provides one of the following possible support levels affecting the break-before-make requirement to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors:

- If level 0 is supported, then software is required to use break-before-make.
- If level 1 is supported, then software can use the level 0 approach or use the block translation entry bit, nT, in the Block descriptor.
- If level 2 is supported, then all of the following apply:
  - Software can use the level 0 approach or the level 1 approach.
  - Changing block size does not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors.

For more information, see [Block translation entry](#) on page D8-5160.

If any level is supported and the TLB entries are not invalidated after the writes that modified the translation table entries are completed, then a TLB conflict abort can be generated because in a TLB there might be multiple translation table entries that all translate the same IA.

For more information, see [TLB conflict abort](#) on page D8-5183.

If level 1 or level 2 is supported, then changing the Contiguous bit in a set of Block descriptors or Page descriptors can be done without breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors.

If level 1 or level 2 is supported and the Contiguous bit in a set of Block descriptors or Page descriptors is changed, then a TLB conflict abort can be generated because multiple translation table entries might exist within a TLB that translates the same IA.

If all of the following apply, then a TLB conflict abort is reported to EL2:

- Level 1 or level 2 is supported.
- Stage 2 translations are enabled in the current translation regime.
- A TLB conflict abort is generated due to changing the block size or Contiguous bit.

If level 1 or level 2 is supported and a TLB conflict abort is generated, then TLB maintenance is required to remove the multiple TLB entries that translate the same address.
For more information, see *TLB maintenance due to TLB conflict*.

When a TLB conflict abort is generated, it is IMPLEMENTATION DEFINED whether it is a stage 1 abort or a stage 2 abort.

D8.13.3 TLB maintenance due to TLB conflict

If multiple TLB entries translate the same address, then the ALL or VMALL form of a TLB maintenance instruction that targets the given translation regime is guaranteed to remove all TLB entries within that regime.

All of the following instructions are guaranteed to remove the TLB entries associated with a conflict:

- For the EL1&0 translation regime, when stage 2 translations are in use, either TLBI VMALLS1E1 or TLBI ALLE1.
- For the EL1&0 translation regime, when stage 2 translations are not in use, either TLBI VMALLE1 or TLBI ALLE1.
- For the EL2&0 translation regime, either TLBI VMALLE1 or TLBI ALLE2.
- For the EL2 translation regime, TLBI ALLE2.
- For the EL3 translation regime, TLBI ALLE3.

If multiple TLB entries translate the same address, then the minimum set of TLB maintenance operations required to guarantee all TLB entries associated with that address and translation regime have been invalidated is IMPLEMENTATION DEFINED.

D8.13.4 The interaction of TLB lockdown with TLB maintenance instructions

If a TLB entry is locked and a TLB invalidate all instruction is executed and, if that entry was not locked the TLB invalidate all instruction would invalidate that entry, then one of the following IMPLEMENTATION DEFINED behaviors occur:

- The locked TLB entry is not affected.
- If the TLB entry is locked or might be locked, an IMPLEMENTATION DEFINED Data Abort exception is generated.

The IMPLEMENTATION DEFINED Data Abort on a TLB invalidate all instruction permits TLB invalidation routines to choose to invalidate a large range of addresses, without considering whether any TLB entries are locked, or to not affect locked TLB entries.

If a TLB entry is locked and a TLB invalidate by VA or invalidate by ASID instruction is executed and, if that entry was not locked the TLB invalidate by VA or invalidate by ASID instruction would invalidate that entry, then one of the following IMPLEMENTATION DEFINED behaviors occur:

- The locked TLB entry is invalidated.
- The locked TLB entry is not affected.
- If the TLB entry is locked or might be locked, an IMPLEMENTATION DEFINED Data Abort exception is generated.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults.

If an implementation uses an abort mechanism when entries that can be locked down are not actually locked down, then all of the following are required:

- The IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down are documented.
- An IMPLEMENTATION DEFINED mechanism is documented that ensures no TLB entries are locked.
- For locked entries, one of the other specified alternatives is implemented.

If an implementation supports TLB lockdown, then Arm recommends that IMPLEMENTATION DEFINED TLB maintenance instruction sequences use the architecturally-defined operations to minimize the number of customized operations required.

For more information on TLB lockdown, see *TLB lockdown* on page D8-5194.
D8.13.5 TLB maintenance instructions

For a given translation regime, the architecture defines TLB maintenance instructions that provide all of the following functions:

- Invalidate all corresponding entries in a TLB.
- Invalidate a corresponding single TLB entry by ASID for a non-global entry.
- Invalidate all corresponding TLB entries that match a specific ASID.
- Invalidate all corresponding TLB entries that match a specific VA, regardless of the ASID.
- Invalidate all corresponding TLB entries within a range of addresses.

Each TLB maintenance instruction can be applied to one of the following:

- Only the PE that executes the instruction
- All PEs in the same Shareability domain as the PE that executes the instruction.

The A64 assembly language syntax of a TLB maintenance instruction is TLBI <operation>{, <Xt>}

The <operation> in TLBI <operation>{, <Xt>} is one of the following:

- ALLE1{NXS}, ALLE2{NXS}, ALLE3{NXS}, ALLE1IS{NXS}, ALLE2IS{NXS}, ALLE3IS{NXS}, ALLE1OS{NXS}, ALLE2OS{NXS}, or ALLE3OS{NXS}.
- VMALLE1{NXS}, VMALLE1IS{NXS}, VMALLE1OS{NXS}, VMALLE1E1{NXS}, VMALLE1E1IS{NXS}, or VMALLE1E1OS{NXS}.
- ASIDE1{NXS}, ASIDE1IS{NXS}, or ASIDE1OS{NXS}.
- {R}VA{L}E1{NXS}, {R}VA{L}E1IS{NXS}, {R}VA{L}E1OS{NXS}, {R}VA{L}E2{NXS}, {R}VA{L}E2IS{NXS}, {R}VA{L}E2OS{NXS}, or {R}VA{L}E3{NXS}.
- {R}VAA{L}E1{NXS}, {R}VAA{L}E1IS{NXS}, or {R}VAA{L}E1OS{NXS}.
- {R}IPAS2{L}E1{NXS}, {R}IPAS2{L}E1IS{NXS}, or {R}IPAS2{L}E1OS{NXS}.

The <operation> in TLBI <operation>{, <Xt>} has a structure of {R}<type><regime><shareability>{NXS} with all of the following components:

- R is optional and determines one of the following:
  - When present, the instruction applies to all TLB entries translating addresses within the address range.
  - When not present, the instruction applies to all TLB entries translating a single address that could be used by the PE that executes the TLBI instruction.
- <type> is one of the following:
  - ALL specifies all translations at <regime>.
  - VA{L} specifies all translations at <regime> using the supplied address and, if an ASID is supplied, the supplied ASID or global entries.
  - VA{L}E1{NXS}, VA{L}E1IS{NXS}, or VA{L}E1OS{NXS}.
  - VMALLE1{NXS}, VMALLE1IS{NXS}, or VMALLE1OS{NXS}.
  - ASIDE1{NXS}, ASIDE1IS{NXS}, or ASIDE1OS{NXS}.
  - {R}VA{L}E1{NXS}, {R}VA{L}E1IS{NXS}, or {R}VA{L}E1OS{NXS}.
  - {R}IPAS2{L}E1{NXS}, {R}IPAS2{L}E1IS{NXS}, or {R}IPAS2{L}E1OS{NXS}.

- <regime> is one of the following Exception levels:
  - If E1, then EL1.
  - If E2, then EL2.
  - If E3, then EL3.
<shareability> is one of the following:
- IS indicates that the instruction applies to all TLBs in the Inner Shareable domain.
- OS indicates that the instruction applies to all TLBs in the Outer Shareable domain.
- The parameter is optional, and no value indicates that the instruction applies to all TLBs that could be used by the PE that executes the instruction.

NXS has all of the following properties:
- The parameter is optional.
- When present, the instruction is considered complete after all issued memory transactions using translation information held in TLB entries that have the associated XS attribute set to 0 and are within the scope of the instruction, are complete.
- When not present, the instruction is considered complete after all issued memory transactions using translation information held in TLB entries that are within the scope of the instruction are complete, regardless of the XS attribute value.
- The parameter can only be present when FEAT_XS is implemented.

If <regime> is higher than the current Exception level, then the TLB maintenance instruction is UNDEFINED.

All TLB maintenance instructions are UNDEFINED at EL0.

TLBI ALLE1{NXS}, TLBI ALLE1IS{NXS}, TLBI ALLE1OS{NXS}, TLBI {R}IPAS2(L)E1{NXS}, TLBI {R}IPAS2(L)E1IS{NXS}, TLBI {R}IPAS2(L)E1OS{NXS}, TLBI VMALLS12E1{NXS}, and TLBI VMALLS12E1IS{NXS} and TLBI VMALLS12E1OS{NXS} are UNDEFINED at EL1.

If EL2 is not implemented, the TLBI {R}VA{L}E2{NXS}, TLBI {R}VA{L}E2IS{NXS}, TLBI {R}VA{L}E2OS{NXS}, TLBI ALLE2{NXS}, TLBI ALLE2IS{NXS}, and TLBI ALLE2OS{NXS} instructions are UNDEFINED.

When a TLB entry is invalidated by one PE, it is inconsistent with the architecture to allow another PE to refill that TLB entry so that the new entry gives the appearance to software that the invalidation did not occur.

The <Xt> in TLBI <operation>{, <Xt>} has all of the following properties:
- It specifies a register that passes one or both of an address and an ASID as an argument.
- For operations that include a VA, if FEAT_TTL is implemented, then the register passes the level hint.
- For range-based TLBI operations, then the register passes information about the address range.
- It is required by the TLBI ASID, TLBI {R}VA{L}, TLBI {R}VAA{L}, and TLBI {R}IPAS2{L} instructions.

**TLB maintenance instructions that do not apply to a range of addresses**

For TLB maintenance instructions that take a VA, an ASID, or both as an argument, and that do not apply to a range of addresses, the register specified by the Xt argument has the following format:
- Register bits[63:48] are one of the following:
  - If the instruction requires an ASID argument, the ASID.
  - If the instruction does not require an ASID argument, RES0.
- If FEAT_TTL is not implemented, then register bits[47:44] are RES0.
- If FEAT_TTL is implemented, then register bits[47:44] are one of the following:
  - If the instruction requires a VA argument, the translation table level hint, TTL.
  - If the instruction does not require a VA argument, RES0.
- Register bits[43:0] are one of the following:
  - If the instruction requires a VA argument, VA[55:12].
  - If the instruction does not require a VA argument, RES0.

For TLB maintenance instructions that take a VA, hardware interprets VA[63:56] as each having the same value as VA[55].
**RFGPTT**

For TLB maintenance instructions that take a VA, if the instruction targets a translation regime that is using AArch32, then all of the following apply:

- Software is required to treat VA[55:32] as RES0.
- VA[55:32] are ignored when the instruction is executed, and interpreted as being zero.
- VA[63:56] are interpreted as being zero.

**ILHKCP**

If the implementation supports 16-bit ASIDs, then software is required to set the upper 8 bits of the ASID to 0 when the context being invalidated uses only 8 bits.

**ICPNYZ**

For TLB maintenance instructions that take a register argument that holds an IPA and that do not apply to a range of addresses, the register specified by the Xt argument has the following format:

- Register bit[63] is one of the following:
  - If the instruction is executed in Secure state, the NS bit specifying the Secure or Non-secure IPA space.
  - If the instruction is executed in Non-secure state, RES0.
- If FEAT_TTL is not implemented, then register bits[62:40] are RES0.
- If FEAT_TTL is implemented, then all of the following apply:
  - Register bits[62:48] are RES0.
  - Register bits[47:44] are the translation table level hint, TTL.
  - Register bits[43:40] are RES0.
- Register bits[39:36] are one of the following:
  - If 52-bit addresses are supported, IPA[51:48].
  - If 52-bit addresses are not supported, RES0.
- Register bits[35:0] are IPA[47:12].

**IHQTLK**

For TLB maintenance instructions that take a register argument that holds a VA or an IPA, register bits that hold the address have all of the following properties:

- If the 4KB granule size is used, all address bits in the register bits are used by the invalidation instruction.
- If the 16KB granule size is used, register bits[1:0] are ignored because address bits[13:12] have no effect on the invalidation instruction.
- If the 64KB granule size is used, register bits[3:0] are ignored because address bits[15:12] have no effect on the invalidation instruction.

**TLB maintenance instructions that apply to a range of addresses**

**IQPHNP**

For TLB maintenance instructions that take a VA, or a VA and an ASID, and that apply to a range of addresses, the register specified by the Xt argument has the following format:

- Register bits[63:48] are one of the following:
  - If the instruction requires an ASID argument, the ASID.
  - If the instruction does not require an ASID argument, RES0.
- Register bits[47:46] are the translation granule size, TG.
- Register bits[45:44] are the SCALE field that is the exponent element of the calculation that produces the upper range.
- Register bits[43:39] are the NUM field that is the base element of the calculation that produces the upper range.
- If FEAT_TTL is not implemented, then register bits[38:37] are RES0.
- If FEAT_TTL is implemented, then register bits[38:37] are the translation table level hint, TTL.
- Register bits[36:0] give the starting address of the range of addresses, BaseADDR.
For TLB maintenance instructions that take a register argument that holds an IPA and that apply to a range of addresses, the register specified by the \texttt{Xt} argument has the following format:

- Register bit[63] is one of the following:
  - If the instruction is executed in Secure state, the NS bit specifying the Secure or Non-secure IPA space.
  - If the instruction is executed in Non-secure state, RES0.
- Register bits[62:48] are RES0.
- Register bits[47:46] are the translation granule size, TG.
- Register bits[45:44] are the SCALE field that is the exponent element of the calculation that produces the upper range.
- Register bits[43:39] are the NUM field that is the base element of the calculation that produces the upper range.
- If \texttt{FEAT_TTL} is not implemented, then register bits[38:37] are RES0.
- If \texttt{FEAT_TTL} is implemented, then register bits[38:37] are the translation table level hint, TTL.
- Register bits[36:0] specify the starting address of the range of addresses, BaseADDR.

For TLB instructions that apply to a range of addresses, the following table shows the TG field encodings that define the translation granule size for the translations that are being invalidated, and the Translation\_Granule\_Size in bytes used in determining the address range.

<table>
<thead>
<tr>
<th>TG</th>
<th>Translation granule size</th>
<th>Translation_Granule_Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved</td>
<td>N/A</td>
</tr>
<tr>
<td>01</td>
<td>4KB translation granule</td>
<td>4096</td>
</tr>
<tr>
<td>10</td>
<td>16KB translation granule</td>
<td>16384</td>
</tr>
<tr>
<td>11</td>
<td>64KB translation granule</td>
<td>65536</td>
</tr>
</tbody>
</table>

For TLB instructions that apply to a range of addresses, if the translations use a different translation granule size than the one specified by the TG field, then the architecture does not require that the instruction invalidate those entries.

For all TLB range maintenance instructions, TLB entries that translate addresses within the address range determined by the following formula are invalidated:

\[ \text{BaseADDR} <= \text{input\_address} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} +1)} + \text{Translation\_Granule\_Size}) \].

For a TLB range maintenance instruction, BaseADDR is derived from bits[36:0] in the register specified by the \texttt{Xt} argument as one of the following:

- For the 4KB granule size, one of the following:
  - If the \texttt{Effective value} of TCR\_EL1\_DS is 0, then BaseADDR[48:12].
  - If the \texttt{Effective value} of TCR\_EL1\_DS is 1, then BaseADDR[52:16]. In this case, BaseADDR[15:12] is treated as all zero.
- For the 16KB granule size, one of the following:
  - If the \texttt{Effective value} of TCR\_EL1\_DS is 0, then BaseADDR[50:14].
  - If the \texttt{Effective value} of TCR\_EL1\_DS is 1, then BaseADDR[52:16]. In this case, BaseADDR[15:14] is treated as all zero.
- For the 64KB granule size, BaseADDR[52:16].
For all of the following, the invalidated address range is UNPREDICTABLE:

- For the 4KB translation granularity, one of the following:
  - The Effective value of TCR_EL1.DS is 1, the TTL field is \(0b00\), and BaseADDR[38:12] are not all zero.
  - The TTL field is \(0b01\) and BaseADDR[29:12] are not all zero.
  - The TTL field is \(0b10\) and BaseADDR[20:12] are not all zero.

- For the 16KB translation granularity, one of the following:
  - The Effective value of TCR_EL1.DS is 1, the TTL field is \(0b01\), and BaseADDR[35:14] are not all zero.
  - The TTL field is \(0b10\) and BaseADDR[24:14] are not all zero.

- For the 64KB translation granularity, one of the following:
  - The TTL field is \(0b01\) and BaseADDR[41:16] are not all zero.
  - The TTL field is \(0b10\) and BaseADDR[28:16] are not all zero.

For more information, see Broadcast TLB maintenance on page D8-5211.

### Translation table level hint

All statements in this section require implementation of FEAT_TTL.

For the address being invalidated by a TLB maintenance instruction, the TTL field in the register specified by \(X_t\) indicates the lookup level of the translation table walk holding the leaf entry.

Hardware can use the TTL field to determine if the page might have been splintered into multiple TLB entries.

For an entry being invalidated by a TLB maintenance instruction, if an incorrect TTL value is specified, then the architecture does not require any entries to be invalidated from a TLB.

For TLB instructions that apply to a single address, the following table shows the 4-bit TTL field encodings.

<table>
<thead>
<tr>
<th>TTL[3:2]</th>
<th>Translation granule</th>
<th>TTL[1:0]</th>
<th>Information supplied</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>-</td>
<td>RES0</td>
<td>No information supplied about the translation level. Hardware assumes that the leaf entry can be from any level.</td>
</tr>
<tr>
<td>01</td>
<td>4KB</td>
<td>00</td>
<td>If FEAT_LPA2 is not implemented, then this value is reserved, and hardware treats this as if TTL[3:2] is (0b00). If FEAT_LPA2 is implemented, then the leaf entry for the address being invalidated is on level 0 of the translation table walk.</td>
</tr>
<tr>
<td>01</td>
<td></td>
<td>01</td>
<td>The leaf entry for the address being invalidated is on level 1 of the page table walk.</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>00</td>
<td>The leaf entry for the address being invalidated is on level 2 of the page table walk.</td>
</tr>
<tr>
<td>11</td>
<td></td>
<td>00</td>
<td>The leaf entry for the address being invalidated is on level 3 of the page table walk.</td>
</tr>
<tr>
<td>10</td>
<td>16KB</td>
<td>00</td>
<td>This value is reserved, and hardware treats this as if TTL[3:2] is (0b00).</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>01</td>
<td>If FEAT_LPA2 is not implemented, then this value is reserved, and hardware treats this as if TTL[3:2] is (0b00). If FEAT_LPA2 is implemented, then the leaf entry for the address being invalidated is on level 1 of the translation table walk.</td>

The AArch64 Virtual Memory System Architecture

D8.13 TLB maintenance

For TLB instructions that apply to a range of addresses, the following table shows the 2-bit TTL field encodings.

**Table D8-66 TTL field encodings in TLB instructions that apply to a range of addresses**

<table>
<thead>
<tr>
<th>TTL</th>
<th>Information supplied</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>The leaf entries in the range can be using any level for the translation table entries.</td>
</tr>
</tbody>
</table>
| 01   | When the 4KB or 64KB translation granule is used, all leaf entries to invalidate are level 1 translation table entries.  
  If FEAT_LPA2 is not implemented, then when using a 16KB translation granule, this value is reserved, and hardware treats this as if TTL is 0b00.  
  If FEAT_LPA2 is implemented, then when using a 16KB translation granule, all leaf entries to invalidate are level 1 translation table entries. |
| 10   | All leaf entries to invalidate are level 2 translation table entries.                 |
| 11   | All leaf entries to invalidate are level 3 translation table entries.                 |

**TLB maintenance instruction scope**

If `<type>` is `ALL` in a TLB maintenance instruction, then all of the following apply:

- For all values of `<regime>`, the instruction exists.
- For the Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`, the instruction applies to all cached copies of the stage 1 and stage 2 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.
- If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies to cached copies of translation table entries with any VMID.
- For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

If `<type>` is `VMALL` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to all of the following:
  - When `HCR_EL2.[E2H, TGE]` is not {1, 1}, then the EL1&0 translation regime.
  - When `HCR_EL2.[E2H, TGE]` is {1, 1}, then the EL2&0 translation regime.
- For the Security state specified by `SCR_EL3.NS` and `SCR_EL3.EEL2`, the instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.

<table>
<thead>
<tr>
<th>TTL[3:2]</th>
<th>Translation granule</th>
<th>TTL[1:0]</th>
<th>Information supplied</th>

</tr>
<tr>
<td>11</td>
<td></td>
<td>11</td>
<td>The leaf entry for the address being invalidated is on level 3 of the page table walk.</td>
</tr>
</tbody>
</table>
• If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries with the current VMID.

• For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  — Global entries.
  — Non-global entries with any ASID.

RBMMCC

If `<type>` is `VMALLS12` in a TLB maintenance instruction, then all of the following apply:

• If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime.

• For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 and stage 2 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.

• The instruction applies only to cached copies of translation table entries with the current VMID.

• For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  — Global entries.
  — Non-global entries with any ASID.

• If one of the following is true and the instruction is executed at EL3, the instruction is not UNDEFINED and has the same effect as `TLBI VMALL` because there are no stage 2 translations to invalidate:
  — EL2 is not implemented.
  — The Effective value of SCR_EL3.NS is 0 and EL2 is disabled

RFKSVM

If `<type>` is `ASID` in a TLB maintenance instruction, then all of the following apply:

• If and only if the value of `<regime>` is E1, then the instruction applies to all of the following:
  — When HCR_EL2.{E2H, TGE} is not {1, 1}, then the EL1&0 translation regime when executing at EL1.
  — When HCR_EL2.{E2H, TGE} is {1, 1}, then the EL2&0 translation regime when executing at EL2.

• For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.

• If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries with the current VMID.

• The instruction applies only to non-global entries from the final lookup level that matches the specified ASID.

RVMSWQ

If `<type>` is `VA` in a TLB maintenance instruction, then all of the following apply:

• For all values of `<regime>`, the instruction exists.

• For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate the address at the specified Exception level.

• If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries with the current VMID.

• For instructions where the value of `<regime>` is E2, the instruction applies to the EL2&0 or EL2 translation regime, as determined by the value of HCR_EL2.E2H.

• For entries from a translation regime in which an ASID is valid, the instruction applies only to all of the following cached copies of translation table entries:
  — A non-global entry from the final lookup level that matches the specified ASID.
  — A global entry from the final lookup level.

RDRCZZ

If `<type>` is `VAL` in a TLB maintenance instruction, then all of the following apply:

• For all values of `<regime>`, the instruction exists.
For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 translation table entries from the final lookup level in the translation table walk required to translate the address at the specified Exception level.

If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries from the final lookup level with the current VMID.

For instructions where the value of <regime> is E2, the instruction applies to the EL2&0 or EL2 translation regime, as determined by the value of HCR_EL2.E2H.

For entries from a translation regime in which an ASID is valid, the instruction applies only to all of the following cached copies of translation table entries:

- A non-global entry from the final lookup level that matches the specified ASID.
- A global entry from the final lookup level.

If <type> is VAA in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of <regime> is E1, then the instruction applies to all of the following:
  - When HCR_EL2.{E2H, TGE} is not {1, 1}, then the EL1&0 translation regime when executing at EL1.
  - When HCR_EL2.{E2H, TGE} is {1, 1}, then the EL2&0 translation regime when executing at EL2.
- For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate the address at the specified Exception level.

If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries with the current VMID.

For instructions where the value of <regime> is E2, the instruction applies to the EL2&0 or EL2 translation regime, as determined by the value of HCR_EL2.E2H.

The instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:

- Global entries.
- Non-global entries with any ASID.

If <type> is VAAL in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of <regime> is E1, then the instruction applies to all of the following:
  - When HCR_EL2.{E2H, TGE} is not {1, 1}, then the EL1&0 translation regime when executing at EL1.
  - When HCR_EL2.{E2H, TGE} is {1, 1}, then the EL2&0 translation regime when executing at EL2.
- For the Security state specified by SCR_EL3.NS and SCR_EL3.EEL2, the instruction applies to all cached copies of the stage 1 translation table entries from the final lookup level in the translation table walk required to translate the address at the specified Exception level.

If EL2 is enabled, then for entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries from the final lookup level with the current VMID.

For instructions where the value of <regime> is E2, the instruction applies to the EL2&0 or EL2 translation regime, as determined by the value of HCR_EL2.E2H.

The instruction applies to all of the following cached copies of translation table entries from the final lookup level in the translation table walk:

- Global entries.
- Non-global entries with any ASID.

If <type> is IPAS2 in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of <regime> is E1, and if EL2 is enabled, then the instruction applies only to the EL1&0 translation regime.
• If all of the following apply, the instruction applies to all cached copies of the stage 2 translation table entries from any lookup level in the translation table walk required to translate the address:
  — The TLB entry holds only a stage 2 translation table entry.
  — The entry applies only to the current VMID.
• The instruction is not required to invalidate TLB entries that combine stage 1 and stage 2 translation table entries.
• If one of the following is true, then the instruction executes as a NOP:
  — EL2 is not implemented.
  — The Effective value of SCR_EL3.NS is 0 and EL2 is disabled.

If <type> is IPAS2l in a TLB maintenance instruction, then all of the following apply:
• If and only if the value of <regime> is E1, and if EL2 is enabled, then the instruction applies only to the EL1&0 translation regime.
• If all of the following apply, the instruction applies to all cached copies of the stage 2 translation table entries from the final lookup level in the translation table walk required to translate the address:
  — The TLB entry holds only a stage 2 translation table entry.
  — The entry applies only to the current VMID.
• The instruction is not required to invalidate TLB entries that combine stage 1 and stage 2 translation table entries.
• If one or more of the following is true, then the instruction executes as a NOP:
  — EL2 is not implemented.
  — The Effective value of SCR_EL3.NS is 0 and EL2 is disabled.

### D8.13.6 Operation of the TLB maintenance instructions

A TLB maintenance instruction applies whether a translation stage is enabled or disabled.

A TLB maintenance instruction can affect any TLB entries that are not locked down.

There is no guarantee that an unlocked TLB entry remains in the cache. Therefore, it is not possible to determine architecturally whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

A TLB maintenance instruction never generates an MMU abort.

If EL3 is implemented, then SCR_EL3.NS modifies the effect of the TLB maintenance instructions in all of the following ways:
• For instructions that apply to the EL2 or EL2&0 translation regime, if SCR_EL3.{EEL2, NS} is not {0, 0}, then SCR_EL3.NS identifies whether the maintenance instructions apply to the Secure or Non-secure variant of the corresponding regime.
• If SCR_EL3.{EEL2, NS} is {0, 0}, then instructions that apply to the EL2 or EL2&0 translation regime are UNDEFINED.
• For instructions that apply to the EL3 translation regime, SCR_EL3.NS has no effect.

A TLB maintenance instruction is not affected by the current state of all of the following control bits involved in the translation process:
• In AArch64 state, all of the following:
  — SCTLR_EL1.M.
  — SCTLR_EL2.M.
  — SCTLR_EL3.{M, RW}.
  — HCR_EL2.{VM, RW}.
— TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}.
— If HCR_EL2.E2H is 0, then TCR_EL2.{TG0, T0SZ}.
— If the Effective value of HCR_EL2.E2H is 1, then TCR_EL2.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}.
— TCR_EL3.{TG0, T0SZ}.
— VTCR_EL2.{SL0, T0SZ}.
— TTBR0_EL1.ASID.
— TTBR1_EL1.ASID.
— If the Effective value of HCR_EL2.E2H is 1, then all of the following:
  — TTBR0_EL2.ASID.
  — TTBR1_EL2.ASID.

• In AArch32 state, all of the following:
  — SCTLR.M.
  — HCR.VM.
  — TTBCR.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1}.
  — HTCR.T0SZ.
  — VTCR.{SL0, T0SZ}.
  — TTBR0.ASID.
  — TTBR1.ASID.
  — CONTEXTIDR.ASID.

Address-based TLBI instructions are applied to the extent of the <shareability> specified by the instruction regardless of the Shareability assigned by any translation of the IA or Shareability attribute stored in TLB entries.

For TLB maintenance instructions that operate only on instruction TLBs or only on data TLBs, Arm deprecates their use in AArch32 state.

When a TLB maintenance instruction is executed, all of the following apply:

• The minimum size of a TLB entry that is required to be invalidated from the TLB is at least the size specified by the corresponding translation table entry.
• The Contiguous bit does not affect the minimum size of a TLB entry that is required to be invalidated from the TLB.

When invalidating a mapping greater than a translation granule size or block size, for example a mapping that is specified using the Contiguous bit, software is required to issue a TLB maintenance instruction for each block or granule within the configured contiguous region size to invalidate the entire mapping.

An implementation is permitted to invalidate more than the minimum required TLB entries.

Arm recommends not invalidating entries that are not required to be invalidated to minimize the performance impact.

Arm expects software to mostly use address-based TLB invalidation instructions that apply to entries cached from the last level of a stage 1 or a stage 2 translation table walk to avoid unnecessary loss of the cached intermediate translation table entries.

For all of the following reasons, software is required to set VTTBR_EL2.VMID[7:0] to a known value as part of the PE initialization sequence:

• The VTTBR_EL2.VMID field resets to a value that is architecturally UNKNOWN.
• If EL2 is enabled, dependencies on the VMID in the EL1&0 translation regime apply whether stage 2 translation is enabled or disabled.
**Invalidating TLB entries from stage 2 translations**

The following code is required to invalidate all cached copies of the stage 2 translation of the IPA held in \( X_t \) using the current VMID, with the corresponding requirement applied to the broadcast versions of the instructions:

\[ \text{TLB} \text{ IPAS2E1, } X_t \text{ DSB TLBI VMALE1} \]

The following code is required to invalidate all cached copies of the stage 2 translations of the IPA held in \( X_t \) used to translate the VA, and the specified ASID when executing TLBI VAE1, held in \( X_t \), with the corresponding requirement applied to the broadcast versions of the instructions:

\[ \text{TLB} \text{ IPAS2E1, } X_t \text{ DSB TLBI VAE1, } X_t \text{ or TLBI VAE1, } X_t \]

The following code is required to invalidate all cached copies of the stage 2 translations of the IPA held in \( X_t \) used to translate the IPA produced by the last level of stage 1 translation table lookup for the VA, and the specified ASID when executing TLBI VAE1, held in \( X_t \), with the corresponding requirement applied to the broadcast versions of the instructions:

\[ \text{TLB} \text{ IPAS2E1, } X_t \text{ DSB TLBI VAE1, } X_t \text{ or TLBI VAE1, } X_t \]

For an EL1&0 translation regime with stage 2 translation enabled, software is required to invalidate all cached copies of the stage 2 translations of the IPA held in \( X_t \) used to translate the IPA produced by the last level of stage 1 translation table lookup for the VA, and the specified ASID when executing TLBI VAE1, held in \( X_t \), with the corresponding requirement applied to the broadcast versions of the instructions:

\[ \text{TLB} \text{ IPAS2E1, } X_t \text{ DSB TLBI VAE1, } X_t \]

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries required to be invalidated by an IPAS2L instruction are those that come from the final translation table lookup level.

**D8.13.7 Broadcast TLB maintenance**

If all of the following apply, then a TLB maintenance instruction executed by a PE in an Exception level that is using AArch64 can affect a PE that executes the same Exception level using AArch32:

- The PE lies within the target Shareability domain of the TLBI maintenance instruction.
- If VA matching is required, then the VA is 0x0000FFFFFFFF or lower in the memory map.
- If ASID matching is required, then one of the following:
  - If the PE using AArch64 is using an 8-bit ASID, then the ASIDs match.
  - If the PE using AArch64 is using a 16-bit ASID and the top 8 bits of the 16-bit ASID are zero, then the ASIDs match.
- If VMID matching is required, then one of the following:
  - If the PE using AArch64 is using an 8-bit VMID, then the VMIDs match.
  - If the PE using AArch64 is using a 16-bit VMID and the top 8 bits of the 16-bit VMID are zero, then the VMIDs match.

If all of the following apply, then a TLB maintenance instruction executed by a PE in an Exception level that is using AArch32 can affect a PE that executes the same Exception level using AArch64:

- The PE lies within the same Inner Shareable Shareability domain of the TLBI maintenance instruction.
- If VA matching is required, then when the supplied VA is zero-extended, the VAs match.
- If IPA matching is required, then when the supplied IPA is zero-extended, the IPAs match.
- If ASID matching is required, then one of the following:
  - If the PE using AArch64 is using an 8-bit ASID, then the ASIDs match.
  - If the PE using AArch64 is using a 16-bit ASID, then when the supplied ASID is zero-extended, then the ASIDs match.
- If VMID matching is required, then one of the following:
  - If the PE using AArch64 is using an 8-bit VMID, then the VMIDs match.
  - If the PE using AArch64 is using a 16-bit VMID, then when the supplied VMID is zero-extended, the VMIDs match.
If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting entries in Secure state, then the instruction is not required to affect one or more of the following in the Inner Shareable domain:

- The EL3 translation regime of the PEs with EL3 using AArch64.
- If EL2 is disabled, then the EL1&0 translation regime of the PEs with EL3 using AArch64, regardless of whether the EL1&0 translation regime is using AArch64 or AArch32.

If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, then the instruction is not required to affect the EL3 translation regime of the PEs with EL3 using AArch32 in the Inner Shareable domain.

If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, then the instruction is not required to affect the EL3 translation regime of the PEs with EL3 using AArch32 in the Inner Shareable domain.

In all of the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE within the target Shareability domain:

- A TLB maintenance instruction specifying a VA and affecting one of the following translation regimes is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that VA in the same translation regime:
  - The EL2 translation regime.
  - The EL2&0 translation regime.
  - The EL3 translation regime.

- A TLB maintenance instruction specifying a VA and affecting the EL1&0 translation regime is broadcast from a PE using a stage 1 translation granule size for that translation regime to a PE using EL1 and a different stage 1 translation granule size for that VA.

- If EL2 is enabled, then a TLB maintenance instruction specifying a VA and affecting the EL1&0 translation regime is broadcast from a PE using a stage 2 translation granule size to a PE using a different stage 2 translation granule size.

- If EL2 is enabled, then a TLB maintenance instruction specifying an IPA and affecting the EL1&0 translation regime is broadcast from a PE using a stage 2 translation granule size to a PE using a different stage 2 translation granule size.

- A TLB maintenance instruction specifying a range of VAs or IPAs is broadcast from one PE to a PE that does not support the TLB range-based operations.

The set of Requesters containing TLBs that support TLB range-based operations is defined by the system architecture.

Arm strongly recommends that within an Inner Shareable domain, all PEs support the same set of broadcast TLB range maintenance instructions.

If an Armv7 PE is in the same Inner Shareable domain as an Armv8 PE, and the Armv8 PE issues a broadcast TLB maintenance instruction that is not defined in Armv7, then that instruction is not required to affect the TLBs of the Armv7 PE.

All of the following TLB maintenance instructions are added to the Armv8 T32 and A32 instruction sets, and do not exist in Armv7:

- For stage 1 translations, all of the following instructions that operate on TLB entries for the final level of translation table walk:
  - TLBIMVALID.
  - TLBIMVALID.
  - TLBIMVAAL.
  - TLBIMVALH.
• For stage 2 translations, all of the following instructions that operate by IPA on TLB entries:
  — TLBIIPAS2IS.
  — TLBIIPAS2LIS.
  — TLBIIPAS2.
  — TLBIIPAS2L.

**D8.13.8 Ordering and completion of TLB maintenance instructions**

For all of the following instructions, the effects of a TLB maintenance instruction can be observed in any order relative to that instruction unless a DSB is executed between the instructions:

- Any load or store instruction.
- Another TLB maintenance instruction.
- A data or instruction cache maintenance instruction.

A TLB maintenance instruction executed by a PE causes a TLB maintenance operation to occur on each PE within the Shareability domain specified by the instruction.

If a TLB maintenance instruction has the nXS qualifier, then the associated TLB maintenance operations have the nXS qualifier.

If a TLB maintenance instruction does not have the nXS qualifier and the Effective value of HCRX_EL2.FnXS is 1, then all of the following apply:

- When the instruction is not executed at EL1, the associated TLB maintenance operations do not have the nXS qualifier.
- When the instruction is executed at EL1, the associated TLB maintenance operations have the nXS qualifier.

If a translation regime uses two translation stages, then the XS attribute used to determine the behavior of a TLB maintenance instruction with the nXS qualifier is the attribute determined after both translation stages have been applied.

When a TLB maintenance instruction is executed, **in-scope old translation information** is any translation information related to addresses within the scope of that instruction that is not consistent with one or more of the following:

- The architectural translation information held in the translation tables.
- Any architecture translation information that is Coherence-after the information held in the translation tables.

In-scope old translation information might be held in TLBs or other non-coherent caching structures.

For a PE that handles a TLB maintenance operation without the nXS qualifier, the TLB maintenance operation is finished when all of the following apply:

- All memory accesses generated by that PE using in-scope old translation information are complete.
- All memory accesses, RWx, generated by that PE are complete, where RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I1 executed by that PE, where all of the following apply:
  — I1 uses the in-scope old translation information.
  — The use of the in-scope old translation information generates a synchronous Data Abort.
  — If I1 did not generate an abort from use of the in-scope old translation information, I1 would generate a memory access that RWx would be locally-ordered-before.

For a PE that handles a TLB maintenance operation with the nXS qualifier, the TLB maintenance operation is finished when all of the following apply:

- All memory accesses with the XS attribute set to 0 generated by that PE using in-scope old translation information are complete.
• All memory accesses, RWx, generated by that PE are complete, where RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I1 executed by that PE, where all of the following apply:
  — I1 uses the in-scope old translation information.
  — The use of the in-scope old translation information generates a synchronous Data Abort.
  — If I1 did not generate an abort from use of the in-scope old translation information, I1 would generate a memory access with the XS attribute set to 0 that RWx would be locally-ordered-before.

IKFTWB For best real-time performance, Arm recommends that the completion of a TLB maintenance instruction with the nXS qualifier executed by a PE should not depend on the completion of any memory accesses with the XS attribute set to 1 generated by a second PE.

RDCJQM When the TLB maintenance operations specified by a TLB maintenance instruction are finished for all PEs, the TLB maintenance instruction is complete.

RLXHLD If a TLB maintenance instruction is complete, then no new memory accesses using the in-scope old translation information are architecturally performed by any observer that is affected by the TLB maintenance instruction.

ICPZSM If it is impossible for software running on any observer to determine that the memory accesses have been performed, then speculative memory accesses can be performed using in-scope old translation information.

RPSMWS When a DSB instruction is used to ensure the completion of TLB maintenance instructions, all of the following apply:
  • The DSB is required to apply to both loads and stores.
  • A DSB is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE.
  • A DSB is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

RYNJCP When a PE, PEx, executes a TLB maintenance instruction, the instruction can complete at any time after it is issued, but the instruction is only guaranteed to be finished for a PE other than PEx after the execution of DSB by the PEx.

RBLDZX For the TLB of a PE that issues a TLB maintenance instruction, one of the following determines when the instruction is guaranteed to be complete:
  • If FEAT_ETS is not implemented, then the instruction is guaranteed to be complete after the execution of DSB by that PE, followed by a Context synchronization event.
  • If FEAT_ETS is implemented, all of the following determine when the instruction is guaranteed to be complete:
    — If the instruction applies only to translations without execute permission and where translation information that is coherence-after also do not have execute permission, then the instruction is guaranteed to be complete after the execution of DSB by that PE.
    — If the instruction applies to any translations with execute permission, then the instruction is guaranteed to be complete after the execution of DSB by that PE, followed by a Context synchronization event.

IMGRK For more information, see Definition of the Arm memory model on page B2-159.
D8.14 Caches

D8.14.1 Data and unified caches

For data and unified caches, if all data accesses to an address do not use mismatched memory attributes, then the use of address translation is transparent to any data access to the address.

For more information, see Mismatched memory attributes on page B2-208.

For data accesses from the same observer to different VAs, if the accesses are translated to the same PA with the same memory attributes, then they are coherent and all of the following behaviors are guaranteed without requiring the use of barrier or cache maintenance instructions:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

When cache maintenance is done to a memory location, the effect of that cache maintenance is visible to all VA or IPA aliases of that physical memory location.

The properties of data and unified caches are consistent with implementing the caches as physically-indexed, physically-tagged caches.

D8.14.2 Instruction caches

An instruction cache has all of the following properties:

- An instruction cache is accessed only as a result of an instruction fetch.
- An instruction cache is never written to by a load or store instruction.
- Cache invalidation is the only cache maintenance that can be done on an instruction cache.

The Arm architecture permits all of the following instruction cache implementations:

- Physically-indexed, physically-tagged (PIPT) instruction cache.
- VMID-aware PIPT (VPIPT) instruction cache.
- Virtually-indexed, physically-tagged (VIPT) instruction cache.

The CTR_EL0.L1Ip field identifies the form of the instruction caches.

For all permitted instruction cache implementations, the Arm IVIPT Extension is also implemented, which reduces instruction cache maintenance requirements to requiring maintenance only after writing new data to a PA that holds an instruction.

Previous versions of the Arm architecture permitted an instruction cache option that does not implement the Arm IVIPT Extension.

For software to be portable between implementations that might use any of the permitted instruction cache implementations, that software is required to invalidate the instruction cache whenever any condition occurs that requires instruction cache maintenance on at least one of the instruction cache types.

Physically-indexed, physically-tagged instruction caches

For PIPT instruction caches, all of the following apply:

- If all instruction fetches to an address do not use mismatched memory attributes, then the use of address translation is transparent to any instruction fetch to the address.
- If instruction cache maintenance is done on a memory location, then the effect of that instruction cache maintenance is visible to all VA or IPA aliases of that physical memory location.
VMID-aware PIPT instruction caches

All statements in this section require implementation of FEAT_VPIPT.

For VPIPT instruction caches, all of the following apply:

- If all instruction fetches to an address do not use mismatched memory attributes, then the use of address translation is transparent to any instruction fetch to the address.
- If instruction cache maintenance is done on a memory location, then the effect of that instruction cache maintenance is visible to all VA or IPA aliases of that physical memory location.
- For EL1 and EL0, if VMIDs are being used for the current Security state, all of the following apply:
  - Only if an instruction fetch is made using the VMID that was used when an instruction cache entry was created, then the instruction fetch is permitted to hit that entry in the cache.
  - Only if the current VMID matches the VMID that was used when an instruction cache entry was created, then an instruction cache maintenance instruction executed at EL1 or EL0 is required to apply to the instruction cache entry.

The first two behaviors of VPIPT instruction caches are the same as the behaviors of PIPT instruction caches.

Virtually-indexed, physically-tagged instruction caches

For VIPT instruction caches, all of the following apply:

- If all instruction fetches to an address do not use mismatched memory attributes, then the use of address translation is transparent to any instruction fetch to the address.
- If instruction cache maintenance by address is done on a memory location, then the effect of that instruction cache maintenance is visible only to the VA supplied with the operation, and the effect of the invalidation might not be visible to any other VA or IPA aliases of that physical memory location.
- The only architecturally-guaranteed way to invalidate all VA or IPA aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

Cache maintenance requirements due to changing memory region attributes

If changes are made to the memory region attributes in translation table entries, TLB maintenance might be required.

For more information, see TLB maintenance on page D8-5197.

The behaviors caused by mismatched memory attributes mean that if any of the following changes are made to the Inner Cacheability or Outer Cacheability attributes in translation table entries, then software is required to ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the cache levels that might hold copies of the locations affected by the attribute change:

- A change from Write-Back to Write-Through.
- A change from Write-Back to Non-cacheable.
- A change from Write-Through to Non-cacheable.
- A change from Write-Through to Write-Back.

For more information, see Mismatched memory attributes on page B2-208 and Using break-before-make when updating translation table entries on page D8-5198.

If the Shareability attributes in translation table entries are changed, then software is required to execute the following sequence to prevent possible coherency errors caused by mismatched memory attributes:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the memory location from caches in the appropriate Shareability domain.
3. Change the Shareability attributes to the new values.
The Arm architecture defines pseudocode that describes the translation table walk.

**Full Physical Address**
A complete PA necessary to identify a location in physical memory is captured by the type `FullAddress`. This is composed of:
- A bitstring address, which identifies the PA.
- An enumeration `paspace` which identifies the PA space.

**Address translation**
`AArch64.TranslateAddress()` acts as the entry point to VMSAv8-64 and performs the required address translation based on the provided parameters and System register configurations. The function returns an `AddressDescriptor()` structure holding valid data for either of the following:
- Target memory address and attributes for a non-faulting translation.
- Fault details holding data to be populated in syndrome registers.

`AArch64.FullTranslate()` selects the translation regime and performs first and potentially second stage of translation returning the PA and attributes of target memory. `AArch64.S1Translate()` carries out the first stage of translation when stage 1 is not disabled, mapping the VA to the IPA and carrying out permission checks. Otherwise, `AArch64.S1DisabledOutput()` assigns the appropriate memory attributes and flat maps the input address to the output address. `AArch64.S2Translate()` carries out stage 2 translation for the EL1&0 translation regime when enabled mapping the IPA to the PA. Otherwise, the IPA is the PA.

**Translation table walk**
Each stage of translation has a separate walk function, `AArch64.S1Walk()` and `AArch64.S2Walk()`, corresponding to the first and second stage of translation respectively. Each use walk parameters extracted from related System registers. Parameters are collected based on the active translation regime. For instance, stage 1 EL2 translation regime parameters are obtained and returned by the function `AArch64.S1TTWParamsEL2()`. Given these parameters, a walk initializes a walk state of the type `TTWState`, holding the base address of the first translation table.

The walk progressively fetches and decodes translation Table descriptors, updating the walk state to the next base address as it descends through the levels of tables until a Block or Page descriptor is discovered or an invalid descriptor is fetched. Decoding the descriptor for both stage 1 and stage 2 walks is carried out by the function `AArch64.DecodeDescriptorType()`.

For a non-faulting walk, three items are returned by a translation table walk:
- The final walk state.
- The final descriptor fetched.
- The address of the final descriptor.

The final descriptor and its address are used to update the descriptor as specified by `Hardware management of the Access flag on page D8-5144` and `Hardware management of the dirty state on page D8-5145`.

A faulting walk could report one of the following at a specified level:
- Translation Fault.
- Address size Fault.
- Access flag Fault.

**Hardware update of Translation Table descriptors**
The walk parameters collected from System registers indicate the ability to update the access flag or set write permissions within descriptors. This is controlled by the Dirty Bit Modifier, and the conditions specified in `Hardware management of the Access flag on page D8-5144` and `Hardware management of the dirty state on page D8-5145`. The translation functions `AArch64.S1Translate()` or `AArch64.S2Translate()` set the appropriate descriptor bits returned by the walk functions and call `AArch64.MemSwapTableDesc()` to swap the old descriptor for the updated one in an atomic fashion.
Address decoding and calculation

The walk state is initialized to hold the base address of the first translation table, using AArch64.TTBaseAddress() to decode TTBR0_ELx and TTBR1_ELx registers. The walk progressively fetches and decodes translation Table descriptors, updating the walk state to the next base address utilizing AArch64.NextTableBase() as it descends through the levels of tables. Prior to every descriptor fetch the base address is indexed by the function AArch64.TTEntryAddress() to point to the specific table entry. Indexing at the start level of stage 2 tables is shown in AArch64.S2SLTTEntryAddress() which caters for concatenated tables. The final walk state would hold the base address for the output block or page; this is extracted from the Leaf descriptor in AArch64.BlockBase() or AArch64.PageBase() respectively.

Memory attribute decoding

If a stage of translation is enabled, fetched descriptors that are blocks or pages encode memory attributes assigned to the output of translation. Stage 1 memory attributes are decoded by the function S1DecodeMemAttrs(). Likewise, the stage 2 memory attributes are decoded by the function S2DecodeMemAttrs() followed by combining stage 1 and stage 2 attributes by the function S2CombineS1MemAttrs(). However, if FEAT_S2FWB is enabled, this behavior is overridden and memory attributes are decoded as specified in Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled on page D8-5155. This is captured by the function AArch64.S2ApplyFWBMemAttrs().

Fault detection

As soon as translation is invoked a reserve FaultRecord accompanies the process capturing the stage and level of translation as it proceeds. When a fault is detected, it is reflected in the FaultRecord and reported back as the result of translation with the most recent state to be reported already captured within. The following functions detect a certain type of fault, their outputs are all Boolean with a TRUE value on detection:

- The AArch64.S1HasPermissionsFault() and AArch64.S2HasPermissionsFault() function detects a permissions fault for stage 1 and stage 2 respectively. Note: For atomic instructions introduced by FEAT_LSE, these functions are called twice, once to check for read permissions and another for write allowing the correct failure to be reported.
- The AArch64.S1HasAlignmentFault() and AArch64.S2HasAlignmentFault() functions detect an alignment fault for stage 1 and stage 2 respectively.
- The AArch64.S1InvalidTxSZ() and AArch64.S2InvalidTxSZ() functions detect a Translation fault caused by erroneous configuration of TCR_ELx.TxSZ field. Also, the AArch64.S2InconsistentSL() and AArch64.S2InvalidSL() functions detect a stage 2 Translation fault caused by erroneous configuration of the VTCR_EL2.{SL2, SL0} and VSTCR_EL2.{SL2, SL0} fields.
- AArch64.VAIsOutOfRange() detects a stage 1 Translation fault caused by VAs larger than the address input size configured. Similarly, AArch64.IPAIsOutOfRange() detects a stage 2 Translation fault caused by the output of stage 1 being larger than the configured input size for stage 2.
- AArch64.ContiguousBitFaults() detects a stage 1 or 2 Translation fault caused by a mis-programmed contiguous bit within a fetched descriptor.

For more information, see aarch64/translation on page J1-11212.
Chapter D9
The Memory Tagging Extension

This chapter describes the Memory Tagging Extension. It contains the following sections:

• Introduction on page D9-5220.
• Allocation Tags on page D9-5221.
• Tag checking on page D9-5223.
• Tagged and Untagged Addresses on page D9-5224.
• PE access to Allocation Tags on page D9-5225.
• Enabling the Memory Tagging Extension on page D9-5226.
• PE handling of Tag Check Fault on page D9-5227.
• PE generation of Tag Checked and Tag Unchecked accesses on page D9-5229.
D9.1 Introduction

There are three versions of the Memory tagging extension:

**FEAT_MTE**

FEAT_MTE supports the Memory tagging instructions accessible in EL0.

When FEAT_MTE is implemented:
- A set of tag load and tag store instructions are provided.
- Instructions to generate and insert Logical Tags in addresses are provided.
- System instructions to Clean, and Clean and Invalidate Allocation Tags from caches are provided.
- If FEAT_MTE2 is not implemented, all System instructions defined by the Memory Tagging Extension are UNDEFINED.
- If FEAT_MTE2 is not implemented, all operations which read Allocation Tags treat the Allocation Tag as zero, and any traps or permission checks continue to apply.
- If FEAT_MTE2 is not implemented, instructions which insert Allocation Tags into addresses treat the Allocation Tag as zero.
- If FEAT_MTE2 is not implemented, the Tagged memory type encoding in the Memory Attribute Indirection Registers are UNPREDICTABLE.

When FEAT_MTE and FEAT_MOPS are implemented, the SETG* instructions are also provided. For more information, see Memory Copy and Memory Set instructions on page C3-274.

**FEAT_MTE2**

FEAT_MTE2 supports all instructions and System registers defined by the extension, Allocation Tags in memory, and Tag Checking of accesses to tagged memory.

When FEAT_MTE2 is implemented:
- All FEAT_MTE functionalities are available for use.
- System register and page level control over access to Allocation Tags in memory is provided.
- Allocation Tags are provided for each 16-byte granule of Conventional memory.
- The tag PA space is separate to the data physical address (data PA) space accessed by data load and store instructions to access data in normal memory and devices.
- Any associated fields in System control registers are available for use.
- All System registers defined by the extension become available for use.
- All System instructions and instructions defined by the extension become available for use.

**FEAT_MTE3**

FEAT_MTE3 adds support for asymmetric Tag Check Fault handling.

When FEAT_MTE3 is implemented:
- All FEAT_MTE and FEAT_MTE2 functionalities are available for use.
- Tag Check Faults can be configured to cause a synchronous exception on reads, and be asynchronously accumulated on writes.
- Any Tag Check Fault on an access that performs both a read and a write can be configured to cause a synchronous exception.
D9.2 Allocation Tags

The tag PA space provides access to Allocation Tags stored in memory. The data PA space provides access to data held in memory.

An Allocation Tag is 4 bits wide.

Each naturally-aligned set of 16 tag PA space locations is a Tag Granule. Each Tag Granule is associated with one Allocation Tag.

——— Note ————
The value 0b1111 may incur a higher performance overhead than other Allocation Tag encodings.

If FEAT_MTE2 is implemented, storage is provided for Allocation Tags at each tag PA where Conventional memory exists at the same physical address in the data PA space.

——— Note ————
Arm recommends that software does not use instructions which write 0b1111 as an Allocation Tag to memory.

The result of an access to the tag PA where Allocation Tag storage is not provided is IMPLEMENTATION DEFINED.

It is IMPLEMENTATION DEFINED whether Allocation Tags are permitted to be accessed through regions of the data PA space. If Allocation Tags are accessible through the data PA space, then the layout of Allocation Tags is IMPLEMENTATION DEFINED.

It is not architecturally required for an Allocation Tag accessed via the tag PA space to be coherent with the same Allocation Tag accessed via the data PA space. A write to one location can be made visible at the other location by the use of the cache maintenance operations.

Unless otherwise stated, the definitions in Chapter B2 The AArch64 Application Level Memory Model and Chapter D7 The AArch64 System Level Memory Model that apply to data accesses and data, apply separately to Allocation Tag accesses and Allocation Tags.

It is IMPLEMENTATION DEFINED whether accesses to the tag PA space are monitored by the global monitor.

D9.2.1 Cache activity and Allocation Tags

When data is evicted from a cache entry at a cache level, the evicted data can overwrite data in memory that has been written by another observer if either, or any of the following are true:

• The data has been written by an observer in the Shareability domain of that memory location, where the maximum size of the memory that can be overwritten is defined by the Cache Write-Back Granule in CTR_EL0.
• The associated Allocation Tags have been written to by an observer in the Shareability domain of that memory location, where the maximum size of the memory that can be overwritten is defined by the Cache Write-Back Granule in CTR_EL0.

When Allocation Tags are evicted from a cache entry at a cache level, the evicted Allocation Tags can overwrite Allocation Tags in memory that has been written by another observer if either, or any of the following are true:

• The Allocation Tags associated with memory within an address range of the size of the Cache Write-Back Granule, aligned to that size, have been written to by an observer in the Shareability domain of that memory location.
• Data within an address range of the size of Cache Write-Back Granule in CTR_EL0, aligned to that size, of the associated data has been written to by an observer in the Shareability domain of that memory location.

If an implementation can overwrite Allocation Tags in memory that have been written by another observer, where the Allocation Tags have not been written by an observer in the Shareability domain of that memory location, then:

• A cache maintenance operation which cleans data from a cache level must also clean the associated Allocation Tags.
A cache maintenance operation which invalidates, or cleans and invalidates data from a cache level, must also clean and invalidate the associated Allocation Tags.

**Note**

If an implementation supports both clean write-back of Allocation Tags, and storage for Allocation Tags can be repurposed to store data when not being used to store Allocation Tags, it is an implementation responsibility to prevent the clean write-back of Allocation Tags from overwriting data.

For more information on DC operations that affect Allocation Tags see *A64 System instructions for cache maintenance* on page C5-776.
D9.3 Tag checking

A memory access that is a read or write can be either Tag Checked or Tag Unchecked. An access to the data PA space can be either Tag Checked or Tag Unchecked. An access to the tag PA space is always Tag Unchecked. A data access which is performed as part of a prefetch operation is Tag Unchecked. When the value of PSTATE.TCO is 1, all loads and stores are Tag Unchecked. A Tag Checked memory access includes a Physical Address Tag. A Tag Checked access causes a Tag Check operation to be performed.

If the Allocation Tag and Physical Address Tag in a Tag Check operation do not match, the Tag Check operation generates a Tag Check Fault. The read of an Allocation Tag due to a Tag Check operation, and the dependent data access, are not required to form an atomic operation.

Software cannot rely on a Load-Exclusive/Store-Exclusive pair to eventually succeed if the Tag Checked properties of the following in a Load-Exclusive/Store-Exclusive instruction pair accessing the same location from the same PE do not match:
• A memory access due to a Store-Exclusive instruction.
• A memory access due to the preceding Load-Exclusive instruction.

D9.3.1 Tag Check Faults

A Tag Check Fault can be configured to cause one of the following:
• A synchronous exception.
• A bit to be asynchronously set in TFSR_ELx.
• To be ignored.

If a store causes a synchronous Tag Check Fault exception, the faulting memory locations being written to by the store that caused the fault are unchanged.

If a Tag Check Fault is not configured to cause a synchronous exception then the following are true:
• There is no effect on the data access, that is the load or store completes unless another exception is taken.
• There is no effect on any of the side effects caused by the completion of the data access.

If FEAT_MTE2 is implemented, a synchronous exception due to a Tag Check Fault is reported as a Data Abort with a Data Fault Status Code of Synchronous Tag Check Fault and the faulting virtual address is reported in FAR_ELx. For more information, see PE handling of Tag Check Fault on page D9-5227.
D9.4 Tagged and Untagged Addresses

Virtual addresses can either be Tagged or Untagged.

An access to memory at:
• An Untagged virtual address generates a Tag Unchecked access.
• A Tagged virtual address permits the generation of a Tag Checked or Tag Unchecked access.

A read of an Allocation Tag from an Untagged virtual address returns the value 0b0000.

A write of an Allocation Tag to an Untagged address is IGNORED.

Accesses of Allocation Tags at Tagged virtual addresses are permitted.

All virtual addresses in AArch32 state are Untagged.

D9.4.1 Virtual address translation

If stage 1 translation at the current Exception level is enabled, stage 1 translations are Tagged or Untagged depending on the Memory Attributes for the memory location being accessed.

If stage 1 translation is disabled for the EL1&0 translation regime:
• If the value of HCR_EL2.DC is 1, stage 1 translations are Tagged or Untagged depending on the value of HCR_EL2.DCT.
• If the value of HCR_EL2.DC is 0, stage 1 translations are treated as Untagged.

For all other translation regimes, if stage 1 translation is disabled, stage 1 translations are treated as Untagged.

Memory locations are treated as Tagged where all of the following is true:
• The combined effects of stage 1 and stage 2 translations define the memory attributes as:
  — Normal memory.
  — Inner, and Outer Write-Back Non-Transient Read-Allocate Write-Allocate.
• The stage 1 translation is treated as Tagged.

Otherwise memory locations are Untagged.

If a memory location is marked as Untagged, a data cache invalidation operation that would invalidate Allocation Tags at that location cleans and invalidates the Allocation Tags.

Note
If a memory location is marked as both Tagged and Non-shared, it is IMPLEMENTATION DEFINED whether the memory location is treated as Tagged or Untagged.

When the EL1&0 stage 1 translation regime is disabled and HCR_EL2.DC is 1, in the current Security state, the execution of any of the AT S1E0, AT S1E1, AT S1Z0, AT S1Z1 address translation instructions will reflect the effect of HCR_EL2.DCT in PAR_EL1.ATTR.

If SCTLR_ELx.C is 0 for a stage 1 translation regime, it is CONstrained Unpredictable between:
• The stage 1 translation is treated as Untagged.
• SCTLR_ELx.C has no effect on whether the stage 1 translation is treated as Tagged or Untagged.

Note
To ensure consistent behavior, software can set SCTLR_ELx.ATA to 0 when SCTLR_ELx.C is 0.

For more information on Virtual address translation, see Address translation on page D8-5080.
D9.5 PE access to Allocation Tags

Instructions that load or store Allocation Tags apply the same address translation and permission checks as a load or store of data to a virtual address.

Instructions that load or store Allocation Tags at a virtual address have the same effect on the Access flag and dirty state as instructions that load or store data at the same virtual address.

An instruction that loads or stores an Allocation Tag:

- Is considered a load or store of data to each location associated with the Allocation Tag for the purpose of triggering Watchpoints and PMU events, other than for events which count bytes of data transferred.
- Is treated as a load or store for the purpose of Statistical Profiling.
- Generates a tag PA with the same physical address as a load or store of data to a virtual address.

Instructions that store Allocation Tags to memory locations marked as Device memory result in a CONstrained UNpredictable choice between:

- Storing the data, if any, to the specified locations.
- Generating an Alignment Fault, which is prioritized in the same way as other alignment faults that are determined by the memory type.

DC GZVA and DC GVA are instructions that store Allocation tags.

Instructions which load or store Allocation tags are considered to perform the access for the purposes of address translation, triggering watchpoints, generating PMU events and Statistical Profiling irrespective of whether access to the Allocation tags in memory is disabled. This includes:

- When FEAT_MTE2 is not implemented.
- Access to Allocation tags in memory is disabled due to Allocation tag access controls in HCR_EL2, SCR_EL3 and SCTLR_ELx.
- The Tagged attribute is absent on the locations being accessed.

A read of an Allocation Tag that returns zero due to access to Allocation tags being disabled by HCR_EL2.ATA, SCR_EL3.ATA or SCTLR_ELx. {ATA, ATA0}, or due to the memory type not having the Tagged attribute, is permitted to generate an External abort if a read of data from the same address would generate an External abort.

For more information on which instructions can be used to access an Allocation tag, see:

- Loads and stores on page C3-256, for load and store instructions.
- Branches, Exception generating, and System instructions on page C3-248, for System instructions.
D9.6 Enabling the Memory Tagging Extension

Access to Allocation Tags in memory can be enabled by use of the following controls:

- SCR_EL3.ATA.
- HCR_EL2.ATA.
- SCTLR_ELx.ATA.
- SCTLR_ELx.ATA0.

When executed at an exception level where accesses to Allocation Tags are disabled, instructions that:

- Load or store data, are Unchecked.
- Load or store Allocation Tags treat the Allocation Tag as RAZ/WI.
- Insert Logical Address Tags into addresses treat the Allocation Tag used to generate the Logical Address Tag as zero,
- Invalidate Allocation Tags from caches, behave as the equivalent Clean and Invalidate operation on Allocation Tags.

For the purpose of determining Allocation Tag access, unprivileged load and store instructions are treated as if executed at EL0 when executed at either:

- EL1, when the Effective value of PSTATE.UAO is 0.
- EL2, when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

Note

Arm recommends that:

- When software requires access to Allocation Tags in a context but Tag Checking is not required, the SCTLR_ELx.TCF or SCTLR_ELx.TCF0 affecting that context is set to 0.
- When software does not require access to Allocation Tags in a context, one or more SCTLR_ELx.ATA affecting that context are set to 0.
D9.7 PE handling of Tag Check Fault

If SCTLR_ELx.TCF has the value of 0b00, a Tag Check Fault due to a load or store at ELx has no effect on the PE.

A Tag Check Fault due to a load or store at EL0 has no effect on the PE if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b00, and HCR_EL2.{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b00, and HCR_EL2.{E2H, TGE} has the value of {1,1}.

If SCTLR_ELx.TCF has the value of 0b01, a Tag Check Fault due to a load or store at ELx generates a synchronous exception.

If SCTLR_ELx.TCF has the value of 0b10, a Tag Check Fault due to a load or store at ELy using TTBR_ELx causes TFSR_ELy.TFx to be asynchronously set to 1.

If FEAT_MTE3 is implemented, and SCTLR_ELx.TCF has the value of 0b11, a Tag Check Fault due to a load, or an atomic operation, generates a synchronous exception.

If FEAT_MTE3 is implemented, and SCTLR_ELx.TCF has the value of 0b11, a Tag Check Fault due to a store at ELy using TTBR_ELx causes TFSR_ELy.TFx to be asynchronously set to 1.

A Tag Check Fault due to a load or store at EL0 has no effect on the PE if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b00, and HCR_EL2{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b00, and HCR_EL2{E2H, TGE} has the value of {1,1}.

A Tag Check Fault due to a load or store at EL0 generates a synchronous exception if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b01, and HCR_EL2{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b01, and HCR_EL2{E2H, TGE} has the value of {1,1}.

A Tag Check Fault due to a load or store at EL0 using TTBRy_EL1 or TTBRy_EL2, causes TFSRE0_EL1.TFy to be set to 1 if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b10, and HCR_EL2{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b10, and HCR_EL2{E2H, TGE} has the value of {1,1}.

If FEAT_MTE3 is implemented, a Tag Check Fault due to a load, or an atomic operation, at EL0 generates a synchronous exception, if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b11, and HCR_EL2{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b11, and HCR_EL2{E2H, TGE} has the value of {1,1}.

If FEAT_MTE3 is implemented, a Tag Check Fault due to a store at EL0 using TTBRy_EL1 or TTBRy_EL2 causes TFSRE0_EL1.TFy to be set to 1, if either of the following conditions are true:

- SCTLR_EL1.TCF0 has the value of 0b11, and HCR_EL2{E2H, TGE} does not have the value of {1,1}.
- SCTLR_EL2.TCF0 has the value of 0b11, and HCR_EL2{E2H, TGE} has the value of {1,1}.

TFSR_ELx and TFSRE0_EL1 are unchanged by a memory data access causing a Tag Check pass.

A synchronous exception due to a Tag Check Fault is reported as a Data Abort, with a Data Fault status code of Synchronous Tag Check Fault, and the faulting virtual address is reported in FAR_ELx.

A Data Abort due to a Tag Check Fault is taken from EL0 to one of the following exception levels:

- EL1 if HCR_EL2.TGE is 0.
- EL2 if HCR_EL2.TGE is 1.

A Data Abort due to a Tag Check Fault is taken from ELx to ELx where x is 1, 2 or 3.

A Data Abort due to a Tag Check Fault is prioritized as a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk.

If an access generates both a Data Abort due to a Synchronous Tag Check Fault, and a Data Abort due to a synchronous External abort that was not generated by a translation table walk, it is IMPLEMENTATION DEFINED which abort is reported. For more information on prioritization of exceptions see Synchronous exception types on page D1-4646.
If an instruction that accesses memory generates both a synchronous Data Abort and a Tag Check Fault, where Tag Check Faults are configured to set a bit in a TFSR_ELx or TFSRE0_EL1 register, and the bit is 0, the bit becomes UNKNOWN.

If an instruction that stores to memory generates a Data Abort that is a Synchronous Tag Check Fault, the value of each memory location that the instruction stores to is UNKNOWN for any location for which no exceptions, and no Debug event is generated. The size of a memory location is defined as being the size for which a memory access is single-copy atomic.

For the purpose of determining Tag Check Fault handling, unprivileged load and store instructions are treated as if executed at EL0 when executed at either:

- EL1, when the Effective value of PSTATE.UAO is 0.
- EL2, when both the Effective value of HCR_EL2.[E 2H, TGE] is {1, 1} and the Effective value of PSTATE.UAO is 0.

Indirect writes to TFSRE0_EL1 and any TFSR_ELx accessible at ELy that are caused by a Tag Check Fault are synchronized by any of:

- An exception entry to ELy, if SCTLR_ELy.ITFSB has the value of 0b1.
- A DSB over the Non-shareable domain at ELy in program order, after the instruction causing the Tag Check Fault.

When FEAT_SVE is implemented, if a load of an element in a SVE Non-faulting or First-faulting load instruction causes a Tag Check Fault, and is not the First active element in a First-faulting instruction, the Tag Check Fault:

- Is recorded in the corresponding FFR register.
- Does not generate a Synchronous Tag Check Fault exception.
- Does not cause any bit in any TFSR_ELx or TFSRE0_EL1 registers to be set.
- The value loaded into the element is UNKNOWN.

When FEAT_SVE is implemented, if a load of an element in a SVE Non-faulting or First-faulting load instruction causes a Tag Check Fault, and is the First active element in a First-faulting instruction, the Tag Check Fault:

- Is not recorded in the corresponding FFR register.
- Generates a Synchronous Tag Check Fault exception if configured to do so.
- Sets a bit in TFSR_ELx or TFSRE0_EL1 registers if configured to do so.
- If a synchronous Tag Check Fault is generated, the value loaded into the element is UNKNOWN.

It is CONSTRAINED UNPREDICTABLE whether the FFR element associated with the read of an Active element in an SVE Non-fault load, or an Active element which is not the First active element in an SVE First-fault load, R2, to location X, is set to FALSE if all of the following are true:

- Tag Check Faults are configured as asynchronous for both reads and writes.
- A read or write RW1 to location Y causes a Tag Check Fault.
- Tag Check Faults for locations X and Y are reported in the same status bit, either:
  - TFSR_ELx.TFy.
  - TFSRE0_EL1.TFy.
- RW1 is in program order before R2, or is the First active element in the first-fault load instruction causing R2.
- There are no other faults caused by R2 that are reported in FFR.
- There is not a DSB and a direct write of 0b0 to that status bit appearing in program order between the instruction causing RW1 and the instruction causing R2.

If a Tag check fault configured to asynchronously set a bit in TFSR_ELx or TFSRE0_EL1 has not been observed in TFSR_ELx or TFSRE0_EL1, and has not been synchronized by a DSB, or by the effects of SCTLR_ELx.ITSB, when a write to a System register affecting Tag check fault handling occurs, the effect of the Tag check fault is CONSTRAINED UNPREDICTABLE between the effect of the old and new value of the System register.
D9.8 **PE generation of Tag Checked and Tag Unchecked accesses**

A Logical Address Tag is formed by bits [59:56] of the 64-bit address that is used for a load or store instruction. The PE generates a Physical Address Tag from the Logical Address Tag for each Tag Checked access to memory. Unless an access is explicitly defined as a Tag Unchecked access, it is a Tag Checked access.

Instructions in Debug state follow the same rules for generation of Tag Checked and Tag Unchecked accesses as in Non-Debug state. See Chapter H2 [Debug State](#) for more information.

### D9.8.1 Tag Unchecked accesses

The following operations generate a Tag Unchecked access:

- An instruction fetch.
- A load instruction that loads an Allocation Tag.
- A store instruction that stores an Allocation Tag.

When PSTATE.TCO is 1, all loads and stores generate Tag Unchecked accesses.

An access due to a translation table walk generates a Tag Unchecked access.

If FEAT_NV2 is implemented, loads and stores relative to VNCR_EL2 generate a Tag Unchecked access.

If the Statistical Profiling Extension is implemented, all accesses to the Profiling Buffer are Tag Unchecked accesses. See Chapter D13 [The Statistical Profiling Extension](#) for more information.

An access which would be translated using TTBR0_ELx is Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, where either of the following conditions apply:

- TCR_ELx.TBI is 0.
- TCR_ELx.TBIO is 0.

If TCR_ELx.TBI1 has the value of zero, an access which would be translated using TTBR1_ELx is Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not.

An access will be Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, where all of the following conditions apply:

- The access would be translated using TTBR0_ELx.
- The Logical Address Tag is 0b0000.
- TCR_ELx.TCMA is 1, or TCR_ELx.TCMA0 is 1.

An access will be Tag Unchecked, irrespective of whether the stage 1 address translation for the ELx translation regime is enabled or not, when all of the following conditions apply:

- The access would be translated using TTBR1_ELx.
- The Logical Address Tag is 0b1111.
- TCR_ELx.TCMA1 is 1.

A Tag Unchecked access will be generated for a load or store that uses either of the following:

- A base register only, with the SP as the base register.
- A base register plus immediate offset addressing form, with the SP as the base register.

Literal (PC-relative) loads generate a Tag Unchecked access.

### D9.8.2 Constrained Unpredictable behavior

When executing a Store-Exclusive instruction, that if Tag Unchecked would not perform the store, and would return a status value of one, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction generates a Tag Checked access.
- The instruction generates a Tag Unchecked access.
The Memory Tagging Extension

D9.8 PE generation of Tag Checked and Tag Unchecked accesses
Chapter D10
The Generic Timer in AArch64 state

This chapter describes the implementation of the Arm Generic Timer. It includes an overview of the AArch64 System register interface to an Arm Generic Timer.

It contains the following sections:

• About the Generic Timer on page D10-5232.
• The AArch64 view of the Generic Timer on page D10-5236.

Chapter G6 The Generic Timer in AArch32 state describes the AArch32 view of the Generic Timer, and Chapter I2 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
D10.1 About the Generic Timer

Figure D10-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The ARM Generic Interrupt Controller Architecture Specification defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter that measures the passing of time in real-time.

--- Note ---

The Generic Timer can also provide other components at a system level, but Figure D10-1 does not show any such components.

- Supports virtual counters that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D10-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G6 The Generic Timer in AArch32 state describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D10-1.
- Optionally, can provide timer components for use at a system level.

Chapter 12 System Level Implementation of the Generic Timer describes this memory-mapped component.
D10.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see The system counter on page D10-5234. Because this must be implemented at the system level, it is accessed through The system level memory-mapped implementation of the Generic Timer. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

• A physical counter, which gives access to the count value of the system counter. When FEAT_ECV is implemented, the CNTPOFF_EL2 register allows offsetting of physical timers and counters.

• A virtual counter, which gives access to virtual time. In AArch64 state, the CNTVOFF_EL2 register defines the offset between physical time, as defined by the value of the system counter, and virtual time.

• A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
  — An EL1 physical timer.
  — A Non-secure EL2 physical timer.
  — An EL3 physical timer.
  — An EL1 virtual timer.
  — A Non-secure EL2 virtual timer.
  — A Secure EL2 virtual timer.
  — A Secure EL2 physical timer.

The Non-secure EL2 virtual timer is available only when FEAT_VHE is implemented.

The Secure EL2 timers are available only when FEAT_SEL2 is implemented.

The AArch64 view of the Generic Timer on page D10-5236 describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into frames. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

• A control frame, CNTControlBase.
• A status frame, CNTReadBase.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

• Which timers are implemented.
• The features of each implemented timer.

This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional

An implemented memory-mapped timer:

• Must provide a privileged view of the timer, in the CNTBaseV frame.
D10.1 About the Generic Timer

- Optionally, provides an unprivileged view of the timer in the CNTELOBaseN frame.

\[ N \text{ is the timer number, and the corresponding frame number, in the range 0-7.} \]

Chapter 12 System Level Implementation of the Generic Timer describes these components.

D10.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

**Width**
- From Armv8.0 to Armv8.5 inclusive, at least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.
- From Armv8.6, must be 64 bits wide.

**Frequency**
- From Armv8.0 to Armv8.5 inclusive, increments at a fixed frequency, typically in the range 1-50MHz. It can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.
- From Armv8.6, increments at a fixed frequency of 1GHz.

**Roll-over**
- Roll-over time of not less than 40 years.

**Accuracy**
- Arm does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
- Use of lower-frequency modes must not affect the implemented accuracy.

**Start-up**
- Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes in architectures from Armv8.0 to Armv8.5, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

From Armv8.6 the counter operates at a higher fixed frequency of 1GHz.

**Note**

Though each unit of the counter is set to 1ns, this does not require that the counter is incremented every 1ns. A step in the counter might be more than a single bit increment. It is recommended that the count is not incremented at a rate that is less than 50MHz in normal running operation.

The CNTFRQ_EL0 register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information, see Initializing and reading the system counter frequency on page D10-5235.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

**Note**

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray-count scheme for timer distribution scheme on page K7-11704 gives more information about this possibility.
Initializing and reading the system counter frequency

The CNTFRQ_EL0 register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the CNTFRQ_EL0 register. Only software executing at the highest implemented Exception level can write to CNTFRQ_EL0.

--- Note ---

The CNTFRQ_EL0 register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the CNTFRQ_EL0 register, to determine the current system counter frequency, in the following states:

- Secure and Non-secure EL2.
- Secure and Non-secure EL1.
- When CNTKCTL_EL1.{EL0PCTEN, EL0VCTEN} is not {0,0} and CNTHCTL_EL2.{EL0PCTEN, EL0VCTEN} is not {0,0}, Secure and Non-secure EL0.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, which a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter I2 System Level Implementation of the Generic Timer.
D10.2 The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- **The physical counter.**
- **The virtual counter** on page D10-5238.
- **Event streams** on page D10-5239.
- **Timers** on page D10-5240.

D10.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT_EL0 register holds the current physical counter value. When FEAT_ECV is implemented, the CNTPOFF_EL2 register holds the optional physical offset that can be applied at EL0 and EL1 whether EL0 and EL1 are using AArch64 state or AArch32 state. For more information, see The physical offset register on page D10-5237.

Reads of CNTPCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

The self-synchronized view of the physical counter

When FEAT_ECV is implemented, an alternative way to read the physical counter is supported. The CNTPCTSS_EL0 register is a non-speculative view of the physical counter, as seen from the Exception level that CNTPCTSS_EL0 is read from.

Accesses to the CNTPCTSS_EL0 are subject to the same traps as accesses to the CNTPCT_EL0.

Reads of CNTPCT_EL0 occur in program order relative to reads of CNTPCT_EL0 or CNTPCTSS_EL0.

Reads of CNTPCTSS_EL0 occur in program order relative to reads of CNTPCT_EL0 or CNTPCTSS_EL0.

**Example D10-1 Ensuring reads of the physical counter occur after signal read from memory**

If a read from memory is used to obtain a signal from another agent that indicates that CNTPCT_EL0 must be read, an ISB is used to ensure that the read of CNTPCT_EL0 occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                   ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]        ; has the value 1 written to it
  CMP X1, #1          ; without this the CNTPCT_EL0 could be read before the memory location in [X2]
  B.NE loop
  ISB                  ; without this the CNTPCT_EL0 could be read before the memory location in [X2]
  MRS X1, CNTPCT_EL0
```

When FEAT_ECV is implemented, an access to CNTPCTSS_EL0 can be used in place of the CNTPCT_EL0 which, because it cannot be accessed speculatively, allows the ISB to be removed. This means that the following code sequence can be used:

```
loop                   ; polling for some communication to indicate a requirement to read the timer
  LDR X1, [X2]        ; has the value 1 written to it
  CMP X1, #1          ; without this the CNTPCT_EL0 could be read before the memory location in [X2]
  B.NE loop
  MRS X1, CNTPCTSS_EL0
```

Similarly where a read of the physical counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following code sequences can be used:

```
...                   ; earlier loads and stores
DSB                    ; completes the earlier loads and stores
ISB                    ; without this the CNTPCT_EL0 could be read before the completion of the earlier
  MRS X1, CNTPCT_EL0   ; loads and stores
```
Or, if FEAT_ECV is implemented:

```assembly
... ; earlier loads and stores
DSB ; completes earlier loads and stores
MRS X1, CNTPCTSS_EL0
```

Neither view of the physical counter ensures that:

- Context changes occurring in program order before the read of the counter have been synchronized.
- Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Where there is a Dependency through registers dependency from the read of the physical counter to a Register effect generated by a read or write, the read or write will be executed after the read of the counter.

**Example D10-2 Ensuring reads of the physical counter occur after previous memory accesses**

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, one of the following sequences should be used:

**either:**

```assembly
DSB
ISB
MRS Xn, CNTPCT{SS}_EL0 ; either view of the physical counter has the same effect in this example
```

**or**

```assembly
DMB
LDR Xa, [Xd] ; this could be any memory location, for example the stack pointer
CBZ Xa, next
```

```assembly
ISB ; this ISB is not needed if the MRS is accessing CNTPCTSS_EL0
MRS Xn, CNTPCT{SS}_EL0
```

To ensure that a memory access occurs only after a read of the counter, then either of the following sequences should be used:

```assembly
MRS Xn, CNTPCT{SS}_EL0 ; either view of the physical counter has the same effect in this example
ISB
LDR Xa, [Xb] ; this load will be executed after the timer has been read
```

**or**

```assembly
MRS Xn, CNTPCT{SS}_EL0 ; either view of the physical counter has the same effect in this example
EOR Xm, Xn, Xn
LDR Xa, [Xb, Xm] ; this load will be executed after the timer has been read
```

**The physical offset register**

When FEAT_ECV is implemented, the CNTPOFF_EL2 register allows an offset to be applied to the physical counter, as viewed from EL1 and EL0, and to the EL1 physical timer. The functionality of this 64-bit register is affected by CNTHCTL_EL2.ECV.

When CNTHCTL_EL2.ECV is 1, an MRS to CNTPCT_EL0 or CNTPCTSS_EL0 from either EL0 or EL1 that is not trapped will return the value \( PCount<63:0> - CNTPOFF_EL2<63:0> \). For information on how the EL1 physical timer interrupt is triggered when CNTHCTL_EL2.ECV is 1, see *Operation of the CompareValue views of the timers* on page D10-5241.

When EL2 is not enabled for the current Security state, or when CNTHCTL_EL2.ECV is 0, then:

- An MRS to CNTPCT_EL0 from either EL0 or EL1 that is not trapped will return the value PCount<63:0>. 

---

*The Generic Timer in AArch64 state*

*D10.2 The AArch64 view of the Generic Timer*
- The physical offset is treated as zero for all timer and counter calculations involving the physical offset.

When EL2 is not enabled for the current Security state, or when CNTHCTL_EL2.ECV is 0, then the behavior of the counters and timers is as described for Armv8.5 and the optional physical offset is not used.

When SCR_EL3.ECVEn is 0, all values of CNTPOFF_EL2 are treated as 0 for all purposes other than direct reads or writes to the register from EL3.

D10.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, which indicates virtual time. The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at EL1 or EL0, the virtual offset value relates to the current virtual machine.

The CNTVOFF_EL2 register contains the virtual offset, see The virtual offset register on page D10-5239.

The CNTVCT_EL0 register holds the current virtual counter value. Reads of CNTVCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

The self-synchronized view of the virtual counter

When FEAT_ECV is implemented, an alternative way to read the virtual counter is supported. The CNTVCTSS_EL0 register is a non-speculative view of the virtual counter, as seen from the Exception level that CNTVCTSS_EL0 is read from.

Accesses to the CNTVCTSS_EL0 are subject to the same traps as accesses to the CNTVCT_EL0.

Reads of CNTVCT_EL0 occur in program order relative to reads of CNTVCT_EL0 or CNTVCTSS_EL0.

Reads of CNTVCTSS_EL0 occur in program order relative to reads of CNTVCT_EL0 or CNTVCTSS_EL0.

Example D10-3 Ensuring reads of the virtual counter occur after signal read from memory

If a read from memory is used to obtain a signal from another agent that indicates that CNTVCT_EL0 must be read, an ISB is used to ensure that the read of CNTVCT_EL0 occurs after the signal has been read from memory, as shown in the following code sequence:

\[
\text{loop} \quad ; \text{polling for some communication to indicate a requirement to read the timer} \\
\quad \text{LDR X1, [X2]} \quad ; \text{has had the value 1 written to it} \\
\quad \text{CMP X1, #1} \\
\quad \text{B.NE loop} \\
\quad \text{ISB} \quad ; \text{without this the CNTVCT_EL0 could be read before the memory location in [X2]} \\
\quad \text{MRS X1, CNTVCT_EL0} \\
\text{When FEAT_ECV is implemented, an access to CNTVCTSS_EL0 can be used in place of the CNTVCT_EL0, which, because it cannot be accessed speculatively, allows the ISB to be removed. This means that the following code sequence can be used:} \\
\text{loop} \quad ; \text{polling for some communication to indicate a requirement to read the timer} \\
\quad \text{LDR X1, [X2]} \quad ; \text{has had the value 1 written to it} \\
\quad \text{CMP X1, #1} \\
\quad \text{B.NE loop} \\
\quad \text{MRS X1, CNTVCTSS_EL0} \\
\text{Similarly where a read of the virtual counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following two sequences can be used:} \\
\text{...} \quad ; \text{earlier loads and stores} \\
\text{DSB} \quad ; \text{completes earlier loads and stores} \\
\text{ISB} \quad ; \text{without this CNTPCT_EL0 could be read before the completion of the earlier loads and stores} \\
\text{MRS X1, CNTVCT_EL0} \]
Or, if FEAT_ECV is implemented:

```
... ; earlier loads and stores
DSB ; completes earlier loads and stores
MRS X1, CNTVCTSS_EL0
```

Neither view of the virtual counter ensures that:

- Context changes occurring in program order before the read of the counter have been synchronized.
- Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Where there is a Dependency through registers dependency from the read of the virtual counter to a Register effect generated by a read or write, the read or write will be executed after the read of the counter.

**Example D10-4 Ensuring reads of the virtual counter occur after previous memory accesses**

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, one of the following sequences should be used:

either:

```
DSB
ISB
MRS Xn, CNTVCT{SS}_EL0 ; either view of the virtual counter has the same effect in this example
```

or

```
DMB
LDR Xa, [Xd] ; this could be any memory location, for example the stack pointer
CBZ Xa, next
```

```
ISB ; this ISB is not needed if the MRS is accessing CNTVCT{SS}_EL0
MRS Xn, CNTVCT{SS}_EL0
```

To ensure that a memory access occurs only after a read of the counter, then either of the following sequences should be used:

```
MRS Xn, CNTVCT{SS}_EL0 ; either view of the virtual counter has the same effect in this example
ISB
LDR Xa, [Xb] ; this load will be executed after the timer has been read
```

or

```
MRS Xn, CNTVCT{SS}_EL0 ; either view of the virtual counter has the same effect in this example
EOR Xm, Xn, Xn
LDR Xa, [Xb, Xm] ; this load will be executed after the timer has been read
```

**The virtual offset register**

The virtual counter is a counter that has a virtual offset relative to the physical counter as viewed from EL2 and EL3. This virtual offset is held in the register CNTVOFF_EL2. The virtual counter value is the count compared by the EL1 virtual timer.

If EL2 is not implemented and enabled, then the virtual counter uses a fixed offset of zero.

**D10.2.3 Event streams**

An implementation that includes the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in *Wait for Event on page D1-4676*. 
Note

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

The `CNTKCTL_EL1.{EVNTEN, EVNTDIR, EVNTI, EVNTIS}` fields define an event stream that is generated from the virtual counter.

In all implementations, the `CNTHCTL_EL2.{EVNTEN, EVNTDIR, EVNTI, EVNTIS}` fields define an event stream that is generated from the physical counter.

The event stream is configured as follows:

- `EVNTI` selects the counter bit that triggers the event.
- If `FEAT_ECV` is not implemented, `EVNTI` selects between bits[0:15].
- If `FEAT_ECV` is implemented, `EVNTIS` selects whether `EVNTI` selects between bits[0:15] or bits[8:23].
- `EVNTDIR` selects whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

Note

If the event stream is configured to produce events from the low order bits of the counter when the counter frequency is very high (for example 1GHz), then the practical update rate of the counter might mean that the event stream is not generated as the low order bit might not change. Software can rely on an event stream rate of at least 1MHz in normal operation.

The pseudocode descriptions of the operation of an event stream are `SetEventRegister`, `TestEventCNTV`, and `TestEventCNTP`.

D10.2.4 Timers

In an implementation of the Generic Timer that includes EL3, if EL3 can use AArch64, the following timers are implemented:

- An EL1 physical timer, which:
  - In Secure state, can be accessed from EL1.
  - In Non-secure state, can be accessed from EL1 unless those accesses are trapped to EL2.
  - When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.
- A Non-secure EL2 physical timer.
- A Secure EL3 physical timer. An EL3 control determines whether this register is accessible from Secure EL1.
- An EL1 virtual timer.
- When `FEAT_VHE` is implemented, a Non-secure EL2 virtual timer.
- When `FEAT_SEL2` is implemented, a Secure EL2 physical timer.
- When `FEAT_SEL2` is implemented, a Secure EL2 virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a `Generic Interrupt Controller` (GIC), signals a `Private Peripheral Interrupt` (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
The Generic Timer in AArch64 state

D10.2 The AArch64 view of the Generic Timer

- Has, in addition, a 32-bit Control register.

### Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, CNTV_CTL_EL0, CNTHV_CTL_EL2, or CNTHVS_CTL_EL2. For CNTP_CTL_EL0, the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch32 register CNTP_CTL.

The operation of this view of a timer is:

\[
\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) >= 0)
\]

Where:

- **TimerConditionMet**: Is TRUE if the timer condition for this counter is met, and FALSE otherwise.
- **Counter**: The physical counter value, which can be read from the CNTPCT_EL0 register when read from EL2 or EL3.
- **Offset**: For the EL1 physical timer, if ID_AA64MMFR0_EL1.ECV is 0b10 and CNTHCTL_EL2.ECV is 0b1, then the offset value is held in the CNTPOFF_EL2 register. Otherwise, the offset value of the EL1 physical timer is zero.
  - For the EL1 virtual timer, the offset value is held in the CNTVOFF_EL2 register.
  - For the EL2 physical and virtual timers, the offset value is zero.
- **CompareValue**: The value of the appropriate CompareValue register, CNTP_CV_AL_EL0, CNTHP_CV_AL_EL2, CNTHPS_CV_AL_EL2, CNTV_CV_AL_EL0, CNTHV_CV_AL_EL2, or CNTHVS_CV_AL_EL2.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.
Note

This means that a timer with a CompareValue of, or close to, 0xFFFFFFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Software can observe the counter value by the offset in some situations by reading CNTVCT_EL0.

Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, CNTV_CTL_EL0, CNTH_CTL_EL2, or CNTHVS_CTL_EL2.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads

\[
\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{ModOffset}))\{31:0\}
\]

Writes

\[
\text{CompareValue} = ((\text{Counter} - \text{ModOffset})\{63:0\} + \text{SignExtend} (\text{TimerValue}))\{63:0\}
\]

Where the arguments other than TimerValue and ModOffset have the definitions used in Operation of the CompareValue views of the timers, and in addition:

TimerValue

The value of a TimerValue register, CNTP_TVAL_EL0, CNTHP_TVAL_EL2, CNTHPS_TVAL_EL2, CNTPS_TVAL_EL1, CNTV_TVAL_EL0, CNTHV_TVAL_EL2, or CNTHVS_TVAL_EL2.

ModOffset

Offset for all timer registers other the EL1 physical timer accessed through CNTP_CTL_EL0.

Offset for the EL1 physical timer accessed through CNTP_CTL_EL0, if ID_AA64MMFR0_EL1.ECV is less than 0b10 or CNTHCTL_EL2.ECV is 0,

Offset for the EL1 physical timer accessed through CNTP_CTL_EL0, if ID_AA64MMFR0_EL1.ECV is 0b10 and CNTHCTL_EL2.ECV is 1, and if the access is from EL0 or EL1.

0 for the EL1 physical timer accessed through CNTP_CTL_EL0 if ID_AA64MMFR0_EL1.ECV is 0b10 and CNTHCTL_EL2.ECV is 1, and if the access is from EL2 or EL3.

In this view of a timer, values are signed in standard two’s complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Note

- Operation of the CompareValue views of the timers on page D10-5241 gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:

  \[\text{TimerConditionMet} = (\text{TimerValue} \leq 0)\]

- Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
Chapter D11
The Performance Monitors Extension

This chapter describes the implementation of the Arm Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the Performance Monitor Unit (PMU) architecture, FEAT_PMUv3. It contains the following sections:

• About the Performance Monitors on page D11-5244.
• Accuracy of the Performance Monitors on page D11-5248.
• Behavior on overflow on page D11-5250.
• Attributability on page D11-5252.
• Controlling the PMU counters on page D11-5254.
• Event filtering on page D11-5260.
• Event counting threshold on page D11-5262.
• Performance Monitors and Debug state on page D11-5264.
• Enabling event counters on page D11-5254.
• Counter access on page D11-5265.
• PMU events and event numbers on page D11-5266.
• Performance Monitors Extension registers on page D11-5428.

Note
Table K17-2 on page K17-11838 disambiguates the general register references used in this chapter.
D11.1 About the Performance Monitors

The Performance Monitors Extension is an OPTIONAL feature of an implementation, but Arm strongly recommends that implementations include version 3 of the Performance Monitors Extension, FEAT_PMUv3.

Note
No previous versions of the Performance Monitors Extension can be implemented in architectures from Armv8.0.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see Time as measured by the Performance Monitors cycle counter on page D11-5246.
- A number of 64-bit or 32-bit event counters. If FEAT_PMUv3p5 is implemented and the highest Exception level is using AArch64, the event counters are 64-bit. If FEAT_PMUv3p5 is not implemented, the event counters are 32-bit.
- The event counted by each event counter is programmable. The architecture provides space for up to 31 event counters. The actual number of event counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

Note
The Performance Monitors Extension permits an implementation with no event counters (PMCR_EL0.N==0). However, Arm recommends that at least two event counters are implemented, and that hypervisors provide at least this many event counters to guest operating systems.

- When EL2 is implemented, the required controls to partition the implemented event counters into the following ranges:
  - A first range which is available for use by the guest operating system accessible at all Exception levels.
  - A second range which is available for use by the hypervisor accessible at EL3 and EL2, and, if FEAT_SEL2 is not implemented or if Secure EL2 is disabled, in Secure state.

- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.
  - Disabling or freezing counters.
  - Threshold counting.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

Note
Implementations that include FEAT_PMUv3 must, as a minimum requirement, implement a subset of the common events. See Common event numbers on page D11-5306.

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. Arm recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, the architecture defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

Note
In AArch32 state, the interface is in the (coproc==0b1111) encoding space.
• An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See Chapter 13 Recommended External Interface to the Performance Monitors.

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:
• A set of events, from which a selection can be exported onto a bus for use as external events.
• The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:
• When executing in AArch64 state, PMCCNTR_EL0.
• When executing in AArch32 state, PMCCNTR.

When executing in AArch32 state, if FEAT_PMUv3p5 is implemented, bits [63:32] of the event counters are not accessible. If the implementation does not support AArch64 at any Exception level, 64-bit event counters are not required to be implemented.

D11.1.1 Interaction with EL3

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

Software executing at EL3 can:
• Prohibit counting of events Attributable to Secure state.
• If FEAT_PMUv3p5 is implemented, prohibit the cycle counter from counting cycles in Secure state, see Controlling the PMU counters on page D11-5254.
• If FEAT_PMUv3p7 is implemented:
  — Prohibit event counters from counting events at EL3 without affecting the rest of Secure state.
  — Prohibit the cycle counter from counting cycles at EL3 without affecting the rest of Secure state.

For more information, see Controlling the PMU counters on page D11-5254 and Freezing event counters on page D11-5255.

In AArch32 state, the Performance Monitors registers are Common registers, see Classification of System registers on page G5-9281.

If FEAT_MTPMU is implemented and EL3 is implemented, MDCR_EL3.MTPME and SDCR.MTPME enable and disable the PMEVTYPE<\alpha>.MT bit.

D11.1.2 Interaction with EL2

Software executing at EL3 or EL2 can program HDCR.HPMN to partition the event counters into two ranges:
• If HDCR.HPMN is not 0 and is less-than PMCR.N, HDCR.HPMN divides the event counters into a first range [0..(HDCR.HPMN-1)], and a second range [HDCR.HPMN..(PMCR.N-1)].
• If FEAT_HPMN0 is implemented and HDCR.HPMN is 0, all event counters are in the second range and none are in the first range.
• If HDCR.HPMN is equal to PMCR.N, all event counters are in the first range and none are in the second range.

This does not depend on whether EL2 is enabled in the current Security state. Each range of event counters has its own global controls.
If `FEAT_HPMN0` is not implemented and `HDCR.HPMN` is 0, the behavior is CONSTRAINED UNPREDICTABLE. See:

- *The Performance Monitors Extension* on page K1-11586.

Software executing at EL3 or EL2 can:

- Trap an access at EL0 or EL1 to the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state. There is a separate trap for the `PMCR` register, and if `FEAT_FGT` is implemented and enabled, fine-grained traps are provided.

- If `FEAT_PMUv3p1` is implemented, prohibit counting of events Attributable to EL2 by the event counters in the first range.

- If `FEAT_PMUv3p5` is implemented, prohibit the cycle counter from counting cycles at EL2.

When EL2 is implemented and enabled in the current Security state, software executing at EL1 and, if enabled by `PMUSERENR`, EL0:

- Will read the value of `HDCR.HPMN` for `PMCR.N`.
- Cannot access the event counters in the second range, or the controls associated with them.

If `FEAT_MTPMU` is implemented, EL3 is not implemented, and EL2 is implemented, `MDCR_EL2.MTPME` and `HDCR.MTPME` enable and disable the `PMEVTPYPER<n>.MT` bit.

For more information, see:

- *Enabling event counters* on page D11-5254.
- *Counter access* on page D11-5265.
- *Controlling the PMU counters* on page D11-5254.
- *Multithreaded implementations* on page D11-5258.

**D11.3 Time as measured by the Performance Monitors cycle counter**

The Performance Monitors cycle counter, accessed through `PMCCNTR_EL0` or `PMCCNTR`, increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

See *Controlling the PMU counters* on page D11-5254 for information about when the cycle counter does not increment.

______ Note ______

- This means that, in an implementation where PEs are multithreaded, when enabled, the cycle counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.

- Although the architecture requires that direct reads of `PMCCNTR_EL0` or `PMCCNTR` occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the `PMCCNTR_EL0` or `PMCCNTR` is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

**D11.4 Interaction with trace**

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a trace unit, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.
Arm recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the trace unit to pass in events to be counted.

Exporting PMU events to the ETM is prohibited for some Exception levels when SelfHostedTraceEnabled() == TRUE. For more information, see Controls to prohibit trace at Exception levels on page D3-4759.
D11.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See Non-invasive behavior.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See A reasonable degree of inaccuracy on page D11-5249.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, that software must configure before using certain PMU events. For example, to configure how the PE generates PMU events for components such as external caches and external memory.
- Other IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to optionally put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D11.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

Note

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

Arm does not define a reasonable variation in performance, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

Note

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative implementation defined event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an implementation defined control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.
D11.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. Arm does not define a reasonable degree of inaccuracy but recommends the following guidelines:

• Under normal operating conditions, the counters must present an accurate value of the count.

• In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.

• Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

Note

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision, and can affect which events are counted.

Where a direct write to a Performance Monitors control register disables a counter, and is followed by a Context synchronization event, any subsequent indirect read of the control register by the Performance Monitors to determine whether the counter is enabled will return the updated value. Any subsequent direct read of the counter or counter overflow status flags will return the value at the point the counter was disabled.

Note

The imprecision means that the counter might have counted an event around the time the counter was disabled, but does not allow the event to be observed as counted after the counter was disabled.

A change of Security state can also affect the accuracy of the Performance Monitors, see Interaction with EL3 on page D11-5245.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.
D11.3 Behavior on overflow

The event counters, PMEVCNTR<n>, are either 32-bit or 64-bit unsigned counters that overflow in the following situations:

- If FEAT_PMUvs3p5 is not implemented, 32-bit event counters are implemented, and if incrementing PMEVCNTR<n> causes an unsigned overflow of an event counter, the PE sets PMOVSCLR[n] to 1.

- If FEAT_PMUvs3p5 is implemented, 64-bit event counters are implemented, HDCR.HPMN is not 0, and either n is in the range [0 .. (HDCR.HPMN-1)] or EL2 is not implemented, then event counter overflow is configured by PMCR.LP:
  - When PMCR.LP is set to 0, if incrementing PMEVCNTR<n> causes an unsigned overflow of bits [31:0] of the event counter, the PE sets PMOVSCLR[n] to 1.
  - When PMCR.LP is set to 1, if incrementing PMEVCNTR<n> causes an unsigned overflow of bits [63:0] of the event counter, the PE sets PMOVSCLR[n] to 1.

- If FEAT_PMUvs3p5 is implemented, 64-bit event counters are implemented, EL2 is implemented, and HDCR.HPMN is less-than PMCR.N, when n is in the range [HDCR.HPMN .. (PMCR.N-1)], event counter overflow is configured by HDCR.HLP:
  - When HDCR.HLP is set to 0, if incrementing PMEVCNTR<n> causes an unsigned overflow of bits [31:0] of the event counter, the PE sets PMOVSCLR[n] to 1.
  - When HDCR.HLP is set to 1, if incrementing PMEVCNTR<n> causes an unsigned overflow of bits [63:0] of the event counter, the PE sets PMOVSCLR[n] to 1.

The cycle counter, PMCCNTR, is a 64-bit unsigned counter, that is configured by PMCR.LC:

- If PMCR.LC is set to 0, if incrementing PMCCNTR causes an unsigned overflow of bits [31:0] of the cycle counter, the PE sets PMOVSCLR[31] to 1.
- If PMCR.LC is set to 1, if incrementing PMCCNTR causes an unsigned overflow of bits [63:0] of the cycle counter, the PE sets PMOVSCLR[31] to 1.

The update of PMOVSCLR occurs synchronously with the update of the counter.

For all 64-bit counters, incrementing the counter is the same whether an unsigned overflow occurs at [31:0] or [63:0]. If the counter increments for an event, bits [63:0] are always incremented,

When any overflow occurs, an interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see Generating overflow interrupt requests.

If FEAT_PMUvs3p7 is implemented, event counting can be frozen after an unsigned overflow is detected, see Freezing event counters on page D11-5255.

--- Note

Software executing at EL1 or higher must take care that setting PMCR.LP or HDCR.HLP does not cause software executing at lower Exception levels to malfunction. If legacy software accesses the PMU at lower Exception levels, software at the higher Exception levels should not set the PMCR.LP or HDCR.HLP fields to 1. However, if the legacy software does not use the counter overflow, it is not affected by setting the PMCR.LP or HDCR.HLP to 1.

D11.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See PMINTENSET and PMINTEGR.

--- Note

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- Arm recommends that the overflow interrupt requests:
  - Translate into a PMUIRQ signal, so that they are observable to external devices.
— Connect to inputs on an IMPLEMENTATION DEFINED Generic Interrupt Controller as a Private Peripheral Interrupt (PPI) for the originating processor. See the ARM Generic Interrupt Controller Architecture Specification for information about PPIs.

— Connect to a Cross Trigger Interface (CTI), see Chapter H5 The Embedded Cross-Trigger Interface.

• Arm strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same System Peripheral Interrupt (SPI) identifier.

• From GICv3, the ARM® Generic Interrupt Controller Architecture Specification recommends that the Private Peripheral Interrupt (PPI) with ID 23 is used for overflow interrupt requests.

Software can write to the counters to control the frequency at which interrupt requests occur. For example, software might set a 32-bit counter to 0xFFFF0000, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflowing interrupt occurs.

Note

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

• Any given PMEVCNTR<\text{n}> counter, when the value of PMOVSET[n] is 1, the value of PMINTENSE[n] is 1, and one of the following is true:
  — EL2 is not implemented and the value of PMCR.E is 1.
  — EL2 is implemented, \text{n} is less than the value of HDCR.HPMN, and the value of PMCR.E is 1.
  — EL2 is implemented, \text{n} is greater than or equal to the value of HDCR.HPMN, and the value of HDCR.HPME is 1.

• The cycle counter, when the values of PMOVSET[31], PMINTENSE[31], and PMCR.E are all 1.

The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMEVCNTR<\text{n}> where \text{n} is greater than or equal to the value of HDCR.HPMN can be signaled from all modes and states but only if the value of HDCR.HPME is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing 1 to PMOVSCLR[n] to clear the overflow bit to 0.

Pseudocode description of overflow interrupt requests

See Chapter J1 Armv8 Pseudocode for a pseudocode description of overflow interrupt requests. The AArch64.CheckForPMUOverflow() and AArch32.CheckForPMUOverflow() pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.
D11.4 **Attributability**

An event caused by the PE counting the event is *Attributable*. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be generated by another PE with the same values for affinity level 1 and higher. This event is further defined as Attributable to:

- The current Security state of that PE.
- The current Exception level of that PE.
- When that PE is in Debug state, operations issued to that PE by the debugger through the external debug interface.

See *Multithreaded implementations on page D11-5258* for information about enabling and restricting counting events in a multithreaded implementation.

--- **Note** ---

- In an implementation containing multiple PEs, each PE is identified by a unique *affinity* value reported by `MPIDR_EL1[Aff3, Aff2, Aff1, Aff0]`, where the value of affinity level 0 is the most significant for determining the PE behavior, and the values of higher affinity levels are less significant. Affinity level 3 is only supported in AArch64 state.

- An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with:
  - `MPIDR_EL1.MT` or `MPIDR.MT` set to 1,
  - Different values for affinity level 0.
  - The same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are *Attributable*, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- *Interaction with EL3 on page D11-5245.*
- *Event filtering on page D11-5260.*
- *Performance Monitors and Debug state on page D11-5264.*
These sections are summarized by Table D11-1 on page D11-5253 for events Attributable to the processor, and Unattributable events. Table D11-1 on page D11-5253 entries apply when the counter and PMU are enabled and not frozen. Otherwise, events are not counted.

D11.5 Controlling the PMU counters

This section describes the mechanisms available for controlling the PMU event and cycle counters. The following sections describe those mechanisms:

- Enabling event counters.
- Freezing event counters on page D11-5255.
- Prohibiting event and cycle counting on page D11-5256.

D11.5.1 Enabling event counters

Table D11-2 on page D11-5254 shows an implementation that does not include EL2, where the PMCR.E bit is a global counter enable bit, and PMCNTENSET provides an enable bit for each counter.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[n] == 0</th>
<th>PMCNTENSET[n] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; enabled</td>
</tr>
</tbody>
</table>

If the implementation includes EL2, then in addition to the PMCR.E and PMCNTENSET enable bits:

- HDCR.HPME overrides the value of PMCR.E for counters configured for access in EL2.
- HDCR.HPMN specifies the number of event counters that the Guest OS can access. When FEAT_HPMN0 is not implemented, the minimum permitted value of HDCR.HPMN is 1, meaning there must be at least one event counter that the Guest OS can access. Otherwise, the minimum permitted value of HDCR.HPMN is 0.

Table D11-3 on page D11-5254 shows the combined effect of all the counter enable controls.

<table>
<thead>
<tr>
<th>HDCR.HPME</th>
<th>PMCR.E</th>
<th>PMCNTENSET[n] == 0</th>
<th>PMCNTENSET[n] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>0</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
</tr>
<tr>
<td>0 1</td>
<td>1</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; enabled</td>
</tr>
<tr>
<td>1 0</td>
<td>0</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
</tr>
<tr>
<td>1 1</td>
<td>1</td>
<td>PMEVCNTR&lt;n&gt; disabled</td>
<td>PMEVCNTR&lt;n&gt; enabled</td>
</tr>
</tbody>
</table>

Note:

- The effect of HDCR.{HPME, HPMN} on the counter enables applies at all Exception levels and in both Security states.
- The value returned for PMCR.N is not affected by HDCR.HPMN at:
  - EL3.
  - EL2.
  - Secure EL1, if FEAT_SEL2 is not implemented or Secure EL2 is disabled.
  - Secure EL0, if FEAT_SEL2 is not implemented or Secure EL2 is disabled.
The cycle counter, PMCCNTR, counts unless disabled or prohibited as described in *Prohibiting event and cycle counting* on page D11-5256.

### D11.5.2 Freezing event counters

When FEAT_SPEv1p2 is implemented, the PMU can be configured to freeze event counters when an SPE buffer management event occurs. A counter is disabled under the following conditions:

- If EL2 is implemented, MDCR_EL2.HPMN is not 0, \( n \) is in the range \([0 .. (MDCR_EL2.HPMN-1)]\), when PMBSR_EL1.S is 1, and PMBLIMITR_EL1.E is 1, indicating an SPE buffer management event occurred, event counter \( n \) does not count if all the following are true:
  - PMBLIMITR_EL1.PMFZ is 1.
  - PMCR_EL0.FZS is 1.
- If EL2 is not implemented, \( n \) is in the range \([0 .. (PMCR_EL0.N-1)]\), when PMBSR_EL1.S is 1 and PMBLIMITR_EL1.E is 1, indicating an SPE buffer management event occurred, event counter \( n \) does not count if all the following are true:
  - PMBLIMITR_EL1.PMFZ is 1.
  - PMCR_EL0.FZS is 1.
- If EL2 is implemented, MDCR_EL2.HPMN is not 0, \( n \) is in the range \([MDCR_EL2.HPMN .. (PMCR_EL0.N-1)]\), when PMBSR_EL1.S is 1 and PMBLIMITR_EL1.E is 1, indicating an SPE buffer management event occurred, event counter \( n \) does not count if all the following are true:
  - PMBLIMITR_EL1.PMFZ is 1.
  - MDCR_EL2.HPMFZ is 1.

**Note**

This also applies when EL2 is disabled in the current Security state.

If the highest implemented Exception level is using AArch32, then the Effective value of PMBLIMITR_EL1.E is 0 and FEAT_SPEv1p2 does not affect the PMU event counters. Otherwise, the effect of FEAT_SPEv1p2 on PMU event counters applies in AArch32 state. See *Profiling Buffer management* on page D13-5463.

When FEAT_PMUv3p7 is implemented, the PMU can be configured to freeze event counters when an unsigned overflow of a counter occurs. A counter is disabled under the following conditions:

- If EL2 is implemented, MDCR_EL2.HPMN is not 0, and \( n \) is in the range \([0 .. (MDCR_EL2.HPMN-1)]\), when PMOVSCLR_EL0[(MDCR_EL2.HPMN-1):0] is nonzero, indicating an unsigned overflow in one of the event counters in the range, event counter \( n \) does not count when PMCR_EL0.FZO is 1.
- If EL2 is implemented, MDCR_EL2.HPMN is less than PMCR_EL0.N and \( n \) is in the range \([MDCR_EL2.HPMN .. (PMCR_EL0.N-1)]\), when PMOVSCLR_EL0[(PMCR_EL0.N-1):MDCR_EL2.HPMN] is nonzero, indicating an unsigned overflow in one of the event counters in the range, event counter \( n \) does not count when MDCR_EL2.HPMFZO is 1.
- If EL2 is not implemented and \( n \) is in the range \([0 .. (PMCR_EL0.N-1)]\), when PMOVSCLR_EL0[(PMCR_EL0.N-1):0] is nonzero, indicating an unsigned overflow in one of the event counters in the range, event counter \( n \) does not count when PMCR_EL0.FZO is 1.

When the applicable PMCR_EL0.FZO or MDCR_EL2.HPMFZO bit is 1, it is **CONSTRAINED UNPREDICTABLE** whether any event happening at or about the same time as the event that caused the overflow is counted. This includes other instances of the same event.

**Note**

The architecture does not define when PMU events are counted relative to the instructions that caused the event. Events caused by an instruction might be counted before or after the instruction becomes architecturally executed, and events might be counted for operations that are not architecturally executed. Events can be counted speculatively, out-of-order, or both with respect to the simple sequential execution of the program. Events might also be counted simultaneously by other event counters when the overflow occurs, including events from different instructions. Multiple instances of an event might occur simultaneously, thus an event counter unsigned overflow can yield a nonzero value in the event counter.
Arm recommends that such counting anomalies are minimized when software uses the freeze on overflow feature. When the freeze on overflow feature is being used, software cannot assume that the event counter stops counting at zero when an overflow occurs.

If an event counter \( n \) overflows, where \( n \) is even and event counter \( n+1 \) is configured to count the CHAIN event, it is \text{CONSTRAINED UNPREDICTABLE} whether the CHAIN event observes the overflow event when the applicable \text{PMCR\_EL0.FZO} or \text{MDCR\_EL2.HPMFZO} bit is 1 and the corresponding \text{PMCR\_EL0.LP} or \text{MDCR\_EL2.HLP} bit is 0.

If a direct read of \text{PMOVSLR\_EL0} returns a nonzero value for a subset of the overflow flags, which means an event counter \( n \) should not count, then a sequence of direct reads of \text{PMEVCNTR<\(n\)} >\_EL0 ordered after the read of \text{PMOVSLR\_EL0} and before the \text{PMOVSLR\_EL0} flags are cleared to zero, will return the same value for each read, because the event counter has stopped counting.

\textbf{Note}

Direct reads of System registers require explicit synchronization for following direct reads of other System registers to be ordered after the first direct read.

\section{Prohibiting event and cycle counting}

Counting \textit{Attributable} events in Secure state is prohibited unless any one of the following is true:

\begin{itemize}
  \item EL3 is not implemented.
  \item \text{FEAT\_PMUv3p7} is not implemented, EL3 is implemented, is using AArch64, and the value of \text{MDCR\_EL3.SPME} is 1.
  \item \text{FEAT\_PMUv3p7} is implemented, EL3 is implemented, EL3 is using AArch64, the value of \text{MDCR\_EL3.SPME} is 1, and the value of \text{MDCR\_EL3.MPMX} is 0.
  \item \text{FEAT\_PMUv3p7} is implemented, EL3 is implemented, the PE is not at EL3, EL3 is using AArch64, and the value of \text{MDCR\_EL3.MPMX} is 1.
  \item EL3 is implemented, is using AArch32, and the value of \text{SDCR.SPME} is 1.
  \item EL3 is implemented, EL3 or EL1 is using AArch32, the PE is executing at EL0, and the value of \text{SDER32\_EL3.SUNIDEN} is 1.
  \item If \text{FEAT\_Debugv8p2} is not implemented, EL3 is implemented, and counting is permitted by an \text{IMPLEMENTATION DEFINED} authentication interface, \text{External\_Secure\_Noninvasive\_Debug\_Enabled()} == TRUE.
\end{itemize}

\textbf{Note}

Software can read the Authentication Status register, \text{DBGAUTHSTATUS} to determine the state of an \text{IMPLEMENTATION DEFINED} authentication interface.

If \text{FEAT\_PMUv3p7} is implemented and \text{MDCR\_EL3.MPMX} is 1, counting \textit{Attributable} events at EL3 for event counter \( n \) is prohibited if any of the following are true:

\begin{itemize}
  \item EL2 is not implemented, and \( n \) is in the range \([0 .. (\text{PMCR\_EL0.N}-1)]\).
  \item EL2 is implemented, \text{MDCR\_EL3.SPME} is 0, and \( n \) is in the range \([0 .. (\text{PMCR\_EL0.N}-1)]\).
  \item EL2 is implemented, \text{MDCR\_EL2.HPMN} is not 0, \text{MDCR\_EL3.SPME} is 1, and \( n \) is in the range \([0 .. \text{MDCR\_EL2.HPMN}-1)]\).
\end{itemize}

If EL2 is implemented and \text{MDCR\_EL3.{SPME, MPMX}} is \{1, 1\}, when \text{MDCR\_EL2.HPMN} is less than \text{PMCR\_EL0.N} and \( n \) is in the range \([\text{MDCR\_EL2.HPMN} .. (\text{PMCR\_EL0.N}-1)]\), counting \textit{Attributable} events at EL3 for event counter \( n \) is allowed.

Counting \textit{Attributable} events at EL2 is prohibited unless any of the following are true:

\begin{itemize}
  \item \text{FEAT\_PMUv3p1} is not implemented.
  \item \text{HDCR.HPMD} is not implemented.
\end{itemize}
The Performance Monitors Extension

D11.5 Controlling the PMU counters

- **MDCR_EL2.HPMN** is less than **PMCR_EL0.N**, the event is being counted by event counter *n*, and *n* is in the range \([MDCR_EL2.HPMN .. (PMCR_EL0.N-1)]\).

If **FEAT_SEL2** is implemented, counting **Attributable** events at Secure EL2 is allowed if and only if counting events is allowed in Secure state, and counting events is allowed at EL2.

The accessibility of Performance Monitors registers is unaffected by whether event counting is enabled or prohibited.

The cycle counter, **PMCCNTR**, counts unless any of the following is true:

- The cycle counter is disabled by **PMCR_EL0.E** or **PMCNTENSET_EL0[31]**.
- Event counting by event counters in the range \([0..(HDCR.HPMN-1)]\) is prohibited or frozen, and **PMCR.DP** is set to 1.

--- **Note**

When **FEAT_HPMN0** is implemented and **HDCR.HPMN** is 0, the cycle counter is disabled by **PMCR.DP** under the same conditions that would prohibit or freeze event counting by event counters in the range \([0..(HDCR.HPMN-1)]\) when **HDCR.HPMN** is not 0.

- The PE is in Debug state.
- **FEAT_PMUv3p5** is implemented, EL3 is implemented, the PE is in Secure state, and **SDCR.SCCD** is set to 1.
- **FEAT_PMUv3p5** is implemented, EL2 is implemented, the PE is executing at EL2, and **HDCR.HCCD** is set to 1.
- **FEAT_PMUv3p7** is implemented, the PE is at EL3, EL3 is using AArch64, and **MDCR_EL3.MCCD** is set to 1.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting **Attributable** events is prohibited.

See **AArch64.CountPMUEvents()** and **AArch32.CountPMUEvents()** in Chapter J1 Armv8 Pseudocode for more information. The CountEvents\(n\) functions return TRUE if PMEVCNTR\(<n>\) is enabled and allowed to count events at the current Exception level or state, and FALSE otherwise. The function CountEvents\(31\) returns TRUE if the cycle counter is enabled and allowed to count cycles at the current Exception level and state and FALSE otherwise. However, these functions do not completely describe the behavior for Unattributable events.

The Performance Monitors are intended to be broadly accurate and statistically useful, see **Accuracy of the Performance Monitors** on page D11-5248. Some inaccuracy is permitted at the point of changing between a state where counting is prohibited and a state where counting is allowed, however. To avoid the leaking of information, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.
D11.6 Multithreaded implementations

If an implementation is multithreaded and the Effective value of PMEVTYPER<\(n\).MT == 1, events on other PEs with the same level 1 Affinity are also counted. A pair of PEs have the same level 1 Affinity if they have the same values for all fields in MPIDR_EL1 or MPIDR except the Aff0 field.

Events on other PEs are not counted when the Effective value of PMEVTYPER<\(n\).MT is 0.

If the CPU implements multithreading, and FEAT_MTPMU is not implemented, for Armv8.5 and earlier, it is IMPLEMENTATION DEFINED whether PMEVTYPER<\(n\).MT is implemented as RW or RES0. From Armv8.6, if the OPTIONAL FEAT_MTPMU feature is not implemented, the Effective value of PMEVTYPER<\(n\).MT is RES0.

If FEAT_MTPMU is implemented, EL3 is implemented, and MDCR_EL3.MTPME is 0 or SDCR.MTPME is 0, FEAT_MTPMU is disabled and the Effective value of PMEVTYPER<\(n\).MT is 0.

If FEAT_MTPMU is implemented, EL3 is not implemented, EL2 is implemented, and MDCR_EL2.MTPME is 0 or HDCR.MTPME is 0, FEAT_MTPMU is disabled and the Effective value of PMEVTYPER<\(n\).MT is 0.

If FEAT_MTPMU is disabled on a Processing Element PEA, it is IMPLEMENTATION DEFINED whether FEAT_MTPMU is disabled on another Processing Element PEB, if all the following are true:

- FEAT_MTPMU is implemented on PEA and PEB.
- PEA and PEB have the same values for Affinity level 1 and higher.
- PEA and PEB both have MPIDR_EL1.MT or MPIDR.MT set to 1.

However, even when the Effective value of PMEVTYPER<\(n\).MT is 1, PEA does not count an event that is Attributable to Secure state on PEB if counting events Attributable to Secure state is prohibited on PEA. Similarly, PEA does not count an event that is Attributable to EL2 on PEB if counting events Attributable to EL2 is prohibited on PEA.

Example D11-1 The effect of having PMEVTYPER<\(n\).MT == 1

If the value of MDCR_EL3.SPME is 0, and \(n\) is less than PMCR.N on PEA, then event counter \(n\) on PEA does not count events Attributable to Secure state on PEB, even if one or both of the following applies:

- PEA is in Non-secure state.
- MDCR_EL3.SPME == 1 on PEB.

---

Example D11-2 The effect of having PMEVTYPER<\(n\).MT == 1

When MDCR_EL2.HPMN is not 0, if the value of MDCR_EL2.HPMD is 1 and \(n\) is less than MDCR_EL2.HPMN on PEA, then event counter \(n\) on PEA does not count events Attributable to EL2 on PEB, even if one of the following applies:

- MDCR_EL2.HPMD == 0 on PEB.
- PEA is not executing at EL2.

---

When the current configuration is not multithreaded, and PEA prohibits counting of events Attributable to Secure state when PEA is in Secure state, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to Secure state when PEA is in Non-secure state is permitted.
- Counting Unattributable events related to other Secure operations in the system when PEA is in Non-secure state is permitted.

Otherwise, counting events in Non-secure state is permitted.

When the current configuration is not multithreaded, and PEA prohibited counting of events Attributable to EL2 when PEA is at EL2, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to EL2 when PEA is using another Exception level is permitted.
• Counting Unattributable events related to EL2 when PE_A is using another Exception level is permitted. Otherwise, counting events at another Exception level is permitted.
D11.7 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D11.7.1 Filtering by Exception level and Security state

In AArch64 state:

- For each event counter, PMEVTYPER<n>_EL0 specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- PMCCFILTR_EL0 specifies the Exception levels in which the cycle counter counts.

For an event that is Attributable to an Exception level, in a multithreaded implementation:

- When the Effective value of PMEVTYPER<n>_EL0.MT is 1, the specified filtering is evaluated using the current Exception level and Security state of the thread to which the event is Attributable. See Example D11-3.
- When the Effective value of PMEVTYPER<n>_EL0.MT is 0, the event is only counted if it is Attributable to the counting thread, and the filtering is evaluated using the Exception level and Security state of the counting thread.

Example D11-3 Example of the effect of the PMEVTYPER<n>_EL0.MT control

In a multithreaded implementation, if the Effective value of PMEVTYPER<n>_EL0.MT is 1 and the value of PMEVTYPER<n>_EL0.U is 1 on the counting thread, then event counter n does not count events Attributable to EL0 on another thread, even if the counting thread is not executing at EL0.

For each Unattributable event, it is implementation defined whether the filtering applies. In a multithreaded implementation, if the filtering applies to an Unattributable event, then the filtering is evaluated using the Exception level and Security state of the counting thread.

In AArch32 state, the filtering controls are provided by the PMEVTYPER<n> and PMCCFILTR registers.

For more information, see the individual register descriptions and Multithreaded implementations on page D11-5258.

D11.7.2 Accuracy of event filtering

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- Exception-related events.
- Software increment events on page D11-5261.

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- EXC_TAKEN, Exception taken.
- EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return.
- CID_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
- TTBR_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to translation table base.
- EXC_UNDEF, Exception taken, other synchronous.
The Performance Monitors Extension

D11.7 Event filtering

- EXC_SVC, Exception taken, Supervisor Call.
- EXC_PABORT, Exception taken, Instruction Abort.
- EXC_DABORT, Exception taken, Data Abort or SError.
- EXC_IRQ, Exception taken,IRQ.
- EXC_FIQ, Exception taken,FIQ.
- EXC_SMC, Exception taken, Secure Monitor Call.
- EXC_HVC, Exception taken, Hypervisor Call.
- EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally.
- EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally.
- EXC_TRAP_OTHER, Exception taken, other traps not Taken locally.
- EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally.
- BRB_FILTRATE, Branch record captured.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR after the return from the exception.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any Speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening Context synchronization event must increment the event counter twice.

For more information, see SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.

D11.7.3 Pseudocode description of event filtering

See AArch64.CountPMUEvents() and AArch32.CountPMUEvents() in Chapter J1 Armv8 Pseudocode for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.
The Performance Monitors Extension

D11.8 Event counting threshold

When `FEAT_PMUv3_TH` is implemented, threshold condition controls are accessible through each `PMEVTYPER<n>_EL0` register. This gives software the ability to count events described by `PMEVTYPER<n>` only when they meet a threshold condition.

D11.8.1 Enabling event counting threshold

When `FEAT_PMUv3_TH` is implemented, threshold counting for event counter `n` is disabled if both of the following are true, and enabled otherwise:

- `PMEVTYPER<n>_EL0.TC` is `0b000`.
- `PMEVTYPER<n>_EL0.TH` is zero.

D11.8.2 Threshold conditions

The `PMEVTYPER<n>_EL0.{TC, TH}` fields define the threshold condition.

If `FEAT_PMUv3_TH` is not implemented, or threshold counting for event counter `n` is disabled, `V` is the amount that the event defined by `PMEVTYPER<n>.{MT, evtCount}` counts by in a given processor cycle.

Otherwise, on each processor cycle, `V` is compared with the value in `PMEVTYPER<n>_EL0.TH` to determine whether it meets the threshold condition. `PMEVTYPER<n>_EL0.TC` determines the threshold condition, and whether the counter increments by `V` or 1 when the threshold condition is met.

`PMMIR_EL1.THWIDTH` describes the maximum value that can be written to `PMEVTYPER<n>_EL0.TH`. The supported threshold conditions are:

- Less-than.
- Greater-than-or-equal-to.
- Not-equals.
- Equal-to.

Example D11-4 Incrementing event counter `n` by `V` when `V` meets the threshold condition

When all of the following are true, the event counter `n` will increment by four:

- `PMEVTYPER<n>_EL0.TC` is `0b010`, equals, meaning threshold counting for event counter `n` is enabled.
- `PMEVTYPER<n>_EL0.TH` is 4.
- `PMEVTYPER<n>.evtCount` is `0x003F`, `STALL SLOT`.
- There are exactly four operation Slots not occupied by an operation Attributable to the PE on the cycle.

Example D11-5 Incrementing event counter `n` by 1 when `V` meets the threshold condition

When all of the following are true, the event counter `n` will increment by one:

- `PMEVTYPER<n>_EL0.TC` is `0b101`, greater-than-or-equal, count, meaning threshold counting for event counter `n` is enabled.
- `PMEVTYPER<n>_EL0.TH` is 2.
- `PMEVTYPER<n>.evtCount` is `0x80C1`, `FP_FIXED_OPS_SPEC`.
- At least one floating-point multiply-add instruction is issued on the cycle.

--- Note ---

The event counter `n` also increments by 1 if, for example, two or more independent floating-point add operations are issued on the cycle.
D11.8.3  Accessing event counting threshold functionality

The PMEVTYPER<n>_EL0.{TC, TH} fields are not accessible through the AArch32 PMEVTYPER<n> System register. However, the threshold condition still applies in AArch32 state, and PMMIR_EL1.THWIDTH is readable in the AArch32 PMMIR System register.

When FEAT_PMUv3_TH is implemented, the PMEVTYPER<n>_EL0.{TC, TH} fields are accessible through the AArch64 PMEVTYPER<n>_EL0 System registers and the external interface PMEVTYPER<n>_EL0 registers. See Chapter 13 Recommended External Interface to the Performance Monitors.

PMMIR_EL1.THWIDTH is readable in the external PMMIR register.

D11.8.4  Pseudocode description of event counting threshold

See PMUCountValue() in Chapter J1 Armv8 Pseudocode for a pseudocode description of the operation of the threshold condition.
**D11.9 Performance Monitors and Debug state**

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the *Effective value* of PMEVTYPE<n>_EL0.MT is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in *Filtering by Exception level and Security state* on page D11-5260 apply for the current Security state in Debug state.
D11.10 Counter access

All implemented event counters are accessible in EL3 and EL2. If EL2 is implemented the hypervisor uses HDCR.HPMN to reserve an event counter, with the effect that if EL2 is enabled in the current Security state, software cannot access that counter and its associated state from EL0 or EL1.

If FEAT_FGT is implemented, if PMSELR.SEL or $n$ indicates an unimplemented event counter, access to PMXEVTYPEP, PMXEVCNTR, PMEVTYPEP<$n$>, or PMEVCNTR<$n$> is UNDEFINED.

--- Note ---

Whether software can access an event counter at an Exception level does not affect whether the counter counts events at that Exception level. For more information, see Controlling the PMU counters on page D11-5254 and Enabling event counters on page D11-5254.

D11.10.1 PMEVCNTR<$n$> event counters

Table D11-4 on page D11-5265 shows how the number of implemented event counters, PMCR.N, and if EL2 is implemented, the value of the HDCR.HPMN field affects the behavior of permitted accesses to the PMEVCNTR<$n$> event counter registers for values of $n$ from 0 to 30.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Access at Exception level</th>
</tr>
</thead>
<tbody>
<tr>
<td>$n$ &lt; PMCR.N and either EL2 is not implemented or EL2 is disabled in the</td>
<td>EL3</td>
</tr>
<tr>
<td>current Security state</td>
<td>Succeeds</td>
</tr>
<tr>
<td>$n$ &lt; HDCR.HPMN and EL2 is implemented and enabled in the current</td>
<td>Succeeds</td>
</tr>
<tr>
<td>Security state</td>
<td></td>
</tr>
<tr>
<td>$n$ ≥ HDCR.HPMN and $n$ &lt; PMCR.N and EL2 is implemented and enabled in</td>
<td>Succeeds</td>
</tr>
<tr>
<td>the current Security state</td>
<td></td>
</tr>
<tr>
<td>$n$ ≥ PMCR.N</td>
<td>No access</td>
</tr>
</tbody>
</table>

Where Table D11-4 on page D11-5265 shows access succeeds for an event counter $n$, the access might be UNDEFINED or generate a trap exception. See the descriptions of PMEVCNTR<$n$> and PMXEVCNTR for details.

Where Table D11-4 on page D11-5265 shows no access for an event counter $n$:

- When PMSELR.SEL is $n$, the PE prevents direct reads and direct writes of PMXEVTYPEP or PMXEVCNTR. See the register descriptions for more information.
- The PE prevents direct reads and direct writes of PMEVTYPEP<$n$> or PMEVCNTR<$n$>. See the register descriptions for more information.
- Direct reads and direct writes of the following registers are RAZ/WI, PMOVSCLR[$n$], PMOVSET[$n$], PMCNTENSET[$n$], PMCNTENCLR[$n$], PMINTENSET[$n$], and PMINTENCLR[$n$].
- Direct writes to PMSWINC[$n$] are ignored.
- A direct write of 1 to PMCR.P does not reset PMEVCNTR<$n$>.

D11.10.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. However, access to the PMU registers are subject to the access permissions described in Configurable instruction controls on page D1-4665.
D11.11 PMU events and event numbers

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

• **Definitions.**
• **The PMU event number space and common events** on page D11-5275.
• **Common event numbers** on page D11-5306.
• **Cycle event counting** on page D11-5421.
• **Meaningful combinations of common microarchitectural events** on page D11-5422.
• **Meaningful combinations of SVE events** on page D11-5424.
• **Required events** on page D11-5425.
• **IMPLEMENTATION DEFINED event numbers** on page D11-5427.

D11.11.1 Definitions

The following subsections give more information about terms used in the event definitions:

• **Definition of terms.**
• **Levels of caches and TLBs** on page D11-5272.
• **Shared caches and buses** on page D11-5272.
• **Counting exceptions taken locally or not taken locally** on page D11-5273.

Definition of terms

This section describes terms used by PMU events as they relate to the implementation of the PMU. For more definitions, see **Glossary.**

**ALU operation counts**

The PMU events 0x80C0 to 0x80C9 count the number of arithmetic logic unit operations performed by each instruction.

Table D11-5 on page D11-5267 gives the ALU operation counts for complex ALU operations. In this table:

- **Input size** The element size of input operands other than the accumulator.
- **Acc size** The element size of the accumulator operand.
- **Count** The number of addition and multiply operations per 128 bits of input:
  • Scalable vector operations increment the counter by the Count value for an applicable *_SCALE_OPS_SPEC event.
  • Advanced SIMD operations operating on a 128-bit register increment the counter by the Count value for an applicable *_FIXED_OPS_SPEC event.
  • Advanced SIMD operations operating on a 64-bit register increment the counter by half the Count value for an applicable *_FIXED_OPS_SPEC event.

- **Type** The data type classification for the operations. This determines for which events the event counter counts the operation.

Predicated operations are counted even if the Governing predicate for the element is FALSE.

**Note**

The FP64 FMUL instruction works on 256-bit segments, and performs 16 operations per 256-bit segment. The table represents counts per 128 bits of input, so the counter increments by 8.
Predicated operations are counted even if the governing predicate for the element is FALSE.

For other instructions, the PMU events that count ALU operations are incremented as follows:

- Multiply-add, multiply-subtract, fused multiply-add, and fused multiply-subtract instructions generate two ALU operations of the specified type per input element. For floating-point operations, these are the instructions counted by FP_FMA_SPEC.
- All other data processing operations generate one ALU operation of the specified type per input element.

The PMU events 0x80CA to 0x80CF count the number of load or store operations performed by each instruction:

- Non-SVE load and store of a single register instructions increment the counter by 1. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2. This includes loads and stores of pairs of Sx, Dx, and Qx SIMD&FP registers.
- AArch32 load and store multiple registers instructions increment the counter by the number of registers transferred.
- Atomic store instructions increment the counter by 1. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by 4.
- SVE and Advanced SIMD LDI instructions increment the counter by 1.
- SVE LDIQ instructions increment the counter by (128 ÷ CSIZE).
- Advanced SIMD LDI[1-4] and ST[1-4] instructions increment the counter by the number of elements transferred per vector multiplied by the number of transferred registers.
- DC ZVA and DC GZVA instructions increment the counter by an IMPLEMENTATION DEFINED amount.

CSIZE

Container size, in bits, that corresponds to the largest non-overlapping SVE or Advanced SIMD vector element size or scalar register size that is encoded in the instruction opcode. This excludes the 64-bit elements of the wide element variants of the SVE bitwise shift and integer compare instructions that overlap the narrower source and destination elements.
Event in progress

Some events count when another event or condition is in progress. This might mean that the event counts the occupancy of a queue or other microarchitectural structure tracking the event. It is usually implementation defined when an event is in progress.

For example, the MEM_ACCESS_RD_PERCYC event counts when the MEM_ACCESS_RD event is in progress, meaning on each Processor cycle, the counter increments by the number of Memory-read operations that are in progress.

These events can be used to calculate the average number of events in progress. In the case of the MEM_ACCESS_RD_PERCYC event, this is also the average read latency. However, the definition of in progress might not include all parts of the operation.

Example D11-6 Stages of an operation not included in the definition of event in progress

In an example implementation, a Memory-read operation generated by a load instruction occupies three pipeline stages in the PE before generating a MEM_ACCESS_RD event when the PE starts to access memory. The event is then considered to be in progress until the data is returned to the PE. In the case of a Normal Cacheable access, the PE first looks in the Level 1 data cache, and if the address is cached, returns data in two cycles. Once the data is returned, it is another cycle before the result can be forwarded to any other instruction.

In this example, if all loads hit in the Level 1 cache, the average read latency calculated using the MEM_ACCESS_RD_PERCYC and MEM_ACCESS_RD events might be two cycles. Although this value is correct for the implementation-specific definition of this event, it has to be adjusted by a constant four additional cycles to match the more commonly understood definition of Level 1 cache access latency, which for this example would be quoted as six cycles.

Instruction architecturally executed

An instruction that is part of the Execution stream. See also Architecturally executed.

A reasonable degree of inaccuracy on page D11-5249 allows for counts to be inaccurate in exceptional circumstances. For an event that counts instructions architecturally executed, this allows an implementation to count instructions that do not form part of the Execution stream because of an exceptional event, such as if the instruction generates a synchronous exception or entry to Debug state.

Instructions that have no visible effect on the architectural state of the PE are architecturally executed and counted even if they form part of the Execution stream.

Examples of instructions that have no visible effect are:

• A NOP.
• A conditional instruction that fails its Condition code check.
• A Compare and Branch on Zero, CBZ, instruction that does not branch.
• A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

However, for events that count only the execution of instructions that update System registers, such as CID_WRITE RETIRED, if such an instruction is executed twice without an intervening Context synchronization event, it is constrained unpredictable whether the first instruction is counted.

Instruction architecturally executed, Condition code check pass

Instruction architecturally executed, Condition code check pass is a class of events that explicitly do not occur for:

• A conditional instruction that fails its Condition code check.
• A Compare and Branch on Zero, CBZ, instruction that does not branch.
• A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
• A Test and Branch on Zero, TBZ, instruction that does not branch.
• A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
• A Store-Exclusive instruction that does not write to memory.
Otherwise, the definition of architecturally executed is the same as for Instruction architecturally executed.

A branch that is architecturally executed, with condition code check pass is also described as a branch taken.

**Instruction memory access**

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:
- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

**Memory-read operations**

A PE accesses memory through memory-read operations and Memory-write operations. A memory-read operation might be due to:
- The result of an architecturally executed memory-reading instructions.
- The result of a Speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:
- Memory-read operations or Memory-write operations that miss in the cache
- The execution of a data preload instruction.
- The execution of a cache maintenance instruction.

--- **Note** ---

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.
- Instruction memory accesses to a unified cache, when the cache does not implement the L<n>I_CACHE event.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an LDPE instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

**Memory-write operations**

Memory-write operations might be due to:
- The result of an architecturally executed memory-writing instructions.
- The result of a Speculatively executed memory-writing instructions.

--- **Note** ---

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.
For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see [Memory-read operations](#).
- The execution of a cache maintenance instruction.

--- **Note** ---

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

---

- The result of a coherency request from another PE.

This list is not exhaustive.

**DC ZVA** is counted as a [Memory-write operation](#). **ST64BV** and **ST64BV0** are Store with Return instructions, but for the purpose of the PMU they are treated as Memory-write operations.

The relationship between memory-writing instructions and memory-write operations is [IMPLEMENTATION DEFINED](#). For example, for some implementations an **STP** instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two **STR** instructions that write to adjacent memory might be merged into a single memory-write operation.

--- **Note** ---

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

**MSIZE**

Memory element access size, in bits, that corresponds to a load or store instruction mnemonic suffix, where B=8, H=16, W=32 and D=64. When an instruction mnemonic does not end with B, H, W or D, the memory access size is implied by the scalar transfer register size or SIMD transfer register element size.

**Non-SIMD SVE instructions**

These instructions are:

- Vector address calculation instructions, **ADDPL**, **ADDVL**, and **RDVL**.
- The scalar **Predicate counts** instructions.
- The compare and terminate instructions, **CTERMEQ**, **CTERMNE**.

**Operation**

An instruction might create one or more microarchitectural operations (μ-ops) at any point in the execution pipeline. Depending on the event definition, the μ-ops might be counted instead of instructions. The definition of a μ-op is implementation specific. An architecture instruction might create more than one μ-op for each instruction. μ-ops might also be removed or merged in the execution stream, so an architecture instruction might create no μ-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of μ-ops is permitted.

This means the relationship between a μ-op and an architecturally executed instruction is [IMPLEMENTATION DEFINED](#).

--- **Note** ---

The architecture does not require that an implementation that generates μ-ops must count μ-ops for operations. An implementation can choose to interpret operation as instruction.
The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

Operations might be defined with reference to a particular instruction or type of instruction. In the case of operations this means operations with semantics that map to that type of instruction. For example, an implementation splits an A32 or T32 LDM instruction of six registers into six μ-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load μ-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operations speculatively executed - Load) events.
- One (Operations speculatively executed - Integer data processing) event.
- One (Operations speculatively executed - Software change of the PC) event if the PC was one of the six registers in the LDM instruction.

Operations speculatively executed

A Operation that is Speculatively executed.

There is no architecturally guaranteed relationship between a Speculatively executed micro-op and an architecturally executed instruction.

The results of such an operation can also be discarded, if it transpires that the operation was not required, following a mispredicted branch. Therefore, the architecture defines these events as operations speculatively executed, where appropriate.

Note

In some events, operation has a more specific meaning described in the event. See ALU operation counts on page D11-5266.

Processor cycle

For a non-multithreaded implementation, this means a cycle of the processor. For a multithreaded implementation, processor cycle means each cycle of the multithreaded processor, not just those cycles for which the PE counting the event is active.

Slot

An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an implementation specific point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

Each possible micro-op that can be executed at that point in a cycle is called a Slot. The maximum number of micro-ops that can be executed is defined by PMMIR.SLOTS.

Software change of the PC

Some events relate to instructions that cause a software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

It is IMPLEMENTATION DEFINED whether any or all of the following are treated as software changes of the PC:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMC.
- Context synchronization barrier ISB instructions.
Speculatively executed

An instruction or operation that is counted by an event when it might be Speculative.

The architecture does not define the point in a pipeline where an event is counted. For some events, this means the operation or instruction is counted when the operation or instruction is Speculative. The results of such an operation or instruction might later be discarded, if it transpires that the operation was not required, such as following a mispredicted branch, or might be later resolved to be Architecturally executed.

Different groups of events might be counted at different points in the pipeline and so can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

VL

The current SVE vector length, in bits.

Levels of caches and TLBs

The mapping of levels of cache and TLB to the PMU events is IMPLEMENTATION DEFINED. Although CLIDR_EL1 and CLIDR define the implemented levels of cache, these are not required to correspond with the levels of cache defined for PMU events. The architecture does not provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations, and Arm recommends the following implementation guidelines:

- If L3D_CACHE events are implemented, then L2D_CACHE and if applicable L2I_CACHE events should be implemented.
- If L2D_CACHE events are implemented, then L1D_CACHE and if applicable L1I_CACHE events should be implemented.
- If L2I_CACHE events are implemented, then L1I_CACHE events should be implemented.
- Where the Last Level of cache is also the Level 3 or Level 2 unified cache, the LL_CACHE events should be implemented in preference to the L3D_CACHE or L2D_CACHE events as applicable.
- For the Level <n> cache, where <n> = 1 and <n> = 2:
  - If the Level <n> cache is unified, but the cache can disambiguate between Data and Instruction accesses to the cache, then both the L<n>D_CACHE and L<n>I_CACHE events should be implemented.
  - If the cache is unified and the cache cannot disambiguate between Data and Instruction accesses, then only the L<n>D_CACHE should be implemented, counting all accesses.

This final property is IMPLEMENTATION DEFINED.

Shared caches and buses

There is no architectural concept of a shared component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.
Example D11-7 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

Note

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

Counting exceptions taken locally or not taken locally

Table D11-6 on page D11-5273 shows the events for exceptions taken to an Exception level using AArch64.

<sup>a</sup> Implementation defined.
The Performance Monitors Extension

D11.11 PMU events and event numbers

The Glossary defines the term Taken locally, that is used in event definitions in Common microarchitectural events on page D11-5317. See also Exception levels on page D1-4632 for more information.

D11.11.2 The PMU event number space and common events

In Armv8.0, the event number space is 10 bits. Armv8.1 extends the event number space, and therefore the PMEVTYPE<n>_EL0.evtCount field to 16 bits, and is allocated as Table D11-7 on page D11-5275 shows. For more information about the entries in the Allocation on page D11-5275 column see the text that follows this table:

The meaning of the entries in the Allocation on page D11-5275 column of Table D11-7 on page D11-5275 is as follows:

Common architectural and microarchitectural events

Arm defines the use of these event numbers. For more information see Common event numbers on page D11-5306.

a. The exception reported with EC 0x1F is IMPLEMENTATION DEFINED, and therefore it is IMPLEMENTATION DEFINED which event counts the exception, except that the event that counts the exception must correctly indicate whether the exception was Taken locally.
IMPLEMENTATION DEFINED event numbers

For more information about the use of these event numbers see IMPLEMENTATION DEFINED event numbers on page D11-5427.

See PMEVTYPERN.EVT Count for details of the PE behavior when an event number for a reserved or unimplemented PMU event is written to evtCount.

Table D11-8 on page D11-5276 lists the number and mnemonic of PMU events.

</table>
The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see *Required events* on page D11-5425.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

**Note**

Arm might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

It is IMPLEMENTATION DEFINED which events, including Common events, are generated by IMPLEMENTATION DEFINED extensions to the architecture, including accesses to IMPLEMENTATION DEFINED System registers and IMPLEMENTATION DEFINED System instructions. However, the functionality of the IMPLEMENTATION DEFINED extension must be appropriate for the generated events.

The common events are described in the following sections:

- *Common architectural events* on page D11-5307.
- *Common microarchitectural events* on page D11-5317.

The supported common architectural and microarchitectural events in the ranges 0x0000-0x003F and 0x4000-0x403F are discoverable to software through:

- The PMCEID0_EL0 and PMCEID1_EL0 registers in AArch64 state.
- The PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers in AArch32 state.

Arm recommends that the value of 0 is used for the PMCEID0_EL0 or PMCEID1_EL0 bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

**Note**

- For example, if an implementation never generates the L1D_CACHE_ALLOCATE event, event 31, Arm recommends that PMCEID0_EL0[31] is RAZ.
- In an implementation that supports both Execution states, each bit in the AArch64 PMCEID0_EL0 and PMCEID1_EL0 registers corresponds to a single bit in the AArch32 PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers, and corresponding bits must have the same behavior.
However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding PMCEIDn_EL0 bit might be RAO.

Event numbers that Table D11-7 on page D11-5275 shows as allocated for common architectural and microarchitectural events that are not described in Common architectural events and Common microarchitectural events on page D11-5317 are reserved. Future revisions of this Manual, or of the architecture, might assign these reserved values to additional common events. Events that do not require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

--- Note ---

The requirement that an event that is implemented retrospectively does not require additional features in the PMU means that it must be possible to represent the event $n$ the PMEVTPER<$n$>_EL0.evtCount field. This means, for example, that an implementation with a 10-bit PMEVTPER<$n$>_EL0.evtCount field can only implement events with event numbers $0x0000$-$0x03FF$.

**Common architectural events**

The Common architectural events are:

$0x0000$, **SW_INCR, Instruction architecturally executed, Condition code check pass, software increment**

The counter counts each write to the PMSWINC_EL0 and PMSWINC register, for each implemented event counter $<n>$:

- In AArch64 state, if PMEVTPER<$n$>_EL0.evtCount is $0x0000$ then the counter counts each MSR write to PMSWINC_EL0 with bit $[n]$ set to 1.
- In AArch32 state, if PMEVTPERN.evtCount is $0x0000$ then the counter counts each MCR write to PMSWINC with bit $[n]$ set to 1.

If the PE performs two architecturally executed writes to the PMSWINC_EL0 or PMSWINC register without an intervening Context synchronization event, then the counter is incremented twice.

--- Note ---

In a multithreaded implementation, if the Effective value of PMEVTPER<$n$>_EL0.MT is 1, then the counter counts writes by all PEs that have the same affinity at level 1 and above.

PMCEID0_EL0[0] reads as $0b1$ if this event is implemented and $0b0$ otherwise.
This event must be implemented.

$0x0006$, **LD_RETIRED, Instruction architecturally executed, Condition code check pass, load**

The counter counts each architecturally-executed memory-reading instruction.

--- Note ---

This event $0x006$ does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PREM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. Arm recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

PMCEID0_EL0[6] reads as $0b1$ if this event is implemented and $0b0$ otherwise.

$0x0007$, **ST_RETIRED, Instruction architecturally executed, Condition code check pass, store**

The counter counts each architecturally-executed memory-writing instruction.
DC ZVA is counted as a store.

The counter does not count a Store-Exclusive instruction that fails.

PMCEID0_EL0[7] reads as $0b1$ if this event is implemented and $0b0$ otherwise.
0x0008, INST_RETIRED, Instruction architecturally executed

The counter counts each architecturally-executed instruction.

It is IMPLEMENTATION DEFINED whether the counter counts architecturally-executed MOVPRFX instructions.

PMCEID0_EL0[8] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if event INST_SPEC is not implemented.

0x0009, EXC_TAKEN, Exception taken

The counter counts each exception taken.

--- Note ---

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, Exception entry on page D1-4641.
- For exceptions taken to an Exception level using AArch32, AArch32 state exception descriptions on page G1-8964.

PMCEID0_EL0[9] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000A, EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return

The counter counts each architecturally-executed exception return instruction. The following sections define the counted instructions:

- For an exception return from an Exception level using AArch64, Exception return on page D1-4644.
- For an exception return from an Exception level using AArch32, Exception return to an Exception level using AArch32 on page G1-8951.

However, it is CONSTRAINED UNPREDICTABLE whether this event counts the execution of an exception return instruction if either:

- Execution of the instruction is, itself, CONSTRAINED UNPREDICTABLE.
- Execution of the instruction sets PSTATE.IL and does not generate an exception return.

--- Note ---

Examples of when an exception return instruction is CONSTRAINED UNPREDICTABLE are if the instruction is executed at EL0, or in AArch32 state in System mode.

A particular consequence of this CONSTRAINED UNPREDICTABLE behavior is that an implementation that does not support AArch32 state at EL1 or higher does not have to treat AArch32 MOV PS, LR instructions, and related instructions, as exception return instructions.

PMCEID0_EL0[10] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000B, CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR

The counter counts each MSR write to CONTEXTIDR_EL1 and each MCR write to CONTEXTIDR.

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

When FEAT_VHE is implemented, the counter:

- Counts each architecturally-executed instruction accessing the named register CONTEXTIDR_EL1, including when executing at EL2 when HCR_EL2.E2H is 0b1.
- Does not count instructions accessing the named register CONTEXTIDR_EL12.
The event is defined by the name used to access the register. The counter does not count writes to the named register CONTEXTIDR_EL2.

PMCEID0_EL0[11] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000C, PC_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, Software change of the PC
The counter counts each architecturally-executed Software change of the PC that is taken. This includes all:
• Branch instructions.
• Memory-reading instructions that explicitly write to the PC.
• Data-processing instructions that explicitly write to the PC.
• Exception return instructions.

Conditional branches are only counted if the branch is taken.

It is IMPLEMENTATION DEFINED whether the following are included as a Software change of the PC:
• BRK and BKPT instructions.
• An UNDEFINED instruction that generates an exception.
• An exception-generating instruction, SVC, HVC, and SMC, that generates an exception.
• Context synchronization barrier instructions, ISB.

The counter does not increment for exceptions other than those explicitly identified in these lists. If PC_WRITE_RETIRED and BR_SKIP_RETIRED are both implemented, the PE must treat the following types of instruction in the same way for both events:
• BRK and BKPT instructions.
• UNDEFINED instructions.
• The exception-generating instructions, SVC, HVC, and SMC.
• Context synchronization barrier instructions.

From Armv8.6, if BR_RETIRED is also implemented, the PE must also treat these types of instruction in the same way for the BR_RETIRED, PC_WRITE_RETIRED, and BR_SKIP_RETIRED events.

PMCEID0_EL0[12] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000D, BR_IMMED_RETIRED, Branch Instruction architecturally executed, immediate
The counter counts all architecturally-executed immediate branch instructions.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:
• B{<c> } <label>.
• BL{<c>} <label>.
• BLX{<c>} <label>.
• CBZ <Rn>, <label>.
• CBNZ <label>.

In AArch64 state, the counter increments each time the PE executes one of the following instructions:
• B <label>.
• B.cond <label>.
• BL <label>.
• CBZ <Rn>, <label>.
• CBNZ <Rn>, <label>.
• TBZ <Rn>, <label>.
• TBNZ <Rn>, <label>.

--- Note ---
Conditional branches are always counted, regardless of whether the branch is taken or not taken.

---
If the Context synchronization barrier instruction ISB is counted as a Software change of the PC instruction by PC_WRITE RETIRED, then it is IMPLEMENTATION DEFINED whether ISB is counted as an immediate branch instruction.

PMCEID0_EL0[13] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000E, BR_RETURN RETIRED, Branch Instruction architecturally executed, procedure return, taken
In AArch32 state, the counter counts the following architecturally executed procedure return instructions:
• BX R14.
• MOV PC, LR.
• POP {..., PC}.
• LDR PC, [SP], #offset.

--- Note ---
The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:
• BX R0, because Rm ≠ R14.
• MOV PC, R0, because Rm ≠ R14.
• LDM SP, {..., PC}, because writeback is not specified.
• LDR PC, [SP, #offset], because this specifies the wrong addressing mode.

---
In AArch64 state, the counter counts architecturally executed RET, RETAA, and RETAB instructions.
PMCEID0_EL0[14] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x000F, UNALIGNED_LDST RETIRED, Instruction architecturally executed, Condition code check pass, unaligned load or store
The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.
The counter does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.
It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.
PMCEID0_EL0[15] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x001C, TTBR_WRITE RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR
The counter counts MSR writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and MCR and MCRR writes to TTBR0 and TTBR1 in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of TTBR0 and TTBR1.
If the PE executes two writes to the same TTBR, without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.
If EL3 is implemented and using AArch64, the counter does not count writes to TTBR0_EL3.
If EL2 is implemented and using AArch64, the counter does not count writes to TTBR0_EL2 and VTTBR_EL2.

If EL2 is implemented and using AArch32, the counter does not count writes to HTTBR and VTTBR.

When FEAT_VHE is implemented, the counter:
• Counts each architecturally-executed instruction accessing the named registers TTBR0_EL1 and TTBR1_EL1, including when executing at EL2 when HCR_EL2.E2H is 0b1.
• Does not count instructions accessing the named registers TTBR0_EL12 and TTBR1_EL12.

PMCEID0_EL0[28] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x001E, CHAIN, Chain a pair of event counters

Even-numbered counters never increment as a result of this event.
For an odd-numbered counter <n+1>, the counter increments when an event increments the preceding even-numbered counter <n> on the same PE causing unsigned overflow of bits [31:0] of the event counter <n>, and any of the following are true:
• FEAT_PMUv3p5 is not implemented.
• EL2 is not implemented and PMCR.LP is 0b1.
• EL2 is implemented, <n> is less than HDCR.HPMN, and PMCR.LP is 0b0.
• EL2 is implemented, <n> is greater than or equal to HDCR.HPMN, and HDCR.HLP is 0b0.
This means the CHAIN event can be used to link the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

Note

When FEAT_PMUv3p5 is not implemented, the CHAIN event allows software to use the N event counters as N 32-bit counters, N/2 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it ignores the Effective value of PMEVTYPER<n>_EL0.MT.
The architecture does not provide atomic access to a pair of counters.

To filter the Exception levels and Security states in which the event is counted, software:
• Programs PMEVTYPER<n>_EL0 to count the event in the required conditions.
• Programs PMEVTYPER<n+1>_EL0 to count the CHAIN event in all Exception levels and states.
The PE might ignore the filter settings for the CHAIN event and behave as if they are set to count in all Exception levels and states. If software does not program the event in this way, the count becomes UNPREDICTABLE.
The architecture does not define the latency between the low counter overflowing and the high counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair by reading the low counter first and the high counter second, with an intervening Context synchronization event, will not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter ensures the completion of the update of the high counter by the CHAIN event.
PMCEID0_EL0[30] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0021, BR_RETIRED, Instruction architecturally executed, branch

The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:
• Unconditional direct branch instructions.
The Performance Monitors Extension

D11.11 PMU events and event numbers

- Exception-generating instructions.
- Exception return instructions.
- Context synchronization instructions.

The counter counts all other branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

Arm recommends that BR_RETIRED counts Unconditional direct branch instructions and Exception return instructions.

From Armv8.6, if PC_WRITE RETIRED and BR_RETIRED are both implemented, the PE must treat the following types of instruction in the same way for both events:
- BRK and BKPT instructions.
- UNDEFINED instructions.
- The exception-generating instructions, SVC, HVC, and SMC.
- Context synchronization barrier instructions.

PMCEID1_EL0[1] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x400C, TRB_WRAP, Trace buffer current write pointer wrapped

The event is generated each time the current write pointer is wrapped to the base pointer.

PMCEID0_EL0[44] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if FEAT_TRBE is implemented.

0x400D, PMU_OVFS, PMU overflow, counters accessible to EL1 and EL0

The event is generated each time one of the following occurs:
- An event is counted by an event counter <n> and all of the following are true:
  - PMINTENSET_EL1[n] is 0b1.
  - One of the following is true:
    - Counting the event causes unsigned overflow of PMEVCNTR<n>_EL0[31:0], and either FEAT_PMUv3p5 is not implemented or PMCR_EL0.LP is 0b0.
    - Counting the event causes unsigned overflow of PMEVCNTR<n>_EL0[63:0], FEAT_PMUv3p5 is implemented, and PMCR_EL0.LP is 0b1.
    - Either EL2 is implemented and <n> in the range [0 .. (MDCR_EL2.HPMN-1)], or EL2 is not implemented and <n> is in the range [0 .. (PMCR_EL0.N-1)].
- A cycle is counted by PMCCNTR_EL0, PMINTENSET_EL1[31] is 0b1, and one of the following is true:
  - Counting the cycle causes unsigned overflow of PMCCNTR_EL0[31:0] and PMCR_EL0.LC is 0b0.
  - Counting the cycle causes unsigned overflow of PMCCNTR_EL0[63:0] and PMCR_EL0.LC is 0b1.

This event cannot be counted by the PMU. PMCEID0_EL0[45] reads as 0b0.

This event must be implemented if all of the following are true:
- FEAT_PMUv3 is implemented.
- FEAT_ETE is implemented.

0x400E, TRB_TRIG, Trace buffer Trigger Event

The event is generated when a Trace Buffer Extension Trigger Event occurs.

It is IMPLEMENTATION DEFINED whether this event can be counted by the PMU.
PMCEID0_EL0[46] reads as 0b1 if this event is implemented and can be counted by the PMU, and 0b0 otherwise.

This event must be implemented if FEAT_TRBE is implemented.

\[0x400F\], **PMU_HOVFS, PMU overflow, counters reserved for use by EL2**

The event is generated each time an event is counted by an event counter \(<n>\) and all of the following are true:

- EL2 is implemented.
- PMINTENSET_EL1[\(n\)] is 0b1.
- One of the following is true:
  - Counting the event causes unsigned overflow of PMEVCNTR\(<n>_EL0[31:0]\), and either FEAT_PMUv3p5 is not implemented or MDCR_EL2.HLP is 0b0.
  - Counting the event causes unsigned overflow of PMEVCNTR\(<n>_EL0[63:0]\), FEAT_PMUv3p5 is implemented, and MDCR_EL2.HLP is 0b1.
- \(<n>\) in the range [MDCR_EL2.HPMN .. (PMCR_EL0.N-1)].

The event is not transmitted to a trace unit if SelfHostedTraceEnabled() is TRUE and TRFCR_EL2.E2TRE is 0b0.

--- Note ---

This is in addition to the rules for the export of all events to a trace unit. See Controls to prohibit trace at Exception levels on page D3-4759.

This event cannot be counted by the PMU. PMCEID0_EL0[47] reads as 0b0.

This event must be implemented if all of the following are true:

- FEAT_PMUv3 is implemented.
- FEAT_ETE is implemented.
- EL2 is implemented.

\[0x8000\], **SIMD_INST_RETIRED, Instruction architecturally executed, SIMD**

The counter counts each architecturally executed SIMD instruction.

That is, the counter counts:

- SVE instructions other than non-SIMD SVE instructions.
- Advanced SIMD instructions other than Advanced SIMD scalar instructions.

\[0x8001\], **ASE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD**

The counter counts each architecturally executed Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts Advanced SIMD scalar instructions.

\[0x8002\], **SVE_INST_RETIRED, Instruction architecturally executed, SVE**

The counter counts each architecturally executed SVE instruction.

It is IMPLEMENTATION DEFINED whether the counter counts non-SIMD SVE instructions.

This event must be implemented if event SVE_INST_SPEC is not implemented.

Implementation of this event requires that FEAT_SVE is implemented.

\[0x8003\], **ASE_SVE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD or SVE**

The counter counts each architecturally executed instruction counted by either ASE_INST_RETIRED or SVE_INST_RETIRED.
0x8107, **BR_SKIP_RETIRED, Branch Instruction architecturally executed, not taken**

The counter counts each conditional **Software change of the PC** instruction that is not taken. This includes all:

- Conditional branch instructions.
- Conditional memory-reading instructions that explicitly write to the PC.
- Conditional data-processing instructions that explicitly write to the PC.
- Conditional exception return instructions.

These are the same instructions which, if unconditional, or conditional and taken, are counted by the **PC_WRITE_RETIRED** event.

It is **IMPLEMENTATION DEFINED** whether the following are included as a **Software change of the PC**, which the counter increments for:

- A conditional **UNDEFINED** instruction that does not generate an exception.
- A conditional exception-generating instruction, **SVC**, **HVC**, or **SMC**, that does not generate an exception.
- A conditional Context synchronization barrier instruction, **ISB**, that fails its condition code check.

**Note**

Many of these instructions can only be conditional in the AArch32 instruction sets.

The counter does not increment for exceptions other than those explicitly identified in these lists. If **PC_WRITE_RETIRED** and **BR_SKIP_RETIRED** are both implemented, the PE must treat the following types of instruction in the same way for both events:

- **BRK** and **BKPT** instructions.
- **UNDEFINED** instructions.
- The exception-generating instructions, **SVC**, **HVC**, and **SMC**.
- Context synchronization barrier instructions.

From Armv8.6, if **BR_RETIRED** is also implemented, the PE must also treat these types of instruction in the same way for the **BR_RETIRED** event.

0x8108, **BR_IMMED_TAKEN_RETIRED, Branch Instruction architecturally executed, immediate, taken**

The counter counts each instruction counted by both **BR_IMMED_RETIRED** and **PC_WRITE_RETIRED**.

These are all direct branch instructions on the architecturally executed path, where the branch is taken.

0x8109, **BR_IMMED_SKIP_RETIRED, Branch Instruction architecturally executed, immediate, not taken**

The counter counts each instruction counted by both **BR_IMMED_RETIRED** and **BR_SKIP_RETIRED**.

These are all direct branch instructions on the architecturally executed path, where the branch is not taken.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.

0x810A, **BR_IND_TAKEN_RETIRED, Branch Instruction architecturally executed, indirect, taken**

The counter counts each instruction counted by both **BR_IND_RETIRED** and **PC_WRITE_RETIRED**.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is taken.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.
0x8108, **BR_IND_SKIP_RETIRED**, Branch Instruction architecturally executed, indirect, not taken

The counter counts each instruction counted by both **BR_IND_RETIRED** and **BR_SKIP_RETIRED**.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is not taken.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.

0x810C, **BR_INDNR_TAKEN_RETIRED**, Branch Instruction architecturally executed, indirect excluding procedure return, taken

The counter counts each instruction counted by both **BR_IND_RETIRED** and **PC_WRITE_RETIRED**, that is not counted by **BR_RETURN_RETIRED**.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is taken.

0x810D, **BR_INDNR_SKIP_RETIRED**, Branch Instruction architecturally executed, indirect excluding procedure return, not taken

The counter counts each instruction counted by both **BR_INDNR_RETIRED** and **BR_SKIP_RETIRED**.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is not taken.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.

0x810E, **BR_RETURN_ANY_RETIRED**, Branch Instruction architecturally executed, procedure return

The counter counts each instruction counted by **BR_IND_RETIRED** where if taken, the branch would be counted by **BR_RETURN_RETIRED**.

These are all return instructions on the architecturally executed path.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.

0x810F, **BR_RETURN_SKIP_RETIRED**, Branch Instruction architecturally executed, procedure return, not taken

The counter counts each instruction counted by both **BR_RETURN_ANY_RETIRED** and **BR_SKIP_RETIRED**.

These are all return instructions on the architecturally executed path, where the branch is not taken.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.

0x8110, **BR_IND_RETIRED**, Instruction architecturally executed, indirect branch

The counter counts each Software change of the PC that is not counted by **BR_IMMED_RETIRED**.

Software change of the PC has the same definition as for the **PC_WRITE_RETIRED** and **BR_SKIP_RETIRED** events.

--- Note

Conditional branches are always counted, regardless of whether the branch is taken.

---

0x811E, **BR_INDNR_RETIRED**, Branch Instruction architecturally executed, indirect excluding procedure return

The counter counts each instruction counted by **BR_IND_RETIRED** that is not counted by **BR_RETURN_ANY_RETIRED**.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path.

Implementation of this optional event requires that AArch32 is implemented at any Exception level.
0x811F, BRB_FILTRATE, Branch Record captured
The counter counts each branch record captured in the branch record buffer. Branch records that are not captured because they are removed by filtering are not counted.
When BRB_FILTRATE is generated for an exception or an exception return, it is an Exception-related event.
This event must be implemented if FEAT_BRBE is implemented.

0x8179, BRNL_INDNR_TAKEN_RETIRED, Branch Instruction architecturally executed, indirect branch without link excluding procedure return, taken
The counter counts each branch counted by BRNL_IND_TAKEN_RETIRED that is not counted by BR_RETURN_RETIRED.
These are all indirect branch without link excluding procedure return instructions on the architecturally executed path, where the branch is taken.

0x817A, BL_TAKEN_RETIRED, Branch Instruction architecturally executed, branch with link, taken
The counter counts each Software change of the PC counted by PC_WRITE_RETIRED that calls a subroutine and sets LR to return address.
These are all branch with link instructions on the architecturally executed path, where the branch is taken.

0x817B, BRNL_TAKEN_RETIRED, Branch Instruction architecturally executed, branch without link, taken
The counter counts each Software change of the PC counted by PC_WRITE_RETIRED that is not counted by BL_TAKEN_RETIRED.
These are all branch without link instructions on the architecturally executed path, where the branch is taken.

0x817C, BRNL_IND_TAKEN_RETIRED, Branch Instruction architecturally executed, indirect branch without link, taken
The counter counts each branch counted by both BRNL_TAKEN_RETIRED and BR_IND_TAKEN_RETIRED.
These are all indirect branch without link instructions on the architecturally executed path, where the branch is taken.

0x817D, BRNL_IND_TAKEN_RETIRED, Branch Instruction architecturally executed, indirect branch without link, taken
The counter counts each branch counted by both BRNL_TAKEN_RETIRED and BR_IND_TAKEN_RETIRED.
These are all indirect branch without link instructions on the architecturally executed path, where the branch is taken.

0x817E, BL_IMMED_TAKEN_RETIRED, Branch Instruction architecturally executed, direct branch with link, taken
The counter counts each branch counted by both BL_TAKEN_RETIRED and BR_IMMED_TAKEN_RETIRED.
These are all direct branch with link instructions on the architecturally executed path, where the branch is taken.

0x817F, BRNL_IMMED_TAKEN_RETIRED, Branch Instruction architecturally executed, direct branch without link, taken
The counter counts each branch counted by both BRNL_TAKEN_RETIRED and BR_IMMED_TAKEN_RETIRED.
These are all direct branch without link instructions on the architecturally executed path, where the branch is taken.
**0x8180, BR_UNCOND_RETIRED, Branch Instruction architecturally executed, unconditional branch**

The counter counts each Software change of the PC counted by BR_RETIRED that is not counted by BR_COND_RETIRED.

These are all unconditional branch instructions on the architecturally executed path.

**0x8181, BR_COND_RETIRED, Branch Instruction architecturally executed, conditional branch**

The counter counts each Software change of the PC counted by BR_RETIRED that is a conditional branch.

These are all conditional branch instructions on the architecturally executed path.

In the A64 instruction set, conditional branches are B.cond, BC.cond, CBNZ, CBZ, TBNZ, and T8Z. This includes B.cond and BC.cond instructions with the AL or W condition code.

In the A32 instruction set, conditional branches are Software change of the PC instructions that have bits [31:29] of the instruction opcode not equal to 0b111.

In the T32 instruction set, conditional branches are B<<>, B<<>.W, Software change of the PC instructions executed in an IT block, CBNZ, and CBZ. Branch instruction encodings, including B{<<>}, W, where << is either omitted or AL are only considered conditional branches when they are the last instruction in an IT block.

**0x8182, BR_COND_TAKEN_RETIRED, Branch Instruction architecturally executed, conditional branch, taken**

The counter counts each Software change of the PC counted by both BR_COND_RETIRED and PC_WRITE_RETIRED.

These are all conditional branch instructions on the architecturally executed path, where the branch is taken.

**0x8183, BR_HINT_COND_RETIRED, Branch Instruction architecturally executed, hinted conditional**

The counter counts each branch counted by BR_COND_RETIRED that is a hinted conditional branch.

These are all hinted conditional branch instructions on the architecturally executed path.

The hinted conditional branch instruction is BC.cond.

Implementation of this optional event requires that FEAT_HBC is implemented.

**Common microarchitectural events**

The Common microarchitectural events are:

**0x0001, L1I_CACHE_REFILL, Level 1 instruction cache refill**

The counter counts each access counted by L1I_CACHE that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[1] reads as 0b1 if this event is implemented and 0b0 otherwise.
0x0002, **L1I_TLB_REFILL, Level 1 instruction TLB refill**

The counter counts each Instruction memory access counted by L1I_TLB that causes a TLB refill of the Level 1 instruction TLB.

This includes each Instruction memory access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access generates a Translation fault for any other reason.
- The refill is not allocated in the TLB.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID0_EL0[2] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0003, **L1D_CACHE_REFILL, Level 1 data cache refill**

The counter counts each access counted by L1D_CACHE that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 data cache. Example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 data cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[3] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if the implementation includes a Level 1 data or unified cache.

0x0004, **L1D_CACHE, Level 1 data cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 1 data or unified cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L1D_CACHE_RW event is implemented:

- If the L1D_CACHE_PRFM event is implemented, accesses to the Level 1 data cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.
- If the L1D_CACHE_HWPRF event is implemented, accesses to the Level 1 data cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the L1D_CACHE_RW event is not implemented, it is IMPLEMENTATION DEFINED whether accesses to the Level 1 data cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[4] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if the implementation includes a Level 1 data or unified cache.

0x0005, L1D_TLB_REFILL, Level 1 data TLB refill

The counter counts each access counted by L1D_TLB that causes a TLB refill of the Level 1 data or unified TLB.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access generates a Translation fault for any other reason.
- The refill is not allocated in the TLB.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID0_EL0[5] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0010, BR_MIS_PRED, Branch instruction Speculatively executed, mispredicted or not predicted

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, Arm recommends that the counter counts all branches that are not taken.

PMCEID0_EL0[16] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if the implementation includes program-flow prediction.

0x0011, **CPU_CYCLES, Cycle**

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a \texttt{WFI} or \texttt{WFE} instruction stops the clock. This means that it is \texttt{CONSTRAINED UNPREDICTABLE} whether or not CPU_CYCLES continues to increment when the clocks are stopped by \texttt{WFI} and \texttt{WFE} instructions.

---

Note

Unlike PMCCNTR or PMCCNTR_EL0, this count is not affected by the cycle counter controls:

- The counter is not incremented in prohibited regions, so is not affected by PMCR.DP or PMCR_EL0.DP.
- The counter increments on every cycle, regardless of the setting of PMCR.D or PMCR_EL0.D.
- The counter is reset when event counters are reset by PMCR.P and PMCR_EL0.P, never by PMCR.C or PMCR_EL0.C.
- If \texttt{FEAT\_PMUv3p5} is implemented, the counter ignores SDCR.SCCD, MDCR_EL3.SCCD, HDCR.HCCD, and MDCR_EL2.HDCCD.

---

In a multithreaded implementation:

- If the Effective value of \texttt{PMEVTYPER<\texttt{n}\_EL0\_MT} for the event counter is 0, then the counter counts each Processor cycle when the counting PE is active.
- If the Effective value of \texttt{PMEVTYPER<\texttt{n}\_EL0\_MT} for the event counter is 1, then the counter counts each Processor cycle.

PMCEID0_EL0[17] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented.

0x0012, **BR_PRED, Predictable branch instruction Speculatively executed**

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is \texttt{IMPLEMENTATION DEFINED} whether other branches are counted as predictable branches. Arm recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by \texttt{BR\_MIS\_PRED}.

If no program-flow prediction resources are implemented, this event is optional, but Arm recommends that \texttt{BR\_PRED} counts all branches.

PMCEID0_EL0[18] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if the implementation includes program-flow prediction.

0x0013, **MEM_ACCESS, Data memory access**

The counter counts each Memory-read operation or Memory-write operation that the PE makes.

The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The number of accesses generated by each instruction is \texttt{IMPLEMENTATION DEFINED}.

The counter does not count:

- Instruction memory accesses.
• Translation table walks.
• Write-back from any cache.
• Refilling of any cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

PMCEID0_EL0[19] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0014, L1I_CACHE, Level 1 instruction cache access

The counter counts each Instruction memory access to at least the Level 1 instruction or unified cache.

Each Instruction memory access to other Level 1 instruction or unified memory structures, such as refill buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L1I_CACHE_RD event is implemented:
  • If the L1I_CACHE_PRFM event is implemented, accesses to the Level 1 instruction cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.
  • If the L1I_CACHE_HWPRF event is implemented, accesses to the Level 1 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the L1I_CACHE_RD event is not implemented, it implements whether accesses to the Level 1 instruction cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[20] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0015, L1D_CACHE_WB, Level 1 data cache write-back

The counter counts each write-back of data from the Level 1 data or unified cache to outside of the Level 1 caches. For example:
  • A write-back of a dirty cache line to a Level 2 cache or memory.
  • A write-back of a recently fetched cache line that has not been allocated to the Level 1 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:
  • A transfer of a dirty cache line from the Level 1 data cache to outside of Level 1 caches made as a result of a coherency request.
  • Write-backs made as a result of cache maintenance instructions.

The counter does not count:
  • The invalidation of a cache line without any write-back to outside of the Level 1 caches or memory.
  • Writes that write through the Level 1 data cache to outside of the Level 1 caches.
A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID0_EL0[21] reads as \texttt{0b1} if this event is implemented and \texttt{0b0} otherwise.

\textbf{0x0016, L2D\_CACHE, Level 2 data cache access}

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 2 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 2 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If \texttt{FEAT\_PMUv3p4} is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If \texttt{FEAT\_PMUv3p4} is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

For example, cache status information is whether the cached data is held in an exclusive or shared state.

When the \texttt{L2D\_CACHE\_RW} event is implemented:

- If the \texttt{L2D\_CACHE\_PRFM} event is implemented, accesses to the Level 2 data cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.
- If the \texttt{L2D\_CACHE\_HWPRF} event is implemented, accesses to the Level 2 data cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the \texttt{L2D\_CACHE\_RW} event is not implemented, it is IMPLEMENTATION DEFINED whether accesses to the Level 2 data cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of \texttt{PMEVTYPER<n>_EL0.MT} for the counter is \texttt{0b1}, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[22] reads as \texttt{0b1} if this event is implemented and \texttt{0b0} otherwise.

\textbf{0x0017, L2D\_CACHE\_REFILL, Level 2 data cache refill}

The counter counts each access counted by \texttt{L2D\_CACHE} that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 data cache that cause a refill that is satisfied by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of and write-backs from any Level 1 data, instruction, or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
• Accesses to the Level 2 data cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 data cache.

The counter does not count accesses that:
• Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
• Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPE<\n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[23] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0018, L2D_CACHE_WB, Level 2 data cache write-back

The counter counts each write-back of data from the Level 2 data or unified cache to outside of the Level 1 and Level 2 caches. For example:
• A write-back of a dirty cache line to a Level 3 cache or memory.
• A write-back of a recently fetched cache line that has not been allocated to the Level 2 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:
• A transfer of a dirty cache line from the Level 2 data cache to outside of Level 1 and Level 2 caches made as a result of a coherency request.
• Write-backs made as a result of cache maintenance instructions.

The counter does not count:
• The invalidation of a cache line without any write-back to outside of the Level 1 and Level 2 caches or memory.
• Writes that write through the Level 2 data cache to outside of the Level 1 and Level 2 caches.
• Transfers of data from the Level 2 data cache to a Level 1 cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID0_EL0[24] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0019, BUS_ACCESS, Bus access

The counter counts each Memory-read operation or Memory-write operation that accesses outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

A bus access is part of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The BUS_ACCESS event counts each beat of each transaction. That is, each bus cycle counted by BUS_CYCLES for which the bus is active.
Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus transaction occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

PMCEID0_EL0[25] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x001A, MEMORY_ERROR, Local memory error
The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

PMCEID0_EL0[26] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x001B, INST_SPEC, Operation speculatively executed
The counter counts instructions that are Speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. The definition of Speculatively executed is IMPLEMENTATION DEFINED.

PMCEID0_EL0[27] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if event INST_RETIRED is not implemented.

0x001D, BUS_CYCLES, Bus cycle
The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

------- Note -------
If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

PMCEID0_EL0[29] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x001F, L1D_CACHE_ALLOCATE, Level 1 data cache allocation without refill
The counter counts each Memory-write operation that writes an entire line into the Level 1 data or unified cache without fetching data from outside the Level 1 data or unified cache.

These are allocations of cache lines in the Level 1 data or unified cache that are not refills counted by L1D_CACHE_REFILL. For example:

• A write of an entire cache line from a coalescing write buffer.

• A DC ZVA operation.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation.

PMCEID0_EL0[31] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0020, L2D_CACHE_ALLOCATE, Level 2 data cache allocation without refill
The counter counts each Memory-write operation that writes an entire line into the Level 2 data or unified cache without fetching data from outside the Level 2 data or unified cache.
These are allocations of cache lines in the Level 2 data or unified cache that are not refills counted by L2D_CACHE_REFILL. For example:

- A write-back of an entire cache line from a Level 1 cache to the Level 2 data cache.
- A write of an entire cache line from a coalescing write buffer.
- A DC_ZVA operation.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPE<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation.

PMCEID1_EL0[0] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0022, BR_MIS_PRED RETIRED, Branch Instruction architecturally executed, mispredicted

The counter counts each instructions counted by BR_RETIRED that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

PMCEID1_EL0[0] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0023, STALL_FRONTEND, No operation sent for execution due to the frontend

The counter counts each cycle counted by CPU_CYCLES where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. All STALL events must count at the same point in the pipeline.

--- Note ---

For a simplified pipeline model of Fetch-Decode-Issue-Execute-Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.

In a single cycle, both the STALL_BACKEND and STALL_FRONTEND events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.

PMCEID1_EL0[3] reads as 0b1 if this event is implemented and 0b0 otherwise. This event must be implemented if FEAT_PMUv3p1 is implemented.

0x0024, STALL_BACKEND, No operation sent for execution due to the backend

The counter counts each cycle counted by CPU_CYCLES where no Attributable instruction or operation was sent for execution and either:

- The backend is unable to accept any of the instruction operations available for the PE.
- The backend is unable to accept any operations for the PE.

For example, the backend might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events must count at the same point in the pipeline.

--- Note ---

In a single cycle, both the STALL_BACKEND and STALL_FRONTEND events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.

PMCEID1_EL0[4] reads as 0b1 if this event is implemented and 0b0 otherwise. This event must be implemented if FEAT_PMUv3p1 is implemented.
0x0025, **L1D_TLB, Level 1 data TLB access**  
The counter counts each Memory-read operation or Memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB.  
Each access to a TLB entry is counted including multiple accesses caused by single instructions such as LDM or STM.  
The counter does not count the access if the access is due to a TLB maintenance instruction.  
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.  
PMCEID1_EL0[5] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0026, **L1I_TLB, Level 1 instruction TLB access**  
The counter counts each Instruction memory access that causes a TLB access to at least the Level 1 instruction TLB.  
The counter does not count the access if the access is due to a TLB maintenance instruction.  
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.  
PMCEID1_EL0[6] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0027, **L2I_CACHE, Level 2 instruction cache access**  
The counter counts each Instruction memory access to at least the Level 2 instruction or unified cache.  
Each Instruction memory access to other Level 2 instruction or unified memory structures, such as refill buffers, is also counted.  
It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.  
If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.  
If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.  
An example of cache status information is whether the cached data is held in an exclusive or shared state.  
When the L2I_CACHE_RD event is implemented:  
• If the L2I_CACHE_PRFM event is implemented, accesses to the Level 2 instruction cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.  
• If the L2I_CACHE_HWPRF event is implemented, accesses to the Level 2 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.  
When the L2I_CACHE_RD event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 2 instruction cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.  
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.  
PMCEID1_EL0[7] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0028, **L2I_CACHE_REFILL, Level 2 instruction cache refill**  
The counter counts each access counted by L2I_CACHE that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.
A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of any Level 1 instruction or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
- Accesses to the Level 2 instruction cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 instruction cache.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[8] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0029, L3D_CACHE_ALLOCATE, Level 3 data cache allocation without refill

The counter counts each Memory-write operation that writes an entire line into the Level 3 data or unified cache without fetching data from outside the Level 3 data or unified cache. These are allocations of cache lines in the Level 3 data or unified cache that are not refills counted by L3D_CACHE_REFILL. For example:

- A write-back of an entire cache line from a Level 2 cache to the Level 3 data cache.
- A write of an entire cache line from a coalescing write buffer.
- A DC ZVA operation.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation.

PMCEID1_EL0[9] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002A, L3D_CACHE_REFILL, Level 3 data cache refill

The counter counts each access counted by L3D_CACHE that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Level 3 caches, even if the data is ultimately not allocated into the Level 3 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 3 data cache that cause a refill that is satisfied by fetching data from memory, a lower level cache, or a Level 3 cache of another PE.
- Refills of and write-backs from any Level 1 or Level 2 data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Level 3 caches of this PE.
- Accesses to the Level 3 data cache that cause a refill of a Level 2 cache of this PE from outside of the Level 1 to Level 3 caches of this PE, even if there is no refill of the Level 3 data cache.
The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[10] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002B, L3D_CACHE, Level 3 data cache access

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 3 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 3 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L3D_CACHE_RW event is implemented:

- If the L3D_CACHE_PRFM event is implemented, accesses to the Level 3 data cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.
- If the L3D_CACHE_HWPRF event is implemented, accesses to the Level 3 data cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the L3D_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 3 data cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[11] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002C, L3D_CACHE_WB, Level 3 data cache write-back

The counter counts each write-back of data from the Level 3 data or unified cache to outside of the Level 1 to Level 3 caches. For example:

- A write-back of a dirty cache line to a lower level cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 3 data cache to outside of Level 1 to Level 3 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.
The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Level 3 caches or memory.
- Writes that write through the Level 3 data cache to outside of the Level 1 to Level 3 caches.
- Transfers of data from the Level 3 data cache to a Level 1 or Level 2 cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID1_EL0[12] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002D, L2D_TLB_REFILL, Level 2 data TLB refill

The counter counts each access counted by L2D_TLB that causes a TLB refill of the Level 2 data or unified TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
- The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access generates a Translation fault for any other reason.
- The refill is not allocated in the TLB.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[13] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002E, L2I_TLB_REFILL, Level 2 instruction TLB refill

The counter counts each Instruction memory access counted by L2I_TLB that causes a TLB refill of the Level 2 instruction TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each Instruction memory access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
• The access misses in the TLB and generates a translation table walk but does not cause a refill of the TLB.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:
• The access generates a Translation fault for any other reason.
• The refill is not allocated in the TLB.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[14] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x002F, L2D_TLB, Level 2 data TLB access

The counter counts each Memory-read operation or Memory-write operation that causes a TLB access to at least the Level 2 data or unified TLB.

Each access to a TLB entry is counted including refills of Level 1 TLBs.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[15] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0030, L2I_TLB, Level 2 instruction TLB access

The counter counts each Instruction memory access that causes a TLB access to at least the Level 2 instruction TLB.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[16] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0031, REMOTE_ACCESS, Access to another socket in a multi-socket system

The counter counts each Memory-read operation or Memory-write operation that causes an access to a different device or socket in a multi-socket system. That is, a socket that does not contain the PE.

System topology is IMPLEMENTATION DEFINED. This means that it is IMPLEMENTATION DEFINED which systems are defined as multi-socket systems, and, in systems defined as multi-socket systems, which components are defined as being in the same or different sockets. Arm recommends that devices where an access through that device incurs a significant latency penalty compared to other accesses are treated as being in a different socket.

For example, in a system comprising multiple integrated circuits in a multi-chip module, an access to a different integrated circuit in the same module might be treated as an access to another socket, even though the multi-chip module is physically connected to a single socket at the motherboard. However, in another system with many such multi-chip modules, an access to a different integrated system in the same module might be treated as an access to the same socket because an access to an integrated circuit on a different module has much higher latency.

The count includes all accesses to external memory counted by REMOTE_MEM. For more information, see REMOTE_MEM.

It is IMPLEMENTATION DEFINED whether an access that causes a snoop into a different socket but does not return data from or pass data to the remote socket is counted.

PMCEID1_EL0[17] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0032, LL_CACHE, Last level cache access

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Last level cache.
Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Last level data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the LL_CACHE_RW event is implemented:

- If the LL_CACHE_PRFM event is implemented, accesses to the Last level cache due to a preload or prefetch instruction are counted. Otherwise, these are not counted.
- If the LL_CACHE_HWPRF event is implemented, accesses to the Last level cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the LL_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Last level cache due to preload or prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[19] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0033, LL_CACHE_MISS, Last level cache miss

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is not completed by the Last level cache.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is not completed by the Last level cache.

That is, the access is one of the following:

- A Memory-read operation that does not return data from the Last level cache.
- A Memory-write operation that does not update the Last level cache.

The counter does not count operations that are completed by a cache above the Last level cache. It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[19] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0034, DTLB_WALK, Data TLB access with at least one translation table walk

The counter counts each access counted by L1D_TLB that causes a refill of a data or unified TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted. If Armv8.7 is implemented, these accesses are counted.
The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[20] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0035, ITLB_WALK, Instruction TLB access with at least one translation table walk

The counter counts each access counted by L1I_TLB that causes a refill of an instruction TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted. If Armv8.7 is implemented, these accesses are counted.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is due to a TLB maintenance instruction.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

PMCEID1_EL0[21] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0036, LL_CACHE_RD, Last level cache access, read

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is a Memory-read operation.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is a Memory-read operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID1_EL0[22] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0037, LL_CACHE_MISS_RD, Last level cache miss, read

The counter counts each access counted by both LL_CACHE_MISS and LL_CACHE_RD.

That is, every miss of the Last level cache counted by LL_CACHE_MISS that is caused by a Memory-read operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
PMCEID1_EL0[23] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0038, `REMOTE_ACCESS_RD`, Access to another socket in a multi-socket system, read
The counter counts each access counted by `REMOTE_ACCESS` that is a Memory-read operation.
PMCEID1_EL0[24] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0039, `L1D_CACHE_LMISS_RD`, Level 1 data cache long-latency read miss
The counter counts each Memory-read operation to the Level 1 data or unified cache counted by `L1D_CACHE` that incurs additional latency because it returns data from outside of the Level 1 data or unified cache of this PE.
The event indicates to software that the access missed in the Level 1 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 data or unified cache.
The counter does not count:
- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data or unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.
An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.
It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
PMCEID1_EL0[25] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_PMUv3p4 is implemented.

0x003A, `OP_RETIRED`, Micro-operation architecturally executed
The counter counts each operation counted by `OP_SPEC` that would be executed in a Simple sequential execution of the program.
PMCEID1_EL0[26] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x003B, `OP_SPEC`, Micro-operation Speculatively executed
The counter counts the number of operations executed by the PE, including those that are executed speculatively and would not be executed in a Simple sequential execution of the program.
PMCEID1_EL0[27] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x003C, `STALL`, No operation sent for execution
The counter counts each cycle counted by `CPU_CYCLES` where no operation was sent for execution.
On a multithreaded implementation:
- If the Effective value of PMEVTYPER<n>_EL0.MT is 0b0, then the counter counts cycles when the PE is active and no operation for the PE is sent for execution, even if operations Attributable to other PEs in the multithreaded implementation are sent for execution in that cycle. The counter does not count cycles when the PE is not active.
- If the Effective value of PMEVTYPER<n>_EL0.MT is 0b1, then the counter counts all cycles when no instructions or operations for any PE in the multithreaded implementation were sent for execution.
All STALL events must count at the same point in the pipeline.

PMCEID1_EL0[28] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x0030, **STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend**

Counts each Slot counted by STALL_SLOT where no Attributable instruction or operation was sent for execution and either:

- The backend is unable to accept any of the instruction operations available on the Slot for the PE.
- The backend is unable to accept any operations on the Slot for the PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events must count at the same point in the pipeline. The maximum value by which STALL_SLOT_BACKEND can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, \( s1\)ots. For more information, see STALL_SLOT.

—— Note ——

In a single cycle, the sum of values counted by STALL_SLOT_BACKEND and STALL_SLOT_FRONTEND might be greater-than \( s1\)ots, if both the backend is unable to accept some operations and there are fewer-than \( s1\)ots operations available to dispatch from the frontend.

PMCEID1_EL0[29] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x003E, **STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend**

Counts each Slot counted by STALL_SLOT where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend for the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events must count at the same point in the pipeline. The maximum value by which STALL_SLOT_FRONTEND can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, \( s1\)ots. For more information, see STALL_SLOT.

—— Note ——

In a single cycle, the sum of values counted by STALL_SLOT_BACKEND and STALL_SLOT_FRONTEND might be greater-than \( s1\)ots, if both the backend is unable to accept some operations and there are fewer-than \( s1\)ots operations available to dispatch from the frontend.

PMCEID1_EL0[30] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x003F, **STALL_SLOT, No operation sent for execution on a Slot**

The counter counts on each cycle the number of instruction or operation Slots that were not occupied by an instruction or operation Attributable to the PE.

All STALL events must count at the same point in the pipeline. The maximum value by which STALL_SLOT can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, \( s1\)ots. The definition of a Slot is IMPLEMENTATION DEFINED. The formula

\[
STALL_SLOT = \frac{(CPU_CYCLES \times s1\)ots)}{TIME}
\]

gives the utilization of the Slots of the processor by Attributable instruction or operations of this PE. Each Slot holds at most one instruction or operation each cycle.

On a multithreaded implementation:

- If the Effective value of PMEVTYPER<\(n\)>_EL0.MT is 0b0, then the counter counts Slots occupied by an instruction or operation Attributable to other PEs of the multithreaded implementation only when the PE was active in that cycle. The counter does not count Slots on cycles when the PE was not active.
- If the Effective value of PMEVTYPER<\(n\)>_EL0.MT is 0b1, then, for every cycle, the counter counts all Slots not occupied by any instruction or operation for any PE of the multithreaded implementation.

PMCEID1_EL0[31] reads as 0b1 if this event is implemented and 0b0 otherwise.
The Performance Monitors Extension
D11.11 PMU events and event numbers

0x0040, L1D_CACHE_RD, Level 1 data cache access, read
If the L1D_CACHE_RW event is implemented, the counter counts each access counted by L1D_CACHE_RW that is a Memory-read operation.
If the L1D_CACHE_RW event is not implemented, the counter counts each access counted by L1D_CACHE that is a Memory-read operation.
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0041, L1D_CACHE_WR, Level 1 data cache access, write
If the L1D_CACHE_RW event is implemented, the counter counts each access counted by L1D_CACHE_RW that is a Memory-write operation.
If the L1D_CACHE_RW event is not implemented, the counter counts each access counted by L1D_CACHE that is a Memory-write operation.
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0042, L1D_CACHE_REFILL_RD, Level 1 data cache refill, read
The counter counts each access counted by both L1D_CACHE_RD and L1D_CACHE_REFILL. That is, every refill of the Level 1 data or unified cache counted by L1D_CACHE_REFILL that is caused by a Memory-read operation.
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0043, L1D_CACHE_REFILL_WR, Level 1 data cache refill, write
The counter counts each access counted by both L1D_CACHE_REFILL and L1D_CACHE_WR. That is, every refill of the Level 1 data or unified cache counted by L1D_CACHE_REFILL that is caused by a Memory-write operation.
If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0044, L1D_CACHE_REFILL_INNER, Level 1 data cache refill, inner
The counter counts each access counted by L1D_CACHE_REFILL that generates a refill satisfied by transfer from another cache inside of the immediate cluster.

Note
The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.
0x0045, L1D_CACHE_REFILL_OUTER, Level 1 data cache refill, outer
The counter counts each access counted by L1D_CACHE_REFILL that generates a refill satisfied by transfer from outside of the immediate cluster.

Note
The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0046, L1D_CACHE_WB_VICTIM, Level 1 data cache write-back, victim
The counter counts each write-back counted by L1D_CACHE_WB that occurs because the line is allocated for an access made by the PE.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache write-back, cleaning and coherency
The counter counts each write-back counted by L1D_CACHE_WB that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.
Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note
The transfer of a dirty cache line from the Level 1 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0048, L1D_CACHE_INV_AL, Level 1 data cache invalidate
The counter counts each invalidation of a cache line in the Level 1 data or unified cache. For example:
• Invalidation of a cache line because of a cache maintenance operation.
• Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 data or unified cache invalidates a line in the Level 1 data or unified cache.
If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.
If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note
Software that uses this event must know whether the Level 1 data cache is shared with other PEs. This event does not follow the general rule of Level 1 data cache events of only counting Attributable events.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.
0x004C, L1D_TLB_REFILL_RD, Level 1 data TLB refill, read

The counter counts each access counted by both L1D_TLB_RD and L1D_TLB_REFILL.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x004D, L1D_TLB_REFILL_WR, Level 1 data TLB refill, write

The counter counts each access counted by both L1D_TLB_REFILL and L1D_TLB_WR.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x004E, L1D_TLB_RD, Level 1 data TLB access, read

If the L1D_TLB_RW event is implemented, the counter counts each access counted by L1D_TLB_RW that is a Memory-read operation.

If the L1D_TLB_RW event is not implemented, the counter counts each access counted by L1D_TLB that is a Memory-read operation.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x004F, L1D_TLB_WR, Level 1 data TLB access, write

If the L1D_TLB_RW event is implemented, the counter counts each access counted by L1D_TLB_RW that is a Memory-write operation.

If the L1D_TLB_RW event is not implemented, the counter counts each access counted by L1D_TLB that is a Memory-write operation.

DC ZVA is counted as a Memory-write operation.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.
0x0050, L2D_CACHE_RD, Level 2 data cache access, read
   If the L2D_CACHE_RW event is implemented, the counter counts each access counted by L2D_CACHE_RW that is a Memory-read operation.
   If the L2D_CACHE_RW event is not implemented, the counter counts each access counted by L2D_CACHE that is a Memory-read operation.
   If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted. When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0051, L2D_CACHE_WR, Level 2 data cache access, write
   If the L2D_CACHE_RW event is implemented, the counter counts each access counted by L2D_CACHE_RW that is a Memory-write operation.
   If the L2D_CACHE_RW event is not implemented, the counter counts each access counted by L2D_CACHE that is a Memory-write operation.
   If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted. When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0052, L2D_CACHE_REFILL_RD, Level 2 data cache refill, read
   The counter counts each access counted by both L2D_CACHE_RD and L2D_CACHE_REFILL. That is, every refill of the Level 2 data or unified cache counted by L2D_CACHE_REFILL that is caused by a Memory-read operation.
   If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted. When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0053, L2D_CACHE_REFILL_WR, Level 2 data cache refill, write
   The counter counts each access counted by both L2D_CACHE_REFILL and L2D_CACHE_WR. That is, every refill of the Level 2 data or unified cache counted by L2D_CACHE_REFILL that is caused by a Memory-write operation.
   If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted. When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0056, L2D_CACHE_WB_VICTIM, Level 2 data cache write-back, victim
   The counter counts each write-back counted by L2D_CACHE_WB that occurs because the line is allocated for an access made by the PE.
   When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0057, L2D_CACHE_WB_CLEAN, Level 2 data cache write-back, cleaning and coherency
   The counter counts each write-back counted by L2D_CACHE_WB that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.
   Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.
Note
The transfer of a dirty cache line from the Level 2 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0058, L2D_CACHE_INV, Level 2 data cache invalidate
The counter counts each invalidation of a cache line in the Level 2 data or unified cache. For example:
• Invalidation of a cache line because of a cache maintenance operation.
• Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 2 data or unified cache invalidates a line in the Level 2 data or unified cache.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.

If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note
Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting Attributable events.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x005C, L2D_TLB_REFILL_RD, Level 2 data TLB refill, read
The counter counts each access counted by both L2D_TLB_RD and L2D_TLB_REFILL.

The counter does not count the access if any of the following are true:
• FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
• FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
• The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x005D, L2D_TLB_REFILL_WR, Level 2 data TLB refill, write
The counter counts each access counted by both L2D_TLB_REFILL and L2D_TLB_WR.

The counter does not count the access if any of the following are true:
• FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
• FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
• The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x005E, L2D\_TLB\_RD, Level 2 data TLB access, read}

The counter counts each access that is a Memory-read operation.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x005F, L2D\_TLB\_WR, Level 2 data TLB access, write}

The counter counts each access that is a Memory-write operation.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\text{n}>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x0060, BUS\_ACCESS\_RD, Bus access, read}

The counter counts each access counted by BUS\_ACCESS that is a Memory-read operation.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x0061, BUS\_ACCESS\_WR, Bus access, write}

The counter counts each access counted by BUS\_ACCESS that is a Memory-write operation.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x0062, BUS\_ACCESS\_SHARED, Bus access, Normal, Cacheable, Shareable}

The counter counts each access counted by BUS\_ACCESS that is Normal, Cacheable, Shareable.

\textbf{Note}

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

\textbf{0x0063, BUS\_ACCESS\_NOT\_SHARED, Bus access, not Normal, Cacheable, Shareable}

The counter counts each access counted by BUS\_ACCESS that is not counted by BUS\_ACCESS\_SHARED.

For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.
_____ Note _____

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0064, BUS_ACCESS_NORMAL, Bus access, normal

The counter counts each access counted by BUS_ACCESS that is to Normal or bulk memory.

For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0065, BUS_ACCESS_PERIPH, Bus access, peripheral

The counter counts each access counted by BUS_ACCESS that is not counted by BUS_ACCESS_NORMAL.

For example, the counter counts accesses to Device memory.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0066, MEM_ACCESS_RD, Data memory access, read

If the MEM_ACCESS_RW event is implemented, the counter counts each access counted by MEM_ACCESS_RW that is a Memory-read operation.

If the MEM_ACCESS_RW event is not implemented, the counter counts each access counted by MEM_ACCESS that is a Memory-read operation.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0067, MEM_ACCESS_WR, Data memory access, write

If the MEM_ACCESS_RW event is implemented, the counter counts each access counted by MEM_ACCESS_RW that is a Memory-write operation.

If the MEM_ACCESS_RW event is not implemented, the counter counts each access counted by MEM_ACCESS that is a Memory-write operation.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0068, UNALIGNED_LD_SPEC, Unaligned access, read

The counter counts each access counted by MEM_ACCESS that is an unaligned Memory-read operation.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0069, UNALIGNED_ST_SPEC, Unaligned access, write

The counter counts each access counted by MEM_ACCESS that is an unaligned Memory-write operation.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.
0x006A, UNALIGNED_LDST_SPEC, Unaligned access
The counter counts each access counted by either UNALIGNED_LD_SPEC or UNALIGNED_ST_SPEC.
The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x006C, LDREX_SPEC, Exclusive operation Speculatively executed, Load-Exclusive
The counter counts Load-Exclusive instructions Speculatively executed.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x006D, STREX_PASS_SPEC, Exclusive operation Speculatively executed, Store-Exclusive pass
The counter counts Store-Exclusive instructions Speculatively executed that completed a write.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x006E, STREX_FAIL_SPEC, Exclusive operation Speculatively executed, Store-Exclusive fail
The counter counts Store-Exclusive instructions Speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of Speculatively executed whether this includes conditional instructions that fail the condition code check.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x006F, STREX_SPEC, Exclusive operation Speculatively executed, Store-Exclusive
The counter counts Store-Exclusive instructions Speculatively executed.
The definition of Speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the LDREX_SPEC event.
Arm recommends that this event is implemented if it is not possible to implement the exclusive operation Speculatively executed, Store-Exclusive pass, and exclusive operation Speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0070, LD_SPEC, Operation speculatively executed, load
The counter counts each operation counted by INST_SPEC that is a memory-reading operation.
Memory-reading instructions are defined by the LD_RETIRED event.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0071, ST_SPEC, Operation speculatively executed, store
The counter counts each operation counted by INST_SPEC that is a memory-writing operation.
Memory-writing instructions are defined by the ST_RETIRED event.
The counter counts DC ZVA as a store operation.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0072, LDST_SPEC, Operation speculatively executed, load or store
The counter counts each operation counted by either LD_SPEC or ST_SPEC.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.
The counter counts each operation counted by **INST_SPEC** that is an integer data-processing operation.

The counter counts the following operations that operate on the general-purpose registers:

- In AArch64 state, *Data processing - immediate* on page C3-297 and *Data processing - register* on page C3-302.
- In AArch32 state, *Data-processing instructions* on page F2-7260.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch32 state, *PSTATE and banked register access instructions* on page F2-7268, *Miscellaneous instructions* on page F2-7273, other than ISB and preloads, and *System register access instructions* on page F2-7277, other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as Software change of the PC then they must count as integer data-processing instructions.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but Arm recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - FMOV (general).

- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - DUP (general).
  - SMOV.
  - UM0V.
  - INS (general).

- For AArch32 state:
  - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - VMRS.
  - VMSR.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

**0x0074, ASE_SPEC, Operation speculatively executed, Advanced SIMD**

The counter counts each operation counted by **INST_SPEC** that is an Advanced SIMD data-processing operation.

See:

- For AArch64 state, the SIMD operations listed in *Data processing - SIMD and floating-point* on page C3-310.
- For AArch32 state, *Advanced SIMD data-processing instructions* on page F2-7281.

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
• Memory-reading operations.
• Memory-writing operations.
• Cryptographic operations other than PMULL, in AArch64 state.
• VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0075, VFP_SPEC, Operation speculatively executed, scalar floating-point

The counter counts each operation counted by INST_SPEC that is a scalar floating-point data-processing operation.

See:
• In AArch64 state, only the scalar floating-point operations listed in Data processing - SIMD and floating-point on page C3-310.
• In AArch32 state, Floating-point data-processing instructions on page F2-7292.

Note
This event does not count the SIMD floating-point operations listed in Data processing - SIMD and floating-point on page C3-310.

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:
• Integer data processing.
• Memory-reading operations.
• Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:
• In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
• In AArch32 state, VCVT{<mode>}, (floating-point), VCVT, VCVT1, and VCVTB.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0076, PC_WRITE_SPEC, Operation speculatively executed, Software change of the PC

The counter counts each operation counted by INST_SPEC that is a Software change of the PC.

Software change of the PC operations are defined by the PC_WRITE_RETIRED event.

When FEAT_PMUv3p8 is implemented, the counter counts the operation even if the branch is not taken. Otherwise, it is IMPLEMENTATION DEFINED whether the counter counts the operation when the branch is not taken.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0077, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction

The counter counts each operation counted by INST_SPEC that is a cryptographic operation other than PMULL or VMULL.

See The Cryptographic Extension on page C3-333.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0078, BR_IMMED_SPEC, Branch Speculatively executed, immediate branch

The counter counts immediate branch instructions Speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see Common event numbers on page D11-5306.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
See also BR_IMMED_RETIRED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0079, BR_RETURN_SPEC, Branch Speculatively executed, procedure return

The counter counts procedure return instructions Speculatively executed. Defined by the BR_RETURN_RETIRED event.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
See also BR_RETURN_RETIRED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x007A, BR_INDIRECT_SPEC, Branch Speculatively executed, indirect branch

The counter counts indirect branch instructions Speculatively executed. This includes Software change of the PC other than exception-generating instructions and immediate branch instructions.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x007C, ISB_SPEC, Barrier Speculatively executed, ISB

The counter counts Instruction Synchronization Barrier instructions Speculatively executed, including CP15ISB.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x007D, DSB_SPEC, Barrier Speculatively executed, DSB

The counter counts data synchronization and speculative load barrier instructions Speculatively executed, including CP15DSB, SS88 and P5SB8.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x007E, DMB_SPEC, Barrier Speculatively executed, DMB

The counter counts data memory barrier instructions Speculatively executed, including CP15DSB.
It does not include the implied barrier operations of load/store operations with release consistency semantics.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x007F, CSDB_SPEC, Barrier Speculatively executed, CSDB

The counter counts control speculation barrier instructions Speculatively executed.
The definition of Speculatively executed is IMPLEMENTATION DEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0081, EXC_UNDEF, Exception taken, other synchronous

The counter counts each exception counted by EXC_TAKEN that is Taken locally and is not counted as any of the following:
• Exception taken, Supervisor Call (EXC_SVC).
• Exception taken, Secure Monitor Call (EXC_SMC).
• Exception taken, Hypervisor Call (EXC_HVC).
• Exception taken, Instruction Abort (EXC_PABORT).
• Exception taken, Data Abort or SError (EXC_DABORT).
• Exception taken, IRQ (EXC_IRQ).
• Exception taken, FIQ (EXC_FIQ).
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0082, EXC_SVC, Exception taken, Supervisor Call
The counter counts each Supervisor Call exception counted by EXC_TAKEN that is Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0083, EXC_PABORT, Exception taken, Instruction Abort
The counter counts each Instruction Abort exception counted by EXC_TAKEN that is Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0084, EXC_DABORT, Exception taken, Data Abort or SError
The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by EXC_TAKEN that is Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0086, EXC_IRQ, Exception taken, IRQ
The counter counts each IRQ or virtual IRQ exception counted by EXC_TAKEN that is Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0087, EXC_FIQ, Exception taken, FIQ
The counter counts each FIQ or virtual FIQ exception counted by EXC_TAKEN that is Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0088, EXC_SMC, Exception taken, Secure Monitor Call
The counter counts each Secure Monitor Call exception counted by EXC_TAKEN. The counter does not count SMC instructions that generate other exceptions, including Trap exceptions and Undefined Instruction exceptions.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008A, EXC_HVC, Exception taken, Hypervisor Call
The counter counts each Hypervisor Call exception counted by EXC_TAKEN. The counter does not count HMC instructions that are UNDEFINED.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally
The counter counts each Instruction Abort exception counted by EXC_TAKEN that is not Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally
The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by EXC_TAKEN, that is not Taken locally.
When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008D, EXC_TRAP_OTHER, Exception taken, other traps not Taken locally
The counter counts each exception counted by EXC_TAKEN that is not Taken locally and not counted as any of the following:
• Exception taken, Secure Monitor Call (EXC_SMC).
• Exception taken, Hypervisor Call (EXC_HVC).
• Exception taken, Instruction Abort not Taken locally (EXC_TRAP_PABORT).
• Exception taken, Data Abort or SError not Taken locally (EXC_TRAP_DABORT).
• Exception taken, IRQ not Taken locally \(\text{EXC\_TRAP\_IRQ}\).
• Exception taken, FIQ not Taken locally \(\text{EXC\_TRAP\_FIQ}\).

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008E, \text{EXC\_TRAP\_IRQ}, \text{Exception taken, IRQ not Taken locally}

The counter counts each IRQ or virtual IRQ exception counted by \(\text{EXC\_TAKEN}\) that is not Taken locally.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x008F, \text{EXC\_TRAP\_FIQ}, \text{Exception taken, FIQ not Taken locally}

The counter counts each FIQ or virtual FIQ exception counted by \(\text{EXC\_TAKEN}\) that is not Taken locally.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0090, \text{RC\_LD\_SPEC}, \text{Release consistency operation Speculatively executed, Load-Acquire}

The counter counts Memory-read operations with acquire or AcquirePC semantics that are Speculatively executed.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x0091, \text{RC\_ST\_SPEC}, \text{Release consistency operation Speculatively executed, Store-Release}

The counter counts Memory-write operations with release semantics that are Speculatively executed.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A0, \text{L3D\_CACHE\_RD}, \text{Level 3 data cache access, read}

If the \text{L3D\_CACHE\_RW} event is implemented, the counter counts each access counted by \text{L3D\_CACHE\_RW} that is a Memory-read operation.

If the \text{L3D\_CACHE\_RW} event is not implemented, the counter counts each access counted by \text{L3D\_CACHE} that is a Memory-read operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of \text{PMEVTYPER<0>_EL0.MT} for the counter is \(0b1\), other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A1, \text{L3D\_CACHE\_WR}, \text{Level 3 data cache access, write}

If the \text{L3D\_CACHE\_RW} event is implemented, the counter counts each access counted by \text{L3D\_CACHE\_RW} that is a Memory-write operation.

If the \text{L3D\_CACHE\_RW} event is not implemented, the counter counts each access counted by \text{L3D\_CACHE} that is a Memory-write operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of \text{PMEVTYPER<0>_EL0.MT} for the counter is \(0b1\), other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A2, \text{L3D\_CACHE\_REFILL\_RD}, \text{Level 3 data cache refill, read}

The counter counts each access counted by both \text{L3D\_CACHE\_RD} and \text{L3D\_CACHE\_REFILL}.

That is, every refill of the Level 3 data or unified cache counted by \text{L3D\_CACHE\_REFILL} that is caused by a Memory-read operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of \text{PMEVTYPER<0>_EL0.MT} for the counter is \(0b1\), other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

When \(\text{FEAT\_PMUv3p8}\) is not implemented, this is an IMPLEMENTATION DEFINED event.
0x00A3, **L3D_CACHE_REFILL_WR, Level 3 data cache refill, write**

The counter counts each access counted by both **L3D_CACHE_REFILL** and **L3D_CACHE_WR**.

That is, every refill of the Level 3 data or unified cache counted by **L3D_CACHE_REFILL** that is caused by a Memory-write operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A6, **L3D_CACHE_WB_VICTIM, Level 3 data cache write-back, victim**

The counter counts each write-back counted by **L3D_CACHE_WB** that occurs because the line is allocated for an access made by the PE.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A7, **L3D_CACHE_WB_CLEAN, Level 3 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by **L3D_CACHE_WB** that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.

Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 3 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a lower level cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x00A8, **L3D_CACHE_INV, Level 3 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 3 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 3 data or unified cache invalidates a line in the Level 3 data or unified cache.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.

If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

When FEAT_PMUv3p8 is not implemented, this is an IMPLEMENTATION DEFINED event.

0x4000, **SAMPLE_POP, Statistical Profiling sample population**

The counter counts each operation that might be sampled, whether or not the operation was sampled. Operations that are executed at an Exception level or Security state in which the Statistical Profiling Extension is disabled are not counted.
PMCEID0_EL0[32] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_SPE is implemented.

0x4001, SAMPLE_FEED, Statistical Profiling sample taken
The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the previous sample. Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.
PMCEID0_EL0[33] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_SPE is implemented.

0x4002, SAMPLE_FILTRATE, Statistical Profiling sample taken and not removed by filtering
The counter counts each sample counted by SAMPLE_FEED that is not removed by filtering.
Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event or because Discard mode is implemented and enabled, are counted.
PMCEID0_EL0[34] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_SPE is implemented.

0x4003, SAMPLE_COLLISION, Statistical Profiling sample collided with previous sample
The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample collides with the previous sample because the previous sampled operation has not completed generating its sample record.
PMCEID0_EL0[35] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_SPE is implemented.

0x4004, CNT_CYCLES, Constant frequency cycles
The counter increments at a constant frequency equal to the rate of increment of the System Counter, CNTPCT_EL0.
PMCEID0_EL0[36] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4005, STALL_BACKEND_MEM, Memory stall cycles
The counter counts each cycle counted by STALL_BACKEND_MEMBOUND where there is a demand data miss in the last level of data or unified cache within the PE clock domain.
If Armv8.7 is implemented, the counter also counts backend stall cycles when a non-cacheable data access is in progress.
If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable data access is in progress.
PMCEID0_EL0[37] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss
If the L1I CACHE_RD event is implemented, the counter counts each access to the Level 1 instruction or unified cache counted by L1I CACHE_RD that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.
If the L1I CACHE_RD event is not implemented, the counter counts each access to the Level 1 instruction or unified cache counted by L1I CACHE that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.
The event indicates to software that the access missed in the Level 1 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 instruction or unified cache.
The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in instructions being returned from a Level 2 cache or elsewhere beyond the Level 1 instruction or unified cache.

- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PM_EVTYPER<\n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[38] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if FEAT_PMUv3p4 is implemented.

0x4009, L2D_CACHE_LMISS_RD, Level 2 data cache long-latency read miss

The counter counts each Memory-read operation to the Level 2 data or unified cache counted by L2D_CACHE that incurs additional latency because it returns data from outside of the Level 1 and Level 2 data or unified caches of this PE.

The event indicates to software that the access missed in the Level 2 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data or unified cache. This might be counted as a Level 1 cache miss.

- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PM_EVTYPER<\n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[41] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x400A, L2I_CACHE_LMISS, Level 2 instruction cache long-latency miss

If the L2I_CACHE_RD event is implemented, the counter counts each access to the Level 2 instruction or unified cache counted by L2I_CACHE_RD that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.

If the L2I_CACHE_RD event is not implemented, the counter counts each access to the Level 2 instruction or unified cache counted by L2I_CACHE that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.
The event indicates to software that the access missed in the Level 2 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 instruction or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in instructions being returned from a Level 3 cache or elsewhere beyond the Level 2 instruction or unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[42] reads as 0b1 if this event is implemented and 0b0 otherwise.

**0x400B, L3D_CACHE_LMISS_RD, Level 3 data cache long-latency read miss**

The counter counts each Memory-read operation to the Level 3 data or unified cache counted by L3D_CACHE that incurs additional latency because it returns data from outside of the Level 1 to Level 3 data or unified caches of this PE.

The event indicates to software that the access missed in the Level 3 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 3 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 3 caches that the access looks up in and results in an access being made to a lower level cache or elsewhere beyond the Level 3 data or unified cache. This might be counted as a Level 2 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

PMCEID0_EL0[43] reads as 0b1 if this event is implemented and 0b0 otherwise.

**0x4010, TRCEXTOUT0, Trace unit external output 0**

The event is generated each time an event is signaled by the trace unit external event 0.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[48] reads as 0b1 if this event is implemented and 0b0 otherwise.

This event must be implemented if FEAT_ETE is implemented.
0x4011, TRCEXTOUT1, Trace unit external output 1
The event is generated each time an event is signaled by the trace unit external event 1.
It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.
PMCEID0_EL0[49] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x4012, TRCEXTOUT2, Trace unit external output 2
The event is generated each time an event is signaled by the trace unit external event 2.
It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.
PMCEID0_EL0[50] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x4013, TRCEXTOUT3, Trace unit external output 3
The event is generated each time an event is signaled by the trace unit external event 3.
It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.
PMCEID0_EL0[51] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x4018, CTI_TRIGOUT4, Cross-trigger Interface output trigger 4
The event is generated each time an event is signaled on CTI output trigger 4.

Note
CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[56] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x4019, CTI_TRIGOUT5, Cross-trigger Interface output trigger 5
The event is generated each time an event is signaled on CTI output trigger 5.

Note
CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[57] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x401A, CTI_TRIGOUT6, Cross-trigger Interface output trigger 6
The event is generated each time an event is signaled on CTI output trigger 6.

Note
CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[58] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.

0x401B, CTI_TRIGOUT7, Cross-trigger Interface output trigger 7
The event is generated each time an event is signaled on CTI output trigger 7.

Note
CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[59] reads as 0b1 if this event is implemented and 0b0 otherwise.
This event must be implemented if FEAT_ETE is implemented.
0x4020, **LDST_ALIGN_LAT, Access with additional latency from alignment**

The counter counts each access counted by MEM_ACCESS that, due to the alignment of the address and size of data being accessed, incurred additional latency.

PMCEID1_EL0[32] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4021, **LD_ALIGN_LAT, Load with additional latency from alignment**

The counter counts each Memory-read operation counted by LDST_ALIGN_LAT.
PMCEID1_EL0[33] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4022, **ST_ALIGN_LAT, Store with additional latency from alignment**

The counter counts each Memory-write operation counted by LDST_ALIGN_LAT.
PMCEID1_EL0[34] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4024, **MEM_ACCESS_CHECKED, Checked data memory access**

The counter counts each memory access counted by MEM_ACCESS that is checked by the Memory Tagging Extension.
PMCEID1_EL0[36] reads as 0b1 if this event is implemented and 0b0 otherwise.

0x4025, **MEM_ACCESS_RD_CHECKED, Checked data memory access, read**

The counter counts each Memory-read operation counted by MEM_ACCESS_CHECKED.
PMCEID1_EL0[37] reads as 0b1 if this event is implemented and 0b0 otherwise.
Implementation of this optional event requires that FEAT_MTE is implemented.

0x4026, **MEM_ACCESS_WR_CHECKED, Checked data memory access, write**

The counter counts each Memory-write operation counted by MEM_ACCESS_CHECKED.
PMCEID1_EL0[38] reads as 0b1 if this event is implemented and 0b0 otherwise.
Implementation of this optional event requires that FEAT_MTE is implemented.

0x8004, **SIMD_INST_SPEC, Operation speculatively executed, SIMD**

The counter counts each Speculatively executed operation due to either:

- An SVE instruction that is not a non-SIMD SVE instruction.
- An A64 Advanced SIMD instruction that is not an Advanced SIMD scalar instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD operations are counted in AArch32 state.

0x8005, **ASE_INST_SPEC, Operation speculatively executed, Advanced SIMD**

The counter counts each Speculatively executed operation due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to Advanced SIMD scalar instructions.

It is IMPLEMENTATION DEFINED which Advanced SIMD operations are counted in AArch32 state.

0x8006, **SVE_INST_SPEC, Operation speculatively executed, SVE, including load and store**

The counter counts each Speculatively executed operation due to an SVE instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to non-SIMD SVE instructions.

This event must be implemented if event SVE_INST_RETIRED is not implemented.
Implementation of this event requires that FEAT_SVE is implemented.

0x8007, **ASE_SVE_INST_SPEC, Operation speculatively executed, Advanced SIMD or SVE**

The counter counts each Speculatively executed operation counted by either ASE_INST_SPEC or SVE_INST_SPEC.

It is IMPLEMENTATION DEFINED which Advanced SIMD operations are counted in AArch32 state.
0x8008, **UOP_SPEC, Microarchitectural operation speculatively executed**

The counter counts each Speculatively executed microarchitectural operation.

The counter counts the operations irrespective of the IMPLEMENTATION DEFINED interpretation of operation speculatively executed.

0x8009, **ASE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD**

The counter counts each Speculatively executed microarchitectural operation counted by UOP_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitectural operations due to Advanced SIMD scalar instructions.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

0x800A, **SVE_UOP_SPEC, Microarchitectural operation speculatively executed, SVE**

The counter counts each Speculatively executed microarchitectural operation counted by UOP_SPEC due to an SVE instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitectural operations due to the instructions listed in Non-SIMD SVE instructions on page D11-5270.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x800B, **ASE_SVE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD or SVE**

The counter counts each Speculatively executed microarchitectural operation counted by either ASE_UOP_SPEC or SVE_UOP_SPEC.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

0x800C, **SIMD_UOP_SPEC, Microarchitectural operation speculatively executed, SIMD**

The counter counts each Speculatively executed microarchitectural operation counted by UOP_SPEC due to either:

- An SVE instruction other than any instruction listed in Non-SIMD SVE instructions on page D11-5270.
- An A64 Advanced SIMD instruction other than an Advanced SIMD scalar instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

0x800E, **SVE_MATH_SPEC, Operation speculatively executed, SVE math accelerator**

The counter counts each Speculatively executed math function operation due to any of the following A64 instructions:

- SVE: FEXPA, FTMAD, FTSML, or FTSEL.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8010, **FP_SPEC, Floating-point operation speculatively executed, including SIMD**

The counter counts each Speculatively executed floating-point operation due to an A64 scalar, Advanced SIMD, or SVE instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to a scalar, Advanced SIMD, or SVE instruction.

It is IMPLEMENTATION DEFINED which floating-point operations are counted in AArch32 state.

——— Note ————

This event differs from the VFP_SPEC event which does not count SIMD operations.
0x8011, **ASE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD**

The counter counts each Speculatively executed floating-point operation counted by FP_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point operations are counted in AArch32 state.

0x8012, **SVE_FP_SPEC, Floating-point operation speculatively executed, SVE**

The counter counts each Speculatively executed floating-point operation counted by FP_SPEC due to an SVE instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8013, **ASE_SVE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE**

The counter counts each Speculatively executed floating-point operation counted by either ASE_FP_SPEC or SVE_FP_SPEC.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point operations are counted in AArch32 state.

0x8014, **FP_HP_SPEC, Floating-point operation speculatively executed, half precision**

The counter counts each Speculatively executed floating-point operation counted by FP_SPEC where the largest type is half precision.

0x8015, **ASE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD half precision**

The counter counts each Speculatively executed half-precision floating-point operation counted by FP_HP_SPEC due to an Advanced SIMD instruction.

0x8016, **SVE_FP_HP_SPEC, Floating-point operation speculatively executed, SVE half precision**

The counter counts each Speculatively executed half-precision floating-point operation counted by FP_HP_SPEC due to an SVE instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8017, **ASE_SVE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE half precision**

The counter counts each Speculatively executed floating-point operation counted by either ASE_FP_HP_SPEC or SVE_FP_HP_SPEC.

0x8018, **FP_SP_SPEC, Floating-point operation speculatively executed, single precision**

The counter counts each Speculatively executed floating-point operation counted by FP_SPEC where the largest type is single precision.

0x8019, **ASE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD single precision**

The counter counts each Speculatively executed single-precision floating-point operation counted by FP_SP_SPEC due to an Advanced SIMD instruction.

0x801A, **SVE_FP_SP_SPEC, Floating-point operation speculatively executed, SVE single precision**

The counter counts each Speculatively executed single-precision floating-point operation counted by FP_SP_SPEC due to an SVE instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x801B, **ASE_SVE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE single precision**

The counter counts each Speculatively executed floating-point operation counted by either ASE_FP_SP_SPEC or SVE_FP_SP_SPEC.
The Performance Monitors Extension

D11.11 PMU events and event numbers

0x801C, FP_DP_SPEC, Floating-point operation speculatively executed, double precision
The counter counts each Speculatively executed floating-point operation counted by FP_SPEC where the largest type is double precision.

0x801D, ASE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD double precision
The counter counts each Speculatively executed double-precision floating-point operation counted by FP_DP_SPEC due to an Advanced SIMD instruction.

0x801E, SVE_FP_DP_SPEC, Floating-point operation speculatively executed, SVE double precision
The counter counts each Speculatively executed double-precision floating-point operation counted by FP_DP_SPEC due to an SVE instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x801F, ASE_SVE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE double precision
The counter counts each Speculatively executed floating-point operation counted by either ASE_FP_DP_SPEC or SVE_FP_DP_SPEC.

0x8020, FP_DIV_SPEC, Floating-point operation speculatively executed, divide
The counter counts each Speculatively executed floating-point divide operation counted by FP_SPEC due to any of the following A64 instructions:
• Scalar: FDIV.
• Advanced SIMD: FDIIV.
• SVE: FDIV or FDIVR.
It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.

0x8021, ASE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD divide
The counter counts each Speculatively executed floating-point divide operation counted by FP_DIV_SPEC due to any of the following A64 instructions:
• Advanced SIMD: FDIIV.
It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.

0x8022, SVE_FP_DIV_SPEC, Floating-point operation speculatively executed, SVE divide
The counter counts each Speculatively executed floating-point divide operation counted by FP_DIV_SPEC due to any of the following instructions:
• SVE: FDIIV or FDIVR.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x8023, ASE_SVE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE divide
The counter counts each Speculatively executed floating-point divide operation counted by either ASE_FP_DIV_SPEC or SVE_FP_DIV_SPEC.
That is, due to any of the following A64 instructions:
• Advanced SIMD: FDIIV.
• SVE: FDIIV or FDIVR.
It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.
The counter counts each Speculatively executed floating-point square-root operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- Scalar: \texttt{FSQRT}.
- Advanced SIMD: \texttt{FSQRT}.
- SVE: \texttt{FSQRT}.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point square-root operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- Advanced SIMD: \texttt{FSQRT}.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point square-root operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- SVE: \texttt{FSQRT}.

Implementation of this optional event requires that FEAT\_SVE is implemented.

The counter counts each Speculatively executed floating-point square-root operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- Advanced SIMD: \texttt{FSQRT}.
- SVE: \texttt{FSQRT}.

That is, due to any of the following A64 instructions:

- Advanced SIMD: \texttt{FSQRT}.
- SVE: \texttt{FSQRT}.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- Scalar: \texttt{FMADD}, \texttt{FMSUB}, \texttt{FNMADD}, or \texttt{FNMSUB}.
- Advanced SIMD: \texttt{BFMLALB}, \texttt{BFMLALT}, \texttt{FCMLA}, \texttt{FMLA}, or \texttt{FMLS}.
- SVE: \texttt{BFMLALB (vectors)}, \texttt{BFMLALT (vectors)}, \texttt{FCMLA (vectors)}, \texttt{FMAD}, \texttt{FMLA (vectors)}, \texttt{FMLS (vectors)}, \texttt{FMAD}, \texttt{FMAL}, \texttt{FMLS}, \texttt{FMFSB}, or \texttt{FTMAD}.
- SVE2: \texttt{BFMLALB (vectors)}, \texttt{BFMLALT (vectors)}, \texttt{FMLAL (vectors)}, \texttt{FMLALT (vectors)}, \texttt{FMLS (vectors)}, \texttt{FMLAL (vectors)}, or \texttt{FMLSLT (vectors)}.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by \texttt{FP\_SPEC} due to any of the following A64 instructions:

- Advanced SIMD: \texttt{BFMLALB}, \texttt{BFMLALT}, \texttt{FCMLA}, \texttt{FMLA}, or \texttt{FMLS}.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.
The counter counts each Speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by FP_FMA_SPEC due to any of the following instructions:

- SVE: BFMLALB (vectors), BFMLALT (vectors), FCMLA (vectors), FMAD, FMLA (vectors), FMLS (vectors), FMSB, FNMAD, FMCLA, FMULS, FMULSLB, or FTMAD.
- SVE2: BFMLALB (vectors), BFMLALT (vectors), FMLALB (vectors), FMLALT (vectors), FMLSLB (vectors), or FMLSLT (vectors).

Implementation of this optional event requires that FEAT_SVE is implemented.

The counter counts each Speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by either ASE_FP_FMA_SPEC or SVE_FP_FMA_SPEC.

That is, due to any of the following A64 instructions:

- Advanced SIMD: BFMLALB, BFMLALT, FCMLA, FMLA, or FMLS.
- SVE: BFMLALB (vectors), BFMLALT (vectors), FCMLA (vectors), FMAD, FMLA (vectors), FMLS (vectors), FMSB, FNMAD, FMCLA, FMULS, FMULSLB, or FTMAD.
- SVE2: BFMLALB (vectors), BFMLALT (vectors), FMLALB (vectors), FMLALT (vectors), FMLSLB (vectors), or FMLSLT (vectors).

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point multiply operation counted by FP_MUL_SPEC due to any of the following A64 instructions:

- Scalar: FMUL or FMULX.
- Advanced SIMD: FMUL or FMULX.
- SVE: FMUL, FMULX, or FTSMUL.

It is IMPLEMENTATION DEFINED which floating-point multiply operations are counted in AArch32 state.

The counter counts each Speculatively executed floating-point multiply operation counted by either ASE_FP_MUL_SPEC or SVE_FP_MUL_SPEC.

That is, due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.
- SVE: FMUL, FMULX, or FTSMUL.

Implementation of this optional event requires that FEAT_SVE is implemented.

The counter counts each Speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by either ASE_FP_MUL_SPEC or SVE_FP_MUL_SPEC.

That is, due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.
- SVE: FMUL, FMULX, or FTSMUL.
It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

0x8030, **FP_ADDSUB_SPEC, Floating-point operation speculatively executed, add or subtract**

The counter counts each Speculatively executed floating-point add or subtract operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FADD or FSUB.
- Advanced SIMD: FADD, FADD, or FSUB.
- SVE: FABD, FADD, FSUB, or FSUBR.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

0x8031, **ASE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD add or subtract**

The counter counts each Speculatively executed floating-point add or subtract operation counted by FP_ADDSUB_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

0x8032, **SVE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, SVE add or subtract**

The counter counts each Speculatively executed floating-point add or subtract operation counted by FP_ADDSUB_SPEC due to any of the following instructions:

- SVE: FABD, FADD, FSUB, or FSUBR.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8033, **ASE_SVE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract**

The counter counts each Speculatively executed floating-point add or subtract operation counted by either ASE_FP_ADDSUB_SPEC or SVE_FP_ADDSUB_SPEC.

That is, due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.
- SVE: FABD, FADD, FSUB, or FSUBR.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

0x8034, **FP_RECPE_SPEC, Floating-point operation speculatively executed, reciprocal estimate**

The counter counts each Speculatively executed floating-point reciprocal estimate operation counted by FP_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRT.
- SVE: FRECPE or FRSQRT.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.

0x8035, **ASE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate**

The counter counts each Speculatively executed floating-point reciprocal estimate operation counted by FP_RECPE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRT.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.
0x8036, SVE_FP_RECPE_SPEC, Floating-point operation speculatively executed, SVE reciprocal estimate
The counter counts each Speculatively executed floating-point reciprocal estimate operation counted by FP_RECPE_SPEC due to any of the following instructions:
- SVE: FRECPE or FRSQRT.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8037, ASE_SVE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate
The counter counts each Speculatively executed floating-point reciprocal estimate operation counted by either ASE_FP_RECPE_SPEC or SVE_FP_RECPE_SPEC.
That is, due to any of the following A64 instructions:
- Advanced SIMD: FRECPE or FRSQRT.
- SVE: FRECPE or FRSQRT.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.

0x8038, FP_CVT_SPEC, Floating-point operation speculatively executed, convert
The counter counts each Speculatively executed floating-point convert operation due to an A64 scalar, Advanced SIMD, or SVE floating-point conversion instruction.
It is IMPLEMENTATION DEFINED which floating-point convert operations are counted in AArch32 state.

0x8039, ASE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD convert
The counter counts each Speculatively executed floating-point convert operation counted by FP_CVT_SPEC due to an A64 Advanced SIMD instruction.
It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point convert operations are counted in AArch32 state.

0x803A, SVE_FP_CVT_SPEC, Floating-point operation speculatively executed, SVE convert
The counter counts each Speculatively executed floating-point convert operation counted by FP_CVT_SPEC due to an SVE instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x803B, ASE_SVE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE convert
The counter counts each Speculatively executed floating-point convert operation counted by either ASE_FP_CVT_SPEC or SVE_FP_CVT_SPEC.
It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point convert operations are counted in AArch32 state.

0x803C, SVE_FP_AREDUCE_SPEC, Floating-point operation speculatively executed, SVE accumulating reduction
The counter counts each Speculatively executed floating-point accumulating reduction operation counted by SVE_FP_SPEC due to any of the following A64 instructions:
- SVE: FADD.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x803D, ASE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise add step
The counter counts each Speculatively executed floating-point pairwise add operation counted by ASE_FP_SPEC due to any of the following A64 instructions:
- Advanced SIMD: FADD.
It is IMPLEMENTATION DEFINED which floating-point pairwise add operations are counted in AArch32 state.

0x803E, SVE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, SVE vector reduction

The counter counts each Speculatively executed floating-point tree-wise reduction operation counted by SVE_FP_SPEC due to any of the following A64 instructions:
- SVE: FADDV, FMAXNW, FMAXV, FMINNW, or FMINV.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x803F, ASE_SVE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction

The counter counts each Speculatively executed floating-point reduction operation counted by ASE_SVE_FP_SPEC due to any of the following A64 instructions:
- Advanced SIMD: FADDP, FMAXNW, FMAXV, FMINNW, or FMINV.
- SVE: FADDV, FMAXNW, FMAXV, FMINNW, or FMINV.

It is IMPLEMENTATION DEFINED which floating-point reduction operations are counted in AArch32 state.

0x8040, INT_SPEC, Integer operation speculatively executed

The counter counts each Speculatively executed integer arithmetic operation due to an A64 scalar, Advanced SIMD, and SVE data-processing instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to a scalar, Advanced SIMD, and SVE data-processing instruction.

It is IMPLEMENTATION DEFINED which integer arithmetic operations are counted in AArch32 state.

0x8041, ASE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD

The counter counts each Speculatively executed integer operation counted by INT_SPEC due to an Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD integer operations are counted in AArch32 state.

0x8042, SVE_INT_SPEC, Integer operation speculatively executed, SVE

The counter counts each Speculatively executed integer operation counted by INT_SPEC due to an SVE instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8043, ASE_SVE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE

The counter counts each Speculatively executed integer arithmetic operation counted by either ASE_INT_SPEC or SVE_INT_SPEC.

It is IMPLEMENTATION DEFINED which Advanced SIMD integer operations are counted in AArch32 state.

0x8044, INT_DIV_SPEC, Integer operation speculatively executed, divide

The counter counts each Speculatively executed integer divide operation counted by INT_SPEC due to any of the following A64 instructions:
- Scalar: SDIV or UDIV.
- SVE: SDIV, SDIVR, UDIV, or UDIVR.

It is IMPLEMENTATION DEFINED which integer divide operations are counted in AArch32 state.

0x8045, INT_DIV64_SPEC, Integer operation speculatively executed, 64-bit divide

The counter counts each Speculatively executed integer divide operation counted by INT_SPEC due to any of the following A64 instructions:
- Scalar: SDIV or UDIV.
The Performance Monitors Extension
D11.11 PMU events and event numbers

- SVE: SDIV, SDIVR, UDIV, or UDIVR.
The counter only counts operations with 64-bit operands or vector elements.

0x8046, SVE_INT_DIV_SPEC, Integer operation speculatively executed, SVE divide
The counter counts each Speculatively executed integer divide operation counted by INT_DIV_SPEC due to any of the following instructions:
- SVE: SDIV, SDIVR, UDIV, or UDIVR.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x8047, SVE_INT_DIV64_SPEC, Integer operation speculatively executed, SVE 64-bit divide
The counter counts each Speculatively executed integer 64-bit divide operation counted by INT_DIV64_SPEC due to any of the following instructions:
- SVE: SDIV, SDIVR, UDIV, or UDIVR.
The counter only counts operations with 64-bit operands or vector elements.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x8048, INT_MUL_SPEC, Integer operation speculatively executed, multiply
The counter counts each Speculatively executed integer multiply or multiply-accumulate operation counted by INT_SPEC due to any of the following A64 instructions:
- Scalar: MADD, MSUB, MUL, SMADD, SMULH, UMAADD, or UMLH.
- Advanced SIMD: MLA, MLS, MUL, PMULL, SMLAL, SMLS, SMULL, SQDMULAL, SQDMULSL, SQDMULH, SQDMULL, SQRDMULAH, SQRDMULSH, SQ-shadow, or UMLH.
- SVE: MAD, MIA, MLS, MSB, ML, SMULH, or UMLH.
- SVE2: CMLA, MLA, MLS, MUL, PMULL, SMLAL, SMLS, SMULL, SQDMULAL, SQDMULSL, SQDMULH, SQDMULL, SQRDMULAH, SQRDMULSH, SQRDMULH, UMLH, or UMLH.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

0x8049, ASE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD multiply
The counter counts each Speculatively executed integer multiply or multiply-accumulate operation counted by INT_MUL_SPEC due to any of the following A64 instructions:
- Advanced SIMD: MLA, MLS, MUL, PMULL, SMLAL, SMLS, SMULL, SQDMULAL, SQDMULSL, SQDMULH, SQDMULL, SQRDMULAH, SQRDMULSH, SQRDMULH, UMLH, or UMLH.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

0x804A, SVE_INT_MUL_SPEC, Integer operation speculatively executed, SVE multiply
The counter counts each Speculatively executed integer multiply or multiply-accumulate operation counted by INT_MUL_SPEC due to any of the following instructions:
- SVE: MAD, MIA, MLS, MSB, ML, SMULH, or UMLH.
- SVE2: CMLA, MLA, MLS, MUL, PMULL, SMLAL, SMLS, SMULL, SQDMULAL, SQDMULSL, SQDMULH, SQDMULL, SQRDMULAH, SQRDMULSH, SQRDMULH, UMLH, or UMLH.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x804B, ASE_SVE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE multiply
The counter counts each Speculatively executed integer multiply or multiply-accumulate operation counted by either ASE_INT_MUL_SPEC or SVE_INT_MUL_SPEC.
That is, due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMULL, SMLAL, SMLS, SMLSL, SMULL, SQDMLAL, SQDMLSL, SQDMLUL, SQDMLULL, SQDMLSH, SQDMLSLH, SQDMLUH, UMLAL, UMLSL, or UMLUL.
- SVE: MAD, MLA, MLS, MSB, MUL, SMULH, or UMLUL.
- SVE2: CMLA, MLA, MLS, MUL, SMLALB, SMLALT, SMLSLB, SMLSLT, SMULH, SMULLB, SMULLT, SQDMLALB, SQDMLALBT, SQDMLALT, SQDMLSLB, SQDMLSLBT, SQDMLSLT, SQDMLUH, SQDMLULL, SQDMLULLT, SQDMLUH, SQRDMULH, SQRDMULLH, SQDMLUH, UMLALB, UMLALT, UMLSLB, UMLSLT, UMLUL, or UMLULL.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

0x804C, **INT_MUL64_SPEC**, Integer operation speculatively executed, 64×64 multiply

The counter counts each Speculatively executed 64×64 integer multiply operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, or SMULH.
- SVE: MAD, MLA, MLS, MSB, MUL, SMULH, or UMLUL.
- SVE2: CMLA (vectors), MLA, MLS, MUL, SMLALB, SMLALT, SMLSLB, SMLSLT, SMULH, SMULLB, SMULLT, SQDMLALB, SQDMLALBT, SQDMLALT, SQDMLSLB, SQDMLSLBT, SQDMLSLT, SQDMLUH, SQDMLULL, SQDMLULLT, SQDMLUH, SQRDMULH (vectors), SQDMLAH, SQDMLSH, SQRDMULH, UMLALB, UMLALT, UMLSLB, UMLSLT, UMLUL, or UMLULL.

The counter only counts operations that perform a 64-bit × 64-bit integer multiply operations.

0x804D, **SVE_INT_MUL64_SPEC**, Integer operation speculatively executed, SVE 64×64 multiply

The counter counts each Speculatively executed 64×64 integer multiply operation counted by INT_MUL64_SPEC due to any of the following instructions:

- SVE: MAD, MLA, MLS, MSB, MUL, SMULH, or UMLUL.
- SVE2: CMLA (vectors), MLA, MLS, MUL, SMLALB, SMLALT, SMLSLB, SMLSLT, SMULH, SMULLB, SMULLT, SQDMLALB, SQDMLALBT, SQDMLALT, SQDMLSLB, SQDMLSLBT, SQDMLSLT, SQDMLUH, SQDMLULL, SQDMLULLT, SQDMLUH, SQRDMULH (vectors), SQDMLAH, SQDMLSH, SQRDMULH, UMLALB, UMLALT, UMLSLB, UMLSLT, UMLUL, or UMLULL.

The counter only counts operations that perform a 64-bit × 64-bit integer multiply operations. Implementation of this optional event requires that FEAT_SVE is implemented.

0x804E, **INT_MULH64_SPEC**, Integer operation speculatively executed, 64×64 multiply returning high part

The counter counts each Speculatively executed widening 64×64 integer multiply operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: SMULH or UMLUL.
- SVE: SMULH or UMLUL.
- SVE2: SMULH, SQDMLUL, SQRDMULH, or UMLUL.

These instructions perform 64-bit × 64-bit integer multiply operations.

0x804F, **SVE_INT_MULH64_SPEC**, Integer operation speculatively executed, SVE 64×64 multiply high part

The counter counts each Speculatively executed 64×64 integer multiply returning high part operation counted by INT_MULH64_SPEC due to any of the following instructions:

- SVE: SMULH or UMLUL.
- SVE2: SMULH, SQDMLUL, SQRDMULH, or UMLUL.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8058, **NONFP_SPEC**, Non-floating-point operation speculatively executed

The counter counts each Speculatively executed operation due to any of:

- A scalar instruction that would be counted by the DP_SPEC event.
**The Performance Monitors Extension**

**D11.11 PMU events and event numbers**

- An A64 Advanced SIMD data processing instruction defined in the section titled *Data processing - SIMD and floating-point* on page C3-310 that would not be counted by *FP_SPEC*.
- An SVE instruction with vector source or destination registers, that would not be counted by *FP_SPEC*.

It is IMPLEMENTATION DEFINED which non-floating-point data processing operations are counted in AArch32 state.

0x8059, **ASE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD**

The counter counts each Speculatively executed non-floating-point operation counted by NONFP_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD non-floating-point data processing operations are counted in AArch32 state.

0x805A, **SVE_NONFP_SPEC, Non-floating-point operation speculatively executed, SVE**

The counter counts each Speculatively executed non-floating-point operation counted by NONFP_SPEC due to an SVE instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x805B, **ASE_SVE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD or SVE**

The counter counts each Speculatively executed non-floating-point operation counted by either ASE_NONFP_SPEC or SVE_NONFP_SPEC.

It is IMPLEMENTATION DEFINED which Advanced SIMD non-floating-point data processing operations are counted in AArch32 state.

0x805D, **ASE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD reduction**

The counter counts each Speculatively executed across-vector and pairwise integer reduction operation counted by ASE_INT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADDVL, UMAXV, or UMINV.

It is IMPLEMENTATION DEFINED which across-vector and pairwise integer reduction operations are counted in AArch32 state.

0x805E, **SVE_INT_VREDUCE_SPEC, Integer operation speculatively executed, SVE reduction**

The counter counts each Speculatively executed across-vector integer reduction operation counted by SVE_INT_SPEC due to any of the following A64 instructions:

- SVE: ANDV, EORV, ORV, SADDV, SMAXV, SMINV, UADDV, UMAXV, or UMINV.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x805F, **ASE_SVE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE reduction**

The counter counts each Speculatively executed across-vector and pairwise integer reduction operation counted by either ASE_INT_VREDUCE_SPEC or SVE_INT_VREDUCE_SPEC.

That is, due to any of the following A64 instructions:

- Advanced SIMD: SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADDVL, UMAXV, or UMINV.
- SVE: ANDV, EORV, ORV, SADDV, SMAXV, SMINV, UADDV, UMAXV, or UMINV.

It is IMPLEMENTATION DEFINED which across-vector and pairwise integer reduction operations are counted in AArch32 state.
0x8060, SVE_PERM_SPEC, Operation speculatively executed, SVE permute

The counter counts each Speculatively executed vector or predicate permute operation due to any of the following A64 instructions:

- SVE: CLASTA, CLASTB, COMPACT, CPY (SIMD&FP scalar), CPY (scalar), DUP (indexed), DUP (scalar), EXT, INSR, LASTA, LASTB, PUNPKHI, PUNPKLO, REV (vector), REV8, REVH, REW, SPLICE, SUNPKHI, SUNPKLO, TBL, TRN1 (vectors), TRN2 (vectors), UUNPKHI, UUNPKLO, UZP1 (vectors), UZP2 (vectors), ZIP1 (vectors), or ZIP2 (vectors).

- SVE2: EXT, SPLICE, TBL, TBX, TRN1, TRN2, UZP1, UZP2, ZIP1, or ZIP2.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8061, SVE_PERM_VARIABLE_SPEC, Operation speculatively executed, SVE intra-granule permute

The counter counts each Speculatively executed vector or predicate permute operation within a 128-bit vector granule or 16-bit predicate granule due to any of the following A64 instructions:

- SVE: REV8, REVH, REW, TRN1 (vectors), or TRN2 (vectors).

- SVE2: TRN1 or TRN2.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8062, SVE_PERM_XGRANULE_SPEC, Operation speculatively executed, SVE cross-granule permute

The counter counts each Speculatively executed vector or predicate permute operation that can cross between 128-bit vector granules or 16-bit predicate granules due to any of the following A64 instructions:

- SVE: CLASTA, CLASTB, COMPACT, CPY (SIMD&FP scalar), CPY (scalar), DUP (indexed), DUP (scalar), EXT, INSR, LASTA, LASTB, PUNPKHI, PUNPKLO, REV (vector), SPLICE, SUNPKHI, SUNPKLO, TBL, UUNPKHI, UUNPKLO, UZP1 (vectors), UZP2 (vectors), ZIP1 (vectors), or ZIP2 (vectors).

- SVE2: EXT, SPLICE, TBL, TBX, UZP1, UZP2, ZIP1, or ZIP2.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8063, SVE_PERM_VARIABLE_SPEC, Operation speculatively executed, SVE programmable permute

The counter counts each Speculatively executed variable vector permute operation due to any of the following A64 instructions:

- SVE: CLASTA, CLASTB, COMPACT, LASTA, LASTB, SPLICE, or TBL.

- SVE2: SPLICE or TBL.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8064, SVE_XPIPE_SPEC, Operation speculatively executed, SVE cross-pipe

The counter counts each Speculatively executed cross-pipeline transfer operation counted by either SVE_XPIPE_RZ2_SPEC or SVE_XPIPE_Z2R_SPEC.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8065, SVE_XPIPE_Z2R_SPEC, Operation speculatively executed, SVE vector to scalar cross-pipe

The counter counts each Speculatively executed vector to general-purpose scalar cross-pipeline transfer operation due to any of the following A64 instructions:

- SVE: CLASTA (scalar), CLASTB (scalar), CNTP, DECP (scalar), INCP (scalar), LASTA (scalar), LASTB (scalar), SQDECP (scalar), SQINCP (scalar), UQDECP (scalar), or UQINCP (scalar).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8066, SVE_XPIPE_RZ2_SPEC, Operation speculatively executed, SVE scalar to vector cross-pipe

The counter counts each Speculatively executed general-purpose scalar to vector cross-pipeline transfer operation due to any of the following A64 instructions:

- SVE: CPY (scalar), DUP (scalar), INDEX (immediate, scalar), INDEX (scalar, immediate), INDEX (scalars), INSR (scalar), WHILEE, WHILELO, WHILELS, or WHILELT.

- SVE2: WHILEGE, WHILEGT, WHILEHI, WHILEHS, WHILERQ, or WHILEWR.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x8067, SVE_PGEN_NVEC_SPEC, Operation speculatively executed, SVE predicate-only

The counter counts each Speculatively executed predicate-generating operation that does not read vector registers due to any of the following A64 instructions:

- SVE: AND (predicates), ANDS, BIC (predicates), BICS, BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBPS, EOR (predicates), EORS, NAND, NANDS, NOR, NORS, ORN (predicates), ORNS, ORR (predicates), ORRS, PFALSE, PFIRST, PNEXT, PTRUE, PTRUEES, PUNPKHI, PUNPKLO, RDFR, RDFFRS, REV (predicate), SEL (predicates), TRN1 (predicates), TRN2 (predicates), UZP1 (predicates), UZP2 (predicates), ZIP1 (predicates), or ZIP2 (predicates).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8068, SVE_PGEN_SPEC, Operation speculatively executed, SVE predicate generating

The counter counts each Speculatively executed predicate-generating operation due to any of the following A64 instructions:

- SVE: AND (predicates), ANDS, BIC (predicates), BICS, BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBPS, CMPEQ, CMPGE, CMPGT, CMPHI, CMPSH, CMPLE (immediate), CMPLE (wide elements), CMPL0 (immediate), CMPL0 (wide elements), CMPLS (immediate), CMPLS (wide elements), CMPLT (immediate), CMPLT (wide elements), CMPNE, EOR (predicates), EORS, FACGE, FACGT, FCMEE, FCOME, FCOME (zero), FCMT (zero), FCME, FCMUO, NAND, NANDS, NOR, NORS, ORN (predicates), ORNS, ORR (predicates), ORRS, PFALSE, PFIRST, PNEXT, PTRUE, PTRUEES, PUNPKHI, PUNPKLO, RDFR, RDFFRS, REV (predicate), SEL (predicates), TRN1 (predicates), TRN2 (predicates), UZP1 (predicates), UZP2 (predicates), WHILELE, WHILELO, WHILELS, WHILELT, ZIP1 (predicates), or ZIP2 (predicates).

- SVE2: MATCH, NMATCH, WHILEGE, WHILEGT, WHILEHS, WHILEHW, or WHILELR.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8069, SVE_PGEN_FLG_SPEC, Operation speculatively executed, SVE predicate flag setting

The counter counts each Speculatively executed predicate-generating operation that sets condition flags due to any of the following A64 instructions:

- SVE: ANDS, BICS, BRKAS, BRKBS, BRKN, BRKNS, BRKPA, BRKPAS, BRKPB, BRKPBPS, CMPEQ, CMPGE, CMPGT, CMPHI, CMPSH, CMPLE (immediate), CMPL0 (immediate), CMPL0 (wide elements), CMPL0 (immediate), CMPL0 (wide elements), CMPLS (immediate), CMPLT (immediate), CMPLT (wide elements), CMPNE, EORS, NANDS, NORS, ORNS, ORRS, PFALSE, PFIRST, PNEXT, PTRUE, PTRUEES, RDFR, RDFFRS, WHILELE, WHILELO, WHILELS, or WHILELT.

- SVE2: MATCH, NMATCH, WHILEGE, WHILEGT, WHILEHS, WHILERW, or WHILERW.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x806A, SVE_PGEN_CMP_SPEC, Operation speculatively executed, SVE vector compare

The counter counts each Speculatively executed vector compare operation due to any of the following A64 instructions:

- SVE: CMPEQ, CMPGE, CMPGT, CMPHI, CMPSH, CMPLE (immediate), CMPL0 (immediate), CMPL0 (wide elements), CMPL0 (immediate), CMPLT (immediate), CMPLT (wide elements), CMPNE, FACGE, FACGT, FCOME, FCOME, FCOME (zero), FCMT (zero), FCME, FCMUO.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x806B, SVE_PGEN_FCM_SPEC, Floating-point operation speculatively executed, SVE vector compare

The counter counts each Speculatively executed vector floating-point compare operation due to any of the following A64 instructions:

- SVE: FACGE, FACGT, FCOME, FCOME, FCOME (zero), FCMT (zero), FCME, or FCMUO.

Implementation of this optional event requires that FEAT_SVE is implemented.
0x806C, SVE_PGEN_LOGIC_SPEC, Operation speculatively executed, SVE predicate logical
The counter counts each Speculatively executed predicate logical operation due to any of the following A64 instructions:

- SVE: AND (predicates), ANDS, BIC (predicates), BICS, EOR (predicates), EORS, NAND, NANDS, NOR, NOR, ORN (predicates), ORNS, ORR (predicates), or ORRS.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x806D, SVE_PPERM_SPEC, Operation speculatively executed, SVE predicate permute
The counter counts each Speculatively executed predicate permute operation due to any of the following A64 instructions:

- SVE: PUNPKHI, PUNPKLO, REV (predicate), TRN1 (predicate), TRN2 (predicate), UZP1 (predicate), ZIP2 (predicate), ZIP2 (predicate), UZP2 (predicate), or ZIP2 (predicate).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x806E, SVE_PSCAN_SPEC, Operation speculatively executed, SVE predicate scan
The counter counts each Speculatively executed predicate scanning and generation operation due to any of the following A64 instructions:

- SVE: BRKA, BRKAS, BRKB, BRKBS, BRKN, BRKPA, BRKPS, BRKPB, BRKPBS, PFIRST, or PNEXT.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x806F, SVE_PCNT_SPEC, Operation speculatively executed, SVE predicate count
The counter counts each Speculatively executed predicate population count operation due to any of the following A64 instructions:

- SVE: CNTP, DECP, INCP, SQDECP, SQINCP, UQDECP, or UQINCP.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8070, SVE_PLOOP_WHILE_SPEC, Operation speculatively executed, SVE predicate loop while
The counter counts each Speculatively executed counted predicate generation operation due to any of the following A64 instructions:

- SVE: WHILELE, WHILELO, WHILELS, or WHILELT.
- SVE2: WHILEGE, WHILEGT, WHILEHI, or WHILEHS.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8071, SVE_PLOOP_TEST_SPEC, Operation speculatively executed, SVE predicate loop test
The counter counts each Speculatively executed loop predicate test operation due to any of the following A64 instructions:

- SVE: BRKAS, BRKBS, BRKN, BRKPA, BRKPS, BRKPB, BRKPBS, WHILELE, WHILELO, WHILELS, or WHILELT.
- SVE2: WHILEGE, WHILEGT, WHILEHI, or WHILEHS.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8072, SVE_PLOOP_ELTS_SPEC, Operation speculatively executed, SVE predicate loop elements
The counter counts each Speculatively executed loop predicate generation operation due to any of the following A64 instructions:

- SVE: WHILELE, WHILELO, WHILELS, or WHILELT.
- SVE2: WHILEGE, WHILEGT, WHILEHI, or WHILEHS.

The counter increments by (128 ÷ CSIZE).

--- Note ---

Multiplying the counter value by (VL ÷ 128) determines the number of vector elements speculatively processed by while loops.

Implementation of this optional event requires that FEAT_SVE is implemented.
0x8073, **SVE_PLOOP_TERM_SPEC, Operation speculatively executed, SVE predicate loop termination**

The counter counts each Speculatively executed loop-terminating predicate generation operation due to any of:

- An SVE **WHILEL**, **WHILES**, or **WHILELT** instruction which sets PSTATE.N to \(0b0\).
- An SVE **BRKAS**, **BRKBS**, **BRKNS**, **BRKPAS**, or **BRKPBS** instruction which sets PSTATE.C to \(0b1\).
- An SVE **CTERMEQ** or **CTERMNE** instruction which sets PSTATE.N to \(0b1\) and PSTATE.V to \(0b0\).
- An SVE **WHILEGE**, **WHILEGT**, **WHILEHL**, or **WHILEHS** instruction which sets PSTATE.N to \(0b0\).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8074, **SVE_PRED_SPEC, Operation speculatively executed, SVE predicated**

The counter counts each Speculatively executed SIMD data-processing, load, or store operation due to an SVE instruction with a Governing predicate operand that determines the Active elements.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8075, **SVE_PRED_EMPTY_SPEC, Operation speculatively executed, SVE predicated with no active predicates**

The counter counts each Speculatively executed predicated SIMD data-processing, load, or store operation counted by **SVE_PRED_SPEC** where all elements are Inactive.

That is, all elements in the Governing predicate are FALSE.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8076, **SVE_PRED_FULL_SPEC, Operation speculatively executed, SVE predicated with all active predicates**

The counter counts each Speculatively executed predicated SIMD data-processing, load, or store operation counted by **SVE_PRED_SPEC** where all elements are Active.

That is, all elements in the Governing predicate are TRUE.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8077, **SVE_PRED_PARTIAL_SPEC, Operation speculatively executed, SVE predicated with partially active predicates**

The counter counts each Speculatively executed predicated SIMD data-processing, load, or store operation counted by **SVE_PRED_SPEC** that is not counted by either **SVE_PRED_EMPTY_SPEC** or **SVE_PRED_FULL_SPEC**.

That is, the elements in the Governing predicate are neither all TRUE nor all FALSE.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8078, **SVE_UNPRED_SPEC, Operation speculatively executed, SVE unpredicated**

The counter counts each Speculatively executed SIMD data-processing, load, or store operation due to an SVE instruction without a Governing predicate operand.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8079, **SVE_PRED_NOT_FULL_SPEC, SVE predicated operations Speculatively executed with no active or partially active predicates**

The counter counts Speculatively executed SIMD data-processing and load and store operations due to SVE instructions with a Governing predicate in which at least one element is FALSE. This includes both those counted by **SVE_PRED_PARTIAL_SPEC** and those counted by **SVE_PRED_EMPTY_SPEC**.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x807C, **SVE_MOVPRFX_SPEC, Operation speculatively executed, SVE MOVPRFX**

The counter counts each Speculatively executed operation due to any of the following A64 instructions:

- SVE: MOVPRFX.
The instruction is counted whether or not it is fused with the prefixed instruction. Implementation of this optional event requires that FEAT_SVE is implemented.

0x807D, SVE_MOVPRFX_Z_SPEC, Operation speculatively executed, SVE MOVPRFX zeroing predication

The counter counts each Speculatively executed operation counted by SVE_MOVPRFX_SPEC where the operation uses zeroing predication. Implementation of this optional event requires that FEAT_SVE is implemented.

0x807E, SVE_MOVPRFX_M_SPEC, Operation speculatively executed, SVE MOVPRFX merging predication

The counter counts each Speculatively executed operation counted by SVE_MOVPRFX_SPEC where the operation uses merging predication. Implementation of this optional event requires that FEAT_SVE is implemented.

0x807F, SVE_MOVPRFX_U_SPEC, Operation speculatively executed, SVE MOVPRFX unfused

The counter counts each Speculatively executed operation counted by SVE_MOVPRFX_SPEC where the MOVPRFX is not fused with the prefixed instruction. Implementation of this optional event requires that FEAT_SVE is implemented.

0x8080, SVE_LDST_SPEC, Operation speculatively executed, SVE load, store, or prefetch

The counter counts each Speculatively executed load, store, or prefetch operation counted by any of SVE_LD_SPEC, SVE_PRF_SPEC, or SVE_ST_SPEC. Implementation of this optional event requires that FEAT_SVE is implemented.

0x8081, SVE_LD_SPEC, Operation speculatively executed, SVE load

The counter counts each Speculatively executed operation that reads from memory due to an SVE load instruction. Implementation of this optional event requires that FEAT_SVE is implemented.

0x8082, SVE_ST_SPEC, Operation speculatively executed, SVE store

The counter counts each Speculatively executed operation that writes to memory due to an SVE store instruction. Implementation of this optional event requires that FEAT_SVE is implemented.

0x8083, SVE_PRF_SPEC, Operation speculatively executed, SVE prefetch

The counter counts each Speculatively executed prefetch operation due to any of the following A64 instructions:

• SVE: PRFB, PRFD, PRFH, or PRFW.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8084, ASE_SVE_LDST_SPEC, Operation speculatively executed, Advanced SIMD or SVE load or store

The counter counts each Speculatively executed load or store operation counted by any of ASE_SVE_LD_SPEC, ASE_SVE_ST_SPEC, or PRF_SPEC. It is IMPLEMENTATION DEFINED which Advanced SIMD load or store operations are counted in AArch32 state.

0x8085, ASE_SVE_LD_SPEC, Operation speculatively executed, Advanced SIMD or SVE load

The counter counts each Speculatively executed operation that reads from memory due to an A64 SVE or Advanced SIMD load instruction. It is IMPLEMENTATION DEFINED which Advanced SIMD load operations are counted in AArch32 state.

0x8086, ASE_SVE_ST_SPEC, Operation speculatively executed, Advanced SIMD or SVE store

The counter counts each Speculatively executed operation that writes to memory due to an A64 SVE or Advanced SIMD store instruction.
It is IMPLEMENTATION DEFINED which Advanced SIMD store operations are counted in AArch32 state.

0x8087, PRF_SPEC, Operation speculatively executed, Prefetch

The counter counts each Speculatively executed operation that prefetches memory due to any of the following A64 instructions:

• Scalar: PRFM.
• SVE: PRFB, PRFD, PRFH, or PRFW.

It is IMPLEMENTATION DEFINED which prefetch operations are counted in AArch32 state.

0x8088, BASE_L DST_REG_SPEC, Operation speculatively executed, general-purpose register load, store, or prefetch

The counter counts each Speculatively executed general-purpose register load, store, or prefetch operation counted by any of BASE_LD_REG_SPEC, BASE_PRF_SPEC, or BASE_ST_REG_SPEC.

0x8089, BASE_LD_REG_SPEC, Operation speculatively executed, general-purpose register load

The counter counts each Speculatively executed operation that loads a general-purpose register from memory.

It is IMPLEMENTATION DEFINED which load operations are counted in AArch32 state.

0x808A, BASE_ST_REG_SPEC, Operation speculatively executed, general-purpose register store

The counter counts each Speculatively executed operation that stores a general-purpose register to memory.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to DC ZVA instructions.

It is IMPLEMENTATION DEFINED which store operations are counted in AArch32 state.

0x808B, BASE_PRF_SPEC, Operation speculatively executed, general-purpose register prefetch

The counter counts each Speculatively executed prefetch operation due to any of the following A64 instructions:

• Scalar: PRFM.

It is IMPLEMENTATION DEFINED which prefetch operations are counted in AArch32 state.

0x808C, FPASE_L DST_REG_SPEC, Operation speculatively executed, SIMD&FP register load or store

The counter counts each Speculatively executed SIMD&FP register load or store operation counted by either FPASE_LD_REG_SPEC or FPASE_ST_REG_SPEC.

0x808D, FPASE_LD_REG_SPEC, Operation speculatively executed, SIMD&FP register load

The counter counts each Speculatively executed operation that reads from memory due to any of the following A64 instructions:

• Scalar: LDP (SIMD&FP) or LDR (SIMD&FP).
• Advanced SIMD: LD1 or LD1R.

It is IMPLEMENTATION DEFINED which load operations are counted in AArch32 state.

0x808E, FPASE_ST_REG_SPEC, Operation speculatively executed, SIMD&FP register store

The counter counts each Speculatively executed operation that writes to memory due to any of the following A64 instructions:

• Scalar: STP (SIMD&FP) or STR (SIMD&FP).
• Advanced SIMD: ST1.

It is IMPLEMENTATION DEFINED which store operations are counted in AArch32 state.

0x8090, SVE_L DST_REG_SPEC, Operation speculatively executed, SVE unpredicated load or store register

The counter counts each Speculatively executed SVE register load or store operation counted by either SVE_LDR_REG_SPEC or SVE_STR_REG_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x8091, **SVE_LDR_REG_SPEC, Operation speculatively executed, SVE unpredicated load register**

The counter counts each speculatively executed SVE operation that reads from memory due to any of the following A64 instructions:

- SVE: LDR.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8092, **SVE_STR_REG_SPEC, Operation speculatively executed, SVE unpredicated store register**

The counter counts each speculatively executed SVE operation that writes to memory due to any of the following A64 instructions:

- SVE: STR.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8094, **SVE_LDR_PREG_SPEC, Operation speculatively executed, SVE load or store predicate register**

The counter counts each speculatively executed SVE predicate register load or store operation counted by either SVE_LDR_PREG_SPEC or SVE_STR_PREG_SPEC.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8095, **SVE_STR_PREG_SPEC, Operation speculatively executed, SVE load predicate register**

The counter counts each speculatively executed SVE load predicate register operation that reads from memory due to any of the following A64 instructions:

- SVE: LDR (predicate).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8096, **SVE_STR_PREG_SPEC, Operation speculatively executed, SVE store predicate register**

The counter counts each speculatively executed SVE store predicate register operation that writes to memory due to any of the following A64 instructions:

- SVE: STR (predicate).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8098, **SVE_LDR_ZREG_SPEC, Operation speculatively executed, SVE load or store vector register**

The counter counts each speculatively executed SVE vector register load or store operation counted by either SVE_LDR_ZREG_SPEC or SVE_STR_ZREG_SPEC.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x8099, **SVE_LDR_ZREG_SPEC, Operation speculatively executed, SVE load vector register**

The counter counts each speculatively executed SVE load vector register operation that reads from memory due to any of the following A64 instructions:

- SVE: LDR (vector).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x809A, **SVE_STR_ZREG_SPEC, Operation speculatively executed, SVE store vector register**

The counter counts each speculatively executed SVE store vector register operation that writes to memory due to any of the following A64 instructions:

- SVE: STR (vector).

Implementation of this optional event requires that FEAT_SVE is implemented.

0x809C, **SVE_LDST_CONTIG_SPEC, Operation speculatively executed, SVE contiguous load, store, or prefetch element**

The counter counts each speculatively executed SVE contiguous element load, store, or prefetch operation counted by any of SVE_LD_CONTIG_SPEC, SVE_PRF_CONTIG_SPEC, or SVE_ST_CONTIG_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x809D, SVE_LD_CONTIG_SPEC, Operation speculatively executed, SVE contiguous load element
The counter counts each Speculatively executed operation that reads from memory due to either:
  • An SVE predicated single vector contiguous element load instruction.
  • An SVE load and replicate LD1R or LD1RQ instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x809E, SVE_ST_CONTIG_SPEC, Operation speculatively executed, SVE contiguous store element
The counter counts each Speculatively executed operation that writes to memory due to an SVE predicated single vector contiguous element store instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x809F, SVE_PRF_CONTIG_SPEC, Operation speculatively executed, SVE contiguous prefetch element
The counter counts each Speculatively executed operation that prefetches memory due to an SVE predicated single contiguous element prefetch instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80A0, SVE_LDSNT_CONTIG_SPEC, Operation speculatively executed, SVE non-temporal contiguous load or store element
The counter counts each Speculatively executed SVE non-temporal contiguous element load or store operation counted by either SVE_LDNT_CONTIG_SPEC or SVE_STNT_CONTIG_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80A1, SVE_LDNT_CONTIG_SPEC, Operation speculatively executed, SVE non-temporal contiguous load element
The counter counts each Speculatively executed operation that reads from memory with a non-temporal hint due to an SVE non-temporal contiguous element load instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80A2, SVE_STNT_CONTIG_SPEC, Operation speculatively executed, SVE non-temporal contiguous store element
The counter counts each Speculatively executed operation that writes to memory with a non-temporal hint due to an SVE non-temporal contiguous element store instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80A4, ASE_SVE_LDSNT_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector
The counter counts each Speculatively executed multiple vector contiguous structure load or store operation counted by either ASE_SVE_LD_MULTI_SPEC or ASE_SVE_ST_MULTI_SPEC.
It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure load or store operations are counted in AArch32 state.

0x80A5, ASE_SVE_LD_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector
The counter counts each Speculatively executed operation that reads from memory due to an A64 SVE or Advanced SIMD multiple vector contiguous structure load instruction.
It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure load operations are counted in AArch32 state.

0x80A6, ASE_SVE_ST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector
The counter counts each Speculatively executed operation that writes to memory due to an A64 SVE or Advanced SIMD multiple vector contiguous structure store instruction.
It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure store operations are counted in AArch32 state.

0x80A8, SVE_LDST_MULTI_SPEC, Operation speculatively executed, SVE contiguous load or store multiple vector

The counter counts each Speculatively executed SVE contiguous load or store multiple vector operation counted by either SVE_LD_MULTI_SPEC or SVE_ST_MULTI_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80A9, SVE_LD_MULTI_SPEC, Operation speculatively executed, SVE contiguous load multiple vector

The counter counts each Speculatively executed load or store operation counted by either SVE_LD_MULTI_SPEC or SVE_ST_MULTI_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80AA, SVE_ST_MULTI_SPEC, Operation speculatively executed, SVE contiguous store multiple vector

The counter counts each Speculatively executed operation that writes to memory due to an SVE multiple vector contiguous structure store instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80AC, SVE_LDST_NONCONTIG_SPEC, Operation speculatively executed, SVE non-contiguous load, store, or prefetch

The counter counts each Speculatively executed gather-load, scatter-store, or gather-prefetch operation counted by any of SVE_LD_GATHER_SPEC, SVE_PRF_GATHER_SPEC, or SVE_ST_SCATTER_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80AD, SVE_LD_GATHER_SPEC, Operation speculatively executed, SVE gather-load

The counter counts each Speculatively executed operation that reads from memory due to an SVE non-contiguous gather-load instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80AE, SVE_ST_SCATTER_SPEC, Operation speculatively executed, SVE scatter-store

The counter counts each Speculatively executed operation that writes to memory due to an SVE non-contiguous scatter-store instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80AF, SVE_PRF_GATHER_SPEC, Operation speculatively executed, SVE gather-prefetch

The counter counts each Speculatively executed operation that prefetches memory due to an SVE non-contiguous gather-prefetch instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80B0, SVE_LDST64_NONCONTIG_SPEC, Operation speculatively executed, SVE 64-bit non-contiguous load, store, or prefetch

The counter counts each Speculatively executed 64-bit gather-load, scatter-store, or gather-prefetch operation counted by any of SVE_LD64_GATHER_SPEC, SVE_PRF64_GATHER_SPEC, or SVE_ST64_SCATTER_SPEC.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80B1, SVE_LD64_GATHER_SPEC, Operation speculatively executed, SVE 64-bit gather-load

The counter counts each Speculatively executed operation that reads from memory due to an SVE non-contiguous gather-load instruction with 64-bit vector elements in the address.
Implementation of this optional event requires that FEAT_SVE is implemented.
0x80B2, **SVE_ST64_SCATTER_SPEC**, Operation speculatively executed, SVE 64-bit scatter-store
The counter counts each Speculatively executed operation that writes to memory due to an SVE non-contiguous scatter-store instruction with 64-bit vector elements in the address.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80B3, **SVE_PRF64_GATHER_SPEC**, Operation speculatively executed, SVE 64-bit gather-prefetch
The counter counts each Speculatively executed operation that prefetches memory due to an SVE non-contiguous gather-prefetch instructions with 64-bit vector elements in the address.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80B4, **ASE_SVE_UNALIGNED_LDST_SPEC**, Advanced SIMD or SVE unaligned accesses
The counter counts each Speculatively executed 64-bit unaligned load or store operation counted by either **ASE_SVE_UNALIGNED_LD_SPEC** or **ASE_SVE_UNALIGNED_ST_SPEC**.
It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD load or store operations are counted in AArch32 state.

0x80B5, **ASE_SVE_UNALIGNED_LD_SPEC**, Advanced SIMD or SVE unaligned read accesses
The counter counts each memory read access due to an A64 SVE or Advanced SIMD load instruction where either:
• A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
• A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.
The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.
It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD load operations are counted in AArch32 state.

0x80B6, **ASE_SVE_UNALIGNED_ST_SPEC**, Advanced SIMD or SVE unaligned write accesses
The counter counts each memory write access due to an A64 SVE or Advanced SIMD store instruction where either:
• A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
• A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.
The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.
It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD store operations are counted in AArch32 state.

0x80B8, **ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC**, Advanced SIMD or SVE unaligned contiguous accesses
The counter counts each Speculatively executed 64-bit unaligned contiguous load or store operation counted by either **ASE_SVE_UNALIGNED_CONTIG_LD_SPEC** or **ASE_SVE_UNALIGNED_CONTIG_ST_SPEC**.
It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD load or store operations are counted in AArch32 state.

0x80B9, **ASE_SVE_UNALIGNED_CONTIG_LD_SPEC**, Advanced SIMD or SVE unaligned contiguous read accesses
The counter counts each Memory-read operation due to an A64 SVE or Advanced SIMD contiguous load instruction where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.
It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD load operations are counted in AArch32 state.

0x80BA, ASE_SVE_UNALIGNED_CONTIG_ST_SPEC, Advanced SIMD or SVE unaligned contiguous write accesses

The counter counts each Memory-write operation due to an A64 SVE or Advanced SIMD contiguous store instruction where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD store operations are counted in AArch32 state.

0x80BC, SVE_LDFF_SPEC, Operation speculatively executed, SVE first-fault load

The counter counts each Speculatively executed Memory-read operation due to an SVE First-fault or Non-fault load instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80BD, SVE_LDFF_FAULT_SPEC, Operation speculatively executed, SVE first-fault load which set FFR bit to 0b0

The counter counts each Speculatively executed Memory-read operation due to an SVE First-fault or Non-fault load instruction that writes 0b0 to at least one bit in FFR.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C0, FP_SCALE_OPS_SPEC, Scalable floating-point element ALU operations Speculatively executed

The counter counts each Speculatively executed floating-point ALU operation counted by SVE_FP_SPEC, except that it is IMPLEMENTATION DEFINED whether operations due to instructions other than those listed in Floating-point arithmetic (SVE) in Arm Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A_ are counted.

See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C1, FP_FIXED_OPS_SPEC, Non-scalable floating-point element ALU operations Speculatively executed

The counter counts each Speculatively executed floating-point ALU operation counted by FP_SPEC but not by SVE_FP_SPEC, and it is IMPLEMENTATION DEFINED whether operations due to instructions other than those listed in Floating-point arithmetic (scalar) in Arm Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A_ and Floating-point arithmetic (Advanced SIMD) in Arm Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A_ are counted.

It does not count operations that are counted by FP_SCALE_OPS_SPEC.

See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

0x80C2, FP_HP_SCALE_OPS_SPEC, Scalable half-precision floating-point element ALU operations Speculatively executed

The counter counts each Speculatively executed scalable floating-point element ALU operation counted by FP_SCALE_OPS_SPEC where the largest type is half precision.

See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C3, FP_HP_FIXED_OPS_SPEC, Non-scalable half-precision floating-point element ALU operations Speculatively executed

The counter counts each Speculatively executed non-scalable floating-point ALU operation counted by FP_FIXED_OPS_SPEC where the largest type is half precision.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

0x80C4, FP_SP_SCALE_OPS_SPEC, Scalable single-precision floating-point element ALU operations Speculatively executed
The counter counts each Speculatively executed scalable floating-point element ALU operation counted by FP_SCALE_OPS_SPEC where the largest type is single precision.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C5, FP_SP_FIXED_OPS_SPEC, Non-scalable single-precision floating-point element ALU operations Speculatively executed
The counter counts each Speculatively executed non-scalable floating-point ALU operation counted by FP_FIXED_OPS_SPEC where the largest type is single precision.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

0x80C6, FP_DP_SCALE_OPS_SPEC, Scalable double-precision floating-point element ALU operations Speculatively executed
The counter counts each Speculatively executed scalable floating-point element ALU operation counted by FP_SCALE_OPS_SPEC where the largest type is double precision.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C7, FP_DP_FIXED_OPS_SPEC, Non-scalable double-precision floating-point element ALU operations Speculatively executed
The counter counts each Speculatively executed non-scalable floating-point ALU operation counted by FP_FIXED_OPS_SPEC where the largest type is double precision.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

0x80C8, INT_SCALE_OPS_SPEC, Scalable integer element ALU operations Speculatively executed
The counter counts each integer ALU operation counted by SVE_INT_SPEC.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.
Implementation of this optional event requires that FEAT_SVE is implemented.

0x80C9, INT_FIXED_OPS_SPEC, Non-scalable integer element ALU operations Speculatively executed
The counter counts each integer ALU operation counted by INT_SPEC that is not counted by SVE_INT_SPEC.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.

0x80CA, LDST_SCALE_OPS_SPEC, Scalable load or store element Operations speculatively executed
The counter counts each Speculatively executed Memory-read operation or Memory-write operation due to an SVE predicated vector load or store instruction other than a replicating LD1R or LD1RQ instruction.
See ALU operation counts on page D11-5266 for information on the counter increment for different types of instruction.
The counter does not count tag loads or tag stores.
Implementation of this optional event requires that FEAT_SVE is implemented.
0x80CB, **LDST_FIXED_OPS_SPEC**, Non-scalable load or store element Operations speculatively executed

The counter counts each Speculatively executed Memory-read operation or Memory-write operation due to any of:

- Any non-SVE load, store, or atomic operation.
- Any SVE non-vector load or store operation.
- An SVE replicating LD1R or LD1RQ instruction.

See *ALU operation counts* on page D11-5266 for information on the counter increment for different types of instruction.

0x80CC, **LD_SCALE_OPS_SPEC**, Scalable load element Operations speculatively executed

The counter counts each Speculatively executed Memory-read operation due to an SVE predicated vector load instruction other than a replicating LD1R or LD1RQ instruction.

See *ALU operation counts* on page D11-5266 for information on the counter increment for different types of instruction.

The counter does not count tag loads.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80CD, **LD_FIXED_OPS_SPEC**, Non-scalable load element Operations speculatively executed

The counter counts each Speculatively executed Memory-read operation due to any of:

- Any non-SVE load or atomic operation.
- Any SVE non-vector load operation.
- An SVE replicating LD1R or LD1RQ instruction.

See *ALU operation counts* on page D11-5266 for information on the counter increment for different types of instruction.

0x80CE, **ST_SCALE_OPS_SPEC**, Scalable store element Operations speculatively executed

The counter counts each Speculatively executed Memory-write operation due to an SVE predicated vector store instruction.

See *ALU operation counts* on page D11-5266 for information on the counter increment for different types of instruction.

The counter does not count tag stores.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80CF, **ST_FIXED_OPS_SPEC**, Non-scalable store element Operations speculatively executed

The counter counts each Memory-write operation due to either:

- Any non-SVE store or atomic operation.
- Any SVE non-vector store operation.

See *ALU operation counts* on page D11-5266 for information on the counter increment for different types of instruction.

0x80DA, **LDST_SCALE_BYTES_SPEC**, Scalable load and store bytes Speculatively executed

The counter counts each byte speculatively read or written due to an SVE vector load or store instruction other than a replicating LD1R or LD1RQ instruction.

For each instruction, the counter is incremented by \((16 ÷ (CSIZE ÷ MSIZE))\), multiplied by the number of transferred vector registers.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80DB, **LDST_FIXED_BYTES_SPEC**, Non-scalable load and store bytes Speculatively executed

The counter counts each byte speculatively read or written due to any of:

- Any non-SVE load, store, or atomic operation.
- Any SVE non-vector load or store operation.
• An SVE replicating LD1R or LD1RQ instruction.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred multiplied by the number of transfers made per register. For example, the counter counts bytes as follows:

• Non-SVE load and store of a single register instructions increment the counter by \((\text{MSIZE} \div 8)\).

• Non-SVE load and store of a pair of registers instructions increment the counter by \(2 \times (\text{MSIZE} \div 8)\).

• AArch32 load and store multiple registers instructions increment the counter by the number of registers transferred multiplied by \((\text{MSIZE} \div 8)\).

• Atomic store instructions increment the counter by \((\text{MSIZE} \div 8)\). These are instructions that atomically update a value in memory without returning a value to a register.

• Atomic load, compare and swap of a single register, and swap instructions increment the counter by \(2 \times (\text{MSIZE} \div 8)\). Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.

• Compare and swap of a pair of registers increment the counter by \(4 \times (\text{MSIZE} \div 8)\).

• SVE and Advanced SIMD LD1R instructions increment the counter by \((\text{MSIZE} \div 8)\).

• SVE LD1RQ instructions increment the counter by \(16\).

• Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of registers transferred multiplied by the number of bytes being transferred per register.

• DC ZVA and DC GZVA instructions increment the counter by \(2^{(\text{DCZID.EL0.BS})}\).

0x80DC, LD_SCALE_BYTES_SPEC, Scalable load bytes Speculatively executed
The counter counts each byte speculatively read due to an SVE vector load instruction other than a replicating LD1R or LD1RQ instruction.

For each instruction, the counter is incremented by \((16 \div (\text{CSIZE} \div \text{MSIZE}))\), multiplied by the number of transferred vector registers.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80DD, LD_FIXED_BYTES_SPEC, Non-scalable load bytes Speculatively executed
The counter counts each byte speculatively read due to any of:

• Any non-SVE load or atomic operation.

• Any SVE non-vector load operation.

• An SVE replicating LD1R or LD1RQ instruction.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

• Half the value that the LDST_FIXED_BYTES_SPEC event counts if the operation is a load atomic, compare and swap, or compare operation.

• The same as for LDST_FIXED_BYTES_SPEC if the operation is any other load operation.

0x80DE, ST_SCALE_BYTES_SPEC, Scalable store bytes Speculatively executed
The counter counts each byte speculatively written due to an SVE vector store instruction.

For each instruction, the counter is incremented by \((16 \div (\text{CSIZE} \div \text{MSIZE}))\), multiplied by the number of transferred vector registers.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80DF, ST_FIXED_BYTES_SPEC, Non-scalable store bytes Speculatively executed
The counter counts each byte written due to either:

• Any non-SVE store or atomic operation.

• Any SVE non-vector store operation.
For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the LDST\_FIXED\_BYTES\_SPEC event counts if the operation is a compare and swap or compare operation.
- The same as for LDST\_FIXED\_BYTES\_SPEC if the operation is any other store operation, including an atomic store operation.

0x80E1, ASE\_INT8\_SPEC, Integer operation speculatively executed, Advanced SIMD 8-bit
The counter counts each operation counted by ASE\_SVE\_INT8\_SPEC that is an Advanced SIMD operation.

0x80E2, SVE\_INT8\_SPEC, Integer operation speculatively executed, SVE 8-bit
The counter counts each operation counted by ASE\_SVE\_INT8\_SPEC that is an SVE operation. Implementation of this optional event requires that FEAT\_SVE is implemented.

0x80E3, ASE\_SVE\_INT8\_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 8-bit
The counter counts each operation counted by ASE\_SVE\_INT\_SPEC where the largest type is 8-bit integer.

0x80E5, ASE\_SVE\_INT16\_SPEC, Integer operation speculatively executed, Advanced SIMD 16-bit
The counter counts each operation counted by ASE\_SVE\_INT16\_SPEC that is an Advanced SIMD operation.

0x80E6, SVE\_INT16\_SPEC, Integer operation speculatively executed, SVE 16-bit
The counter counts each operation counted by ASE\_SVE\_INT16\_SPEC that is an SVE operation. Implementation of this optional event requires that FEAT\_SVE is implemented.

0x80E7, ASE\_SVE\_INT16\_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 16-bit
The counter counts each operation counted by ASE\_SVE\_INT\_SPEC where the largest type is 16-bit integer.

0x80E9, ASE\_INT32\_SPEC, Integer operation speculatively executed, Advanced SIMD 32-bit
The counter counts each operation counted by ASE\_SVE\_INT32\_SPEC that is an Advanced SIMD operation.

0x80EA, SVE\_INT32\_SPEC, Integer operation speculatively executed, SVE 32-bit
The counter counts each operation counted by ASE\_SVE\_INT32\_SPEC that is an SVE operation. Implementation of this optional event requires that FEAT\_SVE is implemented.

0x80EB, ASE\_SVE\_INT32\_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 32-bit
The counter counts each operation counted by ASE\_SVE\_INT\_SPEC where the largest type is 32-bit integer.

0x80ED, ASE\_INT64\_SPEC, Integer operation speculatively executed, Advanced SIMD 64-bit
The counter counts each operation counted by ASE\_SVE\_INT64\_SPEC that is an Advanced SIMD operation.

0x80EE, SVE\_INT64\_SPEC, Integer operation speculatively executed, SVE 64-bit
The counter counts each operation counted by ASE\_SVE\_INT64\_SPEC that is an SVE operation. Implementation of this optional event requires that FEAT\_SVE is implemented.

0x80EF, ASE\_SVE\_INT64\_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 64-bit
The counter counts each operation counted by ASE\_SVE\_INT\_SPEC where the largest type is 64-bit integer.
The counter counts each dot-product operation counted by ASE_SVE_FP_DOT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: BFDOT.

It is IMPLEMENTATION DEFINED which dot-product operations are counted in AArch32 state.

The counter counts each dot-product operation counted by ASE_SVE_FP_DOT_SPEC due to any of the following instructions:

- SVE: BFDOT.
- SVE2: BFDOT.

Implementation of this optional event requires that FEAT_SVE is implemented.

The counter counts each dot-product operation counted by FP_SPEC due to any of the following A64 instructions:

- Advanced SIMD: BFDOT.
- SVE: BFDOT.
- SVE2: BFDOT.

It is IMPLEMENTATION DEFINED which dot-product operations are counted in AArch32 state.

The counter counts each floating-point matrix multiply operation counted by ASE_SVE_FP_MMLA_SPEC due to any of the following A64 instructions:

- Advanced SIMD: BFMMUL.

It is IMPLEMENTATION DEFINED which floating-point matrix multiply operations are counted in AArch32 state.

The counter counts each floating-point matrix multiply operation counted by ASE_SVE_FP_MMLA_SPEC due to any of the following instructions:

- SVE: BFMMUL or FMUL.
- SVE2: BFMMUL or FMUL.

Implementation of this optional event requires that FEAT_SVE is implemented.

The counter counts each floating-point matrix multiply operation counted by FP_SPEC due to any of the following A64 instructions:

- Advanced SIMD: BFMMUL.
- SVE: BFMMUL or FMUL.
- SVE2: BFMMUL or FMUL.

It is IMPLEMENTATION DEFINED which floating-point matrix multiply operations are counted in AArch32 state.

The counter counts each integer dot product operation counted by ASE_SVE_INT_DOT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: SDOT, SUDDOT, UDOT, or USDOT.
It is IMPLEMENTATION DEFINED which integer dot product operations are counted in AArch32 state.

0x80FA, SVE_INT_DOT_SPEC, Integer operation speculatively executed, SVE dot-product

The counter counts each integer dot product operation counted by ASE_SVE_INT_DOT_SPEC due to any of the following instructions:

- SVE: SDOT, SUDOT, UDOT, or USDOT.
- SVE2: CDOT, SUDOT, or USDOT.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80FB, ASE_SVE_INT_DOT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE dot-product

The counter counts each integer dot product operation counted by INT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: SDOT, SUDOT, UDOT, or USDOT.
- SVE: SDOT, SUDOT, UDOT, or USDOT.
- SVE2: CDOT, SUDOT, or USDOT.

It is IMPLEMENTATION DEFINED which integer dot product operations are counted in AArch32 state.

0x80FD, ASE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD matrix multiply

The counter counts each integer matrix multiply operation counted by ASE_SVE_INT_MMLA_SPEC due to any of the following A64 instructions:

- Advanced SIMD: SIMLA, UMMLA, or USMMLA.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80FE, SVE_INT_MMLA_SPEC, Integer operation speculatively executed, SVE matrix multiply

The counter counts each integer matrix multiply operation counted by ASE_SVE_INT_MMLA_SPEC due to any of the following instructions:

- SVE: SIMLA, UMMLA, or USMMLA.
- SVE2: SIMLA, UMMLA, or USMMLA.

Implementation of this optional event requires that FEAT_SVE is implemented.

0x80FF, ASE_SVE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply

The counter counts each integer matrix multiply operation counted by INT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: SIMLA, UMMLA, or USMMLA.
- SVE: SIMLA, UMMLA, or USMMLA.
- SVE2: SIMLA, UMMLA, or USMMLA.

It is IMPLEMENTATION DEFINED which integer matrix multiply operations are counted in AArch32 state.

0x8110, BR_IMMED_PRED_RETIRED, Branch Instruction architecturally executed, predicted immediate

The counter counts each instruction counted by both BR_IMMED_RETIRED and BR_PRED_RETIRED.

These are all direct branch instructions on the architecturally executed path, where the branch is correctly predicted.

0x8111, BR_IMMED_MIS_PRED_RETIRED, Branch Instruction architecturally executed, mispredicted immediate

The counter counts each instruction counted by both BR_IMMED_RETIRED and BR_MIS_PRED_RETIRED.
These are all direct branch instructions on the architecturally executed path, where the branch is mispredicted.

0x8112, BR_IND_PRED_RETIRED, Branch Instruction architecturally executed, predicted indirect

The counter counts each instruction counted by both BR_IND_RETIRED and BR_PRED_RETIRED.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is correctly predicted.

0x8113, BR_IND_MIS_PRED_RETIRED, Branch Instruction architecturally executed, mispredicted indirect

The counter counts each instruction counted by both BR_IND_RETIRED and BR_MIS_PRED_RETIRED.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is mispredicted.

0x8114, BR_RETURN_PRED_RETIRED, Branch Instruction architecturally executed, predicted procedure return

The counter counts each instruction counted by BR_IND_PRED_RETIRED where if taken, the branch would be counted by BR_PRED_RETIRED.

These are all return instructions on the architecturally executed path, where the branch is correctly predicted.

0x8115, BR_RETURN_MIS_PRED_RETIRED, Branch Instruction architecturally executed, mispredicted procedure return

The counter counts each instruction counted by BR_IND_MIS_PRED_RETIRED where if taken, the branch would also be counted by BR_RETURN_RETIRED.

These are all return instructions on the architecturally executed path, where the branch is mispredicted.

0x8116, BR_INDRNR_PRED_RETIRED, Branch Instruction architecturally executed, predicted indirect excluding procedure return

The counter counts each instruction counted by BR_IND_PRED_RETIRED where if taken, the branch would not be counted by BR_RETURN_RETIRED.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is correctly predicted.

0x8117, BR_INDRNR_MIS_PRED_RETIRED, Branch Instruction architecturally executed, mispredicted indirect excluding procedure return

The counter counts each instruction counted by BR_IND_MIS_PRED_RETIRED where if taken, the branch would not be counted by BR_RETURN_RETIRED.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is mispredicted.

0x8118, BR_TAKEN_PRED_RETIRED, Branch Instruction architecturally executed, predicted branch, taken

The counter counts each instruction counted by both BR_PRED_RETIRED and PC_WRITE_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and taken.

0x8119, BR_TAKEN_MIS_PRED_RETIRED, Branch Instruction architecturally executed, mispredicted branch, taken

The counter counts each instruction counted by both BR_MIS_PRED_RETIRED and PC_WRITE_RETIRED.
These are all branch instructions on the architecturally executed path, where the branch is mispredicted and taken.

0x811A, **BR_SKIP_PRED_RETIRED**, Branch **Instruction architecturally executed**, predicted branch, not taken

The counter counts each instruction counted by both BR_PRED_RETIRED and BR_SKIP_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and not taken.

0x811B, **BR_SKIP_MIS_PRED_RETIRED**, Branch **Instruction architecturally executed**, mispredicted branch, not taken

The counter counts each instruction counted by both BR_MIS_PRED_RETIRED and BR_SKIP_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and not taken.

0x811C, **BR_PRED_RETIRED**, Branch **Instruction architecturally executed**, predicted branch

The counter counts each instruction counted by BR_RETIRED that is not counted by BR_MIS_PRED_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted.

0x8120, **INST_FETCH_PERCYC**, Event in progress, **INST_FETCH**

The counter counts by the number of INST_FETCH events in progress on each Processor cycle.

The ratio INST_FETCH_PERCYC ÷ INST_FETCH is the mean duration of INST_FETCH events in Processor cycles.

0x8121, **MEM_ACCESS_RD_PERCYC**, Event in progress, **MEM_ACCESS_RD**

The counter counts by the number of MEM_ACCESS_RD events in progress on each Processor cycle.

The ratio MEM_ACCESS_RD_PERCYC ÷ MEM_ACCESS_RD is the mean duration of MEM_ACCESS_RD events in Processor cycles.

0x8124, **INST_FETCH**, Instruction memory access

The counter counts each Instruction memory access that the PE makes. The counter increments whether the access results in an access to a Level 1 instruction cache, a Level 2 instruction, data or unified cache, or none of these.

The counter does not increment as a result of:

- Data memory accesses.
- Translation table walks.
- Refilling of any cache.
- Accesses that result from cache maintenance instructions.

0x8125, **BUS_REQ_RD_PERCYC**, Bus read transactions in progress

The counter counts by the number of bus read transactions counted by BUS_REQ_RD in progress on each Processor cycle.

The ratio BUS_REQ_RD_PERCYC ÷ BUS_REQ_RD is the mean duration of bus read transactions in Processor cycles.

A bus read transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

If the bus is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPE<\n>EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the bus is not shared, all events are counted.
0x8126, **BUS_REQ_WR_PERCYC, Bus write transactions in progress**

The counter counts the number of bus write transactions counted by BUS_REQ_WR in progress on each Processor cycle.

The ratio BUS_REQ_WR_PERCYC ÷ BUS_REQ_WR is the mean duration of bus write transactions in Processor cycles.

A bus write transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

A mean duration value calculated using this event only measures the latency from the perspective of the bus. This is not necessarily the same as the latency for the write to be Complete, as the write might be completed on the bus before reaching its endpoint.

For some bus implementations, writes are posted, meaning that, from the perspective of the bus, the write completes immediately. There is no response when the write reaches its Completion endpoint. This event is not included for such implementations.

If the bus is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the bus is not shared, all events are counted.

0x8128, **DTLB_WALK_PERCYC, Event in progress, DTLB_WALK**

The counter counts the number of DTLB_WALK events in progress on each Processor cycle.

The ratio DTLB_WALK_PERCYC ÷ DTLB_WALK is the mean duration of DTLB_WALK events in Processor cycles.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x8129, **ITLB_WALK_PERCYC, Event in progress, ITLB_WALK**

The counter counts the number of ITLB_WALK events in progress on each Processor cycle.

The ratio ITLB_WALK_PERCYC ÷ ITLB_WALK is the mean duration of ITLB_WALK events in Processor cycles.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x812A, **SAMPLE_FEED_BR, Statistical Profiling sample taken, branch**

The counter counts each sample counted by SAMPLE_FEED that are branch operations. The values of PMSFCR_EL1.{B,FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.

0x812B, **SAMPLE_FEED_LD, Statistical Profiling sample taken, load**

The counter counts each sample counted by SAMPLE_FEED that are load or load atomic operations. The values of PMSFCR_EL1.{LD,FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.
The counter counts each sample counted by Sample Feed that are store or atomic operations, including load atomic operations.

The values of PMSFCR_EL1.{ST,FT} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.

The counter counts each sample counted by Sample Feed that meets the operation type filter constraints.

That is, one of the following is true:

- The operation is a branch and PMSFCR_EL1.B is 0b1.
- The operation is a load or load atomic, and PMSFCR_EL1.LD is 0b1.
- The operation is a store or atomic operation, and PMSFCR_EL1.ST is 0b1.

The value of PMSFCR_EL1.FT is ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.

The counter counts each sample counted by Sample Feed that meets the Events packet filter constraints.

That is, each sampled operation with all the events in the filter sets defined by PMSEVFR_EL1 and, if implemented, PMSNEVFR_EL1 are counted. The values of PMSFCR_EL1.{FnE,FE} are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.

The counter counts each sample counted by Sample Feed that meets the operation latency filter constraints.

That is, each sampled operation with a total latency greater than or equal to the minimum latency defined by PMSLATFR_EL1.MINLAT are counted. The value of PMSFCR_EL1.FL is ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

This event must be implemented if FEAT_SPEv1p2 is implemented.

Implementation of this event requires that FEAT_SPE is implemented.

The counter counts each access counted by L1D_TLB that is due to a demand Memory-read operation or demand Memory-write operation.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

This event must be implemented if event L1D_TLB_PRFM is implemented.
0x8131, **L1I_TLB_RD, Level 1 instruction TLB demand access**

The counter counts each access counted by L1I_TLB that is due to a demand Instruction memory access.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\alpha>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

This event must be implemented if event L1I_TLB_PRFM is implemented.

0x8132, **L1D_TLB_PRFM, Level 1 data TLB software preload**

The counter counts each access counted by L1D_TLB that is due to a preload or prefetch instruction.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\alpha>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

This event must be implemented if event L1D_TLB_RW is implemented.

0x8133, **L1I_TLB_PRFM, Level 1 instruction TLB software preload**

The counter counts each access counted by L1I_TLB that is due to a preload or prefetch instruction.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\alpha>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

This event must be implemented if event L1I_TLB_RD is implemented.

0x8134, **DTLB_HWUPD, Data TLB hardware update of translation table**

The counter counts each access counted by L1D_TLB that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\alpha>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

0x8135, **ITLB_HWUPD, Instruction TLB hardware update of translation table**

The counter counts each access counted by L1I_TLB that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<el>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

0x8136, DTLB_STEP, Data TLB translation table walk, step

The counter counts each translation table walk access made by a refill of the data or unified TLB. The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the event if any of the following are true:
- FEAT_SVE is implemented and the access causing the refill is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access causing the refill generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the event if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<el>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

0x8137, ITLB_STEP, Instruction TLB translation table walk, step

The counter counts each translation table walk access made by a refill of the instruction TLB. The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the event if any of the following are true:
- The access causing the refill generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the event if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<el>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

0x8138, DTLB_WALK_LARGE, Data TLB large page translation table walk

The counter counts each translation table walk counted by DTLB_WALK where the result of the walk yields a large page size.
The set of large page sizes is the complement of the set of small page sizes defined by the **DTLB_WALK_SMALL** event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared, the counter counts only events attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\(\text{E}_n\) EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

**0x8139, ITLB_WALK_LARGE, Instruction TLB large page translation table walk**

The counter counts each translation table walk counted by **ITLB_WALK** where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the **ITLB_WALK_SMALL** event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared, the counter counts only events attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\(\text{E}_n\) EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

**0x813A, DTLB_WALK_SMALL, Data TLB small page translation table walk**

The counter counts each translation table walk counted by **DTLB_WALK** where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the **DTLB_WALK_LARGE** event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared, the counter counts only events attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\(\text{E}_n\) EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

**0x813B, ITLB_WALK_SMALL, Instruction TLB small page translation table walk**

The counter counts each translation table walk counted by **ITLB_WALK** where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the **ITLB_WALK_LARGE** event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared, the counter counts only events attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\(\text{E}_n\) EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

Implementation of this optional event requires that FEAT_E0PD is implemented.

**0x813C, DTLB_WALK_RW, Data TLB demand access with at least one translation table walk**

The counter counts each demand access counted by **L1D_TLB_RW** that causes a refill or update of a data or unified TLB involving at least one translation table walk access.
The counter does not count the demand access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\rangle_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x813D, ITLB_WALK_RD, Instruction TLB demand access with at least one translation table walk

The counter counts each demand access counted by L1I_TLB_RD that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\rangle_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x813E, DTLB_WALK_PRFM, Data TLB software preload access with at least one translation table walk

The counter counts each access counted by L1D_TLB_PRFM that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- FEAT_SVE is implemented and the access is a non-fault access that fails because the applicable TCR_ELx.NFDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<\rangle_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x813F, ITLB_WALK_PRFM, Instruction TLB software preload access with at least one translation table walk

The counter counts each access counted by L1I_TLB_PRFM that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 0b1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 0b1.
It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPE<\alpha>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.

0x8140, L1D_CACHE_RW, Level 1 data cache demand access
The counter counts each access counted by L1D_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.
This includes accesses made by Speculatively executed instructions.
This event must be implemented if any of the following are true:
• Event L1D_CACHE_PRFM is implemented.
• Event L1D_CACHE_HWPRF is implemented.

0x8141, L1I_CACHE_RD, Level 1 instruction cache demand fetch
The counter counts each access counted by L1I_CACHE that is due to a demand Instruction memory access.
This includes instruction prefetches made by the PE for Speculatively executed instructions.
This event must be implemented if any of the following are true:
• Event L1I_CACHE_PRFM is implemented.
• Event L1I_CACHE_HWPRF is implemented.

0x8142, L1D_CACHE_PRFM, Level 1 data cache software preload
The counter counts each access counted by L1D_CACHE that is due to a preload or prefetch instruction.
This event must be implemented if event L1D_CACHE_RW is implemented.

0x8143, L1I_CACHE_PRFM, Level 1 instruction cache software preload
The counter counts each access counted by L1I_CACHE that is due to a preload or prefetch instruction.
This event must be implemented if event L1I_CACHE_RD is implemented.

0x8144, L1D_CACHE_MISS, Level 1 data cache demand access miss
The counter counts each demand access counted by L1D_CACHE_RW that misses in the Level 1 data or unified cache, causing an access to outside of the Level 1 caches of this PE.

0x8145, L1I_CACHE_HWPRF, Level 1 instruction cache hardware prefetch
The counter counts each access counted by L1I_CACHE that is due to a hardware prefetch.
The hardware prefetch is generated by a hardware prefetcher at the Level 1 instruction or unified cache.
The PE might prefetch instructions as part of instruction pipelining, and might do so for Speculatively executed instruction paths. PE instruction prefetching is not counted as hardware prefetching. Unlike PE instruction prefetching, a hardware prefetch only allocates instructions into the cache.

0x8146, L1D_CACHE_REFILL_PRFM, Level 1 data cache refill, software preload
The counter counts each access counted by L1D_CACHE_PRFM that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

0x8147, L1I_CACHE_REFILL_PRFM, Level 1 instruction cache refill, software preload
The counter counts each access counted by L1I_CACHE_PRFM that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.
The counter counts each access counted by L2D_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes:
- Accesses made by Speculatively executed instructions.
- Accesses to the Level 2 data or unified cache due to a refill of another cache caused by a demand Memory-read operation or demand Memory-write operation.

This event must be implemented if any of the following are true:
- Event L2D_CACHE_PRFM is implemented.
- Event L2D_CACHE_HWPRF is implemented.

The counter counts each access counted by L2I_CACHE that is due to a demand Instruction memory access.

This includes:
- Instruction prefetches made by the PE for Speculatively executed instructions.
- Accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a demand Instruction memory access.

This event must be implemented if any of the following are true:
- Event L2I_CACHE_PRFM is implemented.
- Event L2I_CACHE_HWPRF is implemented.

The counter counts each access counted by L2D_CACHE that is due to a preload or prefetch instruction.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a preload or prefetch instruction.

This event must be implemented if event L2D_CACHE_RW is implemented.

The counter counts each access counted by L2I_CACHE that is due to a preload or prefetch instruction.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a preload or prefetch instruction.

This event must be implemented if event L2I_CACHE_RD is implemented.

The counter counts each demand access counted by L2D_CACHE_RW that misses in the Level 1 and Level 2 data or unified caches, causing an access to outside of the Level 1 and Level 2 caches of this PE.

The counter counts each access counted by L2I_CACHE that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 instruction or unified cache.

The counter counts each access counted by L2D_CACHE_PRFM that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.
The counter counts each access counted by `L2I_CACHE_PRFM` that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

This event must be implemented if any of the following are true:
- Event `L3D_CACHE_PRFM` is implemented.
- Event `L3D_CACHE_HWPRF` is implemented.

The counter counts each access counted by `L3D_CACHE` that is due to a preload or prefetch instruction.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a preload or prefetch instruction.

This event must be implemented if event `L3D_CACHE_RW` is implemented.

The counter counts each demand access counted by `L3D_CACHE_RW` that misses in the Level 1 to Level 3 data or unified caches, causing an access to outside of the Level 1 to Level 3 caches of this PE.

The counter counts each access counted by `L3D_CACHE_PRFM` that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

The counter counts each access counted by `L3D_CACHE_HWPRF` that is due to a hardware prefetch. The hardware prefetch is generated by a hardware prefetcher at the Level 3 data or unified cache.

The counter counts each access counted by `L2D_CACHE_HWPRF` that is due to a hardware prefetch. The hardware prefetch is generated by a hardware prefetcher at the Level 2 data or unified cache.

The counter counts each access counted by `L3D_CACHE_HWPRF` that is due to a hardware prefetch. The hardware prefetch is generated by a hardware prefetcher at the Level 3 data or unified cache.

The counter counts each access counted by `LL_CACHE_HWPRF` that is due to a hardware prefetch. The hardware prefetch is generated by a hardware prefetcher at the Last level cache.

The counter counts each cycle counted by `STALL_FRONTEND` when no instructions are delivered from the memory system.
The counter counts stalls that occur when the frontend interface to memory is busy or stalled. This includes the stalls counted by STALL_FRONTEND_L1I, STALL_FRONTEND_L2I, STALL_FRONTEND_MEM, and STALL_FRONTEND_TLB, and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by STALL_FRONTEND_CPUBOUND. However both events will count the same cycle counted by STALL_FRONTEND if there are both memory and processor-resource stall conditions active.

0x8159, STALL_FRONTEND_L1I, Frontend stall cycles, level 1 instruction cache
The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the first level of instruction cache.

The counter does not count the cycle if any of the following are true:

- The STALL_FRONTEND_L2I event is implemented and there is a demand instruction miss in the second level of instruction cache, meaning the STALL_FRONTEND_L2I event counts the cycle.
- There is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the STALL_FRONTEND_MEM event counts the cycle.

Implementation of this optional event requires that the first level of instruction cache is implemented within the PE clock domain and is not the last level of instruction cache within the PE clock domain.

0x815A, STALL_FRONTEND_L2I, Frontend stall cycles, level 2 instruction cache
The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the second level of instruction or unified cache.

The counter does not count the cycle if there is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the STALL_FRONTEND_MEM event counts the cycle.

Implementation of this optional event requires that the second level of instruction cache is implemented within the PE clock domain and is not the last level of instruction cache within the PE clock domain.

0x815B, STALL_FRONTEND_MEM, Frontend stall cycles, last level PE cache or memory
The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress.

0x815C, STALL_FRONTEND_TLB, Frontend stall cycles, TLB
The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the instruction or unified TLB.

0x8160, STALL_FRONTEND_CPUBOUND, Frontend stall cycles, processor bound
The counter counts each cycle counted by STALL_FRONTEND when the frontend is stalled on a frontend processor resource, not including memory.

The counter counts stalls that occur when a frontend processor resource is busy. This includes the stalls counted by STALL_FRONTEND_FLOW, STALL_FRONTEND_FLUSH, and STALL_FRONTEND_RENAME, and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by STALL_FRONTEND_MEMBOUND. However both events will count the same cycle counted by STALL_FRONTEND if there are both memory and processor-resource stall conditions active.

0x8161, STALL_FRONTEND_FLOW, Frontend stall cycles, flow control
The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when the frontend is stalled on unavailability of prediction flow resources.
The Performance Monitors Extension

D11.11 PMU events and event numbers

--- Note ---

This event is not counting stalls due to mispredictions, but rather stalls when the frontend is unable to make a prediction.

---

0x8162, STALL_FRONTEND_FLUSH, Frontend stall cycles, flush recovery

The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when the frontend is recovering from a flush or resteer.

The situations where the frontend is flushed are IMPLEMENTATION DEFINED. For example, the frontend might be flushed on a branch misprediction or on a Context synchronization event.

0x8163, STALL_FRONTEND_RENAME, Frontend stall cycles, rename full

The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the STALL_BACKEND_RENAME event counts as zero.

0x8164, STALL_BACKEND_MEMBOUND, Backend stall cycles, memory bound

The counter counts each cycle counted by STALL_BACKEND when the backend is waiting for a memory access to complete.

The counter counts stalls that occur when the backend interface to memory is busy or stalled. This includes the stalls counted by STALL_BACKEND_ATOMIC, STALL_BACKEND_L1D, STALL_BACKEND_L2D, STALL_BACKEND_MEM, STALL_BACKEND_MEMCPYSET, STALL_BACKEND_ST, and STALL_BACKEND_TLB, and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by STALL_BACKEND_CPUBOUND, although both events might count on the same cycle counted by STALL_BACKEND if there are both memory and processor-resource stall conditions active.

0x8165, STALL_BACKEND_L1D, Backend stall cycles, level 1 data cache

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the first level of data or unified cache.

The counter does not count the cycle if any of the following are true:

- The STALL_BACKEND_L2D event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the STALL_BACKEND_L2D event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the STALL_BACKEND_MEM event counts the cycle.

Implementation of this optional event requires that the first level of data or unified cache is implemented within the PE clock domain and is not the last level of data or unified cache within the PE clock domain.

0x8166, STALL_BACKEND_L2D, Backend stall cycles, level 2 data cache

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the second level of data or unified cache.

The counter does not count the cycle if there is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the STALL_BACKEND_MEM event counts the cycle.

Implementation of this optional event requires that the second level of data or unified cache is implemented within the PE clock domain and is not the last level of data or unified cache within the PE clock domain.

0x8167, STALL_BACKEND_TLB, Backend stall cycles, TLB

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the data or unified TLB.
0x8168, **STALL_BACKEND_ST**, Backend stall cycles, store
The counter counts each cycle counted by **STALL_BACKEND_MEMBOUND** when the backend is stalled waiting for a store.

0x816A, **STALL_BACKEND_CPUBOUND**, Backend stall cycles, processor bound
The counter counts each cycle counted by **STALL_BACKEND** when the backend is stalled on a processor resource, not including memory.

The counter counts stalls that occur when a backend processor resource is busy. This includes the stalls counted by **STALL_BACKEND_RENAME**, and any other **IMPLEMENTATION DEFINED** processor resource stalls.

It does not include stalls that are counted by **STALL_BACKEND_MEMBOUND**, although both events might count on the same cycle counted by **STALL_BACKEND** if there are both memory and processor-resource stall conditions active.

0x816B, **STALL_BACKEND_BUSY**, Backend stall cycles, backend busy
The counter counts each cycle counted by **STALL_BACKEND** when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy.

For example a complex operation unit such as a divider is executing a previous operation and cannot accept a new operation.

0x816C, **STALL_BACKEND_ILOCK**, Backend stall cycles, input dependency
The counter counts each cycle counted by **STALL_BACKEND** when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency.

0x816D, **STALL_BACKEND_RENAME**, Backend stall cycles, rename full
The counter counts each cycle counted by **STALL_BACKEND_CPUBOUND** when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the **STALL_FRONTEND_RENAME** event counts as zero.

0x816E, **STALL_BACKEND_ATOMIC**, Backend stall cycles, atomic operation
The counter counts each cycle counted by **STALL_BACKEND_MEMBOUND** when the backend is processing an Atomic operation.

Implementation of this optional event requires that **FEAT_LSE** is implemented.

0x816F, **STALL_BACKEND_MEMCPYSET**, Backend stall cycles, Memory Copy or Set operation
The counter counts each cycle counted by **STALL_BACKEND_MEMBOUND** when the backend is processing an Memory Copy or Set instruction.

The Memory Copy instructions are **CPY** and **CPYF**. The Memory Set instructions are **SET** and **SETG**.

Implementation of this optional event requires that **FEAT_MOPS** is implemented.

0x8170, **CAS_NEAR_FAIL**, Atomic memory Operation speculatively executed, Compare and Swap fail
The counter counts each Compare and Swap operation counted by **CAS_NEAR_SPEC** that does not update the location accessed.

Implementation of this optional event requires that **FEAT_LSE** is implemented.

0x8171, **CAS_NEAR_PASS**, Atomic memory Operation speculatively executed, Compare and Swap pass
The counter counts each Compare and Swap operation counted by **CAS_NEAR_SPEC** that updates the location accessed.

Implementation of this optional event requires that **FEAT_LSE** is implemented.

0x8172, **CAS_NEAR_SPEC**, Atomic memory Operation speculatively executed, Compare and Swap near
The counter counts each Compare and Swap operation counted by **CAS_SPEC** that executes locally to the PE.
The definition of *locally* is IMPLEMENTATION DEFINED. Operations counted by CAS_NEAR_SPEC also generate one of the CAS_NEAR_PASS or CAS_NEAR_FAIL events.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8173, **CAS_FAR_SPEC**, Atomic memory Operation speculatively executed, Compare and Swap far

The counter counts each Compare and Swap operation counted by CAS_SPEC that does not execute locally to the PE.

The definition of *locally* is IMPLEMENTATION DEFINED. Operations counted by CAS_FAR_SPEC do not generate CAS_NEAR_PASS or CAS_NEAR_FAIL events.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8174, **CAS_SPEC**, Atomic memory Operation speculatively executed, Compare and Swap

The counter counts each load atomic operation counted by LSE_LD_SPEC that is a Compare and Swap operation.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8175, **LSE_LD_SPEC**, Atomic memory Operation speculatively executed, load

The counter counts each operation counted by INST_SPEC that is an Atomic memory operation that returns a value to the PE, including Swap and Compare-and-Swap operations.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8176, **LSE_ST_SPEC**, Atomic memory Operation speculatively executed, store

The counter counts each operation counted by INST_SPEC that is an Atomic memory operation that does not return a value to the PE.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8177, **LSE_LDST_SPEC**, Atomic memory Operation speculatively executed, load or store

The counter counts each operation counted by either LSE_LD_SPEC or LSE_ST_SPEC.

Implementation of this optional event requires that FEAT_LSE is implemented.

0x8178, **REMOTE_ACCESS_WR**, Access to another socket in a multi-socket system, write

The counter counts each access counted by REMOTE_ACCESS that is a Memory-write operation.

0x8184, **BR_HINT_COND_PRED_RETIRED**, Branch Instruction architecturally executed, predicted hinted conditional

The counter counts each branch counted by both BR_HINT_COND_RETIRED and BR_PRED_RETIRED.

These are all hinted conditional branch instructions on the architecturally executed path, where the branch is correctly predicted.

Implementation of this optional event requires that FEAT_HBC is implemented.

0x8185, **BR_HINT_COND_MIS_PRED_RETIRED**, Branch Instruction architecturally executed, mispredicted hinted conditional

The counter counts each branch counted by both BR_HINT_COND_RETIRED and BR_MIS_PRED_RETIRED.

These are all hinted conditional branch instructions on the architecturally executed path, where the branch is mispredicted.

Implementation of this optional event requires that FEAT_HBC is implemented.

0x8186, **UOP_RETIRED**, Micro-operation architecturally executed

The counter counts each micro-operation that would be executed in a Simple sequential execution of the program.
Unlike \texttt{OP\_RETIRED}, this event is not linked to the definition of \texttt{OP\_SPEC}, meaning it counts micro-operations that are created from other operations after those operations are counted by \texttt{OP\_SPEC}.

\texttt{0x8188, DTLB\_WALK\_BLOCK, Data TLB block translation table walk}
The counter counts each translation table walk counted by \texttt{DTLB\_WALK} where the result of the walk yields a Block.
That is, the translation table walk ends at a Block descriptor, at other than the last level of translation table.
If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.
The counter does not count the walk if the access generates a Translation fault.
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER\langle n\rangle\_EL0.MT for the counter is $0b1$, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.
Implementation of this optional event requires that FEAT\_E0PD is implemented.

\texttt{0x8189, ITLB\_WALK\_BLOCK, Instruction TLB block translation table walk}
The counter counts each translation table walk counted by \texttt{ITLB\_WALK} where the result of the walk yields a Block.
That is, the translation table walk ends at a Page descriptor, at other than the last level of translation table.
If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.
The counter does not count the walk if the access generates a Translation fault.
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER\langle n\rangle\_EL0.MT for the counter is $0b1$, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.
Implementation of this optional event requires that FEAT\_E0PD is implemented.

\texttt{0x818A, DTLB\_WALK\_PAGE, Data TLB page translation table walk}
The counter counts each translation table walk counted by \texttt{DTLB\_WALK} where the result of the walk yields a Page.
That is, the translation table walk ends at a Block descriptor, at the last level of translation table.
If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.
The counter does not count the walk if the access generates a Translation fault.
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER\langle n\rangle\_EL0.MT for the counter is $0b1$, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.
Implementation of this optional event requires that FEAT\_E0PD is implemented.

\texttt{0x818B, ITLB\_WALK\_PAGE, Instruction TLB page translation table walk}
The counter counts each translation table walk counted by \texttt{ITLB\_WALK} where the result of the walk yields a Page.
That is, the translation table walk ends at a Page descriptor, at the last level of translation table.
If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.
The counter does not count the walk if the access generates a Translation fault.
If the TLB is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER\langle n\rangle\_EL0.MT for the counter is $0b1$, other PEs in the multithreaded implementation. If the TLB is not shared, all events are counted.
Implementation of this optional event requires that FEAT_E0PD is implemented.

0x818D, **BUS_REQ_RD, Bus request, read**

The counter counts each transaction counted by BUS_REQ that is a Memory-read operation.

0x818E, **BUS_REQ_WR, Bus request, write**

The counter counts each transaction counted by BUS_REQ that is a Memory-write operation.

0x818F, **BUS_REQ, Bus request**

The counter counts each request generated by a Memory-read operation or Memory-write operation that accesses outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of requests across all buses.

A bus request is the start of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The BUS_REQ event therefore counts the number of transactions. The BUS_ACCESS event counts the occupancy of the transaction on the bus.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED. This must be the same for the BUS_REQ and BUS_ACCESS events.

An Unattributable bus transaction occurs when a requestor outside the PE makes a request that results in a bus transaction, for example, a coherency request.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

If the bus is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the bus is not shared, all events are counted.

0x8190, **ISNP_HIT_RD, Snoop hit, demand instruction fetch**

The counter counts each snoop generated in response to a demand Instruction memory access that hits in a cache outside of the cache hierarchy of this PE.

0x8191, **ISNP_HIT_NEAR_RD, Snoop hit in near cache, demand instruction fetch**

The counter counts each snoop generated in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x8192, **ISNP_HIT_FAR_RD, Snoop hit in far cache, demand instruction fetch**

The counter counts each snoop generated in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache outside the local PE cluster on the same device.

0x8193, **ISNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand instruction fetch**

The counter counts each snoop generated in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache on a remote device.

0x8194, **DSNP_HIT_RD, Snoop hit, demand data read**

The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE.

0x8195, **DSNP_HIT_NEAR_RD, Snoop hit in near cache, demand data read**

The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.
The Performance Monitors Extension

D11.11 PMU events and event numbers

ID081822

Non-Confidential

0x8196, DSNP_HIT_FAR_RD, Snoop hit in far cache, demand data read
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache outside the local PE cluster on the same device.

0x8197, DSNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand data read
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache on a remote device.

0x8198, DSNP_HIT_WR, Snoop hit, demand data write
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE.

0x8199, DSNP_HIT_NEAR_WR, Snoop hit in near cache, demand data write
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x819A, DSNP_HIT_FAR_WR, Snoop hit in far cache, demand data write
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache outside the local PE cluster on the same device.

0x819B, DSNP_HIT_REMOTE_WR, Snoop hit in remote cache, demand data write
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache on a remote device.

0x819C, DSNP_HIT_RW, Snoop hit, demand data access
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation that hits in a cache outside of the cache hierarchy of this PE.

0x819D, DSNP_HIT_NEAR_RW, Snoop hit in near cache, demand data access
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x819E, DSNP_HIT_FAR_RW, Snoop hit in far cache, demand data access
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside the local PE cluster on the same device.

0x819F, DSNP_HIT_REMOTE_RW, Snoop hit in remote cache, demand data access
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache on a remote device.

0x81A0, DSNP_HIT_PRFM, Snoop hit, software data preload
The counter counts each snoop generated in response to a data preload or prefetch instruction that hits in a cache outside of the cache hierarchy of this PE.

0x81A1, DSNP_HIT_NEAR_PRFM, Snoop hit in near cache, software data preload
The counter counts each snoop generated in response to a data preload or prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81A2, DSNP_HIT_FAR_PRFM, Snoop hit in far cache, software data preload
The counter counts each snoop generated in response to a data preload or prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache outside the local PE cluster on the same device.
0x81A3, DSNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software data preload
The counter counts each snoop generated in response to a data preload or prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache on a remote device.

0x81A4, DSNP_HIT_HWPRF, Snoop hit, hardware data prefetch
The counter counts each snoop generated by a data hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

0x81A5, DSNP_HIT_NEAR_HWPRF, Snoop hit in near cache, hardware data prefetch
The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81A6, DSNP_HIT_FAR_HWPRF, Snoop hit in far cache, hardware data prefetch
The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache outside the local PE cluster on the same device.

0x81A7, DSNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware data prefetch
The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache on a remote device.

0x81A8, ISNP_HIT_PRFM, Snoop hit, software instruction preload
The counter counts each snoop generated in response to an instruction preload or prefetch instruction that hits in a cache outside of the cache hierarchy of this PE.

0x81A9, ISNP_HIT_NEAR_PRFM, Snoop hit in near cache, software instruction preload
The counter counts each snoop generated in response to an instruction preload or prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81AA, ISNP_HIT_FAR_PRFM, Snoop hit in far cache, software instruction preload
The counter counts each snoop generated in response to an instruction preload or prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache outside the local PE cluster on the same device.

0x81AB, ISNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software instruction preload
The counter counts each snoop generated in response to an instruction preload or prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache on a remote device.

0x81AC, ISNP_HIT_HWPRF, Snoop hit, hardware instruction prefetch
The counter counts each snoop generated by an instruction hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

0x81AD, ISNP_HIT_NEAR_HWPRF, Snoop hit in near cache, hardware instruction prefetch
The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81AE, ISNP_HIT_FAR_HWPRF, Snoop hit in far cache, hardware instruction prefetch
The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache outside the local PE cluster on the same device.

0x81AF, ISNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware instruction prefetch
The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache on a remote device.

0x81B0, ISNP_HIT, Snoop hit, instruction
The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.
0x81B1, ISNP_HIT_NEAR, Snoop hit in near cache, instruction
The counter counts each snoop counted by ISNP_HIT that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81B2, ISNP_HIT_FAR, Snoop hit in far cache, instruction
The counter counts each snoop counted by ISNP_HIT that hits in a cache outside the local PE cluster on the same device.

0x81B3, ISNP_HIT_REMOTE, Snoop hit in remote cache, instruction
The counter counts each snoop counted by ISNP_HIT that hits in a cache on a remote device.

0x81B4, DSNP_HIT, Snoop hit, data
The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

0x81B5, DSNP_HIT_NEAR, Snoop hit in near cache, data
The counter counts each snoop counted by DSNP_HIT that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x81B6, DSNP_HIT_FAR, Snoop hit in far cache, data
The counter counts each snoop counted by DSNP_HIT that hits in a cache outside the local PE cluster on the same device.

0x81B7, DSNP_HIT_REMOTE, Snoop hit in remote cache, data
The counter counts each snoop counted by DSNP_HIT that hits in a cache on a remote device.

0x81B8, L1I_CACHE_REFILL_HWPRF, Level 1 instruction cache refill, hardware prefetch
The counter counts each hardware prefetch counted by L1I_CACHE_HWPRF that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

0x81B9, L2I_CACHE_REFILL_HWPRF, Level 2 instruction cache refill, hardware prefetch
The counter counts each hardware prefetch counted by L2I_CACHE_HWPRF that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BC, L1D_CACHE_REFILL_HWPRF, Level 1 data cache refill, hardware prefetch
The counter counts each hardware prefetch counted by L1D_CACHE_HWPRF that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

0x81BD, L2D_CACHE_REFILL_HWPRF, Level 2 data cache refill, hardware prefetch
The counter counts each hardware prefetch counted by L2D_CACHE_HWPRF that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BE, L3D_CACHE_REFILL_HWPRF, Level 3 data cache refill, hardware prefetch
The counter counts each hardware prefetch counted by L3D_CACHE_HWPRF that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BF, LL_CACHE_REFILL_HWPRF, Last level cache refill, hardware prefetch
The counter counts each hardware prefetch counted by LL_CACHE_HWPRF that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

0x81C0, L1I_CACHE_HIT_RD, Level 1 instruction cache demand fetch hit
The counter counts each demand fetch counted by L1I_CACHE_RD that hits in the Level 1 instruction or unified cache.
0x81C1, L2I_CACHE_HIT_RD, Level 2 instruction cache demand fetch hit
   The counter counts each demand fetch counted by L2I_CACHE_RD that hits in the Level 2
   instruction or unified cache.

0x81C4, L1D_CACHE_HIT_RD, Level 1 data cache demand hit, read
   The counter counts each demand read counted by L1D_CACHE_RD that hits in the Level 1 data or
   unified cache.

0x81C5, L2D_CACHE_HIT_RD, Level 2 data cache demand hit, read
   The counter counts each demand read counted by L2D_CACHE_RD that hits in the Level 2 data or
   unified cache.

0x81C6, L3D_CACHE_HIT_RD, Level 3 data cache demand hit, read
   The counter counts each demand read counted by L3D_CACHE_RD that hits in the Level 3 data or
   unified cache.

0x81C7, LL_CACHE_HIT_RD, Last level cache demand hit, read
   The counter counts each demand read counted by LL_CACHE_RD that hits in the Last level cache.

0x81C8, L1D_CACHE_HIT_WR, Level 1 data cache demand access hit, write
   The counter counts each demand write counted by L1D_CACHE_WR that hits in the Level 1 data
   or unified cache.

0x81C9, L2D_CACHE_HIT_WR, Level 2 data cache demand access hit, write
   The counter counts each demand write counted by L2D_CACHE_WR that hits in the Level 2 data
   or unified cache.

0x81CA, L3D_CACHE_HIT_WR, Level 3 data cache demand access hit, write
   The counter counts each demand write counted by L3D_CACHE_WR that hits in the Level 3 data
   or unified cache.

0x81CB, LL_CACHE_HIT_WR, Last level cache demand access hit, write
   The counter counts each demand write counted by LL_CACHE_WR that hits in the Last level
   cache.

0x81CC, L1D_CACHE_HIT_RW, Level 1 data cache demand access hit
   The counter counts each demand access counted by L1D_CACHE_RW that hits in the Level 1 data
   or unified cache.

0x81CD, L2D_CACHE_HIT_RW, Level 2 data cache demand access hit
   The counter counts each demand access counted by L2D_CACHE_RW that hits in the Level 2 data
   or unified cache.

0x81CE, L3D_CACHE_HIT_RW, Level 3 data cache demand access hit
   The counter counts each demand access counted by L3D_CACHE_RW that hits in the Level 3 data
   or unified cache.

0x81CF, LL_CACHE_HIT_RW, Last level cache demand access hit
   The counter counts each demand access counted by LL_CACHE_RW that hits in the Last level
   cache.

0x81D0, L1I_CACHE_HIT_RD_FPRFM, Level 1 instruction cache demand fetch first hit, fetched by
   software preload
   The counter counts each demand fetch first hit counted by L1I_CACHE_HIT_RD where the cache
   line was fetched in response to a preload or prefetch instruction.
   That is, the L1I_CACHE_REFILL_PRFM event was generated when the cache line was fetched
   into the cache.
Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81D1, L2I_CACHE_HIT_RD_FPRFM, Level 2 instruction cache demand fetch first hit, fetched by software preload
The counter counts each demand fetch first hit counted by L2I_CACHE_HIT_RD where the cache line was fetched in response to a preload or prefetch instruction.
That is, the L2I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.
Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81D4, L1D_CACHE_HIT_RD_FPRFM, Level 1 data cache demand first hit, read, fetched by software preload
The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRFM that is a demand Memory-read operation.

0x81D5, L2D_CACHE_HIT_RD_FPRFM, Level 2 data cache demand first hit, read, fetched by software preload
The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRFM that is a demand Memory-read operation.

0x81D6, L3D_CACHE_HIT_RD_FPRFM, Level 3 data cache demand first hit, read, fetched by software preload
The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRFM that is a demand Memory-read operation.

0x81D7, LL_CACHE_HIT_RD_FPRFM, Last level cache demand first hit, read, fetched by software preload
The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRFM that is a demand Memory-read operation.

0x81D8, L1D_CACHE_HIT_WR_FPRFM, Level 1 data cache demand access first hit, write, fetched by software preload
The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRFM that is a demand Memory-write operation.

0x81D9, L2D_CACHE_HIT_WR_FPRFM, Level 2 data cache demand access first hit, write, fetched by software preload
The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRFM that is a demand Memory-write operation.

0x81DA, L3D_CACHE_HIT_WR_FPRFM, Level 3 data cache demand access first hit, write, fetched by software preload
The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRFM that is a demand Memory-write operation.

0x81DB, LL_CACHE_HIT_WR_FPRFM, Last level cache demand access first hit, write, fetched by software preload
The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRFM that is a demand Memory-write operation.

0x81DC, L1D_CACHE_HIT_RW_FPRFM, Level 1 data cache demand access first hit, fetched by software preload
The counter counts each demand access first hit counted by L1D_CACHE_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.
That is, the L1D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.
Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DD, **L2D_CACHE_HIT_RW_FPRFM**, Level 2 data cache demand access first hit, fetched by software preload

The counter counts each demand access first hit counted by L2D_CACHE_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the L2D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DE, **L3D_CACHE_HIT_RW_FPRFM**, Level 3 data cache demand access first hit, fetched by software preload

The counter counts each demand access first hit counted by L3D_CACHE_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the L3D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DF, **LL_CACHE_HIT_RW_FPRFM**, Last level cache demand access first hit, fetched by software preload

The counter counts each demand access first hit counted by LL_CACHE_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the LL_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E0, **L1I_CACHE_HIT_RD_FHWPRF**, Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by L1I_CACHE_HIT_RD where the cache line was fetched by a hardware prefetcher.

That is, the L1I_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E1, **L2I_CACHE_HIT_RD_FHWPRF**, Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by L2I_CACHE_HIT_RD where the cache line was fetched by a hardware prefetcher.

That is, the L2I_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E4, **L1D_CACHE_HIT_RW_FHWPRF**, Level 1 data cache demand first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FHWPRF that is a demand Memory-read operation.
0x81E5, **L2D_CACHE_HIT_RD_FHWPRF**, Level 2 data cache demand first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by **L2D_CACHE_HIT_RW_FHWPRF** that is a demand Memory-read operation.

0x81E6, **L3D_CACHE_HIT_RD_FHWPRF**, Level 3 data cache demand first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by **L3D_CACHE_HIT_RW_FHWPRF** that is a demand Memory-read operation.

0x81E7, **LL_CACHE_HIT_RD_FHWPRF**, Last level cache demand first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by **LL_CACHE_HIT_RW_FHWPRF** that is a demand Memory-read operation.

0x81E8, **L1D_CACHE_HIT_WR_FHWPRF**, Level 1 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by **L1D_CACHE_HIT_RW_FHWPRF** that is a demand Memory-write operation.

0x81E9, **L2D_CACHE_HIT_WR_FHWPRF**, Level 2 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by **L2D_CACHE_HIT_RW_FHWPRF** that is a demand Memory-write operation.

0x81EA, **L3D_CACHE_HIT_WR_FHWPRF**, Level 3 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by **L3D_CACHE_HIT_RW_FHWPRF** that is a demand Memory-write operation.

0x81EB, **LL_CACHE_HIT_WR_FHWPRF**, Last level cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by **LL_CACHE_HIT_RW_FHWPRF** that is a demand Memory-write operation.

0x81EC, **L1D_CACHE_HIT_RW_FHWPRF**, Level 1 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by **L1D_CACHE_HIT_RW** where the cache line was fetched by a hardware prefetcher.

That is, the **L1D_CACHE_REFILL_HWPRF** event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81ED, **L2D_CACHE_HIT_RW_FHWPRF**, Level 2 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by **L2D_CACHE_HIT_RW** where the cache line was fetched by a hardware prefetcher.

That is, the **L2D_CACHE_REFILL_HWPRF** event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81EE, **L3D_CACHE_HIT_RW_FHWPRF**, Level 3 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by **L3D_CACHE_HIT_RW** where the cache line was fetched by a hardware prefetcher.
That is, the L3D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81EF, LL_CACHE_HIT_RW_FHWPRF, Last level cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by LL_CACHE_HIT_RW where the cache line was fetched by a hardware prefetcher.

That is, the LL_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81F0, L1I_CACHE_HIT_RD_FPRF, Level 1 instruction cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either L1I_CACHE_HIT_RD_FHWPRF or L1I_CACHE_HIT_RD_FPRFM.

0x81F1, L2I_CACHE_HIT_RD_FPRF, Level 2 instruction cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either L2I_CACHE_HIT_RD_FHWPRF or L2I_CACHE_HIT_RD_FPRFM.

0x81F4, L1D_CACHE_HIT_RD_FPRF, Level 1 data cache demand access first hit, read, fetched by preload or prefetch

The counter counts each first hit counted by either L1D_CACHE_HIT_RD_FHWPRF or L1D_CACHE_HIT_RD_FPRFM.

0x81F5, L2D_CACHE_HIT_RD_FPRF, Level 2 data cache demand access first hit, read, fetched by preload or prefetch

The counter counts each first hit counted by either L2D_CACHE_HIT_RD_FHWPRF or L2D_CACHE_HIT_RD_FPRFM.

0x81F6, L3D_CACHE_HIT_RD_FPRF, Level 3 data cache demand access first hit, read, fetched by preload or prefetch

The counter counts each first hit counted by either L3D_CACHE_HIT_RD_FHWPRF or L3D_CACHE_HIT_RD_FPRFM.

0x81F7, LL_CACHE_HIT_RD_FPRF, Last level cache demand access first hit, read, fetched by preload or prefetch

The counter counts each first hit counted by either LL_CACHE_HIT_RD_FHWPRF or LL_CACHE_HIT_RD_FPRFM.

0x81F8, L1D_CACHE_HIT_WR_FPRF, Level 1 data cache demand access first hit, write, fetched by preload or prefetch

The counter counts each first hit counted by either L1D_CACHE_HIT_WR_FHWPRF or L1D_CACHE_HIT_WR_FPRFM.

0x81F9, L2D_CACHE_HIT_WR_FPRF, Level 2 data cache demand access first hit, write, fetched by preload or prefetch

The counter counts each first hit counted by either L2D_CACHE_HIT_WR_FHWPRF or L2D_CACHE_HIT_WR_FPRFM.

0x81FA, L3D_CACHE_HIT_WR_FPRF, Level 3 data cache demand access first hit, write, fetched by preload or prefetch

The counter counts each first hit counted by either L3D_CACHE_HIT_WR_FHWPRF or L3D_CACHE_HIT_WR_FPRFM.
0x81FB, LL_CACHE_HIT_WR_FPRF, Last level cache demand access first hit, write, fetched by preload or prefetch

The counter counts each first hit counted by either LL_CACHE_HIT_WR_FHWPRF or LL_CACHE_HIT_WR_FPRFM.

0x81FC, L1D_CACHE_HIT_RW_FPRF, Level 1 data cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either L1D_CACHE_HIT_RW_FHWPRF or L1D_CACHE_HIT_RW_FPRFM.

0x81FD, L2D_CACHE_HIT_RW_FPRF, Level 2 data cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either L2D_CACHE_HIT_RW_FHWPRF or L2D_CACHE_HIT_RW_FPRFM.

0x81FE, L3D_CACHE_HIT_RW_FPRF, Level 3 data cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either L3D_CACHE_HIT_RW_FHWPRF or L3D_CACHE_HIT_RW_FPRFM.

0x81FF, LL_CACHE_HIT_RW_FPRF, Last level cache demand access first hit, fetched by preload or prefetch

The counter counts each first hit counted by either LL_CACHE_HIT_RW_FHWPRF or LL_CACHE_HIT_RW_FPRFM.

0x8200, L1I_CACHE_HIT, Level 1 instruction cache hit

The counter counts each access counted by L1I_CACHE that hits in the Level 1 instruction or unified cache.

0x8201, L2I_CACHE_HIT, Level 2 instruction cache hit

The counter counts each access counted by L2I_CACHE that hits in the Level 2 instruction or unified cache.

0x8204, L1D_CACHE_HIT, Level 1 data cache hit

The counter counts each access counted by L1D_CACHE that hits in the Level 1 data or unified cache.

0x8205, L2D_CACHE_HIT, Level 2 data cache hit

The counter counts each access counted by L2D_CACHE that hits in the Level 2 data or unified cache.

0x8206, L3D_CACHE_HIT, Level 3 data cache hit

The counter counts each access counted by L3D_CACHE that hits in the Level 3 data or unified cache.

0x8207, LL_CACHE_HIT, Last level cache hit

The counter counts each access counted by LL_CACHE that hits in the Last level cache.

0x8208, L1I_CACHE_HIT_PRFM, Level 1 instruction cache software preload hit

The counter counts each software preload counted by L1I_CACHE_PRFM that hits in the Level 1 instruction or unified cache.

0x8209, L2I_CACHE_HIT_PRFM, Level 2 instruction cache software preload hit

The counter counts each software preload counted by L2I_CACHE_PRFM that hits in the Level 2 instruction or unified cache.
0x820C, L1D_CACHE_HIT_PRFM, Level 1 data cache software preload hit
   The counter counts each software preload counted by L1D_CACHE_PRFM that hits in the Level 1
data or unified cache.

0x820D, L2D_CACHE_HIT_PRFM, Level 2 data cache software preload hit
   The counter counts each software preload counted by L2D_CACHE_PRFM that hits in the Level 2
data or unified cache.

0x820E, L3D_CACHE_HIT_PRFM, Level 3 data cache software preload hit
   The counter counts each software preload counted by L3D_CACHE_PRFM that hits in the Level 3
data or unified cache.

0x820F, LL_CACHE_HIT_PRFM, Last level cache software preload hit
   The counter counts each software preload counted by LL_CACHE_PRFM that hits in the Last level
cache.

0x8214, L1D_CACHE_HITM_RD, Level 1 data cache demand hit modified, read
   The counter counts each cache access counted by L1D_CACHE_HIT_RD that accesses a
previously modified cache location.

0x8215, L2D_CACHE_HITM_RD, Level 2 data cache demand hit modified, read
   The counter counts each cache access counted by L2D_CACHE_HIT_RD that accesses a
previously modified cache location.

0x8216, L3D_CACHE_HITM_RD, Level 3 data cache demand hit modified, read
   The counter counts each cache access counted by L3D_CACHE_HIT_RD that accesses a
previously modified cache location.

0x8217, LL_CACHE_HITM_RD, Last level cache demand hit modified, read
   The counter counts each cache access counted by LL_CACHE_HIT_RD that accesses a previously
modified cache location.

0x8218, L1D_CACHE_HITM_WR, Level 1 data cache demand access hit modified, write
   The counter counts each cache access counted by L1D_CACHE_HIT_WR that accesses a
previously modified cache location.

0x8219, L2D_CACHE_HITM_WR, Level 2 data cache demand access hit modified, write
   The counter counts each cache access counted by L2D_CACHE_HIT_WR that accesses a
previously modified cache location.

0x821A, L3D_CACHE_HITM_WR, Level 3 data cache demand access hit modified, write
   The counter counts each cache access counted by L3D_CACHE_HIT_WR that accesses a
previously modified cache location.

0x821B, LL_CACHE_HITM_WR, Last level cache demand access hit modified, write
   The counter counts each cache access counted by LL_CACHE_HIT_WR that accesses a previously
modified cache location.

0x821C, L1D_CACHE_HITM_RW, Level 1 data cache demand access hit modified
   The counter counts each cache access counted by L1D_CACHE_HIT_RW that accesses a
previously modified cache location.

0x821D, L2D_CACHE_HITM_RW, Level 2 data cache demand access hit modified
   The counter counts each cache access counted by L2D_CACHE_HIT_RW that accesses a
previously modified cache location.
0x821E, L3D_CACHE_HITM_RW, Level 3 data cache demand access hit modified
The counter counts each cache access counted by L3D_CACHE_HIT_RW that accesses a previously modified cache location.

0x821F, LL_CACHE_HITM_RW, Last level cache demand access hit modified
The counter counts each cache access counted by LL_CACHE_HIT_RW that accesses a previously modified cache location.

0x8224, DSNP_HITM_RD, Snoop hit, demand data read, modified
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_RD that accesses a previously modified cache location.

0x8225, DSNP_HITM_NEAR_RD, Snoop hit in near cache, demand data read, modified
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_NEAR_RD that accesses a previously modified cache location.

0x8226, DSNP_HITM_FAR_RD, Snoop hit in far cache, demand data read, modified
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_FAR_RD that accesses a previously modified cache location.

0x8227, DSNP_HITM_REMOTE_RD, Snoop hit in remote cache, demand data read, modified
The counter counts each snoop generated in response to a demand Memory-read operation counted by DSNP_HIT_REMOTE_RD that accesses a previously modified cache location.

0x8228, DSNP_HITM_RW, Snoop hit, demand data write, modified
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_WR that accesses a previously modified cache location.

0x8229, DSNP_HITM_NEAR_WR, Snoop hit in near cache, demand data write, modified
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_NEAR_WR that accesses a previously modified cache location.

0x822A, DSNP_HITM_FAR_WR, Snoop hit in far cache, demand data write, modified
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_FAR_WR that accesses a previously modified cache location.

0x822B, DSNP_HITM_REMOTE_WR, Snoop hit in remote cache, demand data write, modified
The counter counts each snoop generated in response to a demand Memory-write operation counted by DSNP_HIT_REMOTE_WR that accesses a previously modified cache location.

0x822C, DSNP_HITM_RW, Snoop hit, demand data access, modified
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that accesses a previously modified cache location.

0x822D, DSNP_HITM_NEAR_RW, Snoop hit in near cache, demand data access, modified
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_NEAR_RW that accesses a previously modified cache location.

0x822E, DSNP_HITM_FAR_RW, Snoop hit in far cache, demand data access, modified
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_FAR_RW that accesses a previously modified cache location.
0x822F, DSNP_HITM_REMOTE_RW, Snoop hit in remote cache, demand data access, modified
The counter counts each snoop generated in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_REMOTE_RW that accesses a previously modified cache location.

0x8230, LOCAL_MEM, Access to memory attached to this device
The counter counts each Memory-read operation or Memory-write operation access to external memory attached to this device or socket. In a multi-socket system this means the socket that contains the PE. For more information, see REMOTE_ACCESS.

In systems where there multiple types of memory attached to this device with different performance characteristics, it is IMPLEMENTATION DEFINED whether accesses to all external memory types are counted by this event, or are classified as remote accesses and counted by REMOTE_MEM.

For example, in a system with an expansion memory connected to the device that has significantly higher latency than the main system memory, accesses to the main system memory might be counted by this event and accesses to the expansion memory by REMOTE_MEM.

0x8231, LOCAL_MEM_RD, Access to memory attached to this device, read
The counter counts each demand access counted by LOCAL_MEM_RW that is a Memory-read operation.

0x8232, LOCAL_MEM_WR, Access to memory attached to this device, write
The counter counts each demand access counted by LOCAL_MEM_RW that is a Memory-write operation.

0x8233, LOCAL_MEM_RW, Access to memory attached to this device, demand read or write
The counter counts each access counted by LOCAL_MEM that is a demand Memory-read operation or demand Memory-write operation.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by LOCAL_MEM_RW or LOCAL_MEM_PRFM.

0x8234, LOCAL_MEM_PRFM, Access to memory attached to this device, preload or prefetch
The counter counts each access counted by LOCAL_MEM that is due to a preload or prefetch instruction, or a prefetch to a cache.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by LOCAL_MEM_RW or LOCAL_MEM_PRFM.

0x8238, REMOTE_MEM, Access to memory attached to another socket in a multi-socket system
The counter counts each Memory-read operation or Memory-write operation access counted by REMOTE_ACCESS that causes an access to external memory attached to a different socket in a multi-socket system.

The counter also counts any accesses to external memory that are not counted by LOCAL_MEM because the implementation classifies them as remote accesses. For example, accesses to expansion memory connected to the device that has significantly higher latency than the main system memory might be classified as remote accesses. For more information, see LOCAL_MEM.

0x8239, REMOTE_MEM_RD, Access to memory attached to another socket in a multi-socket system, read
The counter counts each access counted by REMOTE_MEM_RW that is a Memory-read operation.

0x823A, REMOTE_MEM_WR, Access to memory attached to another socket in a multi-socket system, write
The counter counts each access counted by REMOTE_MEM_RW that is a Memory-write operation.

0x823B, REMOTE_MEM_RW, Access to memory attached to another socket in a multi-socket system, demand read or write
The counter counts each access counted by REMOTE_MEM that is a demand Memory-read operation or demand Memory-write operation.
0x823C, REMOTE_MEM_PRFM, Access to memory attached to another socket in a multi-socket system, preload or prefetch

The counter counts each access counted by REMOTE_MEM that is due to a preload or prefetch instruction, or a prefetch to a cache.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by LOCAL_MEM_RW or LOCAL_MEM_PRFM.

0x8240, L1I_LFB_HIT_RD, Level 1 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by L1I_CACHE_HIT_RD that hits a recently fetched line in the Level 1 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8241, L2I_LFB_HIT_RD, Level 2 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by L2I_CACHE_HIT_RD that hits a recently fetched line in the Level 2 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8244, L1D_LFB_HIT_RD, Level 1 data cache demand line-fill buffer hit, read

The counter counts each demand access counted by L1D_CACHE_HIT_RD that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8245, L2D_LFB_HIT_RD, Level 2 data cache demand line-fill buffer hit, read

The counter counts each demand access counted by L2D_CACHE_HIT_RD that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8246, L3D_LFB_HIT_RD, Level 3 data cache demand line-fill buffer hit, read

The counter counts each demand access counted by L3D_CACHE_HIT_RD that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8247, LL_LFB_HIT_RD, Last level cache demand line-fill buffer hit, read

The counter counts each demand access counted by LL_CACHE_HIT_RD that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8248, L1D_LFB_HIT_WR, Level 1 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by L1D_CACHE_HIT_WR that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.
0x8249, **L2D_LFB_HIT_WR**, Level 2 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by L2D_CACHE_HIT_WR that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824A, **L3D_LFB_HIT_WR**, Level 3 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by L3D_CACHE_HIT_WR that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824B, **LL_LFB_HIT_WR**, Last level cache demand access line-fill buffer hit, write

The counter counts each demand access counted by LL_CACHE_HIT_WR that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824C, **L1D_LFB_HIT_RW**, Level 1 data cache demand access line-fill buffer hit

The counter counts each demand access counted by L1D_CACHE_HIT_RW that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824D, **L2D_LFB_HIT_RW**, Level 2 data cache demand access line-fill buffer hit

The counter counts each demand access counted by L2D_CACHE_HIT_RW that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824E, **L3D_LFB_HIT_RW**, Level 3 data cache demand access line-fill buffer hit

The counter counts each demand access counted by L3D_CACHE_HIT_RW that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824F, **LL_LFB_HIT_RW**, Last level cache demand access line-fill buffer hit

The counter counts each demand access counted by LL_CACHE_HIT_RW that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8250, **L1I_LFB_HIT_RD_FPRFM**, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software preload

The counter counts each demand fetch line-fill buffer first hit counted by L1I_LFB_HIT_RD where the cache line was fetched in response to a preload or prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L1I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.
Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8251, L21_LFB_HIT_RD_FPRFM, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software preload

The counter counts each demand fetch line-fill buffer first hit counted by L21_LFB_HIT_RD where the cache line was fetched in response to a preload or prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L2I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8254, L1D_LFB_HIT_RD_FPRFM, Level 1 data cache demand line-fill buffer first hit, read, recently fetched by software preload

The counter counts each line-fill buffer first hit counted by L1D_LFB_HIT_RW_FPRFM that is a demand Memory-read operation.

0x8255, L2D_LFB_HIT_RD_FPRFM, Level 2 data cache demand line-fill buffer first hit, read, recently fetched by software preload

The counter counts each line-fill buffer first hit counted by L2D_LFB_HIT_RW_FPRFM that is a demand Memory-read operation.

0x8256, L3D_LFB_HIT_RD_FPRFM, Level 3 data cache demand line-fill buffer first hit, read, recently fetched by software preload

The counter counts each line-fill buffer first hit counted by L3D_LFB_HIT_RW_FPRFM that is a demand Memory-read operation.

0x8257, LL_LFB_HIT_RD_FPRFM, Last level cache demand line-fill buffer first hit, read, recently fetched by software preload

The counter counts each line-fill buffer first hit counted by LL_LFB_HIT_RW_FPRFM that is a demand Memory-read operation.

0x8258, L1D_LFB_HIT_WR_FPRFM, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L1D_LFB_HIT_RW_FPRFM where the cache line was fetched in response to a preload or prefetch instruction.

0x8259, L2D_LFB_HIT_WR_FPRFM, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L2D_LFB_HIT_RW_FPRFM where the cache line was fetched in response to a preload or prefetch instruction.

0x825A, L3D_LFB_HIT_WR_FPRFM, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L3D_LFB_HIT_RW_FPRFM where the cache line was fetched in response to a preload or prefetch instruction.

0x825B, LL_LFB_HIT_WR_FPRFM, Last level cache demand access line-fill buffer first hit, write, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by LL_LFB_HIT_RW_FPRFM where the cache line was fetched in response to a preload or prefetch instruction.

0x825C, L1D_LFB_HIT_RW_FPRFM, Level 1 data cache demand access line-fill buffer first hit, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L1D_LFB_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.
That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L1D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825D, L2D_LFB_HIT_RW_FPRFM, Level 2 data cache demand access line-fill buffer first hit, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L2D_LFB_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L2D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825E, L3D_LFB_HIT_RW_FPRFM, Level 3 data cache demand access line-fill buffer first hit, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by L3D_LFB_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L3D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825F, LL_LFB_HIT_RW_FPRFM, Last level cache demand access line-fill buffer first hit, recently fetched by software preload

The counter counts each demand access line-fill buffer first hit counted by LL_LFB_HIT_RW where the cache line was fetched in response to a preload or prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the LL_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8260, L1I_LFB_HIT_RD_FHWPRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by L1I_LFB_HIT_RD where the cache line was fetched by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L1I_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8261, L2I_LFB_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by L2I_LFB_HIT_RD where the cache line was fetched by a hardware prefetcher.
That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction
or unified cache, and so does not generate a new refill, but has to wait for the previous refill to
complete, and the L2I_CACHE_REFILL_HWPRF event was generated when the cache line was
fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the
event is not generated again for the same cache line while it remains in the cache.

0x8264, L1D_LFB_HIT_RD_FHWPRF, Level 1 data cache demand line-fill buffer first hit, read, recently
fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L1D_LFB_HIT_RW_FHWPRF that is a demand Memory-read operation.

0x8265, L2D_LFB_HIT_RD_FHWPRF, Level 2 data cache demand line-fill buffer first hit, read, recently
fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L2D_LFB_HIT_RW_FHWPRF that is a demand Memory-read operation.

0x8266, L3D_LFB_HIT_RD_FHWPRF, Level 3 data cache demand line-fill buffer first hit, read, recently
fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L3D_LFB_HIT_RW_FHWPRF that is a demand Memory-read operation.

0x8267, LL_LFB_HIT_RD_FHWPRF, Last level cache demand line-fill buffer first hit, read, recently fetched
by hardware prefetcher

The counter counts each line-fill buffer first hit counted by LL_LFB_HIT_RW_FHWPRF that is a demand Memory-read operation.

0x8268, L1D_LFB_HIT_WR_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, write,
recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L1D_LFB_HIT_RW_FHWPRF that is a demand Memory-write operation.

0x8269, L2D_LFB_HIT_WR_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, write,
recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L2D_LFB_HIT_RW_FHWPRF that is a demand Memory-write operation.

0x826A, L3D_LFB_HIT_WR_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, write,
recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by L3D_LFB_HIT_RW_FHWPRF that is a demand Memory-write operation.

0x826B, LL_LFB_HIT_WR_FHWPRF, Last level cache demand access line-fill buffer first hit, write, recently fetched
by hardware prefetcher

The counter counts each line-fill buffer first hit counted by LL_LFB_HIT_RW_FHWPRF that is a demand Memory-write operation.

0x826C, L1D_LFB_HIT_RW_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, recently
fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by L1D_LFB_HIT_RW
where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or
unified cache, and so does not generate a new refill, but has to wait for the previous refill to
complete, and the L1D_CACHE_REFILL_HWPRF event was generated when the cache line was
fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the
event is not generated again for the same cache line while it remains in the cache.
0x826D, L2D_LFB_HIT_RW_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by L2D_LFB_HIT_RW where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L2D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x826E, L3D_LFB_HIT_RW_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by L3D_LFB_HIT_RW where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L3D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x826F, LL_LFB_HIT_RW_FHWPRF, Last level cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by LL_LFB_HIT_RW where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the LL_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8270, L1L_LFB_HIT_RD_FPRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by preload or prefetch

The counter counts each line-fill buffer first hit counted by either L1L_LFB_HIT_RD_FHWPRF or L1L_LFB_HIT_RD_FPRFM.

0x8271, L2L_LFB_HIT_RD_FPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by preload or prefetch

The counter counts each line-fill buffer first hit counted by either L2L_LFB_HIT_RD_FHWPRF or L2L_LFB_HIT_RD_FPRFM.

0x8274, L1D_LFB_HIT_RD_FPRF, Level 1 data cache demand line-fill buffer first hit, read, recently fetched by preload or prefetch

The counter counts each line-fill buffer first hit counted by either L1D_LFB_HIT_RD_FHWPRF or L1D_LFB_HIT_RD_FPRFM.

0x8275, L2D_LFB_HIT_RD_FPRF, Level 2 data cache demand line-fill buffer first hit, read, recently fetched by preload or prefetch

The counter counts each line-fill buffer first hit counted by either L2D_LFB_HIT_RD_FHWPRF or L2D_LFB_HIT_RD_FPRFM.
0x8276, L3D_LFB_HIT_RD_FPRF, Level 3 data cache demand line-fill buffer first hit, read, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L3D_LFB_HIT_RD_FHWPRF or L3D_LFB_HIT_RD_FPRFM.

0x8277, LL_LFB_HIT_RD_FPRF, Last level cache demand line-fill buffer first hit, read, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either LL_LFB_HIT_RD_FHWPRF or LL_LFB_HIT_RD_FPRFM.

0x8278, L1D_LFB_HIT_WR_FPRF, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L1D_LFB_HIT_WR_FHWPRF or L1D_LFB_HIT_WR_FPRFM.

0x8279, L2D_LFB_HIT_WR_FPRF, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L2D_LFB_HIT_WR_FHWPRF or L2D_LFB_HIT_WR_FPRFM.

0x827A, L3D_LFB_HIT_WR_FPRF, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L3D_LFB_HIT_WR_FHWPRF or L3D_LFB_HIT_WR_FPRFM.

0x827B, LL_LFB_HIT_WR_FPRF, Last level cache demand access line-fill buffer first hit, write, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either LL_LFB_HIT_WR_FHWPRF or LL_LFB_HIT_WR_FPRFM.

0x827C, L1D_LFB_HIT_RW_FPRF, Level 1 data cache demand access line-fill buffer first hit, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L1D_LFB_HIT_RW_FHWPRF or L1D_LFB_HIT_RW_FPRFM.

0x827D, L2D_LFB_HIT_RW_FPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L2D_LFB_HIT_RW_FHWPRF or L2D_LFB_HIT_RW_FPRFM.

0x827E, L3D_LFB_HIT_RW_FPRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either L3D_LFB_HIT_RW_FHWPRF or L3D_LFB_HIT_RW_FPRFM.

0x827F, LL_LFB_HIT_RW_FPRF, Last level cache demand access line-fill buffer first hit, recently fetched by preload or prefetch
The counter counts each line-fill buffer first hit counted by either LL_LFB_HIT_RW_FHWPRF or LL_LFB_HIT_RW_FPRFM.

0x8280, L1I_CACHE_PRF, Level 1 instruction cache, preload or prefetch hit
The counter counts each fetch counted by either L1I_CACHE_HWPRF or L1I_CACHE_PRFM.

0x8281, L2I_CACHE_PRF, Level 2 instruction cache, preload or prefetch hit
The counter counts each fetch counted by either L2I_CACHE_HWPRF or L2I_CACHE_PRFM.

0x8284, L1D_CACHE_PRF, Level 1 data cache, preload or prefetch hit
The counter counts each fetch counted by either L1D_CACHE_HWPRF or L1D_CACHE_PRFM.
0x8285, L2D_CACHE_PRF, Level 2 data cache, preload or prefetch hit
The counter counts each fetch counted by either L2D_CACHE_HWPRF or L2D_CACHE_PRFM.

0x8286, L3D_CACHE_PRF, Level 3 data cache, preload or prefetch hit
The counter counts each fetch counted by either L3D_CACHE_HWPRF or L3D_CACHE_PRFM.

0x8287, LL_CACHE_PRF, Last level cache, preload or prefetch hit
The counter counts each fetch counted by either LL_CACHE_HWPRF or LL_CACHE_PRFM.

0x8288, L1I_CACHE_REFILL_PRF, Level 1 instruction cache refill, preload or prefetch hit
The counter counts each refill counted by either L1I_CACHE_REFILL_HWPRF or L1I_CACHE_REFILL_PRFM.

0x8289, L2I_CACHE_REFILL_PRF, Level 2 instruction cache refill, preload or prefetch hit
The counter counts each refill counted by either L2I_CACHE_REFILL_HWPRF or L2I_CACHE_REFILL_PRFM.

0x828C, L1D_CACHE_REFILL_PRF, Level 1 data cache refill, preload or prefetch hit
The counter counts each refill counted by either L1D_CACHE_REFILL_HWPRF or L1D_CACHE_REFILL_PRFM.

0x828D, L2D_CACHE_REFILL_PRF, Level 2 data cache refill, preload or prefetch hit
The counter counts each refill counted by either L2D_CACHE_REFILL_HWPRF or L2D_CACHE_REFILL_PRFM.

0x828E, L3D_CACHE_REFILL_PRF, Level 3 data cache refill, preload or prefetch hit
The counter counts each refill counted by either L3D_CACHE_REFILL_HWPRF or L3D_CACHE_REFILL_PRFM.

0x828F, LL CACHE REFILL PRF, Last level cache refill, preload or prefetch hit
The counter counts each refill counted by either LL_CACHE_REFILL_HWPRF or LL_CACHE_REFILL_PRFM.

0x8290, ISNP_HIT_PRF, Snoop hit, any instruction prefetch
The counter counts each snoop counted by either ISNP_HIT_HWPRF or ISNP_HIT_PRFM.

0x8291, ISNP_HIT_NEAR_PRF, Snoop hit in near cache, instruction preload or prefetch
The counter counts each snoop counted by either ISNP_HIT_NEAR_HWPRF or ISNP_HIT_NEAR_PRFM, that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

0x8292, ISNP_HIT_FAR_PRF, Snoop hit in far cache, instruction preload or prefetch
The counter counts each snoop counted by either ISNP_HIT_FAR_HWPRF or ISNP_HIT_FAR_PRFM, that hits in a cache outside the local PE cluster on the same device.

0x8293, ISNP_HIT_REMOTE_PRF, Snoop hit in remote cache, instruction preload or prefetch
The counter counts each snoop counted by either ISNP_HIT_REMOTE_HWPRF or ISNP_HIT_REMOTE_PRFM, that hits in a cache on a remote device.

0x8294, DSNP_HIT_PRF, Snoop hit, any data prefetch
The counter counts each snoop counted by either DSNP_HIT_HWPRF or DSNP_HIT_PRFM.

0x8295, DSNP_HIT_NEAR_PRF, Snoop hit in near cache, data preload or prefetch
The counter counts each snoop counted by either DSNP_HIT_NEAR_HWPRF or DSNP_HIT_NEAR_PRFM, that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.
0x8296, **DSNP_HIT_FAR_PRF, Snoop hit in far cache, data preload or prefetch**

The counter counts each snoop counted by either **DSNP_HIT_FAR_HWPRF** or **DSNP_HIT_FAR_PRFM**, that hits in a cache outside the local PE cluster on the same device.

0x8297, **DSNP_HIT_REMOTE_PRF, Snoop hit in remote cache, data preload or prefetch**

The counter counts each snoop counted by either **DSNP_HIT_REMOTE_HWPRF** or **DSNP_HIT_REMOTE_PRFM**, that hits in a cache on a remote device.

0x8298, **LL_CACHE_RW, Last level cache demand access**

The counter counts each access counted by **LL_CACHE** that is due to a demand Memory-read operation or demand Memory-write operation.

This includes:
- Accesses made by Speculatively executed instructions.
- Accesses to the Last level cache due to a refill of another cache caused by a demand Memory-read operation or demand Memory-write operation.

This event must be implemented if any of the following are true:
- Event **LL_CACHE_PRFM** is implemented.
- Event **LL_CACHE_HWPRF** is implemented.

0x8299, **LL_CACHE_PRFM, Last level cache software preload**

The counter counts each access counted by **LL_CACHE** that is due to a preload or prefetch instruction.

This includes accesses to the Last level cache due to a refill of another cache caused by a preload or prefetch instruction.

This event must be implemented if event **LL_CACHE_RW** is implemented.

0x829a, **LL_CACHE_REFILL, Last level cache refill**

The counter counts each access counted by **LL_CACHE** that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Last level caches, even if the data is ultimately not allocated into the Last level cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:
- Accesses to the Last level cache that cause a refill that is satisfied by fetching data from memory, or a Last level cache of another PE.
- Refills of and write-backs from any other data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Last level caches of this PE.
- Accesses to the Last level cache that cause a refill of a higher level cache of this PE from outside of the Level 1 to Last level caches of this PE, even if there is no refill of the Last level cache.

The counter does not count accesses that:
- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.
0x829B, LL_CACHE_REFILL_PRFM, Last level cache refill, software preload
The counter counts each access counted by LL_CACHE_PRFM that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

0x829C, LL_CACHE_WB, Last level cache write-back
The counter counts each write-back of data from the Last level cache to outside of the Level 1 to Last level caches. For example:
- A write-back of a dirty cache line to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Last level cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:
- A transfer of a dirty cache line from the Last level cache to outside of Level 1 to Last level caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:
- The invalidation of a cache line without any write-back to outside of the Level 1 to Last level caches or memory.
- Writes that write through the Last level cache to outside of the Level 1 to Last level caches.
- Transfers of data from the Last level cache to another cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache. An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

0x829D, LL_CACHE_WR, Last level cache access, write
If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is a Memory-write operation.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is a Memory-write operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

0x829F, LL_CACHE_REFILL_WR, Last level cache refill, write
The counter counts each access counted by both LL_CACHE_REFILL and LL_CACHE_WR.
That is, every refill of the Last level cache counted by LL_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared, the counter counts only events Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0b1, other PEs in the multithreaded implementation. If the cache is not shared, all events are counted.

0x82A0, MEM_ACCESS_RW, Data memory access, demand access
The counter counts each access counted by MEM_ACCESS that is a demand Memory-read operation or demand Memory-write operation.
This includes accesses made by speculative instructions.
0x82A1, **INST_FETCH_RD, Instruction memory access, demand fetch**

The counter counts each fetch counted by **INST_FETCH** that is a demand fetch.

This includes any fetch made for a speculative instruction.

0x82A2, **MEM_ACCESS_PRFM, Data memory access, preload**

The counter counts each access counted by **MEM_ACCESS** that is due to a software preload instruction.

0x82A3, **INST_FETCH_PRFM, Instruction memory access, preload**

The counter counts each access counted by **INST_FETCH** that is due to a software preload instruction.

### D11.11.4 Cycle event counting

The **CPU_CYCLES** event and the cycle counter, **PMCCNTR**, count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is implementation specific whether **CPU_CYCLES** and **PMCCNTR** count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as **STALL**, **STALL_FRONTEND** and **STALL_BACKEND** that are defined to only count cycles that are counted by the **CPU_CYCLES** event have the same limitation.

### Multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- **Simultaneous Multithreading** (SMT), where every PE thread is active on every Processor cycle.
- **Fine-grained Multithreading** (FGMT), also known as a Barrel processor, where one PE thread is active on each Processor cycle, and this changes regularly.
- **Switch on Event Multithreading** (SoEMT), also known as **Coarse-grained Multithreading** (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is implementation specific whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, and the **Effective value** of **PMEVTYPER<n>_EL0.MT** bit is 0, the **CPU_CYCLES** event does not count Processor cycles on which the thread was not active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the **CPU_CYCLES** event counts every Processor cycle.
- For a particular FGMT implementation, that alternates between two threads on each Processor cycle, the **CPU_CYCLES** event counts every other Processor cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the **CPU_CYCLES** event does not count Processor cycles, as the PE thread is not active.

If the **Effective value** of **PMEVTYPER<n>_EL0.MT** bit is 1, the **CPU_CYCLES** event counts each Processor cycle, and can only count a maximum of one each Processor cycle.

Events that only count cycles that are counted by the **CPU_CYCLES** event have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as **STALL_BACKEND** cycles.

If the **Effective value** of **PMEVTYPER<n>_EL0.MT** bit is 1, the PE only counts cycles on which no operation is issued from any thread.
The cycle counter, PMCCNTR, is not affected by whether the thread is active or inactive. When enabled, PMCCNTR counts every processor cycle.

See Multithreaded implementations on page D11-5258, MDCR_EL3.MTPME, SDCR.MTPME, MDCR_EL2.MTPME, and HDR.C.MTPME for more information about when the Effective value of PMEVTYPE<\n>_EL0.MT is 0.

D11.11.5 Meaningful combinations of common microarchitectural events

The architecture highlights some meaningful combinations of common microarchitectural events. The following tables list the highlighted combinations:

- Table D11-9 on page D11-5422, REFILL events and associated access events.
- Table D11-10 on page D11-5423, Meaningful combinations of latency events.
- Table D11-11 on page D11-5423, Cache hit events and associated data source events.
- Table D11-12 on page D11-5424, Meaningful combinations of cache line state tracking events.
- Table D11-13 on page D11-5424, Meaningful combinations of TLB events.

<sup>a</sup> Similar ratios can be defined for other caches.
D11.11.6 Meaningful combinations of SVE events

Scalar-equivalent operations

The number of speculatively executed operations performed on individual scalar values, assuming that all SVE vector elements are active, can be determined from a pair of event counters. For example, the total number of individual floating-point operations performed can be computed as follows:

\[
\text{FP\_SCALE\_OPS\_SPEC} \times \text{VL} \div 128 + \text{FP\_FIXED\_OPS\_SPEC}
\]

A summary of these event pairs is given below. Combined multiply-add and multiply-subtract instructions are counted as two operations per element.

<table>
<thead>
<tr>
<th>Operation type</th>
<th>Scalable operations</th>
<th>Fixed width operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating-point operations (any precision)</td>
<td>FP_SCALE_OPS_SPEC</td>
<td>FP_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Half-precision floating-point operations</td>
<td>FP_HP_SCALE_OPS_SPEC</td>
<td>FP_HP_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Single-precision floating-point operations</td>
<td>FP_SP_SCALE_OPS_SPEC</td>
<td>FP_SP_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Double-precision floating-point operation</td>
<td>FP_DP_SCALE_OPS_SPEC</td>
<td>FP_DP_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Integer operations (any size)</td>
<td>INT_SCALE_OPS_SPEC</td>
<td>INT_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Load/store accesses (any size)</td>
<td>LDST_SCALE_OPS_SPEC</td>
<td>LDST_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Load accesses (any size)</td>
<td>LD_SCALE_OPS_SPEC</td>
<td>LD_FIXED_OPS_SPEC</td>
</tr>
<tr>
<td>Store accesses (any size)</td>
<td>ST_SCALE_OPS_SPEC</td>
<td>ST_FIXED_OPS_SPEC</td>
</tr>
</tbody>
</table>
Bytes loaded and stored

The number of bytes speculatively loaded from memory or stored to memory, assuming that all SVE vector elements are active, can be determined from a pair of event counters. For example, the total number of bytes loaded from memory can be computed as follows:

\[ \text{LD\_SCALE\_BYTES\_SPEC} \times \text{VL} \div 128 + \text{LD\_FIXED\_BYTES\_SPEC} \]

A summary of the total byte count pairs is as follows:

<table>
<thead>
<tr>
<th>Operation type</th>
<th>Scalable operations</th>
<th>Fixed width operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load/store byte count</td>
<td>LDST_SCALE_BYTES_SPEC</td>
<td>LDST_FIXED_BYTES_SPEC</td>
</tr>
<tr>
<td>Load byte count</td>
<td>LD_SCALE_BYTES_SPEC</td>
<td>LD_FIXED_BYTES_SPEC</td>
</tr>
<tr>
<td>Store byte count</td>
<td>ST_SCALE_BYTES_SPEC</td>
<td>ST_FIXED_BYTES_SPEC</td>
</tr>
</tbody>
</table>

Overall vector utilization

Vector utilization rates for SVE events which ignore the number of Active elements can be estimated by adjusting them using the following ratios:

<table>
<thead>
<tr>
<th>Numerator</th>
<th>Denominator</th>
<th>Utilization rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVE_PRED_FULL_SPEC</td>
<td>SVE_PRED_SPEC</td>
<td>All predicates active</td>
</tr>
<tr>
<td>SVE_PRED_PARTIAL_SPEC</td>
<td>SVE_PRED_SPEC</td>
<td>Partial predicates active</td>
</tr>
<tr>
<td>SVE_PRED_EMPTY_SPEC</td>
<td>SVE_PRED_SPEC</td>
<td>No predicates active</td>
</tr>
</tbody>
</table>

Vector loop efficiency

The effectiveness with which sequential or scalar source loops are vectorized can be estimated using ratios of the SVE\_PLOOP\_*\_SPEC predicated loop events, as shown in the following table:

<table>
<thead>
<tr>
<th>Numerator</th>
<th>Denominator</th>
<th>Vector loop metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVE_PLOOP_ELTS_SPEC \times VL \div 128</td>
<td>SVE_PLOOP_TERM_SPEC</td>
<td>Source level iterations per loop</td>
</tr>
<tr>
<td>SVE_PLOOP_TEST_SPEC</td>
<td>SVE_PLOOP_TERM_SPEC</td>
<td>Vectorized iterations per loop</td>
</tr>
<tr>
<td>SVE_PLOOP_ELTS_SPEC \times VL \div 128</td>
<td>SVE_PLOOP_TEST_SPEC</td>
<td>Parallelism per vector loop</td>
</tr>
</tbody>
</table>

D11.11.7 Required events

**FEAT\_PMUv3** requires that an implementation includes the following common events:

- \(0x0000\), SW\_INCR, Instruction architecturally executed, Condition code check pass, software increment.
- \(0x0003\), L1D\_CACHE\_REFILL, Level 1 data cache refill.

--- Note ---
Event \(0x0003\) is only required if the implementation includes a Level 1 data or unified cache.

--- Note ---
Event \(0x0004\), L1D\_CACHE, Level 1 data cache access.

--- Note ---
Event \(0x0004\) is only required if the implementation includes a Level 1 data or unified cache.
The Performance Monitors Extension

D11.11 PMU events and event numbers

• 0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed.
  
  **Note**
  Event 0x0010 is only required if the implementation includes program-flow prediction. However, Arm strongly recommends that the event is implemented as described in Common microarchitectural events on page D11-5317.

• 0x0011, CPU_CYCLES, Cycle.

• 0x0012, BR_PRED, Predictable branch Speculatively executed.
  
  **Note**
  Event 0x0012 is only required if the implementation includes program-flow prediction. However, Arm recommends that the event is implemented as described in Common microarchitectural events on page D11-5317.

• At least one of:
  — 0x0008, INST_RETIRED, Instruction architecturally executed.
  — 0x001B, INST_SPEC, Operation Speculatively executed.
  
  **Note**
  Arm strongly recommends that event 0x008 is implemented.

• When FEAT_PMUv3p1 is implemented:
  — 0x0023, STALL_FRONTEND, No operation issued due to the frontend.
  — 0x0024, STALL_BACKEND, No operation issued due to the backend.

• When The Scalable Vector Extension (SVE) is implemented, at least one of:
  — 0x8002, SVE_INST_RETIRED, SVE instruction architecturally retired.
  — 0x8006, SVE_INST_SPEC, SVE operation speculatively executed.

• When FEAT_SPE is implemented:
  — 0x4000, SAMPLE_POP, Statistical Profiling sample population.
  — 0x4001, SAMPLE_FEED, Statistical Profiling sample taken.
  — 0x4002, SAMPLE_FILTRATE, Statistical Profiling sample filtered.
  — 0x4003, SAMPLE_COLLISION, Statistical Profiling sample collision.

• When FEAT_PMUv3p4 is implemented:
  — 0x003C, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend.
  — 0x003D, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend.
  — 0x003E, STALL_SLOT, No operation sent for execution on a Slot.

Arm strongly recommends that the following events are implemented:

• 0x0021, BR_RETIRED.
• 0x0022, BR_MIS_PRED_RETIRED.
• 0x003A, OP_RETIRED.

When any of the following common events are implemented, all three of them are implemented:

• 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend,
• 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend,
• 0x003F, STALL_SLOT, No operation sent for execution on a Slot.

When any of the following common events are implemented, all three of them are implemented:

• 0x812A, SAMPLE_FEED_BR, Statistical Profiling sample taken, branch.
• 0x812B, SAMPLE_FEED_LD, Statistical Profiling sample taken, load.
• 0x812C, SAMPLE_FEED_ST, Statistical Profiling sample taken, store.
• 0x812D, SAMPLE_FEED_OP, Statistical Profiling sample taken, matching operation type.
• 0x812E, SAMPLE_FEED_EVENT, Statistical Profiling sample taken, matching events.
• 0x812F, SAMPLE_FEED_LAT, Statistical Profiling sample taken, exceeding minimum latency.

Arm strongly recommends that the following events are implemented:

• 0x0021, BR_RETIRED.
• 0x0022, BR_MIS_PRED_RETIRED.
• 0x003A, OP_RETIRED.
The Performance Monitors Extension

D11.11 PMU events and event numbers

D11.11.8 IMPLEMENTATION DEFINED event numbers

Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common event numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

The Arm architecture guarantees not to define any event prefixed with IMP_ as part of the standard Arm architecture.

Arm strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the STALL_FRONTEND and STALL_SLOT_FRONTEND events to count holes in instruction availability.
- Separating each of the STALL_BACKEND and STALL_SLOT_BACKEND events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.{A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The range of possible IMPLEMENTATION DEFINED event numbers is described in The PMU event number space and common events on page D11-5275.
D11.12 Performance Monitors Extension registers

Further information on the Performance Monitors Extension Registers can be found in the following sections:

• Table K17-2 on page K17-11838 lists the Performance Monitors register names for AArch32 and AArch64 states.

• Performance monitors registers on page K17-11871 summarizes the Performance Monitors Extension registers in AArch64 state.

• Performance monitors registers on page K17-11901 summarizes the Performance Monitors Extension registers in AArch32 state.
This chapter describes version 1 of the Activity Monitor Unit (AMU) architecture, AMUv1, an optional non-invasive component. It contains the following sections:

- About the Activity Monitors Extension on page D12-5430.
- Properties and behavior of the activity monitors on page D12-5431.
- AMU events and event numbers on page D12-5433.
D12.1 About the Activity Monitors Extension

The Activity Monitors Extension is an OPTIONAL extension to the Armv8.4 architecture.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, AMUv1, and interfaces to the registers defined by AMUv1, the Activity Monitors registers.

Version 1 of the Activity Monitors architecture implements:

- A counter group of four architected 64-bit event counters. The events counted by the architected event counter are fixed and architecturally defined.

  **Note**

  The Activity Monitors architecture provides space for up to 16 architected event counters. Future versions of the Activity Monitors architecture may use this space to implement additional architected event counters.

- A counter group of up to 16 auxiliary 64-bit event counters. The event counted for each auxiliary event counter may be fixed or programmable, and whether it is fixed or programmable is IMPLEMENTATION DEFINED. When the event counted by an auxiliary event counter is fixed, this event is IMPLEMENTATION DEFINED.

- Controls for enabling and disabling counters.

- When the event counted by an auxiliary event counter is programmable, controls for assigning an event to the counter.

- Controls that determine whether the activity monitor counters continue to count while the PE is halted in Debug state.

The read-only registers AMCFGR and AMCGCR provide information about features supported by the Activity Monitors Extension, the number of counter groups implemented, the total number of counters implemented, the number of counters implemented within each group, and the size of the counters.

The Activity Monitors Extension provides:

- A mandatory System register interface to the Activity Monitors registers, for both AArch64 and AArch32 states.

  *Base system registers on page K17-11883* lists the AArch64 Activity Monitors registers, and *Base system registers on page K17-11908* lists the AArch32 Activity Monitors registers. *Table K17-3 on page K17-11839* shows the relationship between the AArch64 and the AArch32 Activity Monitors register.

- Controls that allow software to enable or disable access by software running at lower Exception levels to the Activity Monitors registers.

- When FEAT_AMUv1p1 is implemented, and the hypervisor is using AArch64, offset registers that support virtualization of the Activity Monitor event counters.

- An optional external interface providing read-only memory-mapped access to the Activity Monitors registers.

  *Alphabetical index of memory-mapped registers on page K17-11911* lists the Activity Monitors memory-mapped registers. For more information on the recommended external interface, see *Chapter I4 Recommended External Interface to the Activity Monitors.*
### D12.2 Properties and behavior of the activity monitors

#### D12.2.1 Basic characteristics of the activity monitor event counters

Every activity monitor event counter is a 64-bit wrapping counter. When an activity monitor event counter wraps, the counter overflows.

**Note**

The Activity Monitor architecture does not provide support for overflow status indication or interrupts.

The state of the authentication signals do not affect counting.

Any change in clock frequency, including when a WFI and WFE instruction stops the clock, can affect any counter.

If FEAT_AMUv1p1 is implemented, for the architected event counters 0, 2 and 3, and each auxiliary event counter configured to use an offset, there is an offset register which is used to virtualize the count on a read from EL1 or EL0. At EL2, EL3 or from the memory-mapped view, permitted accesses to the counters use the physical view without any offset. See [Virtualization](page:D12-5432)

#### D12.2.2 Counter configuration and controls

For each architected event counter AMEVCNTR0<n>, there is a corresponding event type register AMEVTYPEPER0<n> which provides information on the event counted by that counter. The event type registers AMEVTYPEPER0<n> are read-only.

For each auxiliary event counter AMEVCNTR1<n>, there is a corresponding event type register AMEVTYPEPER1<n> which provides information on the event counted by that counter. When the event counted by an auxiliary event counter is fixed, the corresponding event type register AMEVTYPEPER1<n> is read-only. When the event counted by an auxiliary event counter is programmable, the corresponding event type register AMEVTYPEPER1<n> is read/write.

For each counter group, there is a pair of separate controls to enable and disable the counters in that counter group. AMCNTENCLR0 and AMCNTENSET0 are used to disable and enable the architected event counters. AMCNTENCLR1 and AMCNTENSET1 are used to disable and enable the auxiliary event counters.

While the PE is halted in Debug state, AMCR.HDBG controls whether activity monitor counting is halted.

AMUSERENR.EN controls access from EL0 to the Activity Monitor Extension System registers. CPTR_EL2.TAM and HCPTR.TAM control access from EL0 and EL1 to the Activity Monitor Extension System registers. CPTR_EL3.TAM control access from EL0, EL1, and EL2 to the Activity Monitor Extension System registers.

**Note**

These controls obey the priority order described in [Prioritization of Synchronous exceptions taken to AArch64 state](page:D1-4650) and [Synchronous exception prioritization for exceptions taken to AArch32 state](page:G1-8933).

AMUSERENR.EN is configurable at EL1, EL2, and EL3. All other controls, as well as the value of the counters, are configurable only at the highest implemented Exception level.

If FEAT_AMUv1p1 is implemented, AMCG1IDR_EL0 defines which auxiliary counters are implemented, and if virtual offsets are enabled, indicates which of the implemented auxiliary counters have a virtual offset when read from EL0 and EL1.

If FEAT_AMUv1p1 is implemented, AMCR.CG1RZ controls whether the auxiliary event counters read as zero if they are accessed at an Exception level lower than the highest implemented Exception level.

#### D12.2.3 Power and reset domains

The power domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU domain.

The reset domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU reset.
The AMU power domain may be the Core power domain.

When an AMU reset of the AMU power domain occurs, the Activity Monitoring Unit is reset and the counters are reset to zero.

When the PE is not in reset, the Activity Monitoring Unit is available.

### D12.2.4 Accuracy and non-invasive behavior

The activity monitors are a non-invasive component which must provide broadly accurate and statistically useful count information.

The implementation of an architecturally required event might create a conflict between the requirement to be non-invasive and the requirement to present an accurate value of the count under normal operating conditions. An implementation might provide an IMPLEMENTATION DEFINED control that disables accurate count of the event to restore performance and document the impact on performance of accurate counting. The expectations for non-invasive behavior and the degree of inaccuracy of the activity monitors are otherwise as described for the Performance Monitors architecture.

--- Note ---

For information on the expectations for non-invasive behavior and the degree of inaccuracy of the Performance Monitors, see Non-invasive behavior on page D11-5248 and A reasonable degree of inaccuracy on page D11-5249.

### D12.2.5 Virtualization

**FEAT_AMUv1p1** supports virtualized access to the Activity Monitors event counters at EL1 and EL0.

The fields **HCR_EL2.AMVOFFEN** and **SCR_EL3.AMVOFFEN** enable and disable virtualization. When enabled, the architected event counters 0, 2 and 3 have counter offsets. Architected event counter 1 does not have an offset. The register **AMCG1IDR_EL0** indicates which of the implemented auxiliary event counters has implemented counter offsets. An implemented event counter that does not have a defined offset has an effective offset of zero. The offset registers can be accessed only at EL2 or EL3, and affect views of the event counters at EL1 and EL0 from the System register interfaces only.

The **AMEVCNTVOFF0<n>_EL2** registers hold the offsets for the implemented and enabled architected event counters.

The **AMEVCNTVOFF1<n>_EL2** registers hold the offsets for the implemented and enabled auxiliary event counters.
D12.3 AMU events and event numbers

The Activity Monitors architecture uses the event number space defined by the Performance Monitors architecture to identify events.

The Activity Monitors architecture defines additional events and adds them to the event number space defined by the Performance Monitors architecture for common events.

If the event is counting an IMPLEMENTATION DEFINED event, it must use an event number from the IMPLEMENTATION DEFINED event space.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event.

When a common event is available to both the Performance Monitors architecture and the Activity Monitors architecture within one implementation, both architectures use the same event number.

D12.3.1 Architected event counters

Version 1 of the Activity Monitors architecture, AMUv1, requires four events to be counted by the architected activity monitor event counters.

The events required to be counted are:

0x0011, CPU_CYCLES, Processor frequency cycles
The counter increments on every cycle when the PE is not in WFI or WFE state. When the PE is in WFI or WFE state, this counter does not increment.
This event is counted by AMEVCNTR0<n>, where n is 0.

0x4004, CNT_CYCLES, Constant frequency cycles
The counter increments at a constant frequency when the PE is not in WFI or WFE state, equal to the rate of increment of the System counter, CNTPCT_EL0. When the PE is in WFI or WFE state, this counter does not increment.
This event is counted by AMEVCNTR0<n>, where n is 1.

0x0008, INST_RETIRED, Instructions retired
This event is defined identically to INST_RETIRED in the FEAT_PMUv3 architecture.
This event is counted by AMEVCNTR0<n>, where n is 2.

0x4005, STALL_BACKEND_MEM, Memory stall cycles
The counter counts cycles in which the PE is unable to dispatch instructions from the frontend to the backend of the PE due to a backend stall caused by a demand data miss in the last level of data or unified cache within the PE clock domain or, if Armv8.7 is implemented, a non-cacheable data access in progress.
If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable data access is in progress.
This event is counted by AMEVCNTR0<n>, where n is 3.

D12.3.2 Auxiliary event counters

Auxiliary event counters can count events defined by the Performance Monitors architecture and IMPLEMENTATION DEFINED events defined specifically for activity monitoring.

Implementations must not reuse an IMPLEMENTATION DEFINED event number for different hardware events across the Performance Monitors architecture and the Activity Monitors architecture.
Chapter D13
The Statistical Profiling Extension

This chapter describes the Statistical Profiling Extension. It contains the following sections:

- About the Statistical Profiling Extension on page D13-5436.
- Defining the sample population on page D13-5438.
- Controlling when an operation is sampled on page D13-5439.
- Enabling profiling on page D13-5442.
- Filtering sample records on page D13-5444.
- The profiling data on page D13-5446.
- The Profiling Buffer on page D13-5458.
- Profiling Buffer management on page D13-5463.
- Synchronization and Statistical Profiling on page D13-5468.
D13.1 About the Statistical Profiling Extension

When the Statistical Profiling Extension is implemented, the PE includes a Statistical Profiling Unit (SPU). When profiling is enabled, the SPU does the following:

1. Chooses an operation from a sample population, that can be restricted by Exception level, at a programmable interval that might have some random, or pseudorandom, perturbation.
2. Takes a trace of the sampled operation. This includes the PC, events, timings, and data addresses, related to the sampled operation. This is the profiling operation.
3. If defined, filters out potential sample records generated by the profiling operation by reference to any or all of the following:
   a. The type of operation.
   b. Events.
   c. Latency.
4. Creates a record that contains the traced information. Sample records that meet the criteria of the filter are written to and stored in a memory buffer. These sample records can be processed by software when the memory buffer is full.

D13.1.1 Non-invasive behavior

Statistical Profiling is a non-invasive debug operation:

• While profiling is enabled, the operation and performance of the processing element (PE) must not be significantly impacted between sampled operations, that is, other than for writing out sample records and processing Profiling Buffer management interrupts.
• The performance of the sampled operation and the performance of the PE in general must not be significantly impacted. The sample records are not written to memory until after the sampled operation has finished execution. However, this does not apply if the sample records are physical addresses for data access operations. In this case, the impact is IMPLEMENTATION DEFINED.
• The profiling operation to write sample records must not be excessively impactful on the performance of the sampled operation or the performance of the PE generally.

D13.1.2 PMU extensions

If the Statistical Profiling and Performance Monitors Extensions are implemented, then the following PMU events must be implemented:

• SAMPLE_POP.
• SAMPLE_FEED.
• SAMPLE_FILTRATE.
• SAMPLE_COLLISION.

Note These events are discoverable through a read of PMCEID0_EL0[35:32].

If FEAT_SPEv1p2 is implemented, the following PMU events must be implemented:

• SAMPLE_FEED_BR.
• SAMPLE_FEED_LD.
• SAMPLE_FEED_ST.
• SAMPLE_FEED_OP.
• SAMPLE_FEED_EVENT.
• SAMPLE_FEED_LAT.
D13.1.3 **Multithreaded implementations**

In a multithreaded implementation:
- Statistical Profiling is implemented per-thread.
- The sample interval counter counts only operations for the thread that is being profiled.
- Latency and other cycle counters count each cycle for the PE for which the thread was active and could issue an operation.

The architecture does not define features for inter-thread profiling and does not support sharing the Profiling Buffer between threads.

--- **Note** ---

An implementation is described as multithreaded when the lowest level of *affinity* consists of logical processors that are implemented using a multi-threading type approach. That is, the performance of processors at the lowest affinity level is very interdependent.
D13.2 Defining the sample population

All samples are taken from a population of operations. The population is dynamic rather than static. That is, if a program executes the same operation multiple times (for example, because of loops and subroutines) then that operation appears multiple times in the population.

The operations are an implementation defined choice between:

- Architecture instructions.
- IMPLEMENTATION DEFINED microarchitectural operations (micro-ops).

Architecture instruction means a single instruction that is defined by the Armv8 instruction set architecture in AArch64 state.

An architecture instruction might create one or more micro-ops at any point in the execution pipeline. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the execution stream, so an architecture instruction might create no micro-ops for an instruction.

Any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted. In some implementations, the relationship between architecture instructions and micro-ops might vary over time.

Note
Sampling from architecture instructions does not require that the instruction is architecturally executed.

D13.2.1 Operations that might be excluded from the sample population

It is implementation defined whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations (specifically micro-ops) that do not relate to any architecture instruction.
- Operations that generate non-architectural exceptions.

If the operation is not part of the sample population, the operation does not cause the sample interval counter to decrement, is not counted by the SAMPLE_POP event and therefore is never sampled.

If the operation is part of the sample population, the operation causes the sample interval counter to decrement, is counted by the SAMPLE_POP event, and might be sampled and counted by the SAMPLE_FEED event. However, it is implementation defined whether the sample record for such a sampled operation is captured in the Profiling Buffer. For more information, see Sample operation records for misspeculated and non-architectural operations on page D13-5454 and Non-architectural exceptions on page D13-5457.

If such a sample record is not captured into the Profiling Buffer, then no packets are output and the sample is not counted by the SAMPLE_FILTRATE event.

Note
If the owning Exception level passes this data to less privileged software for processing, it can set PMSFCR_EL1.FE to 1 and PMSEVFR_EL1[1] to 1 to prevent speculative instructions from being recorded in the Profiling Buffer.
D13.3 Controlling when an operation is sampled

The sample interval counter, PMSICR_EL1.COUNT controls when an operation is selected for sampling. In some implementations, a secondary sample interval counter, PMSICR_EL1.ECOUNT, is also used.

The following sections describe the operation of the sample interval counters.

Details of the random or pseudorandom number generator used when PMSIRR_EL1.RND is set to 1 are IMPLEMENTATION DEFINED. See Generating random numbers for sampling.

D13.3.1 Operation sampling

A sample operation is as follows:

1. A sampling interval is written to PMSICR_EL1.COUNT by software. The interval is measured in operations.
2. The sample interval counter is decremented by hardware for each operation when sampling is enabled.
3. When the sample interval counter reaches zero, then:
   a. If random perturbation is enabled, the PE continues to count for a random number of further operations while sampling is enabled.
   b. An operation is chosen for profiling. The choice of operation around the sampling point is implementation-specific, but does not introduce sampling bias.
4. The sample interval counter is reloaded and the process loops to step 2. It is IMPLEMENTATION DEFINED whether the sample interval counter is reloaded before step 3.a) or at step 3.b). That is, before or after counting the random number of further operations.
5. The chosen operation is marked as the sampled operation. The PE collects information about the sampled operation as it executes by a profiling operation.
6. The sample record is created when the sampled operation has finished execution.

D13.3.2 Generating random numbers for sampling

The random number generator is IMPLEMENTATION DEFINED. Implementations might use a pseudorandom number. The random number generator must be reset into a useable state. An implementation might include IMPLEMENTATION DEFINED registers to further configure the random number generator.

It is IMPLEMENTATION DEFINED whether the PE adds the random number to the sample interval counter prior to counting down the interval, or after the counter reaches zero and the counter has been reloaded.

D13.3.3 Initializing the sample interval counters

When the PE moves from a state where profiling is disabled to a state where profiling is enabled:

- If PMSICR_EL1 is nonzero, then sampling restarts from the current values in PMSICR_EL1.
- If PMSICR_EL1 is zero, then it is loaded with an initial value. The behavior depends on PMSIRR_EL1.RND and an IMPLEMENTATION DEFINED choice discoverable by a read of PMSIDR_EL1.ERnd.
  - If PMSIRR_EL1.RND is 0:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to 0x00.
  - If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range 0x00 to 0xFF.
  - If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 1:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to 0x00.
D13.3.4 Behavior of the sample interval counter while profiling is enabled

While profiling is enabled, the counters control when an operation is selected for sampling. The behavior depends on PMSIRR_EL1.RND and an IMPLEMENTATION DEFINED choice discoverable in PMSIDR_EL1.ERnd.

If PMSIRR_EL1.RND is 0:

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to 0x00.

Note

Because the counter counts down to zero, when PMSIRR_EL1.RND is 0 the interval between operations being selected for sampling is (INTERVAL×256+1).

If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range 0x00 to 0xFF.

Note

When PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 0, the mean interval between operations being selected for sampling is (INTERVAL×256+128), if the random number generator is uniform.

If PMSIRR_EL1.RND is 1 and PMSIDR_EL1.ERnd is 1

While nonzero, the primary sample interval counter decrements by 1 for each member of the sample population. When the primary counter reaches zero:

- The primary sample interval counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to 0x00.
- The secondary sample interval counter, PMSICR_EL1.ECOUNT, is set to a random or pseudorandom value in the range 0x00 to 0xFF.

While the secondary sample interval counter is nonzero, the secondary sample interval counter decrements by 1 for each member of the sample population. The primary sample interval counter also continues to decrement because it is also nonzero.

When the secondary sample interval counter reaches zero, an operation is selected for sampling.

Note

When PMSIRR_EL1.RND is set to 1 and PMSIDR_EL1.ERnd is 1, the mean interval between operations being selected for sampling is (INTERVAL×256+1), if the random number generator is uniform.
D13.3.5 Behavior of the sample interval counter while profiling is disabled

When profiling is disabled:
• No operations are selected for sampling.
• No sample records are collected.
• The sample interval counters retain their values and do not decrement.

D13.3.6 Where operations are sampled

The exact point in the sampled lifespan of operations at which operations are chosen for profiling is IMPLEMENTATION DEFINED.

Note
Arm recommends that the point at which operations are sampled is linked to the definition of the Performance Monitors Extension (PMU) STALL_FRONTEND and STALL_BACKEND events, so that sampling records information for STALL_BACKEND stalls.

D13.3.7 Sample collisions

The maximum number of sampled operations that a PE can support simultaneously is IMPLEMENTATION DEFINED. If the maximum number of simultaneous sampled operations has been reached at the point when a new operation must be sampled, the new sample is said to have collided with a previous sampled operation.

The PE records the fact that a sampled operation has collided with another sampled operation. Software can also count the number of collisions and gauge the impact of the collisions.

On a sample collision:
• The PMU event SAMPLE_COLLISION is generated.
• PMBSR_EL1.COLL is set to 1.
• The new operation is not sampled.

Following a context synchronization event an indirect write to PMBSR_EL1.COLL is guaranteed to be visible to instructions in program order after the sampled operation that collided. There is no guarantee of visibility without a context synchronization event. For more information, see Synchronization and Statistical Profiling on page D13-5468.

Note
This means that following a context synchronization event PMBSR_EL1.COLL will not change on entry to a state where profiling is disabled.
D13.4 Enabling profiling

Profiling is enabled when all of the following are true:

- The PE is in AArch64 state.
- PMBLIMITR_EL1.E is 1 and PMBSR_EL1.S is 0.
- The PE is executing at either the Profiling Buffer owning Exception level or any lower Exception level.
- The PE is executing in the Security state of the Profiling Buffer owning Exception level.
- The PE is in Non-debug state.
- PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} enable profiling at the current Exception level.

Note

The owning Exception level is controlled by MDCR_EL3.NSPB and MDCR_EL2.E2PB. See *The owning Exception level* on page D13-5459.

PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} enable sampling by Exception level:

- In a guest operating system or Secure state, PMSCR_EL1.E1SPE enables profiling at EL1 and PMSCR_EL1.E0SPE at EL0.
- In a hypervisor or host operating system, PMSCR_EL2.E2SPE enables profiling at EL2 and PMSCR_EL2.E0HSPE at EL0.
- Sampling is always disabled at EL3.

Table D13-1 on page D13-5442 defines the valid combinations of the Effective values of SCR_EL3.NS, SCR_EL3.EEL2, MDCR_EL3.NSPB, MDCR_EL2.E2PB, and HCR_EL2.TGE that define when sampling is enabled.

In Table D13-1 on page D13-5442:

D Disabled.

E2SPE Enabled if PMSCR_EL2.E2SPE == 1, disabled otherwise.

E1SPE Enabled if PMSCR_EL1.E1SPE == 1, disabled otherwise.

E0HSPE Enabled if PMSCR_EL2.E0HSPE == 1, disabled otherwise.

E0SPE Enabled if PMSCR_EL1.E0SPE == 1, disabled otherwise.

**Table D13-1 Enabling by Exception level and Security state (for all Exception levels using AArch64 state)**

D13.5 Filtering sample records

PMSFCR_EL1.FT enables filtering by operation type. When enabled PMSFCR_EL1.{ST, LD, B} define the collected types:

- ST enables collection of store sampled operations, including all atomic operations.
- LD enables collection of load sampled operations, including atomic operations that return a value to a register.
- B enables collection of branch sampled operations, including direct and indirect branches and exception returns.

--- Note ---
When micro-op sampling is implemented, filtering is based on the micro-op type.

Table D13-2 on page D13-5444 summarizes the controls for filtering by operation type. In this table:

Load Atomic: Refers to atomic operations which return a value to a general-purpose register. Other atomic operations are classed as Store.

D: Indicates that the operation is discarded.
C: Indicates that the operation is collected.
C/D: Indicates it is CONstrained Unpredictable whether the operation is collected or discarded.

PMSFCR_EL1.FE enables filtering by a set of events that are defined by PMSEVFR_EL1. When enabled, only sampled operations with all the events in the filter set are recorded and written to the Profiling Buffer.

If FEAT_SPEv1p2 is implemented, PMSFCR_EL1.FnE enables filtering by a set of events that are defined by PMSNEVFR_EL1. When enabled, only sampled operations with all the events in the filter clear are recorded and written to the Profiling Buffer.

PMSFCR_EL1.FL enables filtering by total latency. PMSLATFR_EL1.MINLAT defines the minimum latency. When enabled, only sampled operations with a total latency greater than or equal to the minimum latency are recorded and written to the Profiling Buffer.

These controls combine together as a logical AND.
Example D13-1 Collection of sampled operations

If PMSFCR_EL1.FE is 1, PMSFCR_EL1.FnE is 0, PMSFCR_EL1.FT is 1, and PMSFCR_EL1.FL is 1, then only sampled operations that meet all of the following criteria are recorded and written to the Profiling Buffer:

- The sampled operation is one of the selected operation types.
- The operation has all of the events in the filter set.
- The total latency is equal to or greater than the minimum latency.

This is described in the pseudocode function SPEcollectRecord().

D13.5.1 Discard mode

FEAT_SPEv1p2 adds an operating mode, Discard mode, that allows all sampled operations to be discarded and not written to the Profiling Buffer. Discard mode is enabled when PMBLIMITR_EL1.FM is 0b10, and has all of the following effects:

- All profiling data is discarded after filtering.
- The PMBLIMITR_EL1.LIMIT and PMBPTR_EL1 fields are ignored. PMBPTR_EL1 does not increment for each sampled operation.
- The restrictions on setting PMBLIMITR_EL1.LIMIT and PMBPTR_EL1 do not apply, see Restrictions on the current write pointer on page D13-5458.
- Buffer management events are not generated.

Other profiling behaviors are unchanged, including:

- The discarding of profiling data logically occurs after SAMPLE_FILTRATE and other PMU events are counted.
- Sample collisions will still set PMBSR_EL1.COLL to 1.
The profiling data

Unless otherwise stated, all sample records that are generated by a profiling operation contain:

- A timestamp, if enabled. This is one of:
  - The physical counter, CNTPCT_EL0.
  - The offset physical counter, CNTPCT_EL0 - CNTPOFF_EL2. When any of the following are true, the Effective value of CNTPOFF_EL2 is 0 for all profiling purposes:
    - EL3 is using AArch32.
    - EL2 is not implemented.
    - FEAT_ECV is not implemented.
    - The Effective value of SCR_EL3.{NS,RW} is {1,0}.
    - CNTHCTL_EL2.ECV is 0.
    - SCR_EL3.ECVEn is 0.
  - The virtual counter, CNTVCT_EL0.

It is IMPLEMENTATION DEFINED how this timestamp relates to the sampled operation. It might be the time when the sampled operation was taken or any later time during the lifetime of the sampled operation, that is, up to the time when the sampled operation finishes execution.

If the Generic Timer system counter is disabled and timestamps are enabled, then it is IMPLEMENTATION DEFINED whether:

- The SPU behaves as if timestamps are disabled.
- The timestamp that is collected in the sample record is UNKNOWN.

Note: This behavior describes when CNTCR.EN is 0, the Generic Timer system counter is disabled. This behavior does not apply when the Generic Timer system counter is enabled but not accessible at the current Exception level.

- The context, if enabled, which is one or more of:
  - CONTEXTIDR_EL1.
  - CONTEXTIDR_EL2.
  - The Exception level.
  - The Security state.

- Information about whether the sampled operation generated an exception:
  - The target address for an exception generating operation is not collected.

- Information about whether the sampled operation was Architecturally executed.

If the sampled operation is Architecturally executed and does not generate an exception, the sample record also contains:

- The PC virtual address for the sampled operation.
- Information about whether the sampled operation is a branch, a load, a load atomic, a store, or other.
- Information about whether the sampled operation is conditional, conditional select, or not.
- The total latency, a cycle count from the start of the sampled operation up to the point where the operation has finished execution and is no longer capable of stalling any instruction that consumes its output.
- The issue latency, a cycle count from the start of the sampled operation up to the point when at least one part of the sampled operation starts executing. A sampled operation might be delayed, for example, because the input operands were not available.

If the sampled operation is not Architecturally executed or generates an exception, it is UNPREDICTABLE whether the record contains all or any of this information and the other information about the operation listed in this section and the following subsections. For information on exceptions being taken in sampled operations, see Exceptions on page D13-5456.
The architecture defines a set of additional data that is collected in the sample record for each sampled operation. This is described in the following subsections, and comprises:

- Events, which are required to be implemented consistently with PMU Events. For more information, see Chapter D14 Statistical Profiling Extension Sample Record Specification and Chapter D11 The Performance Monitors Extension.
- Cycle counters. Cycle count values as described in this architecture, which, for a particular implementation, are fixed with an IMPLEMENTATION DEFINED value, might be omitted from the sample record.
- Addresses.

In addition, the architecture permits IMPLEMENTATION DEFINED events, counters, and addresses to be collected.

**D13.6.1 Information collected for micro-ops**

Because architectural instructions might create zero, one, or more micro-ops, micro-ops might have different characteristics from the architectural instructions they are created from. The data collected for each micro-op is IMPLEMENTATION DEFINED. Implementations should collect the subset of data appropriate to the micro-op.

**Example D13-2 Sampling of micro-ops**

If an architectural load instruction is split into an address generation micro-op and a load micro-op, then when generating the sample record and filtering based on operation type:

- If the address generation micro-op is sampled, the sampled operation is treated as other.
- If the load micro-op is sampled, the sampled operation is treated as a load.

**D13.6.2 Additional information for each profiled branch or exception return**

For an Architecturally executed sampled branch or exception return operation, the profiling operation records:

- The sampled operation type as an unconditional branch or a conditional branch. Sampled exception returns are treated as unconditional branches by the Statistical Profiling Extension.
- If the branch is taken, the target virtual address of the branch. The target virtual address of the branch includes the Exception level and Security state of the target. The target virtual address includes the Exception level and Security state of the target. If the sampled operation is an illegal exception return, it is CONSTRAINED UNPREDICTABLE whether the context information recorded in the target virtual address is the actual target context, or the target context that is described by the SPSR.
- If the PE implements branch prediction, whether the branch was correctly predicted or mispredicted.
- Whether the branch was taken or not taken.
- Whether the branch was direct or indirect.
- If the branch is not taken, a target virtual address might be recorded. Software must treat this value if present as UNKNOWN.
- If the optional behavior in FEAT_SPEv1p2 is implemented, the target address of the most recently executed branch that was taken and retired in program order before the sampled operation.

**Note**

A sampled operation that generates an exception is not treated as a branch.

It is IMPLEMENTATION DEFINED whether an ISB instruction is treated as a branch to the next instruction.

**Previous branch target**

FEAT_SPEv1p2 adds an optional capability to record a packet for each event that provides the target address of the previous taken branch. PMSIDR_EL1.PBT describes whether this feature is implemented.

When implemented, the profiling operation records the target address of the most recent branch that was taken and retired in program order before the sampled operation.
It is IMPLEMENTATION DEFINED whether or not the profiling operation records the target address of the most recently taken branch instruction in the following cases:

- The sampled operation is not a sampled retired taken branch operation.
- The most recently taken branch instruction was a Context synchronization operation, exception-generating instruction, or exception return.
- No branch instruction has been retired, prior to the sampled operation, since the most recent Context synchronization operation or taken exception.

The profiling operation does not record the target address of the most recently taken branch instruction in the following cases:

- The most recently taken branch instruction was executed when profiling was disabled or prohibited.
- Either the most recently taken branch instruction or the sampled operation is still speculative.

### D13.6.3 Additional information for each profiled memory access operation

For an *Architecturally executed* sampled load, store, or atomic operation that does not generate an exception, the profiling operation records:

- The data virtual and, if enabled, physical addresses being accessed.
  - If the applicable Top Byte Ignore (TBI) bit is set to one, the virtual address includes any top-byte tag.
  - The physical address is the address the PE accesses in the physical address space, and so includes the Secure address space identifier.
- The sampled operation type, which includes:
  - Whether the sampled operation is a load, store, or atomic.
  - When FEAT_SPEv1p3 and FEAT_MTE are implemented, whether the sampled operation is a Tag load or store.
  - When FEAT_NV2 is implemented, whether the sampled operation is a System register access transformed into a memory access.
  - When FEAT_SPEv1p3 and FEAT_MOPS are implemented, whether the sampled operation is a Memory Copy or Memory Set load or store.
  - Whether the sampled operation is Load-Exclusive, Store-Exclusive or Load-acquire, Store-release.
  - Whether the sampled operation accesses the general-purpose or SIMD&FP registers.
- The translation latency. Cycle count from a virtual address being passed to the MMU for translation to the result of the translation being available.
- Whether the sampled operation accessed the Level 1 data cache and the result.
- Whether the sampled operation accessed the data TLB and the result.
- An optional record of whether the sampled operation accessed Last Level data cache and the result.
- An optional record of whether the sampled operation accessed another socket in a multi-socket system.
- An optional, IMPLEMENTATION DEFINED, indicator of the data source for a load. If the sampled operation makes multiple accesses, it is IMPLEMENTATION DEFINED whether this indicator combines information for all parts of the load or applies only for a chosen part of the load.
- If FEAT_SPEv1p1 is implemented, an optional indication that the sampled memory operation is non-optimal for the access size. For more information, see *Data Alignment Flag* on page D13-5451.

For each of the cache and another socket indicators, it is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this information is present for store accesses. The Last level cache and another socket indicators are optional and might not be present.

For more information, see *Events packet* on page D14-5486.

---

**Note**

A store might be marked as not accessing a cache or another socket because it microarchitecturally finished before doing so. For example, the write was placed into a write buffer. This behavior is IMPLEMENTATION DEFINED and might change from time to time, and such events must be interpreted with care.

If the sampled load, store, or atomic operation performs multiple accesses, it is IMPLEMENTATION DEFINED whether the implementation chooses to profile all of the access or a chosen part of that access.
If the implementation chooses to profile a chosen part of the access:

- It is IMPLEMENTATION DEFINED how the PE chooses the part of the access. The choice does not introduce any systematic bias.

--- Note ---

For an example of inadvertent systematic bias, consider an implementation where a multiple-register load operation is split into multiple accesses. If the PE systematically chooses the first operation at the lower address for sampling translation latency and data source indicator, and the operation is executed in a loop with an incrementing address, then the first access has better spatial locality with preceding accesses than later accesses and is more likely to both:

- Hit in the TLB, giving a shorter translation latency.
- Return data from the Level 1 data cache.

In this case, or if the PE systematically chooses the last access at the higher address, then sampling would be biased.

- If the accesses are architecturally contiguous, it is further IMPLEMENTATION DEFINED whether the recorded data virtual address is the lowest virtual address that is accessed by the sampled operation or applies to the chosen part of the access.
- If the accesses are not architecturally contiguous, the recorded data virtual address applies for the chosen part of the access.
- It is IMPLEMENTATION DEFINED whether the events and total operation latency apply to the whole operation or the chosen part of the operation.
- The translation latency applies to the chosen part of the operation, and is the count of cycles for which the chosen part of the operation is waiting for the MMU to complete an address translation.

Arm recommends that if the implementation chooses to profile a chosen part of the access, then the recorded addresses, events, and total operation latency apply to the chosen access. That is, the PE behaves as if the chosen part of the access is the sampled operation.

If the sampled load, store, or atomic operation performs a single access, or the implementation chooses to profile all parts of a multiple access:

- If the accesses are architecturally contiguous, the recorded data virtual addresses is the lowest virtual address that is accessed by the sampled operation.
- If the accesses are not architecturally contiguous, the recorded data virtual addresses apply for the chosen part of the access.
- The events and total operation latency apply to the whole operation. For example, when recording whether the sampled operation accessed the Level 1 data cache, the PE records whether any part of the access accessed the Level 1 data cache, and the result, and the total operation latency applies from the issue of the operation to the completion of all parts of the operation.
- The translation latency is an IMPLEMENTATION DEFINED choice between:
  - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation, and no part of the operation is accessing memory.
  - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation.

The sampled data physical address packet is not output if any of the following are true:

- The PE does not translate the address, for example because it does not perform the access or the address translation generates a Translation fault.
- The sampled data virtual address packet is not output.
- Sampling of physical addresses is prohibited by System register controls.

If a sampled virtual address packet is not output, or the PE does not perform the access, then all of the following apply:

- It is IMPLEMENTATION DEFINED whether the Translation latency Counter packet for the load or store is either not recorded, or recorded with a value of zero. If the access does not occur and the address is not translated, the packet is not recorded.
- It is IMPLEMENTATION DEFINED whether the bits corresponding to the access in the Events packet are recorded or always zero. If the access does not occur, these bits are zero.
Additional effects when FEAT_MTE2 is implemented and Allocation Tags are used

If profiling is enabled, each Allocation Tag covers multiple locations in a Tag Granule. It is IMPLEMENTATION DEFINED whether the implementation treats each Allocation Tag access as an access to the data location addressed in the operation, or the whole Tag Granule. That is, whether the data virtual address associated with the sampled access or chosen part of the access is the address of the location being accessed, or the lowest address covered by the same Allocation Tag or Allocation Tags.

If the operation is an access to an Allocation Tag or multiple Allocation Tags, the sampled data physical address has two possibilities:

- The address generated from translating the sampled data virtual address.
- The address generated from translating the lowest address covered by the same Allocation Tag or Allocation Tags.

If the two possibilities have different values, it is IMPLEMENTATION DEFINED which one is used as the sampled data physical address. Otherwise, the sampled data physical address is the address generated from translating the sampled data virtual address.

If FEAT_MTE and FEAT_SPEv1p3 are implemented, Tag load and store instructions are sampled using a dedicated Operation Type packet subclass, (Tags load/store). See Operation Type packet payload (load/store) on page D14-5493.

--- Note

Operations that store both Tags and data are recorded as store operations targeting the general-purpose registers or targeting an unspecified registers subclass.

---

For more information, see Chapter D9 The Memory Tagging Extension.

Additional effects when FEAT_NV2 is implemented

When the sampled operation is a System register access transformed into a memory access by the mechanism described in Enhanced support for nested virtualization on page D8-5175, the operation is recorded as an MRS or MSR operation at EL1 transformed into a load/store. If Statistical Profiling is disabled at EL2, the virtual address for the memory access is not recorded.

Additional effects when FEAT_MOPS is implemented

Memory Copy and Memory Set instructions are sampled as retired if they have started processing. This is true even if the execution is not completed at the time of sampling, for example, due to an interrupt.

Memory Copy operations CPY and CPYF are sampled using Operation Type packet subclass (Memory Copy load/store), and Memory Set operations SET and SETG are sampled using Operation Type packet subclass (Memory Set load/store).

If a sampled Memory Copy operation performs both a load and a store, then the following are true:

- The sampled data virtual address is:
  - The corresponding one of load and store addresses if the filter controls are set to sample only one of load and store operations, respectively.
  - An unbiased sampling of one of load and store addresses if the filter controls are set to sample both load and store operations.

- The value of the LDST bit in the Operation Type packet is 0 if the source address is sampled, and 1 if the destination address is sampled.
Additional effects when FEAT_LS64, FEAT_LS64_V, and FEAT_LS64_ACCDATA are implemented

FEAT_LS64, FEAT_LS64_V, and FEAT_LS64_ACCDATA add the LD64B, ST64B, ST64BV, and ST64BV0 instructions. For SPE:

- LD64B is treated as a load.
- ST64B, ST64BV, and ST64BV0 are treated as stores. ST64BV and ST64BV0 are store with return instructions and might have performance properties similar to a Device memory load. Sampled ST64BV and ST64BV0 instructions might have the following additional behaviors normally associated with sampled loads:
  - A Data Source packet is generated. This is optional for these instructions. For example, if the Data Source packet can only describe Normal memory sources, then they are not relevant for these instructions.
  - The total latency counter for the sampled operation preferably includes cycles to the point where the return value is returned to the PE.

**Note**

These behaviors are optional. The information in these packets might not be available or relevant for all implementations.

Data Alignment Flag

If FEAT_SPEv1p1 is implemented Events packet.E[11] is set to 1 for a sampled memory operation if the address alignment is non-optimal for the access size.

Address alignment is defined as *non-optimal* if that access incurs an additional performance penalty only because of the address alignment, and is unrelated to whether the access is architecturally misaligned for the access size.

**Example D13-3 Data Alignment Flag operation**

- A 32-bit word access that is not word aligned is architecturally misaligned, but (if Alignment faults are disabled) might not incur an additional penalty because of this alignment unless the word also happens to span a cache-line boundary.
- A contiguous load operation that loads a vector that is the length of two cache lines is optimally aligned if it has cache-line alignment, even though the operation makes two cache line accesses.
- A non-contiguous SVE load operation that makes a sequence of access is optimal only if all of the access are optimal.

The definition of non-optimal is IMPLEMENTATION DEFINED and support for the Alignment Flag is OPTIONAL.

**D13.6.4 Additional information for each profiled conditional instruction**

For an *Architecturally executed* sampled conditional operation that finishes execution, the profiling operation records:

- That the sampled operation was conditional.
- Whether the condition passed or failed.

A conditional compare operation is treated as a conditional operation.

It is IMPLEMENTATION DEFINED which conditional select operations (both integer and floating-point), including general-purpose, SIMD&FP, and SVE operations, are treated as conditional:

- Conditional select.
- Conditional select increment.
- Conditional select negate.
- Conditional select invert operations.
Predicated SVE operations are not conditional operations, as the conditionality of the operation is controlled by a predicate.

Micro-ops might have different characteristics from the architectural instructions they are created from. See Information collected for micro-ops on page D13-5447 for more information.

Note

If the implementation samples architectural instructions, for some alias instructions, the alias specifies the opposite condition to the machine instruction that they alias. For example, CSET and CSETM. The event as captured by SPE always captures the result of the machine instruction, not the alias.

For conditional branches, see Additional information for each profiled branch or exception return on page D13-5447.

D13.6.5 Additional information for each profiled Scalable Vector Extension operation

When FEAT_SPEv1p1 and The Scalable Vector Extension (SVE) are implemented, SVE operations are sampled as described in this section.

In this section the following terms are used:

Maximum implemented vector length

Means the implemented width of the vector registers. This value is IMPLEMENTATION DEFINED.

Accessible vector length

Means the accessible width of the SVE vector registers at the current Exception level, as constrained by the ZCR_EL1, ZCR_EL2 or ZCR_EL3 System registers. The Accessible vector length is always less-than-or-equal-to the Maximum implemented vector length.

Sampled SVE operation

Means an instruction or micro-operation defined by the Arm Architecture Reference Manual Supplement: The Scalable Vector Extension (SVE), for Armv8-A and sampled by the SPU that has a vector or a predicate as an input or output. This includes instructions with scalar outputs, but excludes the Non-SIMD SVE instructions.

If an implementation samples micro-operations, then it is IMPLEMENTATION DEFINED, and might vary between operation types, whether an operation for which all the following are true is treated as a Sampled SVE operation or the equivalent Advanced SIMD operation:

• The Accessible vector length is 128 bits.
• The operation is unpredicated, and does not have a predicate register as an input or output.
• The operation has an equivalent Advanced SIMD operation.

This includes SVE load and store operations where an equivalent Advanced SIMD operation is defined.

Sampled operation vector

Means the portion of the accessible vector operated on by the Sampled SVE operation.

Effective vector length

Is the length of the Sampled operation vector. The Effective vector length is always less-than-or-equal-to the Accessible vector length.

Note

The Accessible vector length is always quantized into multiples of 128-bits. However, the Sampled operation vector can be any size down to the element size of the operation.
Sampled predicated SVE operation

Means a Sampled SVE operation that is one of:

- An SVE operation that writes to a vector destination register under a Governing predicate using either zeroing or merging predication.
- A predicated store of a vector register or registers.

For an implementation that samples micro-operations, an SVE instruction might be split up into one or more micro-operations, some of which are predicated and some of which are not predicated.

Note

Sampled predicated SVE operation excludes operations that do not write a vector register, or do so but not using zeroing or merging predication, and applies to machine instructions rather than aliases. For example, the following instructions are not predicated SVE instructions under this definition:

- CNTP, LASTA, and PTRUE do not write to vector registers.
- FADDV, and SMAXV write scalar values to SIMD&FP registers.
- COMPACT and SEL (vectors) write to vector registers, and have a predicate operand, but do not use that predicate as a Governing predicate for zeroing or merging predication.
- MOV (vector, predicated) appears to be a predicated SVE instruction because it specifies merging predication through the <PG>/M operand, but it is actually an alias for the SEL (vectors) instruction.

If an implementation samples micro-operations, it is IMPLEMENTATION DEFINED whether individual elements, or groups of elements, are treated as single micro-operations.

The division of instructions into micro-operations must be fixed prior to sampling to guarantee consistently accurate statistical sampling.

Example D13-4 Vector length

For example, to support a vector length of 1024 bits, an implementation might split all instructions into four micro-operations on 256-bit vector paths. The implementation must, however, implement 1024-bit wide vector registers.

This behavior might vary based on operation type. For example, an implementation that has a full-width data-path for most operations might choose to break certain complex operations, such as non-contiguous load or stores, into shorter vectors.

Example D13-5 Accessible vector length less-than the Maximum implemented

To support an Accessible vector length less-than the Maximum implemented vector length, an implementation might choose to do all operations at the Maximum implemented vector length and discard the results above the Accessible vector length. Discarded results, arising from difference between Maximum implemented vector length and Accessible vector length, do not form part of the sampled operation and the Effective vector length must not include any discarded portions of the vector.

Results discarded because of predication are part of the sampled operation.

For a sampled SVE cache prefetch operation:

- The profiling operation captures an IMPLEMENTATION DEFINED subset of the information captured for an SVE load instruction.
- The profiling operation treats the operation type as Other when generating the sample records and filtering based on operation.
• It is IMPLEMENTATION DEFINED whether the operation is treated as a Sampled SVE operation:
  — If treated as a Sampled SVE operation, the Operation Type packet payload format is the Operation Type packet on page D14-5491.
  — If not treated as a Sampled SVE operation, the Operation Type packet format is the Operation Type packet payload (Other) on page D14-5491.

For a Sampled SVE operation, the Operation Type packet is one of:
• The SVE operation format.
• The SVE load or store format.

For a Sampled SVE operation, the Operation Type packet.EVL field records an upper bound on the Effective vector length. The value recorded in the Operation Type packet.EVL field is the Effective vector length rounded up to a power-of-two value.

For a Sampled SVE operation that is a Sampled predicated SVE operation;
• Operation Type packet.PRED, Predicated SVE operation, is set to 1.
• If any elements in the Sampled operation vector are Inactive elements, then Events packet.E[17], Partial predicate, is set to 1.
• If all elements in the Sampled operation vector are Inactive elements, then Events packet.E[18], Empty predicate, is set to 1 and Events packet.E[17] (Partial predicate) is set to 1.
• If all elements in the Sampled operation vector are Active elements then Events packet.E[18:17] is set to 0b00.

For a Sampled SVE operation that is not a Sampled predicated SVE operation:
• Operation Type packet.PRED, Predicated SVE operation, is set to 0.
• Events packet.E[18:17] is set to 0b00.

For a sampled non-contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is the address accessed by a random one of the load or store operations chosen from the Sampled operation vector. If the chosen load or store operation is for an Inactive element, the data virtual address packet is not output.

For more information on memory access operations, see Additional information for each profiled memory access operation on page D13-5448.

For a sampled contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is an IMPLEMENTATION DEFINED choice of:
• The address accessed for the lowest element in the Sampled operation vector.
• The address used for the access containing the lowest Active element in the Sampled operation vector.

If the corresponding element is an Inactive element, it is IMPLEMENTATION DEFINED whether the data virtual address packet is output.

**D13.6.6 Sample operation records for misspeculated and non-architectural operations**

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:
• Operations on misspeculated paths.
• Operations that do not relate to any architecture instruction.

If the operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for the sampled operation is captured in the Profiling Buffer. For more information, see Operations that might be excluded from the sample population on page D13-5438.

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then some information for the operation might not be present. However, the Events packet and either the End packet or the Timestamp packet is always output. Neither event 0 (generated exception) nor event 1 (architecturally retired) will be set in the Events packet.

The record must not contain information that cannot be accessed by privileged software of the owning Exception level.
D13.6.7 Additional information for other operations

For cache maintenance operations by virtual address, cache prefetch, other than SVE cache prefetch, or address translation instructions, the profiling operation:

- Captures an IMPLEMENTATION DEFINED subset of the information captured for a load instruction.
- Treats the operation type as other when generating the sample record and filtering based on operation type.

See Filtering sample records on page D13-5444, Operation Type packet and Additional information for each profiled Scalable Vector Extension operation on page D13-5452.

D13.6.8 Controlling the data that is collected

Certain data in sample records is collected only if permitted by one or both of EL1 and EL2. This is to restrict exposure of data to a lower Exception level or to Non-secure state.

CONTEXTIDR_EL1 is collected only if PMSCR_EL1.CX is set to 1, the PE is executing at EL1 or EL0 and any of the following are true when an operation is sampled:

- EL2 is not implemented.
- FEAT_SEL2 is implemented and EL2 is disabled for the current Security state.
- The Effective value of HCR_EL2.TGE is 0.

CONTEXTIDR_EL2 is collected only if the Effective value of PMSCR_EL2.CX is 1 and EL2 is implemented and enabled for the current Security state.

This is described in the pseudocode functions CollectContextIDR1() and CollectContextIDR2().

Timestamps are collected only if one of the following is true:

- PMSCR_EL1.TS is set to 1 and the Profiling Buffer is owned by EL1.
- PMSCR_EL2.TS is set to 1 and the Profiling Buffer is owned by EL2.

The timestamp is a choice between:

- Physical time, which is defined by the physical count value returned by PhysicalCountInt().
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of (PhysicalCountInt() - CNTPOFF_EL2). However, the physical offset is treated as zero if FEAT_ECV is disabled.
- Virtual time, which is defined as the value of (PhysicalCountInt() - CNTVOFF_EL2). However, the virtual offset is treated as zero if a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

Table D13-3 on page D13-5456 summarizes the choice of value for the Timestamp packet when FEAT_ECV is implemented and StatisticalProfilingEnabled() is TRUE. In Table D13-3 on page D13-5456:

**Owning EL** This is the Exception level that owns the Profiling Buffer. This is returned by the function ProfilingBufferOwner(). If EL2 is disabled in the current Security state, this is always EL1.

**EL2 enabled** This is TRUE when EL2 is enabled in the current Security state. When EL2 is disabled in the current Security state, this is FALSE.

**Virtual offset** If any of the following are true, the virtual offset is zero, otherwise the virtual offset is the value of CNTVOFF_EL2:

- The Effective value of HCR_EL2.E2H is 1, and the sampled operation was executed at EL2.
- The Effective values of HCR_EL2.{E2H, TGE} is {1, 1}, and the sampled operation was executed at EL0.

**Physical offset** If any of the following are true, the physical offset is zero, otherwise the physical offset is the value of CNTPOFF_EL2:

- EL2 is not implemented.
- FEAT_ECV is not implemented.
- CNTHCTL_EL2.ECV is 0.
SCR_EL3.ECVEn is 0.

### Table D13-3 Recorded timestamp when FEAT_ECV is implemented

</tbody>
</table>

If EL2 is not implemented, see the register descriptions of PMSCR_EL1.PCT and PMSCR_EL2.PCT for details of their behavior. This behavior is described by the pseudocode function `CollectTimeStamp()`.

Physical data addresses are collected only if one of the following is true:

- PMSCR_EL1.PA is set to 1 and the Profiling Buffer is owned by Secure EL1, and Secure EL2 is disabled or not implemented.
- PMSCR_EL2.PA is set to 1 and the Profiling Buffer is owned by Secure or Non-secure EL2.
- PMSCR_EL1.PA is set to 1 and PMSCR_EL2.PA is set to 1 and either the Profiling Buffer is owned by Non-secure EL1, or the Profiling Buffer is owned by Secure EL1 and Secure EL2 is implemented and enabled.

If EL2 is not implemented or is disabled for the current Security state, the PE behaves as if PMSCR_EL2.PA is set to 1, other than for a direct read of the register.

Physical data address collection is described by the pseudocode function `CollectPhysicalAddress()`.

Enabling collection of the physical data addresses has an IMPLEMENTATION DEFINED impact on the sampled operation.

### D13.6.9 Exceptions

All sample records written to the Profiling Buffer contain the Events packet and either the End packet or the Timestamp packet.

If the sampled operation generates an exception condition, it is UNPREDICTABLE whether the sample record contains any other information. This includes operations that generate faults or other exception conditions but do not generate exceptions. For example:

- An instruction on a misspeculated path.
- A load operation that is part of a Non-fault load instruction or is not the First active element of a First-fault load instruction that generates an MMU fault or watchpoint.
- An address translation operation or prefetch instruction that generates an MMU fault.

Where a sampled operation generates an exception and the type of exception means that a particular item is not computed by the sampled operation, that information is not collected by the profiling operation. For more information, see Synchronization and Statistical Profiling on page D13-5468.
Example D13-6 Translation Faults

If a sampled operation generates a Translation Fault, the physical address for the sampled operation was not generated by the MMU and cannot be recorded.

Non-architectural exceptions

It is IMPLEMENTATION DEFINED whether operations that generate non-architectural exceptions are part of the sample population. If such an operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for a sampled operation that generates a non-architectural exception is captured in the Profiling Buffer. For more information, see Operations that might be excluded from the sample population on page D13-5438.

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then the sample might record handling of the non-architectural exception. If the sample record does not record handling of the non-architectural exception, then the sampled operation is not Architecturally executed because of the non-architectural exception and it is recorded using E[1] == 0 (operation is not architecturally executed) in the Events packet. Bit E[0] (operation generated an exception) might be used to indicate the operation did not complete because of the non-architectural exception.
The Statistical Profiling Extension

D13.7 The Profiling Buffer

The profile data is collected in a memory Profiling Buffer. The Profiling Buffer is defined by:

• \( \text{PMBPTR\_EL1} \), the current write pointer.
• \( \text{PMBLIMITR\_EL1} \), the write limit pointer.

The Profiling Buffer starts at the current write pointer and extends to the current limit pointer minus one. The write limit pointer must be aligned to the smallest implemented translation granule size. The alignment of the current write pointer is IMPLEMENTATION DEFINED.

\( \text{PMBLIMITR\_EL1} \) and \( \text{PMBPTR\_EL1} \) are virtual addresses in the stage 1 translation regime of the owning Exception level. This is called the owning translation regime.

Note

The translation of virtual addresses to physical addresses is identical to that for any other virtual address in the owning Exception level. For example, \( \text{PMBPTR\_EL1}[63:56] \) are ignored by address translation if the respective TBI bit is set to 1.

D13.7.1 Restrictions on the current write pointer

This section describes the software rules on setting the current write pointer, \( \text{PMBPTR\_EL1} \). If these rules are not followed, the value returned for a direct read of \( \text{PMBPTR\_EL1} \) is UNKNOWN, the behavior is UNPREDICTABLE, and the PE might do any of the following at any point after profiling is enabled:

• Write sample records to any writeable address in memory that is writable at the owning Exception level.
• Generate a Profiling Buffer management event, with or without indicating data loss, for one of the following reasons:
  — The Profiling Buffer is full.
  — Any MMU Fault.

When profiling becomes enabled, all the following must be true:

• The current write pointer must be at least one sample record below the write limit pointer. That is:
  \[
  \text{UInt}(\text{PMBPTR\_EL1.PTR}) \leq \text{UInt}(\text{PMBLIMITR\_EL1.LIMIT : Zeros(12)}) - 2\text{PMSIDR\_EL1.MaxSize}.
  \]
• \( \text{PMBPTR\_EL1.PTR}[63:56] \) must equal \( \text{PMBLIMITR\_EL1.LIMIT}[63:56] \).

When the Profiling Buffer is first configured, \( \text{PMBPTR\_EL1.PTR} \) must be aligned to \( \text{PMBIDR\_EL1.Align} \). That is, if \( \text{PMBIDR\_EL1.Align} \) is nonzero, \( \text{PMBPTR\_EL1.PTR} [\text{UInt}(\text{PMBIDR\_EL1.Align})-1:0] \) must be all zeros.

However, the current write pointer can usually be restored to the saved write pointer value it had when profiling was disabled, providing a PSB CSYNC and a context synchronization event were executed before reading \( \text{PMBPTR\_EL1} \):

• If no Profiling Buffer management event was signaled then profiling can be restarted from the saved write pointer. In this case, the saved write pointer points within one sample record of the write limit pointer.
• If a Profiling Buffer management event was signaled then:
  — If \( \text{PMBSR\_EL1.S} \) is restored to 1, then profiling is not being enabled, and there are no constraints on the value written to \( \text{PMBPTR\_EL1} \).
  — If \( \text{PMBSR\_EL1.S} \) is restored to 0, and the Profiling Buffer management event was caused by an MMU fault, profiling can be restarted from the saved write pointer; if \( \text{PMBSR\_EL1.\{EA, DL\}} \) did not also indicate an External abort or data loss, and the saved write pointer is at least one sample record below the write limit pointer.

Note

If a signaled MMU fault has not been corrected, the SPU generates a new MMU fault Profiling Buffer management event when it next tries to write a sample record.

— If \( \text{PMBSR\_EL1.S} \) is restored to 0, and the Profiling Buffer management event was caused by a buffer full event, the Profiling Buffer can be extended and profiling restarted from the saved write pointer; if \( \text{PMBSR\_EL1.\{EA, DL\}} \) did not also indicate an External abort or data loss and the saved write pointer is at least one sample record below the extended write limit pointer.
The current write pointer must not be restored from the saved write pointer following a Profiling Buffer management event if PMBSR_EL1.DL was set to 1.

The saved write pointer might not be aligned to 2^PMBDIR_EL1.Align and might point to within one sample record of the write limit pointer.

For more information, see Synchronization and Statistical Profiling on page D13-5468.

### D13.7.2 The owning Exception level

The owning Exception level is:

- **Non-secure EL1**, if all of the following are true:
  - Either EL3 is not implemented and the PE is executing in Non-Secure state, or MDCR_EL3.NSPB is either 0b10 or 0b11.
  - Either EL2 is not implemented, or MDCR_EL2.E2PB is either 0b10 or 0b11.

- **Non-secure EL2**, if all of the following are true:
  - EL2 is implemented.
  - Either EL3 is not implemented and the PE is executing in Non-secure state, or MDCR_EL3.NSPB is either 0b10 or 0b11.
  - MDCR_EL2.E2PB is 0b00.

- **Secure EL1**, if all of the following are true:
  - Either EL3 is not implemented and the PE is executing in Secure state, or MDCR_EL3.NSPB is either 0b00 or 0b01.
  - Either Secure EL2 is not implemented or is disabled, or MDCR_EL2.E2PB is either 0b10 or 0b11.

- **Secure EL2**, if all of the following are true:
  - Secure EL2 is implemented and enabled.
  - Either EL3 is not implemented and the PE is executing in Secure state, or MDCR_EL3.NSPB is either 0b00 or 0b01.
  - MDCR_EL2.E2PB is 0b00.

#### When the owning Exception level is Non-secure EL1

The Profiling Buffer addresses are in the Non-secure EL1&0 translation regime using the current ASID from TTBRx_EL1. This is a two-stage translation using the current VMID if EL2 is implemented and HCR_EL2.VM is 1.

If EL3 is implemented, then profiling is disabled in Secure state.

If EL2 is implemented, then profiling is disabled at EL2 and at Non-secure EL0 when HCR_EL2.TGE is 1.

#### When the owning Exception level is Non-secure EL2

The Profiling Buffer addresses are in the Non-secure EL2 translation regime. If HCR_EL2.E2H is 1, this is an EL2&0 translation regime using the current EL2&0 translation regime ASID from TTBRx_EL2.

If EL3 is implemented, then profiling is disabled in Secure state.

---

**Note**

If either HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, and the PE is executing at EL1 or EL0, the EL2 translation regime is not the current stage 1 translation regime because the current stage 1 translation regime is EL1&0.

---

#### When the owning Exception level is Secure EL1

The Profiling Buffer addresses are in the Secure EL1&0 translation regime using the current ASID from TTBRx_EL1. This is a two-stage translation using the current VMID if Secure EL2 is implemented and enabled and HCR_EL2.VM is 1.

If EL3 is implemented, then profiling is disabled in Non-secure state.
If Secure EL2 is implemented and enabled, then profiling is disabled at EL2 and at Secure EL0 when HCR_EL2.TGE is 1.

When the owning Exception level is Secure EL2

The Profiling Buffer addresses are in the Secure EL2 translation regime. If HCR_EL2.E2H is 1, this is an EL2&0 translation regime using the current EL2&0 translation regime ASID from TTBRx_EL2.

If EL3 is implemented, then profiling is disabled in Non-secure state.

Summary of the owning translation regime

Profiling is disabled if any of the following are true:

- The owning Exception level is using AArch32 state.
- PMBLIMITR_EL1.E is 0.

Table D13-4 on page D13-5460 summarizes the owning translation regime.

</table>

a. Depending on the values of HCR_EL2.{E2H,TGE}.

D13.7.3 Memory access types and coherency

 Writes to any Device memory type by the SPU occur once.

The memory type and attributes that are used for a write by the SPU to the Profiling Buffer is taken from the translation table entries for the virtual address being written to. That is:

- The writes are treated as coming from an observer that is coherent with all observers in the Shareability domain that is defined by the translation tables.
- There is no requirement to manage coherency for observers in the same Shareability domain but coherency for other observers in the system might require explicit management.

For more information, see Synchronization and Statistical Profiling on page D13-5468.

If FEAT_MTE2 is implemented, a PE will generate a Tag Unchecked access for each access to the Profiling Buffer as part of writing a sample record.

For more information on FEAT_MTE2, see Chapter D9 The Memory Tagging Extension.
Writes to the Profiling Buffer are made as privileged writes within the owning translation regime. However, the value of PSTATE.PAN is ignored for these writes and treated as zero, see Faults and watchpoints on page D13-5464.

This means that if FEAT_E0PD is implemented, the values of TCR_ELx.E0PDy, where ELx is the owning Exception level, do not apply to accesses to the Profiling Buffer made by the SPU.

D13.7.4 Memory access and crossing page boundaries

A memory access from the SPU that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- Each memory access generated by the SPU uses the memory type and Shareability attribute associated with its own address.
- The access generates an Alignment fault caused by the memory type:
  - If only the stage 1 translation generated the mismatch, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
  - If only the stage 2 translation generated the mismatch, the resulting Buffer Management event is a stage 2 Data Abort.
  - If both stages of translation generate the mismatch, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

A memory access from the SPU to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The access generates an Alignment fault caused by the memory type:
  - If only the stage 1 translation causes the boundary to be crossed, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
  - If only the stage 2 translation causes the boundary to be crossed, the resulting Buffer Management event is a stage 2 Data Abort.
  - If both stages of translation cause the boundary to be crossed, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

--- Note ---

The boundary referred to is between two Device memory regions that are both:
- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

If PMSIDR_EL1.MaxSize indicates the same value as PMBIDR_EL1.Align, then records are a fixed power-of-two size and never cross a page boundary.

D13.7.5 Cache and TLB operations

TLB maintenance operations that affect the TLB of the PE also affect any TLB caching translations for the SPU of that PE.

Cache maintenance operations that affect the caches of the PE also affect data caching by the SPU of that PE.
This means that the completion of any cache or TLB maintenance instruction includes its completion on all SPUs for PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction. See Completion and endpoint ordering on page B2-168.

D13.7.6 Effect on the exclusive monitors

If a Load-exclusive instruction or an operation between Load-exclusive and Store-exclusive instructions is sampled, and the sample record is written to an unrelated address, then to avoid a probe effect, Arm recommends that the Store-exclusive does not systematically fail on account of the sampled operation.

If a Store-exclusive instruction is sampled, and the sample record is written to an unrelated address, then the Store-exclusive must not systematically fail on account of the instruction having been sampled.
D13.8 Profiling Buffer management

A Profiling Buffer management event occurs:

- On a fault, see *Faults and watchpoints on page D13-5464.*
- On an External abort, see *External aborts on page D13-5466.*
- When the Profiling Buffer fills, see *Buffer full event on page D13-5464.*

--- Note ---

The Profiling Buffer management event behavior differs from that of the FEAT TRBE trace buffer management event.

---

On a Profiling Buffer management event:

- The service bit, PMBSR_EL1.S, is set to 1.
- The data loss bit, PMBSR_EL1.DL, is set as described in the event description.
- The Profiling Buffer management interrupt request signal, PMBIRQ, is asserted:
  - **PMBIRQ** is a level-sensitive interrupt request driven by PMBSR_EL1.S. This means that a direct write that sets PMBSR_EL1.S to 1 causes the interrupt to be asserted, and PMBIRQ remains asserted until software clears PMBSR_EL1.S to 0.
  - If a Generic Interrupt Controller (GIC) is implemented, PMBIRQ must be configured as a Private Peripheral Interrupt (PPI) in a multiprocessor system. PMBIRQ is signaled by the PE that implements the SPU.

--- Note ---

A standard PPI number is allocated by the Arm® Base System Architecture (BSA).

- Additional syndrome for the event is written to PMBSR_EL1.MSS. Unless otherwise stated in the event description, other PMBSR_EL1 fields are unchanged.

While PMBSR_EL1.S is set to 1:

- The buffer is disabled and profiling is disabled.
- All remaining buffered sample records are discarded.
- The values in PMBPTR_EL1 are retained and PMSICR_EL1 does not decrement.

Buffer full events and MMU fault Profiling Buffer management events are reported synchronously.

--- Note ---

*Reported synchronously* means that profiling is disabled before the SPU samples further operations. The interrupt exception resulting from asserting the Profiling Buffer interrupt request is an asynchronous exception.

---

It is IMPLEMENTATION DEFINED whether External aborts are reported to the SPU synchronously or asynchronously. If External aborts are reported as asynchronous:

- The External abort might not be received until after a first Profiling Buffer management event has set PMBSR_EL1.S to 1.
- Writes to the buffer might generate a second Profiling Buffer management event after the External abort has set PMBSR_EL1.S to 1.

The architecture does not require that a sample record is written sequentially by the SPU, only that:

- The SPU never writes past the PMBLIMITR_EL1 limit pointer.
- On a Profiling Buffer management interrupt, PMBSR_EL1.DL indicates whether PMBPTR_EL1 points to the first byte after the last complete sample record.
- On an MMU fault or synchronous External abort, PMBPTR_EL1 serves as a Fault Address Register.

--- Note ---

- This means that it must not be assumed that:
  - There is ever any valid data beyond the current PMBPTR_EL1 write pointer.
— The PE has not written a valid sample record between the current PMBPTR_EL1 write pointer and the PMBLIMITR_EL1 limit pointer.
— If PMBSR_EL1.DL is set to 1 on a Profiling Buffer management interrupt, that there is any valid data between the end of the last complete sample record and the current PMBPTR_EL1 write pointer.
— Any valid data has been written to the Profiling Buffer if an External abort is reported asynchronously to the SPU.

• The last complete sample record must end at most 2(PMSIDR_EL1.MaxSize) bytes below PMBPTR_EL1.

D13.8.1 Prioritization of Profiling Buffer management events

Where multiple synchronous Profiling Buffer management events occur on writing a sample record, the PE prioritizes them as follows (from highest to lowest priority):
1. Synchronous fault.
2. Synchronous External abort.
3. Buffer full event.

Asynchronous External aborts are not prioritized with respect to other events.

Note
Prioritization of Profiling Buffer management interrupt requests is managed by the interrupt controller. Profiling Buffer management events are prioritized internally by the PE.

D13.8.2 Buffer full event

If, after writing a sample record, there is not sufficient space in the Profiling Buffer for a sample record of the size indicated by PMSIDR_EL1.MaxSize, and PMBSR_EL1.S is 0, a Profiling Buffer management event is generated:
• PMBSR_EL1.EC is set to 0b000000, other buffer management event.
• The BSC field of PMBSR_EL1.MSS is set as follows:
  — PMBSR_EL1.BSC is set to 0b000001, buffer filled.
• PMBPTR_EL1 is set to the first byte after the last complete sample record. PMBSR_EL1.DL is unchanged.
• The other PMBSR_EL1 fields are unchanged.
• PMBSR_EL1.S is set to 1.

That is, the Profiling Buffer management event is generated when the PE writes past the write limit pointer minus 2(PMSIDR_EL1.MaxSize). The SPU never writes beyond the write limit pointer.

For more information, see Restrictions on the current write pointer on page D13-5458.

D13.8.3 Faults and watchpoints

Table D13-5 on page D13-5464 lists the faults that might be generated by a write to the Profiling Buffer by the SPU. Writes to the Profiling Buffer never generate watchpoints.

<table>
<thead>
<tr>
<th>Fault</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Translation</td>
<td>The translation of a virtual address to a physical address might generate a Translation fault.</td>
</tr>
<tr>
<td>Address Size</td>
<td>The translation of a virtual address to a physical address might generate an Address Size fault.</td>
</tr>
<tr>
<td>Alignment</td>
<td>If PMBPTR_EL1 is not aligned to an IMPLEMENTATION DEFINED minimum alignment, the behavior is UNPREDICTABLE and a write to the Profiling Buffer by the SPU might generate an Alignment fault. For more information, see Restrictions on the current write pointer on page D13-5458.</td>
</tr>
</tbody>
</table>
If a write to the Profiling Buffer generates a fault and PMBSR_EL1.S is 0, then a Profiling Buffer management event is generated:

- PMBSR_EL1.S is set to 1.
- PMBSR_EL1.EC is set to one of:
  - 0b100100, stage 1 Data Abort on write to the Profiling Buffer.
  - 0b100101, stage 2 Data Abort on write to the Profiling Buffer.
- The FSC field of PMBSR_EL1.MSS is set as follows:
  - PMBSR_EL1.FSC is set to indicate the type of the fault.
- PMBPTR_EL1 is set to the address that generated the fault.
- If PMBPTR_EL1 is not the address of the first byte after the last complete sample record written by the SPU, then PMBSR_EL1.DL is set to 1. Otherwise, PMBSR_EL1.DL is unchanged.
- The other PMBSR_EL1 fields are unchanged.

If a write to the Profiling Buffer generates an External abort on a translation table walk or translation table update, it is IMPLEMENTATION DEFINED whether PMBSR_EL1.EA is set to 1 or unchanged.

**Note**

Each of these faults gives rise to a Profiling Buffer management interrupt, not an actual MMU fault exception. The ESR and FAR registers are unchanged.

For more information, see *MMU fault-checking sequence* on page D8-5186.

---

### Hardware management of dirty state and the Access flag by the Statistical Profiling Extension

If FEAT_SPEv1p3 is implemented, address translations performed by the SPU manage dirty state and the Access flag. Otherwise, it is IMPLEMENTATION DEFINED whether address translations performed by the SPU manage dirty state and the Access flag. This is discoverable by software using PMBIDR_EL1.F. See *Hardware management of the dirty state on page D8-5145* and *Hardware management of the Access flag on page D8-5144*.
If the SPU manages dirty state and hardware management of dirty state is enabled for the owning translation regime, then the SPU can speculatively update the Translation Table descriptor for any Page or Block in the Statistical Profiling buffer before writing data to it, if the write is otherwise permitted. This includes the case where a buffer management event means the SPU stops writing data before the page or block is written to. For more information, see *The Profiling Buffer* on page D13-5458.

**D13.8.4 External aborts**

When a write to the Profiling Buffer generates an External abort, including an External abort on a translation table walk or translation table update, the permitted IMPLEMENTATION DEFINED behaviors are:

- The External abort is ignored.
- The External abort generates an SError interrupt exception.
- If FEAT_SPEv1p3 is not implemented, the External abort is reported to the SPU. The SPU generates a Profiling Buffer management event.

The choice of IMPLEMENTATION DEFINED behavior is not required to be the same for each of:

- An External abort on the write to the Profiling Buffer.
- An External abort on a translation table walk.
- An External abort on a translation table update.

An External abort on a translation table walk or translation table update might be treated as a synchronous MMU fault, as described by *Faults and watchpoints* on page D13-5464.

PMBIDR_EL1.EA indicates to software the mechanism used by the SPU when a write to memory generates an External abort.

The originator of the abort might additionally take other actions. For more information, see *Arm® Architecture Reference Manual Supplement: Reliability, Availability, and Serviceability (RAS), for Armv8-A*.

**The External abort is ignored**

If the External abort is ignored, this has the same visible behavior as when a write does not generate any External abort. PMBSR_EL1 is not modified.

**The External abort generates an SError interrupt exception**

If a write to the Profiling Buffer generates an External abort that is taken as an SError interrupt exception, the PE takes the SError interrupt exception as normal, and PMBSR_EL1 fields are unchanged.

**The External abort is reported to the SPU**

This behavior is not permitted if FEAT_SPEv1p3 is implemented.

If a write to the Profiling Buffer generates an External abort that is reported to the SPU:

- The External abort bit, PMBSR_EL1.EA, is set to 1.
- The SPU stops writing sample records to the Profiling Buffer. It is IMPLEMENTATION DEFINED whether an External abort on a write to the Profiling Buffer is reported as synchronous or asynchronous:
  - The External abort is reported as *synchronous* if PMBPTR_EL1 is set to the address that was externally aborted.
  - The External abort is reported as *asynchronous* if PMBPTR_EL1 is not guaranteed to be set to the address that was externally aborted.
- If the External abort is reported as asynchronous or PMBPTR_EL1 is not the address of the first byte of the sample record being written by the SPU, then PMBSR_EL1.DL is set to 1. Otherwise, PMBSR_EL1.DL is unchanged.

--- **Note** ---

Following an External abort reported asynchronously to the SPU, software must not assume that any valid data has been written to the Profiling Buffer.
• If PMBSR_EL1.S is 0, a buffer management event is generated:
  — PMBSR_EL1.S is set to 1.
  — PMBSR_EL1.EC is set to one of:
    — 0b100100, stage 1 Data Abort on write to buffer.
    — 0b100101, stage 2 Data Abort on write to buffer.
  — PMBSR_EL1.MSS is set as follows:
    — PMBSR_EL1.FSC is set to indicate a synchronous or asynchronous External abort.
• The other PMBSR_EL1 fields are unchanged.
The profiling operation of the SPU:

- Makes indirect reads and indirect writes of System registers.
- Writes to memory.
- Makes further indirect writes to PMBPTR_EL1 as a result of an External abort on a write to memory.

The indirect reads of the PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} controls when determining whether to select an operation for profiling are treated as indirect reads made by the instruction being executed, and subject to the standard requirements for synchronization.

Otherwise, although the profiling operation is generated by a sampled operation, the profiling operation executes independently of the instructions that are executed on the PE.

A DSB instruction guarantees that all memory transactions that are made by the PE are observable by writes made by a profiling operation relating to a sampled operation in program order after the DSB instruction.

A Context synchronization event guarantees that a direct write to a System register made by the PE in program order before the context synchronization event are observable by indirect reads and indirect writes of the same System register made by a profiling operation relating to a sampled operation in program order after the context synchronization event.

To synchronize previous profiling operations, software must execute a PSB CSYNC Buffer Synchronization instruction.

--- Note ---

The PSB CSYNC instruction is not defined in the AArch32 instruction set architecture.

---

Following a context synchronization event, a PSB CSYNC instruction is guaranteed to synchronize the profiling operations for all instructions that are executed in program order before the context synchronization event.

Synchronized by the PSB CSYNC instruction means:

- A direct read of a System register in program order following a PSB CSYNC instruction requires explicit synchronization to observe an indirect write to the same System register made by a profiling operation synchronized by the PSB CSYNC instruction.
- An indirect write to a System register made by a profiling operation synchronized by a PSB CSYNC instruction does not affect a direct write to the same System register made in program order following the PSB CSYNC instruction.
- A direct write to a System register in program order following a PSB CSYNC instruction is not allowed to affect an indirect read of the same System register made by a profiling operation synchronized by the PSB CSYNC instruction.
- A DSB instruction in program order following a PSB CSYNC instruction does not complete before the writes to the Profiling Buffer of sample records for profiling operations synchronized by the PSB CSYNC instruction have completed. The DSB instruction must apply to both loads and stores.

For the indirect write to PMBSR_EL1 that is made as a result of an External abort on a write of a sample record to memory, the synchronization rules apply only after the write has completed.

--- Note ---

If profiling is not disabled when the context synchronization event occurs, further profiling operations might be generated that are not guaranteed to be synchronized by the PSB CSYNC instruction.

If the PE takes an exception to an Exception level where profiling is disabled, no new operations are selected for sampling. Profiling is always disabled if the owning Exception level is a lower Exception level than the current Exception level.

---

In the absence of a context synchronization event, a PSB CSYNC instruction is not required to execute in program order with respect to sampled operations.
D13.9.1 UNPREDICTABLE behavior

In the absence of correct context synchronization events, it is UNPREDICTABLE whether an indirect read of a System register made by a profiling operation will return the old or the new values.

If the indirect reads mean that ProfilingBufferEnabled() returns FALSE when a sample record or records are about to be written to memory, then it is further UNPREDICTABLE whether the sample record or records:

- Are written to memory.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and a Profiling Buffer management event is generated:
  - PMBSR_EL1.DL is set to 1.
  - PMBSR_EL1.EC is set to 0x00.
  - PMBSR_EL1.BSC is set to 0x00 to indicate that the buffer is not full.

If SCR_EL3.NS does not match the Security state of the owning translation regime, it is UNPREDICTABLE whether an address translation made by the PE writing a sample record to memory uses the value of SCR_EL3.NS or the identity of the owning translation regime.

This means that software must execute a PSB CSYNC instruction to force any sample records to be written to the Profiling Buffer before changing context.
This chapter describes the sample records generated by the Statistical Profiling Extension. It contains the following sections:

- *About the Statistical Profiling Extension sample records* on page D14-5472.
- *Alphabetical list of Statistical Profiling Extension packets* on page D14-5475.
D14.1 About the Statistical Profiling Extension sample records

The Statistical Profiling Extension sample record format version is identified by PMSIDR_EL1.Format. The architecture currently defines only version 0.

Note

Armv8.7 defines the SPE sample record format version, allowing future architecture updates to extend or change the record format. PMSIDR_EL1.Format was previously a RES0 field in a read-only register. Software that reads and checks PMSIDR_EL1.Format on any implementation prior to Armv8.7 that includes SPE will read a value indicating format version 0 is supported.

The sample record format version 0 is self-describing and extensible. This format allows software to parse profile data even when that profile data contains extended information.

The Statistical Profiling Extension writes a series of sample records to memory, each record consisting of a sequence of packets, and each packet consisting of:

• One or two header bytes.
• Zero, 1, 2, 4, or 8 payload bytes.

D14.1.1 Headers

The first header byte encodes the number of payload bytes:

- 0x00–0x1F: Single byte header, no payload.
- 0x20–0x3F: First byte of extended header. Second byte encodes the payload length.
- 0x40–0x4F, 0x80–0x8F, 0xC0–0xCF: Header with an 8-bit payload.
- 0x50–0x5F, 0x90–0x9F, 0xD0–0xDF: Header with a 16-bit payload.
- 0x60–0x6F, 0xA0–0xAF, 0xE0–0xEF: Header with a 32-bit payload.
- 0x70–0x7F, 0xB0–0xBF, 0xF0–0xFF: Header with a 64-bit payload.

D14.1.2 Records

A record consists of multiple packets. A record comprises, in ascending address order:

• A sequence of headers, each followed by their payload byte or bytes.
• Either:
  — An End packet header.
  — A Timestamp packet.

Figures in this chapter show each packet as a sequence of bytes. Figure D14-1 on page D14-5473 shows how bytes are stored in memory in increasing addresses from left to right.
Figure D14-1 Convention for packet descriptions

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.

The header bytes and payload bytes are described in ascending memory address order. Within a payload value, values are in little-endian byte order.

The size of the access granule for writes to the Profiling Buffer by the Statistical Profiling Unit is IMPLEMENTATION DEFINED, up to a maximum of 2KB. The size of the access granule can vary from time to time.

D14.1.3 Protocol framing packets and forwards compatibility

The padding header, alignment command, Timestamp packet, and end packet are protocol framing packets that frame the records created by the Statistical Profiling Unit. Only padding headers and alignment commands are permitted between records.

--- Note ---

PMBIDR_EL1.Align defines a minimum alignment for records. However, implementations must nevertheless create a valid protocol stream that can be parsed without knowledge of the minimum alignment.

---

The packet types are described in the following sections. Software must ignore unknown packets, using the size field encoded in the header. This includes packets containing reserved values in fields.

The following sections give an overview of the Statistical Profiling Unit packets output to a memory-mapped Profiling Buffer or Device memory:

- Statistical Profiling Extension protocol packet headers

D14.1.4 Statistical Profiling Extension protocol packet headers

8-bit headers

For Address packets and Counter packets, the 8-bit header format is described as the short format.

D14.2 Alphabetical list of Statistical Profiling Extension packets

This section lists every SPE packet and their description.
D14.2.1 Address packet

The Address packet characteristics are:

**Purpose**  Provides an address value for the record. Addresses are always 64 bits.

**Attributes**  Multi-part packet comprising:

- 8 or 16-bit header.
- 64-bit payload.

Address packet header

When Extended format is used, the Address packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>0 0 1 0 0 0 0 INDEX[4:3]</td>
</tr>
<tr>
<td>Byte 1</td>
<td>1 0 0 SZ 1 1 0 INDEX[2:0]</td>
</tr>
</tbody>
</table>

When Short format is used, the Address packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>1 0 0 SZ 1 1 0 INDEX</td>
</tr>
</tbody>
</table>

**Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format**

This field reads as 0b10.

**SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format**

Payload size. The defined values of this field are:

- 0b11 Doubleword.
  
  This field reads as 0b11.

**Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format**

This bit reads as 0b0.

**Byte 0 bits [7:5], when Extended format**

This field reads as 0b001.

**Byte 0 bits [4:2], when Extended format**

This field reads-as-zero.

**INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format**

The defined values of this field are:

- 0b00000 Issued instruction virtual address (PC). Included for all operations.
- 0b00001 Branch target address:
  - It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this address is included for an Exception Return to an Exception level where profiling is disabled.
  - Included for all other branch and exception return instructions.
- 0b00010 Data access virtual address. Included for all load, store and atomic operations.
- 0b00011 Data access physical address:
  - Not included if disabled by CollectPhysicalAddress, or if the access generates an abort other than a Permission or Access Flag fault.
• It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this is included for accesses that generate Permission or Access Flag faults.
• Included for all other load, store and atomic operations.

0b00100  Previous branch target address. The target virtual address of the most recently taken branch operation in program order before the sampled operation. PMSIDR_EL1.PBT indicates whether this is implemented. This value is defined when FEAT_SPEv1p2 is implemented and reserved otherwise.

0b0011x  IMPLEMENTATION DEFINED address.

0b1xxxx  IMPLEMENTATION DEFINED address.

All other values are reserved.

In the Short format header, bits [4:3] are zero.

Address packet payload

When Data access physical address, the Address packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>

When Data access virtual address, the Address packet payload bit assignments are:

![Address packet payload bit assignments diagram for Data access virtual address]

When Instruction virtual address, the Address packet payload bit assignments are:

![Address packet payload bit assignments diagram for Instruction virtual address]

**TAG byte <7>, when Data access virtual address**

Top-byte tag.

If the value of the applicable TBI bit is one, a data access virtual address includes the top-byte tag. If the applicable TBI bit is zero, it is IMPLEMENTATION DEFINED whether this field reads as zero or holds the address tag of the applicable address.
NS, byte 7 bit [7], when Instruction virtual address
Non-secure state. The Security state associated with the address. For an issued instruction virtual address (PC) this is the Security state the instruction was executed in. For a branch target address, this is the Security state at the target of the branch. The defined values of this bit are:
0 Secure state.
1 Non-secure state.

NS, byte 7 bit [7], when Data access physical address
Physical address space identifier. The Security attribute for the physical address. The defined values of this bit are:
0 Secure physical address space.
1 Non-secure physical address space.

CH, byte 7 bit[6], when Data access physical address
When FEAT_MTE2 is implemented, Checked access identifier. Checked or Unchecked access. The defined values of this bit are:
0 Tag Unchecked access.
1 Tag Checked access.
For more information, see Chapter D9 The Memory Tagging Extension.
If FEAT_MTE2 is not implemented this bit is RAZ.
When Tag Check Faults are configured to be ignored by SCTLR_ELx.TCF or SCTLR_ELx.TCF0, it is IMPLEMENTATION DEFINED whether this bit is 1 or 0 on a Tag Checked access.

EL, byte 7 bits [6:5], when Instruction virtual address
Exception level. The Exception level associated with the address. For an issued instruction virtual address (PC) this is the Exception level the instruction was executed in. For a branch target address, this is the Exception level at the target of the branch. The defined values of this field are:
0b00 EL0.
0b01 EL1.
0b10 EL2.
0b11 EL3.

--- Note ---
For an Exception Return, the Exception level at the target of the branch might be different to the Exception level the instruction was executed in.

---

Byte 7 bits [5:4], when Data access physical address
This field reads as 0b00.

PAT, Byte 7 bits [3:0], when Data access physical address
When FEAT_MTE2 is implemented, this field provides the Physical Address Tag for a Tag Checked access. If the access is Unchecked this field reads as an IMPLEMENTATION DEFINED choice between 0b0000 and the Physical Address Tag used to perform the access.
For more information, see Chapter D9 The Memory Tagging Extension.
If FEAT_MTE2 is not implemented this field is RAZ.

Byte 7 bits [4:0], when Instruction virtual address
This field reads as 0b0000.

ADDR, bytes <6:0>
D14.2.2 Context packet

The Context packet characteristics are:

**Purpose**
Provides context information for the record.

**Attributes**
Multi-part packet comprising:
- 8-bit header.
- 32-bit payload.

### Context packet header

The Context packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SZ, byte 0 bits [5:4]</td>
<td>0b10</td>

<td></td>
</tr>
<tr>
<td></td>
<td>Identifies the context value. The defined values of this field are:</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>0b00 CONTEXTIDR_EL1. Included for all operations if enabled by CollectContextIDR1.</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>0b01 CONTEXTIDR_EL2. Included for all operations if enabled by CollectContextIDR2.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>All other values are reserved.</td>
<td></td>
</tr>
</tbody>
</table>

### Context packet payload

The Context packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>CONTEXT[7:0]</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>CONTEXT[15:8]</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>CONTEXT[23:16]</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>CONTEXT[31:24]</td>
<td></td>
</tr>
</tbody>
</table>

**CONTEXT, bytes <3:0>**

The context value.
D14.2.3 Counter packet

The Counter packet characteristics are:

**Purpose**
Count of cycles the operation spent performing all or part of its behavior. The counter value occupies the least significant bits of the payload. The remaining bits are set to zero.

**Attributes**
Multi-part packet comprising:
- 8 or 16-bit header.
- 16-bit payload.

### Counter packet header

**When Extended format**, the Counter packet header bit assignments are:

```
  7  6  5  4  3  2  1  0
0 0 0 1 0 0 0 INDEX[4:3] Byte 0
1 0 SZ 0 1 INDEX[2:0] Byte 1
```

**When Short format**, the Counter packet header bit assignments are:

```
  7  6  5  4  3  2  1  0
1 0 SZ 0 1 INDEX Byte 0
```

**Byte 1 bits [7:6], when Extended format, Byte 0 bits [7:6], when Short format**

This field reads as `0b10`.

**SZ, byte 1 bits [5:4], when Extended format, SZ, byte 0 bits [5:4], when Short format**
Payload size. The defined values of this field are:
- `0b01` Halfword.
  This field reads as `0b01`.

**Byte 1 bit [3], when Extended format, Byte 0 bit [3], when Short format**

This bit reads as `0b1`.

**Byte 0 bits [7:5], when Extended format**

This field reads as `0b001`.

**Byte 0 bits [4:2], when Extended format**

This field reads-as-zero.

**INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format, INDEX, byte 0 bits [2:0], when Short format**

The defined values of this field are:
- `0b0000` Total latency. Cycle count from the operation being dispatched for issue to the operation being microarchitecturally-finished. Included for all operations.
- `0b0001` Issue latency. Cycle count from the operation being dispatched for issue to the operation being issued for execution. This counts any delay in waiting the operation being ready to issue. Included for all operations.
- `0b0010` Translation latency. Cycle count from a virtual address being passed to the MMU for translation to the result of the translation being available. Included for all load, store and atomic operations.
- `0b0011x` IMPLEMENTATION DEFINED counter value.
0b1xxxx  IMPLEMENTATION DEFINED counter value.
All other values are reserved.
In the Short format header, bits [4:3] are zero.
For the purposes of defining these counter values:
  • Dispatched for issue means:
    — The operation has been decoded.
    — The operation might not be ready to start execution because it is waiting for input values. The operation might be put into a queue.
  • Issued for execution means the operation is ready to start executing:
    — For example, for a memory operation, this should be indicative of the cycle count from memory operation being dispatched for issue to access being initiated (virtual address).
  • Microarchitecturally-finished means:
    — The operation has completed execution and is no longer capable of stalling any instruction that consumes its output. The results of the operation are not required to be coherent or observable by other PEs.
    — It is IMPLEMENTATION DEFINED whether the operation is speculative, or has committed its results to the architectural state of the PE.
    — For example:
      — For an arithmetic, floating-point, or SIMD operation with variable timing, such as divide, the results of the operation are available.
      — For load and atomic operations that return data, all data have been returned from memory.
      — For store and atomic operations that do not return data, it is not required that the store is complete for other observers.
      — For branch operations, the branch has been resolved as taken or not taken.
      — For barrier operations, the barrier has completed.
For WFE and WFI operations, it is IMPLEMENTATION DEFINED whether:
  • The instruction is complete before the PE enters a low-power state or when the PE wakes from the low-power state.
  • Counters count in the low power state.
  • Sampling an operation is itself a wake-up event.

**Counter packet payload**

It is IMPLEMENTATION DEFINED whether Counter packet is 12-bit or 16-bit counters. PMSIDR_EL1.CountSize indicates the size of counter implemented.

When 12-bit counters are implemented, the Counter packet payload bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>COUNT[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Byte 1 bits [7:4]**

This field reads-as-zero.
COUNT, byte 1 bits [3:0], byte <0>

The counter value occupies the least significant bits of the payload. The remaining bits are set to zero. The counters are:

- Unsigned numbers.
- 12 bits.
- Saturating.
- The value 0xFFF indicates the count has saturated.

When 16-bit counters are implemented, the Counter packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>COUNT[7:0]</td>
<td>Byte 0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>COUNT[15:8]</td>
<td>Byte 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

COUNT, bytes <1:0>

The counter value occupies the least significant bits of the payload. The remaining bits are set to zero. The counters are:

- Unsigned numbers.
- 16 bits.
- Saturating.
- The value 0xFFFF indicates the count has saturated.
D14.2.4 Data Source packet

The Data Source packet characteristics are:

**Purpose**

If the implementation includes support for indicating the loaded data source, the Data Source packet indicates where the data returned for a load operation was sourced. It might also include other information, such as the state of the data at the source. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this is included for load and atomic operations that generate an External abort. It is IMPLEMENTATION DEFINED whether this is included for atomic operations that do not return data to a PE register. Included for all other load and atomic operations.

**Attributes**

Multi-part packet comprising:
- 8-bit header.
- 8 or 16-bit payload.

**Data Source packet header**

The Data Source packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7-6</td>
<td>0b01</td>
</tr>
<tr>
<td>5-4</td>
<td>Payload size. Defined values are: 0b00 - Byte, 0b01 - Halfword</td>
</tr>
<tr>
<td>3-0</td>
<td>0b0011</td>
</tr>
</tbody>
</table>

**Byte 0 bits [7:6]**

This field reads as 0b01.

**SZ, byte 0 bits [5:4]**

Payload size. The defined values of this field are:
- 0b00: Byte
- 0b01: Halfword

**Byte 0 bits [3:0]**

This field reads as 0b0011.

**Data Source packet payload**

When \(SZ = 0b00\), the Data Source packet payload bit assignments are:

```
7 6 5 4 3 2 1 0
SOURCE
```

When \(SZ = 0b01\), the Data Source packet payload bit assignments are:

```
7 6 5 4 3 2 1 0
  SOURCE[7:0]
```

```
7 6 5 4 3 2 1 0
  SOURCE[15:8]
```

**SOURCE, byte <0>**, when \(SZ = 0b00\), **SOURCE, bytes <1:0>**, when \(SZ = 0b01\)**

Because the list of data sources varies from system to system, the definition of this field is IMPLEMENTATION DEFINED. If a sampled operation generated multiple data accesses, it is IMPLEMENTATION DEFINED how the data source information is combined.
D14.2.5 End packet

The End packet characteristics are:

**Purpose**
Defines the end of a record if a Timestamp packet is not present.

**Attributes**
8-bit packet.

**Field descriptions**

The End packet bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

**Byte <0>**

This field reads as 0b00000001.
D14.2.6 Events packet

The Events packet characteristics are:

**Purpose**

Indicates up to 64 events generated by the sampled operation. If FEAT_PMUv3p1 is implemented and an event counter is configured to count PMU events, then a sampled operation that causes the event counter to be incremented has the event recorded as one, and conversely a sampled operation that does not cause the counter to be incremented is recorded as zero.

**Note**

Arm recommends that the Performance Monitors Extension implements the Events.

**Attributes**

Multi-part packet comprising:

- 8-bit header.
- 8, 16, 32, or 64-bit payload.

**Events packet header**

The Events packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>SZ</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Byte 0 bits [7:6]**

This field reads as 0b01.

**SZ, byte 0 bits [5:4]**

Payload size. The defined values of this field are:

- 0b00 Byte.
- 0b01 Halfword.
- 0b10 Word.
- 0b11 Doubleword.

Software must treat bits that are not output as zero.

**Byte 0 bits [3:0]**

This field reads as 0b0010.

**Events packet payload**

When **SZ** == 0b00, the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

When **SZ** == 0b01, the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>
When SZ == 0b10, the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>
| 0 | 0 | 0 | 0 | 0 | E[18] | E[17] | E[16] | Byte 2
| E[31:24] | Byte 3

When SZ == 0b11, the Events packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>
| 0 | 0 | 0 | 0 | 0 | E[18] | E[17] | E[16] | Byte 2
| E[31:24] | Byte 3
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 4
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 5
| E[55:48] | Byte 6
| E[63:56] | Byte 7

E[63:48], bytes <7:6>, when SZ == 0b11

Events 63 to 48. IMPLEMENTATION DEFINED.

Bytes <5:4,2>, byte 1 bit [3], when SZ == 0b11

This field reads-as-zero.

E[31:24], byte <3>, when SZ == 0b10, or when SZ == 0b11

Events 31 to 24. IMPLEMENTATION DEFINED.

E[18], byte 2 bit [18], when SZ == 0b10, or SZ == 0b11

Empty predicate.

When The Scalable Vector Extension (SVE) and FEAT_SPEv1p1 are implemented the defined values of this bit are:

0 Operation was not an SVE operation, was unpredicated or executed with all elements Active.

1 SVE operation executed with all elements Inactive.

Otherwise this bit reads-as-zero.
If \texttt{FEAT\_PMUv3} and \texttt{FEAT\_SVE} are implemented, this Event is required to be implemented consistently with \texttt{SVE\_PRED\_EMPTY\_SPEC}.

\textbf{E[17], byte 2 bit [17], when SZ == \texttt{0b10}, or SZ == \texttt{0b11}}

Partial predicate.

When The Scalable Vector Extension (SVE) and \texttt{FEAT\_SPEv1p1} are implemented the defined values of this bit are:

0 Operation was not an SVE operation, was unpredicated, or executed with all elements Active.

1 Predicated SVE operation executed with at least one Inactive element.

Otherwise this bit reads-as-zero.

If \texttt{FEAT\_PMUv3} and \texttt{FEAT\_SVE} are implemented this Event is required to be implemented consistently with \texttt{SVE\_PRED\_NOT\_FULL\_SPEC}.

\textbf{E[15:12], byte 1 bits [7:4], when SZ == \texttt{0b01, when SZ == 0b10, or when SZ == 0b11}}

Events 15 to 12. IMPLEMENTATION DEFINED.

\textbf{E[11], byte 1 bit [3], when SZ == \texttt{0b01, when SZ == 0b10, or when SZ == 0b11}}

Alignment.

When \texttt{FEAT\_SPEv1p1} is implemented the defined values of this bit are:

0 Load/store operation that was optimally aligned for the size of data being accessed.

1 Load/store operation that, due to the alignment of the address and size of data being accessed, incurred additional latency.

Otherwise this bit reads-as-zero.

If \texttt{FEAT\_PMUv3} is implemented this Event is required to be implemented consistently with \texttt{LDST\_ALIGN\_LAT}.

\textbf{E[10], byte 1 bit [2], when SZ == \texttt{0b01, when SZ == 0b10, or when SZ == 0b11}}

Remote access. The defined values of this bit are:

0 Did not cause access to another socket.

1 Load/store operation caused an access to another socket in a multi-socket system. This includes each data memory access that accesses another socket in a multi-socket system, including those that do not return data.

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If this event and \texttt{FEAT\_PMUv3} are both implemented, this event is required to be implemented consistently with \texttt{REMOTE\_ACCESS} or \texttt{REMOTE\_ACCESS\_RD}.

\textbf{E[9], byte 1 bit [1], when SZ == \texttt{0b01, when SZ == 0b10, or when SZ == 0b11}}

Last Level cache miss. The defined values of this bit are:

0 Did not miss Last Level cache.

1 Load/store operation caused an access to at least the Last Level cache but is not completed by the Last Level cache. That is, each:

- Load operation that does not return data from the Last Level cache.
- Store operation that does not update the Last Level cache.

The event is not set for operations that are completed by a cache above the Last Level cache.

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.
If this event and FEAT_PMUv3 are both implemented, this event is required to be implemented consistently with LL_CACHE_MISS or LL_CACHE_MISS_RD.

E[8], byte 1 bit [0], when SZ == 0b01, when SZ == 0b10, or when SZ == 0b11
Last Level cache access. The defined values of this bit are:
0  Did not access Last Level data or unified cache.
1  Load/store operation caused a cache access to at least the Last Level data or unified cache.

Note
The architecture does not define the Last Level cache. The Last Level cache is typically the largest cache on this device shared by all PEs in the Inner or Outer Shareable domain of this PE. In a multi-socket system, it is IMPLEMENTATION DEFINED whether this includes caches on other sockets.

This event is optional. When this event is implemented, it is further IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If this event and FEAT_PMUv3 are both implemented, this event is required to be implemented consistently with LL_CACHE or LL_CACHE_RD.

E[7], byte 0 bit [7]
Mispredicted. The defined values of this bit are:
0  Did not cause correction to the predicted program flow.
1  A branch that caused a correction to the predicted program flow.

If FEAT_PMUv3 is implemented this Event is required to be implemented consistently with either BR_MIS_PRED or BR_MIS_PRED_RETIRED.

E[6], byte 0 bit [6]
Not taken. The defined values of this bit are:
0  Did not fail condition code check.
1  A conditional instruction that failed its condition code check. This includes conditional branches, compare-and-branch, conditional select, and conditional compares:
   •  For a conditional branch or compare-and-branch instruction, this means the branch was not taken.
   •  For a conditional select, this means the second operand was written to the result.
   •  For a condition compare, this means the condition flags were set to the immediate value and not the result of the compare.

This field is valid only if the OpType defines this as either a Conditional Branch or a Conditional operation, and is RAZ otherwise.

E[5], byte 0 bit [5]
TLB walk. The defined values of this bit are:
0  Did not generate TLB walk.
1  Load/store operation that causes a refill of a data or unified TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

If FEAT_PMUv3 is implemented this Event is required to be implemented consistently with DTLB_WALK.

E[4], byte 0 bit [4]
TLB access. The defined values of this bit are:
0  Did not access TLB.
1  Load/store operation caused an access to at least the first level of data or unified TLB.
If FEAT_PMUv3 is implemented this Event is required to be implemented consistently with L1D_TLB.

E[3], byte 0 bit [3]
Level 1 Data cache refill. The defined values of this bit are:
0  Did not cause level 1 data cache refill.
1  Load/store operation caused a refill of at least the first level of data or unified cache. This includes each data memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If FEAT_PMUv3 is implemented this event is required to be implemented consistently with L1D_CACHE_REFILL or L1D_CACHE_REFILL_RD.

E[2], byte 0 bit [2]
Level 1 Data cache access. The defined values of this bit are:
0  Did not access level 1 data cache.
1  Load/store operation caused a cache access to at least the first level of data or unified cache.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether a store can finish execution before this event is generated, meaning this event is never recorded for stores.

If FEAT_PMUv3 is implemented this event is required to be implemented consistently with L1D_CACHE or L1D_CACHE_RD.

E[1], byte 0 bit [1]
Architecturally executed. The defined values of this bit are:
0  Did not retire.
1  Committed its results to the architectural state of the PE, or completed with a synchronous architectural exception.

Note
A conditional instruction can retire even if it fails its condition code check.

If FEAT_PMUv3 is implemented this Event is required to be implemented consistently with INST_RETIRED.

E[0], byte 0 bit [0]
Generated exception. The defined values of this bit are:
0  Did not generate an exception.
1  Completed with a synchronous exception.

If E[1] in the same Events packet is set to 0, then the meaning of this bit is IMPLEMENTATION DEFINED.

If FEAT_PMUv3 is implemented this Event is required to be implemented consistently with EXC_TAKEN.
### D14.2.7 Operation Type packet

The Operation Type packet characteristics are:

**Purpose**
- Defines the type of operation sampled. Included for all operations.

**Attributes**
- Multi-part packet comprising:
  - 8-bit header.
  - 8-bit payload.

#### Operation Type packet header

The Operation Type packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0 bits [7:6]</td>
<td>0b01</td>
<td>This field reads as 0b01.</td>
</tr>
<tr>
<td>SZ, byte 0 bits [5:4]</td>
<td>0b00</td>
<td>Payload size. The defined values of this field are: 0b00 Byte. This field reads as 0b00.</td>
</tr>
<tr>
<td>Byte 0 bits [3:2]</td>
<td>0b10</td>
<td>This field reads as 0b10.</td>
</tr>
<tr>
<td>CLASS, byte 0 bits [1:0]</td>
<td></td>
<td>Top-level instruction class. The defined values of this field are: 0b00 Other. 0b01 Load, store, or atomic. 0b10 Branch or exception return. All other values are reserved.</td>
</tr>
</tbody>
</table>

#### Operation Type packet payload (Other)

When Other operation, the Operation Type packet payload (Other) bit assignments are:  

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 0</td>
<td>0b0000000</td>
<td></td>
</tr>
</tbody>
</table>
When an SVE operation, the Operation Type packet payload (Other) bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EVL</td>
<td>1</td>
<td>PRED</td>
<td>FP</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SUBCLASS, byte<0>**

Second-level instruction class. Defines the type of instruction. The defined values of this field are:

- **0b0000000x** Other operation.
- **0b0xxx1xx0** SVE operation. If FEAT_SVE is implemented, and if FEAT_SPE is implemented, bits [6:4:2:1] are further defined as the EVL, PRED, and FP fields. Otherwise this value is reserved.

**EVL, byte 0 bits [6:4], when SVE operation**

Effective Vector Length. Defines the sampled operation vector length, rounded up to a power of two. That is, the length of vector operated on by the sampled operation. The defined values of this field are:

- **0b000** 32 bits.
- **0b001** 64 bits.
- **0b010** 128 bits.
- **0b011** 256 bits.
- **0b100** 512 bits.
- **0b101** 1024 bits.
- **0b110** 2048 bits.

All other values reserved.

The accessible vector length is always quantized into multiples of 128 bits. However, the effective vector length can be any size down to the smallest element size.

If the effective vector length is not a power of two, or is less than 32 bits, the value is rounded up before it is encoded in this field.

**PRED, byte 0 bit[2], when SVE operation**

Predicated SVE operation. The defined values of this bit are:

- **0** Not predicated.
- **1** Predicated SVE operation. The operation is an SVE operation that writes to a vector destination register under a Governing predicate using either zeroing or merging predication.

**FP, byte 0 bits [6:4], when SVE operation**

Floating-point operation. The defined values of this bit are:

- **0** Integer.
- **1** Floating-point.

**COND, byte 0 bit [0], when Other operation**

Conditional. The defined values of this bit are:

- **0** Unconditional operation.
- **1** Conditional select or conditional compare operation. See Additional information for each profiled conditional instruction on page D13-5451.
**Operation Type packet payload (Branch)**

The Operation Type packet payload (Branch) bit assignments are:

```
   7 6 5 4 3 2 1 0
   SUBCLASS COND Byte 0
```

**SUBCLASS, byte <0>**

Second-level instruction class. Describes the branch type. The defined values of this field are:

- 0b0000000x Direct branch.
- 0b0000001x Indirect branch.
- All other values are reserved.

**COND, byte 0 bit [0]**

Conditional. The defined values of this bit are:

- 0 Unconditional branch.
- 1 Conditional branch.

**Operation Type packet payload (load/store)**

When FEAT_NV2 transformed System register access, the Operation Type packet payload (load/store) bit assignments are:

```
   7 6 5 4 3 2 1 0
   SUBCLASS LDST Byte 0
```

When Extended load/store, the Operation Type packet payload (load/store) bit assignments are:

```
   7 6 5 4 3 2 1 0
   SUBCLASS AR EXCL AT 1 LDST Byte 0
```

When General-purpose load/store, the Operation Type packet payload (load/store) bit assignments are:

```
   7 6 5 4 3 2 1 0
   SUBCLASS 0 0 0 0 0 0 0 LDST Byte 0
```

When SIMD&FP load/store, the Operation Type packet payload (load/store) bit assignments are:

```
   7 6 5 4 3 2 1 0
   SUBCLASS 0 0 0 0 0 1 0 LDST Byte 0
```
When SVE load/store, the Operation Type packet payload (load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>SUBCLASS</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SG</td>
<td>EVL</td>
</tr>
<tr>
<td>1</td>
<td>PRED</td>
</tr>
<tr>
<td>0</td>
<td>LDST</td>
</tr>
</tbody>
</table>
```

When Unspecified load/store, the Operation type packet payload (load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>SUBCLASS</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0000000</td>
</tr>
<tr>
<td>1</td>
<td>0000000</td>
</tr>
<tr>
<td>2</td>
<td>0000000</td>
</tr>
<tr>
<td>3</td>
<td>0000000</td>
</tr>
<tr>
<td>4</td>
<td>0000000</td>
</tr>
</tbody>
</table>
```

When Tags load/store, the Operation Type packet payload (load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>SUBCLASS</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0000000</td>
</tr>
<tr>
<td>1</td>
<td>0000000</td>
</tr>
<tr>
<td>2</td>
<td>0000000</td>
</tr>
<tr>
<td>3</td>
<td>0000000</td>
</tr>
<tr>
<td>4</td>
<td>0000000</td>
</tr>
</tbody>
</table>
```

When Memory Copy load/store, the Operation Type packet payload (load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>SUBCLASS</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0000000</td>
</tr>
<tr>
<td>1</td>
<td>0000000</td>
</tr>
<tr>
<td>2</td>
<td>0000000</td>
</tr>
<tr>
<td>3</td>
<td>0000000</td>
</tr>
<tr>
<td>4</td>
<td>0000000</td>
</tr>
</tbody>
</table>
```

When Memory Set load/store, the Operation Type packet payload (load/store) bit assignments are:

```
<table>
<thead>
<tr>
<th>SUBCLASS</th>
<th>Byte 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0000000</td>
</tr>
<tr>
<td>1</td>
<td>0000000</td>
</tr>
<tr>
<td>2</td>
<td>0000000</td>
</tr>
<tr>
<td>3</td>
<td>0000000</td>
</tr>
</tbody>
</table>
```

**SUBCLASS, byte <0>**

Second-level instruction class. Indicates the load/store type. The defined values of this field are:

- **0b0000000x** A load/store targeting the general-purpose registers, other than an atomic operation, load-acquire, store-release or exclusive.
- **0b0000001x** An atomic operation, load-acquire, store-release or exclusive. Bits [4:2] are further subdivided as described by the AR, EXCL and AT fields.
- **0b0000010x** A load/store targeting the SIMD&FP registers.
- **0b0000011x** A load/store targeting the SVE registers. Bits [7:4.2] are further defined as SG, EVL and PRED fields.
- **0b0001000x** A load/store targeting unspecified registers.
  - This value is defined only if FEAT_SPEv1p1 is implemented.
  - This value is reserved otherwise.
- **0b0011000x** An MRS or MSR operation at EL1 transformed to a load/store when HCR_EL2.NV2 is 1.
  - This value is defined only if FEAT_NV2 is implemented and reserved otherwise.
0b0001010x A load/store of an Allocation Tag or multiple Allocation Tags.
This value is defined only if FEAT_SPEv1p3 and FEAT_MTE are implemented. This value is reserved otherwise.

0b0010000x A load/store from a Memory Copy operation. This value is defined only if
FEAT_SPEv1p3 and FEAT_MOPS are implemented. This value is reserved otherwise.

0b00100101 A store from a Memory Set operation. This value is defined if FEAT_SPEv1p3 and
FEAT_MOPS are implemented. This value is reserved otherwise.

All other values are reserved.

SG, byte 0 bit [7], when SVE load/store
Gather/scatter load/store. The defined values of this bit are:
0 Not gather load or scatter store.
1 Gather load or scatter store.

EVL, byte 0 bits [6:4], when SVE load/store
Effective Vector Length. Defines the sampled operation vector length, rounded up to a power of two.
That is, the length of vector operated on by the sampled operation. The defined values of this field are:
0b00 32 bits.
0b01 64 bits.
0b10 128 bits.
0b11 256 bits.
0b100 512 bits.
0b101 1024 bits.
0b110 2048 bits.
All other values reserved.
The accessible vector length is always quantized into multiples of 128 bits. However, the effective vector length can be any size down to the smallest element size.
If the effective vector length is not a power of two, or is less than 32 bits, the value is rounded up before it is encoded in this field.

AR, byte 0 bit [4], when Extended load/store
Acquire/Release. The defined values of this bit are:
0 Load/store/atomic without Acquire or Release semantics.
1 Load/store/atomic with Acquire or Release semantics.

EXCL, byte 0 bit [3], when Extended load/store
Exclusive. The defined values of this bit are:
0 Load/store/atomic without Exclusive.
1 Load/store with Exclusive.
This bit is RES0 if AT == 1.

PRED, byte 0 bit[2], when SVE load/store
Predicated SVE operation. The defined values of this bit are:
0 Not predicated.
1 Predicated SVE operation. The operation is one of the following:
   • If FEAT_SPEv1p2 is implemented, a predicated load operation that writes to one or more vector destination registers under a Governing predicate using zeroing predication.
   • A predicated store of one or more vector registers.
If FEAT_SPEv1p2 is not implemented, it is IMPLEMENTATION DEFINED whether this field is 0 or 1 for a predicated load operation that writes to one or more vector destination registers under a Governing predicate using zeroing predication.

**AT, byte 0 bit [2], when Extended load/store**
Atomic load/store. The defined values of this bit are:
- 0: Not atomic.
- 1: Atomic.

**LDST, byte 0 bit [0], when Memory Copy operation**
Store not load. The defined values of this bit are:
- 0: Load, sampled virtual address is the source address.
- 1: Store, sampled virtual address is the destination address.

**LDST, byte 0 bit [0], otherwise**
Store not load. The defined values of this bit are:
- 0: Load or swap.
- 1: Store.
This bit is always one for a Memory Set operation.
**D14.2.8 Padding**

The Padding characteristics are:

**Purpose**
Allows the PE to create alignment in the protocol buffer.

**Attributes**
8-bit packet.

**Field descriptions**

The Padding bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Byte <0>

This field reads as 0b00000000.
D14.2.9  Timestamp packet

The Timestamp packet characteristics are:

**Purpose**  The 64-bit timestamp value when the operation was sampled. The Timestamp packet must come at the end of the record. If the Timestamp packet is not present, an End packet must come at the end of the record.

**Attributes**  Multi-part packet comprising:
- 8-bit header.
- 64-bit payload.

**Timestamp packet header**

The Timestamp packet header bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
```

**Byte 0 bits [7:6]**

This field reads as 0b01.

**SZ, byte 0 bits [5:4]**

Payload size. The defined values of this field are:
- 0b11  Doubleword.
  This field reads as 0b11.

**Byte 0 bits [3:0]**

This field reads as 0b0001.
**Timestamp packet payload**

The Timestamp packet payload bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Byte</th>
</tr>
</thead>
<tbody>
<tr>
<td>TS[7:0]</td>
<td>0</td>
</tr>
<tr>

**TS, bytes <7:0>**

Timestamp value when the operation was sampled. The value depends on the result of `CollectTimeStamp()`:

- If `TimeStamp_Virtual`, this is the virtual timestamp, `CNTVCT_EL0`.
- If `TimeStamp_Physical`, this is the physical timestamp, `CNTPCT_EL0`.
- If `TimeStamp_OffsetPhysical`, this is the offset physical timestamp, `CNTPCT_EL0 - CNTPOFF_EL2`.
- If `TimeStamp_None`, the Timestamp packet is not included and an End packet must come at the end of the record.

However, if the Generic Timer System counter is disabled and `CollectTimeStamp()` returns a value other than `TimeStamp_None`, then it is IMPLEMENTATION DEFINED whether:

- The Statistical Profiling Unit behaves as if `CollectTimeStamp()` returns the value `TimeStamp_None`.
- The value of this field in the record is UNKNOWN.

**Note**

This relaxation refers to when the actual System counter is disabled, that is, CNTEN.EN == 0. It does not apply when the System counter is enabled but not accessible at the current Exception level.
Chapter D15
The Branch Record Buffer Extension

This chapter describes the Branch Record Buffer Extension (BRBE). It contains the following sections:

• About the Branch Record Buffer Extension on page D15-5502.
• Branch record filtering on page D15-5507.
• Branch record buffer operation on page D15-5511.
• Branch record buffer on page D15-5513.
• Programmers’ model on page D15-5515.
D15.1 About the Branch Record Buffer Extension

The Branch Record Buffer Extension provides control path information for compiling and optimizing software. These directed optimizations extract information about hotspots and common control paths in the code. FEAT_BRBE provides a mechanism for capturing control path history in a low-cost manner. FEAT_BRBEv1p1 extends FEAT_BRBE to enable branch recording at EL3.

D15.1.1 Branch records

Each Branch record consists of 3 registers:
• BRBINF<n>_EL1.
• BRBSRC<n>_EL1.
• BRBTGT<n>_EL1.

Taken branch instructions, as defined by Branches, Exception generating, and System instructions on page C3-248, generate a Branch record.

Exceptions generate a Branch record.

A Half-source Branch record has BRBINF<n>_EL1.VALID set to 0b10.

A Half-target Branch record has BRBINF<n>_EL1.VALID set to 0b01.

A Full Branch record has BRBINF<n>_EL1.VALID set to 0b11.

BRBINF<n>_EL1.VALID indicates the validity of a Branch record:
• If BRBINF<n>_EL1.VALID is 0b00, the Branch record is invalid.
• Otherwise, the Branch record is valid.

When a Branch record is generated for any branch or exception which does not transition between a BRBE Prohibited region and a BRBE Non-prohibited region, the Branch record is a Full Branch record. See Branch records for exceptions on page D15-5504 and Branch records for exception returns on page D15-5505 for more details on when a Half-source Branch record or a Half-target Branch record is generated.

When an exception, exception return instruction, or Instruction Synchronization Barrier instruction causes a Context synchronization event which synchronizes an update to one or more System registers which are indirectly read when generating a Branch record, the synchronization of those register updates occurs before the registers are indirectly read. Such order is generally consistent with indirect reads of System registers performed by events which cause a Context synchronization event.

The reason for the Branch record is captured in BRBINF<n>_EL1.TYPE.

D15.1.2 Cycle counting

Each Branch record contains a cycle count value which is representative of the time taken between each Branch record being generated. The cycle count value can be used to determine the relative performance of the program between each Branch record. For large cycle count values, the value stored in each Branch record is encoded to use less storage, with a small loss of precision in the value.

The size of the cycle counter used to generate cycle count values is IMPLEMENTATION DEFINED, from one of the sizes indicated in BRBIDR0_EL1.CC.

Each Branch record contains a cycle count value which indicates the number of PE clock cycles that occurred between the previous Branch record being generated and this Branch record being generated.

In a multithreaded implementation, the cycle counter only counts cycles on which the thread was active.

The Branch record counts cycles in the same way as the CPU_CYCLES PMU event counts cycles when PMEVTYPE<n>_EL0.MT is 0. For more information, see Cycle event counting on page D11-5421.
For the purposes of the cycle count, a Branch record is generated only when the corresponding branch instruction or exception is guaranteed to be architecturally executed and the target address has been calculated. Arm recommends that the Branch record is generated as soon after this point as possible.

When a branch target address contains an address tag, the target address captured in the Branch record is the virtual address with the address tag removed.

The cycle count value in a Branch record is Branch cycle count unknown when any of the following are true:

- If EL2 is implemented, BRBCR_EL2.CC is 0.
- BRBCR_EL1.CC is 0.
- This is the first Branch record after the PE exited a BRBE Prohibited region.
- This is the first Branch record after cycle counting has been enabled.
- This is the first Branch record after BRBFCR_EL1.PAUSED is cleared from 1 to 0.
- This is the first Branch record after execution of a BRB IALL instruction.

Note: This applies even when EL2 is disabled in the current Security state.

When the cycle count value in a Branch record is Branch cycle count unknown:

- BRBINF<n>_EL1.CCU has the value 1.
- BRBINF<n>_EL1.CC contains a value which is all zeros.

The number of cycles indicated by this Branch record is UNKNOWN.

If the cycle count value in a Branch record would exceed the maximum value of the cycle counter, then:

- BRBINF<n>_EL1.CCU has the value 0.
- BRBINF<n>_EL1.CC contains a value which is all ones.

If the cycle count value in a Branch record is not UNKNOWN and would not exceed the maximum value of the cycle counter, then:

- BRBINF<n>_EL1.CCU has the value 0.
- BRBINF<n>_EL1.CC contains the cycle count value, encoded as defined in BRBINF<n>_EL1.CC.

### Mispredicated branches

Each Branch record generated for a branch instruction contains an indication of whether the branch was correctly or incorrectly predicted by the PE. Branch prediction behavior is IMPLEMENTATION DEFINED and this is an indication of whether such prediction succeeded, or not.

For a Branch record of a branch instruction, one of the following occurs:

- If EL2 is implemented and BRBCR_EL2.MPRED is 0, then BRBINF<n>_EL1.MPRED is set to 0.
- Else if BRBCR_EL1.MPRED is 0, then BRBINF<n>_EL1.MPRED is set to 0.
- Otherwise:
  - BRBINF<n>_EL1.MPRED is 0 for a correctly predicted branch.
  - BRBINF<n>_EL1.MPRED is 1 for an incorrectly predicted branch.

Note: This applies even when EL2 is disabled in the current Security state.

For a Branch record of an exception, BRBINF<n>_EL1.MPRED has the value 0.

An incorrectly predicted branch is when any of the following is true:

- The direction of a conditional branch was incorrectly predicted at least once during the execution of the instruction.
- The target of a branch was incorrectly predicted at least once during the execution of the instruction.
- The branch was not predicted by a branch predictor.

A correctly predicted branch is one that is not incorrectly predicted.
D15.1.4 BRBE Prohibited regions

An executable program might contain regions of code that are prohibited to generate Branch records, and these regions are called BRBE Prohibited regions. These regions are usually associated with a different Security state or Exception level.

BRBE Prohibited regions are controlled by the following:

- BRBCR_EL1.E0BRE.
- BRBCR_EL1.E1BRE.
- BRBCR_EL2.E0HBRE.
- BRBCR_EL2.E2BRE.
- MDCR_EL3.SBRBE.

While executing outside a BRBE Prohibited region, Branch records might not be generated because the Branch Record Buffer Extension has a number of filtering functions.

Execution in AArch32 state is a BRBE Prohibited region.

Execution in Debug state is a BRBE Prohibited region.

When FEAT_BRBEv1p1 and EL3 are implemented:
- When MDCR_EL3.{E3BREC, E3BREW} is {0b01, 0b10}, self-hosted EL3 branch recording is enabled.
- When MDCR_EL3.{E3BREC, E3BREW} is {0b00, 0b00} or MDCR_EL3.{E3BREC, E3BRE} is {0b11, 0b11}, self-hosted EL3 branch recording is disabled.

Execution at EL3 is a BRBE Prohibited region when any of the following are true:
- FEAT_BRBEv1p1 is not implemented.
- Self-hosted EL3 branch recording is disabled.

Execution at EL2 is a BRBE Prohibited region when any of the following are true:
- BRBCR_EL2.E2BRE is 0.
- MDCR_EL3.SBRBE is 0b00.
- MDCR_EL3.SBRBE is 0b01 and the PE is in Secure state.

Execution at EL1 is a BRBE Prohibited region when any of the following are true:
- BRBCR_EL1.E1BRE is 0.
- MDCR_EL3.SBRBE is 0b00.
- MDCR_EL3.SBRBE is 0b01 and the PE is in Secure state.

Execution at EL0 is a BRBE Prohibited region when any of the following are true:
- EL2 is disabled in the current Security state or HCR_EL2.TGE is 0, and BRBCR_EL1.E0BRE is 0.
- EL2 is enabled in the current Security state and HCR_EL2.TGE is 1, and BRBCR_EL2.E0HBRE is 0.
- MDCR_EL3.SBRBE is 0b00.
- MDCR_EL3.SBRBE is 0b01 and the PE is in Secure state.

While the PE is executing code from a BRBE Prohibited region, no data is captured in Branch records that might provide information about execution in the BRBE Prohibited region.

D15.1.5 Branch records for exceptions

When an exception is taken from a BRBE Prohibited region to a BRBE Prohibited region, no Branch record is generated.
When an exception is taken from a BRBE Non-prohibited region, or an exception is taken to a BRBE Non-prohibited region:

- If the target Exception level is EL1, a Branch record is generated only if BRBCR_EL1.EXCEPTION is 1.
- If the target Exception level is EL2, a Branch record is generated only if BRBCR_EL2.EXCEPTION is 1.
- If the target Exception level is EL3, a Branch record is generated only if FEAT_BRBEv1p1 is implemented and self-hosted EL3 branch recording is enabled.

When a Branch record is generated for an exception:

- If the exception is taken from a BRBE Prohibited region, then a Half-target Branch record is generated.
- If the exception is taken from a BRBE Non-prohibited region to a BRBE Prohibited region, then a Half-source Branch record is generated.
- If the exception is taken from a BRBE Non-prohibited region to a BRBE Non-prohibited region, then a Full Branch record is generated.

When entering Debug state:

- If the entry is from a BRBE Prohibited region, no Branch record is generated.
- If the entry is from a BRBE Non-prohibited region, then a Half-source Branch record is generated.

When a Half-source Branch record or a Full Branch record is generated for an Illegal Execution state exception, the source information in the Branch record indicates where the exception was taken from, in the same way as all other exceptions.

A Branch record for an exception which contains a valid source address has the source address set to the preferred exception return address for the exception.

A Branch record for an exception which contains a valid target address has the target address set to the address of the exception vector.

D15.1.6  Branch records for exception returns

When an exception return instruction is executed in a BRBE Prohibited region and branches to a BRBE Prohibited region, no Branch record is generated.

When an exception return instruction is executed in a BRBE Non-prohibited region, or an exception return instruction branches to a BRBE Non-prohibited region:

- If the exception return instruction is executed at EL3, a Branch record is generated only if FEAT_BRBEv1p1 is implemented and self-hosted EL3 branch recording is enabled.
- If the exception return instruction is executed at EL2, a Branch record is generated only if BRBCR_EL2.ERTN is 1.
- If the exception return instruction is executed at EL1, a Branch record is generated only if BRBCR_EL1.ERTN is 1.

When a Branch record is generated for an exception return instruction:

- If the exception return instruction is executed in a BRBE Prohibited region, then a Half-target Branch record is generated.
- If the exception return instruction is executed in a BRBE Non-prohibited region and branches to a BRBE Prohibited region, then a Half-source Branch record is generated.
- If the exception return instruction is executed in a BRBE Non-prohibited region and branches to a BRBE Non-prohibited region, then a Full Branch record is generated.

When exiting from Debug state:

- If the exit is to a BRBE Prohibited region, no Branch record is generated.
- If the exit is to a BRBE Non-prohibited region, then a Half-target Branch record is generated.
When a half-target branch record or a full branch record is generated for an exception return instruction which is an illegal return or a legal return which sets PSTATE.IL to 1, the target information in the branch record indicates the target of the branch:

- BRBTGT<\text{n}> EL1.ADDRESS contains the target of the branch.
- BRBINF<\text{n}> EL1.EL contains the value that is loaded into PSTATE.EL.

When a half-target branch record or a full branch record is generated for an exception return instruction which is an illegal return or a legal return which sets PSTATE.IL to 1, for the purposes of determining whether the target is a BRBE prohibited region, the value that is loaded into PSTATE.EL is used as the target exception level.

PSTATE.EL is unchanged on an illegal return, so the current exception level is the target of the illegal return, regardless of where the return was attempting to return to.

### D15.1.7 The Branch Record Buffer Extension and the Transactional Memory Extension

When an entire transaction is executed in a BRBE Non-prohibited region and the transaction fails or is canceled then BRBFCR_EL1.LASTFAILED is set to 1.

When an entire transaction is executed in a BRBE Prohibited region and the transaction fails or is canceled then BRBFCR_EL1.LASTFAILED is unchanged.

When a transaction is executed partially in a BRBE Prohibited region and partially in a BRBE Non-prohibited region and the transaction fails or is canceled then it is constrained unpredictable whether BRBFCR_EL1.LASTFAILED is set to 1 or is unchanged.

When a branch record is generated, other than through the injection mechanism, the value of BRBFCR_EL1.LASTFAILED is copied to the LASTFAILED field in the branch record and BRBFCR_EL1.LASTFAILED is set to 0.

When a transaction fails or is canceled, a branch record is not generated.

When a transaction fails or is canceled, branch records generated in the transaction are not removed from the branch record buffer.

Attempting to execute the BRB IALL or BRB INJ instructions in Transactional state results in the transaction failing with ERR cause.

### D15.1.8 PE speculation

The branch records only contain information for a branch, exception, or exception return that is architecturally executed.
D15.2 Branch record filtering

For Branch records generated outside a BRBE Prohibited region, it is useful to reduce the number of records that are generated to match their use. Table D15-1 on page D15-5507 lists some different use cases.

### Table D15-1 Example use cases for filtering

<table>
<thead>
<tr>
<th>Use case</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control path</td>
<td>• All branches</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>• Subroutine returns</td>
</tr>
<tr>
<td>Kernel calls</td>
<td>• Exceptions</td>
</tr>
<tr>
<td></td>
<td>• Exception returns</td>
</tr>
</tbody>
</table>

D15.2.1 Filtering on type

The Branch records can be filtered by independently enabling the generation of the following types:

- Exception.
- Exception return.
- Direct Branch with link.
- Indirect Branch with link.
- Return from subroutine.
- Indirect Branches.
- Conditional Direct Branches.
- Unconditional Direct Branches.

Control of when Branch records for exceptions are generated is controlled by BRBCR_EL1.EXCEPTION and BRBCR_EL2.EXCEPTION. See Branch records for exceptions on page D15-5504 for details.

### Table D15-2 Exception mapping for exceptions taken to AArch64 state

</tr>
</tbody>
</table>

Each of the direct branch with link instructions only generates a *Branch record* when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.DIRCALL is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.DIRCALL is 0 and BRBFCR_EL1.EnI is 1.

### Table D15-4 A64 direct branch with link instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BL</td>
<td>Branch with link.</td>
</tr>
</tbody>
</table>

Each of the indirect branch with link instructions only generates a *Branch record* when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.INDCALL is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.INDCALL is 0 and BRBFCR_EL1.EnI is 1.

Table D15-5 A64 indirect branch with link instructions

</tr>
<tr>
<td>BLRABZ</td>
<td>Authenticate and branch with link.</td>
</tr>
</tbody>
</table>

Each of the return from subroutine instructions only generates a Branch record, when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:
• BRBFCR_EL1.RTN is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.RTN is 0 and BRBFCR_EL1.EnI is 1.

Table D15-6 A64 return from subroutine instructions

<table>
<thead>
<tr>
<th>Instruction</th>

</tr>
</thead>
<tbody>
<tr>
<td>RET</td>
<td>Return From subroutine.</td>
</tr>
<tr>
<td>RETAA</td>
<td>Authenticate and function return.</td>
</tr>
<tr>
<td>RETAB</td>
<td>Authenticate and function return.</td>
</tr>
</tbody>
</table>

Unless covered by other rules, each of the indirect branch instructions only generates a Branch record when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:
• BRBFCR_EL1.INDIRECT is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.INDIRECT is 0 and BRBFCR_EL1.EnI is 1.

Table D15-7 A64 indirect branch instructions

<table>
<thead>
<tr>

<td>Authenticate and branch.</td>
</tr>
<tr>
<td>BRAB</td>
<td>Authenticate and branch.</td>
</tr>
<tr>
<td>BRABZ</td>
<td>Authenticate and branch.</td>
</tr>
</tbody>
</table>

Unless covered by other rules, each of the conditional direct branch instructions only generates a Branch record when the instruction is taken, is executed in a BRBE Non-prohibited region, and if any of the following are true:
• BRBFCR_EL1.CONDDIR is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.CONDDIR is 0 and BRBFCR_EL1.EnI is 1.

**Table D15-8 A64 conditional direct branch instructions**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B.cond</td>
<td>Conditional Branch.</td>
</tr>
<tr>
<td>BC.cond</td>
<td>Branch Consistent conditionally.</td>
</tr>
<tr>
<td>CBZ or CBNZ</td>
<td>Compare with zero and branch.</td>
</tr>
<tr>
<td>TBZ or TBNZ</td>
<td>Test and branch.</td>
</tr>
</tbody>
</table>

Note: BC.cond and B.cond instructions with the AL or NW condition code are considered conditional.

Unless covered by other rules, each of the unconditional direct branch instructions only generates a *Branch record* when the instructions are executed in a BRBE Non-prohibited region and if any of the following are true:

• BRBFCR_EL1.DIRECT is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.DIRECT is 0 and BRBFCR_EL1.EnI is 1.

Table D15-9 A64 unconditional direct branch instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Unconditional Branch.</td>
</tr>
</tbody>
</table>

It is IMPLEMENTATION DEFINED whether *Branch records* are generated for each of the following taken unconditional direct branch instructions when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

• BRBFCR_EL1.DIRECT is 1 and BRBFCR_EL1.EnI is 0.
• BRBFCR_EL1.DIRECT is 0 and BRBFCR_EL1.EnI is 1.

Table D15-10 Optional A64 unconditional direct branch instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISB</td>
<td>Instruction Synchronization Barrier.</td>
</tr>
</tbody>
</table>

Writing a value of 0b0000_0001 to the filter controls, BRBFCR_EL1<23:16>, ensures *Branch records* are generated for all branch instructions.
D15.3 Branch record buffer operation

The Branch Record Buffer Extension operation is controlled by the BRBCR_EL1, BRBCR_EL2, and BRBFCR_EL1 registers.

Generation of Branch records is paused when BRBFCR_EL1.PAUSED is 1.

When generation of Branch records is paused, Branch records are not generated.

If EL2 is implemented, a BRBE freeze event occurs when all of the following are true:
- BRBCR_EL1.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSLR_EL0[(MDCR_EL2.HPMN-1):0] is nonzero.
- The PE is in a BRBE Non-prohibited region.

If EL2 is implemented, a BRBE freeze event occurs when all of the following are true:
- BRBCR_EL2.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSLR_EL0[(PMCR_EL0.N-1):MDCR_EL2.HPMN] is nonzero.
- The PE is in a BRBE Non-prohibited region.

This applies even when EL2 is disabled in the current Security state.

If EL2 is not implemented, a BRBE freeze event occurs when all of the following are true:
- BRBCR_EL1.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSLR_EL0[(PMCR_EL0.N-1):0] is nonzero.
- The PE is in a BRBE Non-prohibited region.

On a BRBE freeze event:
- BRBFCR_EL1.PAUSED is set to 1.
- The current timestamp is captured in BRBTS_EL1.

The source of value of the timestamp captured in BRBTS_EL1 is selected by the combination of programming of BRBCR_EL2.TS and BRBCR_EL1.TS. See Table D15-11 on page D15-5511 and BRBETimeStamp().

<table>
<thead>
<tr>
<th>BRBCR_EL2.TS</th>
<th>BRBCR_EL1.TS</th>
<th>Captured timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00 (delegate)</td>
<td>0b01 (virtual)</td>
<td>PhysicalCountInt() - CNTVOFF_EL2</td>
</tr>
<tr>
<td>0b10 (offset physical)</td>
<td>0b11 (physical)</td>
<td>PhysicalCountInt() - physical offset</td>
</tr>
<tr>
<td>0b01 (virtual)</td>
<td>0bxx</td>
<td>PhysicalCountInt() - CNTVOFF_EL2</td>
</tr>
<tr>
<td>0b10 (offset physical)</td>
<td>0bxx</td>
<td>PhysicalCountInt() - physical offset</td>
</tr>
<tr>
<td>0b11 (physical)</td>
<td>0bxx</td>
<td>PhysicalCountInt()</td>
</tr>
</tbody>
</table>

If any of the following are true, the physical offset is zero, otherwise the physical offset is the value of CNTPOFF_EL2:
- EL3 is implemented and SCR_EL3.ECVEn is 0.
- EL2 is implemented and CNTHCTL_EL2.ECV is 0.

When a valid Branch record is captured in the Branch record buffer storage, the BRB_FILTRATE event is generated.
When BRB_FILTRATE is generated for an exception or an exception return, it is an Exception-related event. For more information on PMU event filtering, see Exception-related events on page D11-5260.

It is CONstrained UNpredictable whether a BRB_FILTRATE event is generated after a BRB_INJ causes a Branch record to be injected.

It is expected that the Branch record buffer storage is in a BRBE Prohibited region during software context switches. During software context switches, if the PMU event counters are not prohibited from counting events, it is expected that event counters set to count the BRB_FILTRATE event are prohibited from counting.

The architecture does not define when PMU events are counted relative to the instructions that caused the event. Events generated by an instruction might be counted before or after the instruction becomes architecturally executed, and events might be counted for operations that do not become architecturally executed. This means that events can be counted speculatively and/or out-of-order regarding the simple sequential execution of the program. Events might also be counted simultaneously by other event counters when the overflow occurs, including events from different instructions. In addition, multiple instances of an event might occur simultaneously, meaning that an event counter unsigned overflow can yield a nonzero value in the event counter.

Furthermore, the Branch records are generated only for architecturally executed operations. See RKXTKS:

These properties mean that, unless otherwise stated, on a BRBE freeze event, it is CONstrained UNpredictable whether the branches that define the basic block containing the instruction causing that event are captured in the Branch record buffer.

An exception to this relaxation applies for the BRB_FILTRATE event.

If a direct read of PMOVSLR_EL0 returns a nonzero value for a subset of the overflow flags, such that one of RNXCWF, RGXGWY, or RPKTXQ means that a BRBE freeze event should occur, then a direct read of BRBFDR_EL1 ordered after the direct read of PMOVSLR_EL0 will return BRBFDR_EL1.PAUSED is 1.

Direct reads of System registers require explicit synchronization for following direct reads of other System registers to be ordered after the first direct read. For more information, see General behavior of accesses to the AArch64 System registers on page D17-5546.

If a direct read of BRBFDR_EL1.PAUSED returns 1, then no operations ordered after the direct read will generate further Branch records until BRBFDR_EL1.PAUSED is cleared by software.

Note: The subsequent operations can be ordered by a Context synchronization event.
D15.4 Branch record buffer

IFBHCC The Branch record buffer can contain:

- 8 Branch records.
- 16 Branch records.
- 32 Branch records.
- 64 Branch records.

This is known as the Branch record buffer storage.

RKSLSM The Branch record buffer storage has a maximum number of Branch records as defined by BRBIDR0_EL1.NUMREC.

IPPBZP The Branch record buffer provides System registers to access the Branch records stored in the Branch record buffer storage. These System registers provide access to up to 32 Branch records without the need for explicit synchronization between each System register read. When more than 32 Branch records are implemented, the Branch record buffer provides a banking mechanism to provide access to multiple banks, each bank containing up to 32 Branch records. BRBFCR_EL1.BANK controls which bank is currently selected, and updates to BRBFCR_EL1.BANK require explicit synchronization before accessing the bank.

WLSQL The Branch record buffer storage has a capacity to store up to 32 Branch records. Accessing Branch records 0-31 is performed by setting BRBFCR_EL1.BANK to 0b0. Accessing Branch records 32-63 is performed by setting BRBFCR_EL1.BANK to 0b1.

TJGLK The Branch record with index 0 is the youngest captured branch.

HRTRNR The Branch record with index n is younger than Branch record with index n+1.

DTPDK On the generation of a new Branch record, if the Branch record buffer storage is full, then the oldest Branch record is lost.

SQLCX When the buffer contains M valid Branch records, where M > 0 and M is less than the maximum number of Branch records, all of the following are true:

- Branch records with index 0 to M-1 are all valid.
- All other Branch records are invalid.

PGDLX The creation of a Branch record is considered an indirect write to BRBTGT<n>_EL1, BRBSRC<n>_EL1 and BRBINF<n>_EL1, and therefore requires explicit synchronization before being read.

SFFNF The generation of Branch records performs indirect reads and indirect writes of System registers.

KFTYTV Synchronization requirements for AArch64 System registers on page D17-5547 defines the synchronization requirements for direct reads, direct writes, indirect reads, and indirect writes of System registers made by instructions and external agents.

D15.4.1 Invalidating the record buffer

LLIHYN Execution of BRR IALL causes all Branch records to be invalidated.

PFERNW A Branch record, R, is invalidated by the instruction BRR IALL, W, if all of the following are true:

- R is caused by a branch operation or exception, B.
- B is either:
  - In program order before a Context synchronization event, CSE.
  - Is the Context synchronization event.
- CSE is in program order before W.

LWPKR A Branch record R is not invalidated by the instruction BRR IALL, W, if all of the following are true:

- R is caused by a branch operation or exception, B.
- B is in program order after a Context synchronization event, CSE
- CSE is in program order after W.
It is constrained unpredictable whether a Branch record $R$ is invalidated by the instruction BRB IALL, $W$, if all of the following are true:

- $CSE_1$ is in program order before $W$.
- $R$ is caused by a branch operation or exception, $B$.
- $B$ is in program order after a Context synchronization event, $CSE_1$
- $B$ is either:
  - In program order before a Context synchronization event, $CSE_2$.
  - Is the Context synchronization event, $CSE_2$.
- $CSE_2$ is in program order after $W$ and there are no other CSEs between $CSE_1$ and $CSE_2$.

If a Branch record is invalidated, all older Branch records are invalidated.

When a Branch record has been invalidated, it remains invalid until it is overwritten by any of the following:

- A new Branch record is created.
- A Branch record is injected using the BRB INJ instruction.
D15.5 Programmers’ model

RBNGTH

Reads from an unimplemented Branch record return the value zero.

RPKZCF

All Branch records captured while generation of Branch records is not paused, must represent a continuous block of execution for all BRBE Non-prohibited regions.

IXSBPR

The captured Branch records might not represent a continuous block if generation of Branch records is paused at any time. To avoid this non-continuous nature, the BRB IALL instruction can be used to invalidate all Branch records while generation is paused.

RPMBRRL

If a Branch record cannot be captured for a branch instruction or exception that is not prohibited and has been selected to generate a record, then all the Branch records must be invalidated. The reasons for a PE being unable to capture a Branch record are IMPLEMENTATION DEFINED and Arm recommends that such reasons are rare.

IQJFSV

When a process is migrated to a PE with a smaller number of Branch records implemented then the information from the older Branch records will be lost.

IBDKJ

When FEAT_BRBE is implemented, the following fields are added to System registers to control access to the Branch record buffer functionality:

- When EL2 is implemented:
  - HDFGRTR_EL2.nBRBIDR.
  - HDFGRTR_EL2.nBRBCTL.
  - HDFGWTR_EL2.nBRBCTL.
  - HDFGRTR_EL2.nBRBDATA.
  - HDFGWTR_EL2.nBRBDATA.
  - HFGITR_EL2.nBRBINJ.
  - HFGITR_EL2.nBRBIALL.
- When EL3 is implemented:
  - MDCR_EL3.SBRBE.

SGCYTK

When self-hosted EL3 branch recording is enabled, the following registers must be programmed:

- BRBCR_EL1 and BRBCR_EL2. Software must program these registers to control the following:
  - Recording of exceptions taken to EL1 and EL2.
  - Recording of exception returns from EL1 and EL2.
  - Branch recording at EL0, EL1, and EL2.
  - Occurrence of BRBE freeze events on PMU overflows.
  - Timestamp source.
  - Misprediction information.
  - Cycle count information.
- BRBFCSR_EL1. Software must program this register to control the following:
  - Selection of Branch record buffer bank.
  - Selection of branch types to record at all Exception levels.
  - Pausing of Branch recording.
  - If FEAT_TME is implemented, recording of transaction failure information.

Software should also consider how MDCR_EL3.SBRBE should be programmed to either allow or prohibit access to the captured branch records from lower Exception levels. Even if self-hosted EL3 branch recording is not being used, software should consider whether a BRB IALL instruction should be executed before executing software at lower Exception levels.

SYLMQQ

Software must invalidate the Branch records after a PE reset to ensure that details of execution before the reset event are not leaked.

IPJPPQ

MDCR_EL3.E3BREC resets to 0 on a Cold reset, and MDCR_EL3.E3BREW resets to 0 on a Warm reset. This allows software to program MDCR_EL3.E3BREC and MDCR_EL3.E3BREW such that the BRBE continues recording after Warm reset, or stops recording at Warm reset.
When FEAT_BRBEv1p1 is implemented, certain fields in the following registers are reset to an architecturally unknown value on a Cold reset and unchanged on a Warm reset:

- BRBCR_EL1.
- BRBCR_EL2.
- BRBFCCR_EL1.

### D15.5.1 Manual injection of Branch records

The Branch Record Buffer Extension supports the ability to manually create *Branch records* and inject them in to the Branch record buffer storage. The primary purpose of the injection functionality is to support the restore of the Branch record buffer storage contents, particularly during software context switch events, including migration of software between PEs. The Branch record buffer storage contents are read out using direct reads of BRBSRC<\(n\)>_EL1, BRBTGT<\(n\)>_EL1, and BRBINF<\(n\)>_EL1.

The Branch Record Injection data registers are:

- BRBSRCINJ_EL1.
- BRBTGTINJ_EL1.
- BRBINFINJ_EL1.

*Branch record* injection consists of creating a single *Branch record* using direct writes to the Branch Record Injection data registers, then injecting the record into the Branch record buffer storage using BRB INJ. This process injects a single *Branch record* as the youngest entry in the Branch record buffer storage. This process is repeated for each *Branch record* to be added to the Branch record buffer storage.

When BRB INJ is executed outside of a BRBE Prohibited region, it is CONSTRAINED UNPREDICTABLE whether a *Branch record* is injected.

When BRB INJ is executed inside a BRBE Prohibited region, the contents of the Branch Record Injection data registers are used to create a *Branch record* which is added to the Branch record buffer storage as the youngest entry.

When a BRB INJ instruction is executed inside a BRBE Prohibited region and the contents of the Branch Record Injection data registers indicates an invalid record, it is CONSTRAINED UNPREDICTABLE whether a *Branch record* is injected to the Branch record buffer. An invalid record is one with BRBINFINJ_EL1.VALID set to 0b00.

For a BRB INJ instruction, it is CONSTRAINED UNPREDICTABLE whether a *Branch record* is injected to the Branch record buffer when all of the following are true:

- The BRB INJ instruction is executed inside a BRBE Prohibited region.
- The contents of the Branch Record Injection data registers indicates a valid record.
- The other contents of the Branch Record Injection data registers indicate an incorrectly formatted record.

If a *Branch record* is injected, then the contents of the Branch record are CONSTRAINED UNPREDICTABLE.

An example of an incorrectly formatted record is one where BRBINFINJ_EL1.VALID is 0b01 and BRBINFINJ_EL1.MPRED is 0b1.

Execution of BRB INJ does not require explicit synchronization to use the result of direct writes to the Branch Record Injection data registers in program order before BRB INJ.

The creation of a *Branch record* as a result of execution of BRB INJ does not use the result of direct writes to the Branch Record Injection data registers in program order after BRB INJ. Explicit synchronization is not required to ensure this ordering. For more information, see *Synchronization requirements for AArch64 System registers* on page D17-5547.

After the execution of BRB INJ, the contents of the Branch Record Injection data registers are UNKNOWN.

Changes to the BRB registers are subject to the rules for synchronization for System registers. See *Synchronization requirements for AArch64 System registers* on page D17-5547.
Chapter D16
AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- *The System register encoding space* on page D16-5518.
- *op0*=0b10, Moves to and from debug and trace System registers* on page D16-5519.
- *op0*=0b11, Moves to and from non-debug System registers, Special-purpose registers* on page D16-5523.
D16.1 The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in Chapter D17 AArch64 System Register Descriptions.

--- Note ---

- See Fixed values in AArch64 instruction and System register descriptions on page C2-243 for information about abbreviations used in the System instruction descriptions.

- In AArch32 state, much of this functionality is provided through the System register interface described in The AArch32 System register interface on page G1-8993. In AArch64 state, the parameters used to characterize the System register encoding space are \{\text{op0}}, \text{op1}, \text{CRn}, \text{CRm}, \text{op2}\). These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface on page G1-8994. There is no particular significance to the naming of these parameters, and no functional distinction between the \text{opn} parameters and the \text{CRx} parameters.

---

Principles of the System instruction class encoding on page C5-654 describes some general properties of these encodings. System instruction class encoding overview on page C5-655 then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set \{\text{op0}}, \text{op1}, \text{CRn}, \text{CRm}, \text{op2}\}.
- \text{op0} is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in Chapter C5 The A64 System Instruction Class. This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- \text{op0}==0b10, Moves to and from debug and trace System registers on page D16-5519.
- \text{op0}==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D16-5523.
D16.2  \( \text{op0} = 0b10 \), Moves to and from debug and trace System registers

The instructions that move data to and from the debug, Execution environment, and trace System registers are encoded with \( \text{op0} = 0b10 \). This means the encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 16 15</th>
<th>8 7 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 1 0 1 0 0</td>
<td>L 1 0</td>
<td>op1</td>
<td>CRn</td>
<td>CRm</td>
<td>op2</td>
</tr>
</tbody>
</table>

\( \text{op0} \)

--- Note ---

- The section describes the use of all of the \( \text{op0} = 0b10 \) region of the System register encoding space.
- These encodings access the registers that are equivalent to the AArch32 System registers in the \( \text{coproc} = 0b1110 \) encoding space.

The value of \( \text{op1} \) provides the next level of decode of these instructions, as follows:

\( \text{op1} = \{0, 3, 4\} \)

Debug. See Instructions for accessing debug System registers

--- Note ---

The standard encoding of debug registers is \( \text{op0} = 0b10, \text{op1} = \{0, 3, 4\} \). The registers in the \( \text{op0} = 0b11 \) encoding space that are classified as debug registers are DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3. See Instructions for accessing non-debug System registers on page D16-5523 for the encodings of these registers.

\( \text{op1} = 1 \)

Trace and BRBE registers. See FEAT_ETE, FEAT_BRBE, or the appropriate trace architecture specification for more information.

D16.2.1 Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

- \text{MSR <System register>, Xt} ; Write to System register
- \text{MRS Xt, <System register>} ; Read from System register

Where \(<\text{system register}>\) is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:
- \( \text{op0} \) is \( 0b10 \).
- The value of \( \text{op1} \) is one of \( \{0, 1, 3, 4, 5\} \).

--- Note ---

These encodings access the registers that are equivalent to the AArch32 System registers in the \( \text{coproc} = 0b1110 \) encoding space.

Table D16-1 shows the mapping of the System register encodings for debug System register access.

For more information, see *Mapping of the System registers between the Execution states* on page D1-4686.

---

**Note**

Table D16-1 lists the Armv8 debug System registers. For encoding information of the registers introduced by Armv9, see the register descriptions in Chapter D17 *AArch64 System Register Descriptions*.
**D16.3 op0==0b11, Moves to and from non-debug System registers, Special-purpose registers**

The instructions that move data to and from non-debug System registers are encoded with op0==0b11, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0</th>
<th>1 1 0 1 0 1 0 1 0 0</th>
<th>L</th>
<th>1 1</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
<th>Rt</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The value of CRn provides the next level of decode of these instructions, as follows:

CRn==\{0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14\}

See Instructions for accessing non-debug System registers.

CRn==4 See Instructions for accessing Special-purpose registers on page C5-668.

CRn==\{11, 15\} See Reserved encodings for IMPLEMENTATION DEFINED registers on page D16-5542.

**D16.3.1 Instructions for accessing non-debug System registers**

The A64 instructions for accessing System registers are:

- MSR <system_register>, Xt ; Write to System register
- MSR Xt, <system_register> ; Read from System register

Where <system_register> is the register name, for example MIDR_EL1.

This section includes only the System register access encodings for which both:

- op0 is 0b11.
- The value of CRn is one of \{0, 1, 2, 3, 4, 5, 6, 7, 9, 10, 12, 13, 14\}.

Note

- These encodings access the registers that are equivalent to the AArch32 System registers in the (coproc==0b1111) encoding space.
- While this group is described as accessing the non-debug System registers, its correct characterization is by the \{op0, CRn\} values given in this subsection, and the group includes the debug registers DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3, which are described in Debug registers on page D17-6393. These registers are exceptions to the standard encoding of debug registers, which has op0==0b10, see Instructions for accessing debug System registers on page D16-5519.

The instruction encoding for these accesses is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0</th>
<th>1 1 0 1 0 1 0 1 0 0</th>
<th>L</th>
<th>1 1</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
<th>Rt</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

See text for permitted values of CRn

Table D16-2 on page D16-5523 shows the encodings of the register access instructions.

About the GIC System registers

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

ICC_  GIC physical CPU interface System registers.
ICH_  GIC virtual interface control System registers.
ICV_  GIC Virtual CPU interface System registers.

Note

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

As Table D16-2 on page D16-5523 shows, the ICV_* registers have the same \{op0, op1, CRn, CRm, op2\} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).

D16.3.2  Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0==0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
<th>Access</th>
<th>Mnemonic</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1101</td>
<td>0000</td>
<td>010</td>
<td>RW</td>
<td>TPIDR_EL3</td>
<td>TPIDR_EL3</td>
</tr>
<tr>
<td>11</td>
<td>110</td>
<td>1101</td>
<td>0000</td>
<td>111</td>
<td>RW</td>
<td>SCXTNUM_EL3</td>
<td>SCXTNUM_EL3</td>
</tr>
<tr>
<td>11</td>
<td>111</td>
<td>1110</td>
<td>0010</td>
<td>000</td>
<td>-</td>
<td>CNTPS_TVAL_EL1</td>
<td>-</td>
</tr>
<tr>
<td>11</td>
<td>111</td>
<td>1110</td>
<td>0010</td>
<td>001</td>
<td>RW</td>
<td>CNTPS_CTL_EL1</td>
<td>CNTPS_CTL_EL1</td>
</tr>
<tr>
<td>11</td>
<td>111</td>
<td>1110</td>
<td>0010</td>
<td>010</td>
<td>RW</td>
<td>CNTPS_CVAL_EL1</td>
<td>CNTPS_CVAL_EL1</td>
</tr>
<tr>
<td>11</td>
<td>op1[2:0]</td>
<td>1x11</td>
<td>Cm[3:0]</td>
<td>op2[2:0]</td>
<td>-</td>
<td>S3_&lt;op1&gt;<em>&lt;Cn&gt;</em>&lt;Cm&gt;_&lt;op2&gt;</td>
<td>-</td>
</tr>
</tbody>
</table>

The value of L defines the access type and the use of Rt as follows:

0  Write the value in Rt to the IMPLEMENTATION DEFINED register.
1  Read the value of the IMPLEMENTATION DEFINED register to Rt.

For more information about these encodings, see S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers on page D17-6153. As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using MRS and MSR instructions, see:

- MRS on page C6-1707.
- MSR (immediate) on page C6-1708.
- MSR (register) on page C6-1712.
The Arm architecture guarantees not to define any register name prefixed with *IMP_* as part of the standard Arm architecture.

**Note**

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with *IMP_* and postfixed with *ELx*, where appropriate.
AArch64 System Register Encoding
D16.3 op0==0b11, Moves to and from non-debug System registers, Special-purpose registers
Chapter D17
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- About the AArch64 System registers on page D17-5546.
- General system control registers on page D17-5555.
- Debug registers on page D17-6393.
- Trace registers on page D17-6519.
- Performance Monitors registers on page D17-6740.
- Activity Monitors registers on page D17-6816.
- Statistical Profiling Extension registers on page D17-6858.
- Branch Record Buffer Extension registers on page D17-6912.
- RAS registers on page D17-6956.
- Generic Timer registers on page D17-7014.
- Realm Management Extension registers on page D17-7004.
D17.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- Fixed values in the System register descriptions.
- General behavior of accesses to the AArch64 System registers.
- Principles of the ID scheme for fields in ID registers on page D17-5551.

D17.1.1 Fixed values in the System register descriptions

See Fixed values in AArch64 instruction and System register descriptions on page C2-243. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

D17.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- Reset behavior of AArch64 System registers.
- Synchronization requirements for AArch64 System registers on page D17-5547.

Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.

- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.

- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.

- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.

- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- Reset behavior on page D1-4674.
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and Reset behavior on page D1-4674 summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

Note

When the PE resets into an Exception level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.
Pseudocode description of resetting System registers

The `AArch64.ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and `Reset behavior` on page D1-4674.

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent Context synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context synchronization event. For example, where a memory access is used to communicate a read of such a counter, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Direct writes using the instructions in Table D16-2 on page D16-5523 require synchronization before software can rely on the effects of changes to the System registers to affect instructions appearing in program order after the direct write to the System register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an Arm Architecture Specification or equivalent specification defines as not requiring synchronization.
- When FEAT_BRBE is implemented, execution of BRB INJ does not require explicit synchronization to use the result of direct writes to the Branch record injection data registers in program order before BRB INJ.

Explicit synchronization occurs as a result of a Context synchronization event, which is one of the following events:

- Execution of an ISB instruction.
- Exception entry, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception entries to this Exception level are context synchronization events.
- Exception return, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception returns from this Exception level are context synchronization events.
- Execution of a DCPs instruction in Debug state.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

Note

The ISB and exception entry events are applicable both in Debug state and in Non-debug state.
Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

--- Note ---

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of System registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- ISR_EL1.
- The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TV_AL_EL0, CNTV_TV_AL_EL0, CNTHP_TV_AL_EL2, and CNTPS_TV_AL_EL1.
- DBGCLAIMCLR_EL1.
- The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<e> EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSET_EL0.
- The Debug Communications Channel registers, that is, DBGDTRRX_EL0, DBGDTR_EL0, and MDCCSR_EL0.

All other direct reads of System registers can occur in any order if synchronization has not been performed.

**Table D17-1** describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

<tr>
<td></td>
<td>Indirect write</td>
<td>None</td>
</tr>
</tbody>
</table>
The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D17-1 on page D17-5548, are defined as follows:

**Direct read** Where software uses an MRS system register access instruction to read that register into a general purpose register.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

**Direct write** Where software uses an MSR (register) access instruction to write to that register from a general purpose register.

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

**Indirect read** Where an instruction uses a System register to establish operating conditions for the instruction, for example, the TTBR_ELx address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

**Indirect write** Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

**Note** Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

---

**Notes**

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D17-1 on page D17-5548, are defined as follows:
Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in Table D17-2, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

### Table D17-2 Registers with a guarantee of observability, VMSAv8-64

</tbody>
</table>

In addition to the requirements shown in Table D17-2 on page D17-5550:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - OSLAR_EL1. OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.
  - EDLAR, if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

  **Note**

  This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table D17-2 on page D17-5550 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.
For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a Context synchronization event. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state on page H4-10313.

**Note**

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.

- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.

- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

- If FEAT_MTE2 is implemented, a DSB instruction over the Non-shareable domain or an exception entry to ELy with SCTLR_ELy.ITFSB = 0b1 is required between an indirect write to TFSRE0_EL1, or any TFSR_ELx accessible at ELy, and a direct read or direct write of that register.

**D17.1.3 Principles of the ID scheme for fields in ID registers**

The Arm architecture specifies a number of ID registers that are characterized as comprising a set of 4-bit ID fields. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. ID registers to which this scheme applies on page D17-5553 identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

**Note**

- The ID fields described here are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

- ID fields that do not follow this scheme include the ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, see Alternative ID scheme used for the Performance Monitors Extension version on page D17-5553.

- The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.
The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of $0x1$ indicates the presence of some instructions, then the value $0x2$ will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```c
if (value >= number) {
    // do something that relies on the value of the feature
}
```

For ID fields where the value $0x0$ defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value $0xF$ indicates that the feature is not implemented.
- The field value $0x0$ indicates that the feature is implemented.
- Software that depends on the feature can use the test:
  ```c
  if value >= 0 {
    // Software features that depend on the presence of the hardware feature
  }
  ```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a fractional field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example D17-1 shows the use of such a field.

### Example D17-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value $0x1$ was defined as indicating that item A is present.
- The value $0x2$ was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value $0x1$ when A and B only are present. This fractional field is valid only when the original ID field has the value $0x1$.

This approach means that:

- Software that depends on the test if (value $>= 0x2$) can rely on features A, B, and C being present,
- Software that depends on the test if (value $>= 0x1$) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:
  ```c
  if (value $>= 0x2$ || (value $== 0x1$ && fractional_value $>= 0x1$)) {
    // Software features that depend on A and B only
  }
  ```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are $RES0$ to allow their future use when features, or fractional implementation options, are added.
**ID registers to which this scheme applies**

This scheme applies to the following registers:

**AArch64 System registers**

- The AArch64 views of the AArch32 feature ID registers given by:
  - The AArch32 Auxiliary Feature register ID_AFR0_EL1.
  - The AArch32 Processor Feature registers ID_PFR0_EL1 and ID_PFR1_EL1.
  - The AArch32 Debug Feature register ID_DFR0_EL1.
  - The AArch32 Memory Model Feature registers ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1.
  - The AArch32 Instruction Set Attribute registers ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.
  - The AArch32 Media and VFP Feature registers MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
- The AArch64 Auxiliary Feature registers ID_AA64AFR0_EL1 and ID_AA64AFR1_EL1.
- The AArch64 Processor Feature registers ID_AA64PFR0_EL1 and ID_AA64PFR1_EL1.
- The AArch64 Debug Feature registers ID_AA64DFR0_EL1 and ID_AA64DFR1_EL1.
- The AArch64 Memory Model Feature registers ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, and ID_AA64MMFR2_EL1.
- The AArch64 Instruction Set Attribute registers ID_AA64ISAR0_EL1 and ID_AA64ISAR1_EL1.

**AArch32 System registers**

- The AArch32 Auxiliary Feature register ID_AFR0.
- The AArch32 Processor Feature registers ID_PFR0 and ID_PFR1.
- The AArch32 Debug Feature register ID_DFR0.
- The AArch32 Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.
- The AArch32 Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
- The AArch32 Media and FP Feature registers MVFR0, MVFR1, and MVFR2.

**Memory-mapped registers**

- The External Debug Processor Feature register EDPFR.
- The External Debug Feature register EDDFR.

**Alternative ID scheme used for the Performance Monitors Extension version**

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0xF indicates that the Arm-architected Performance Monitors Extension is not implemented.
- If the field value is not 0xF the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```c
if (value != 0xF and value >= number) {
    // do something that relies on version 'number' of the feature
}
```

For these fields, Arm deprecates use of the value 0xF in new implementations.
Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes

The ID_AA64MMFR0_EL1.TGran4_2, ID_AA64MMFR0_EL1.TGran16_2 and ID_AA64MMFR0_EL1.TGran64_2 fields that identify the memory translation stage 2 granule size, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0x0 indicates that support is identified by another field.
- If the field value is not 0x0, the value indicates the level of support provided.

This means that software should use a test of the form:

```c
if (field != 0 and field > value) {
    // do something that relies on the value of the feature
}
```
D17.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.
D17.2.1 ACCDATA_EL1, Accelerator Data

The ACCDATA_EL1 characteristics are:

**Purpose**

Holds the lower 32 bits of the data that is stored by an ST64BV0, Single-copy atomic 64-byte EL0 store instruction.

**Configurations**

This register is present only when FEAT_LS64_ACCDATA is implemented. Otherwise, direct accesses to ACCDATA_EL1 are UNDEFINED.

**Attributes**

ACCDATA_EL1 is a 64-bit register.

**Field descriptions**

**Bits [63:32]**

Reserved, RES0.

**ACCDATA, bits [31:0]**

Accelerator Data field. Holds bits[31:0] of the data that is stored by an ST64BV0 instruction.

**Accessing ACCDATA_EL1**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, ACCDATA_EL1**

<table>

D17.2.2 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

### Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

--- Note ---

Arm recommends the contents of this register have no effect on the PE when HCR_EL2.E2H, TGE is [1, 1], and instead the configuration and control fields are provided by the ACTLR_EL2 register. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

### Configurations

AArch64 System register ACTLR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ACTLR[31:0].

AArch64 System register ACTLR_EL1 bits [63:32] are architecturally mapped to AArch32 System register ACTLR2[31:0].

### Attributes

ACTLR_EL1 is a 64-bit register.

### Field descriptions

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

D17.2.3 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

--- **Note** ---

Arm recommends the contents of this register are updated to apply to EL0 when HCR_EL2.E2H, TGE\} is {1, 1}, gaining configuration and control fields from the ACTLR_EL1. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

---

**Configurations**

AArch64 System register ACTLR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HACTLR[31:0].

AArch64 System register ACTLR_EL2 bits [63:32] are architecturally mapped to AArch32 System register HACTLR2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

ACTLR_EL2 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>

D17.2.6 AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

**Configurations**

AArch64 System register AFSR0_EL2 bits [31:0] are architecturally mapped to AArch32 System register HADFSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

AFSR0_EL2 is a 64-bit register.

**Field descriptions**

 IMPLEMENTATION DEFINED, bits [63:0]

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing AFSR0_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic AFSR0_EL2 or AFSR0_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

The AFSR1_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to AFSR1_EL3 are UNDEFINED.

Attributes

AFSR1_EL3 is a 64-bit register.

**AArch64 System Register Descriptions**  
**D17.2 General system control registers**
D17.2.13  AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL2.

**Configurations**

AArch64 System register AMAIR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HAMAIR0[31:0].

AArch64 System register AMAIR_EL2 bits [63:32] are architecturally mapped to AArch32 System register HAMAIR1[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

AMAIR_EL2 is a 64-bit register.

**Field descriptions**

![Field diagram](image)

AMAIR_EL2 is permitted to be cached in a TLB.

D17.2.17 APDBKeyHi_EL1, Pointer Authentication Key B for Data (bits[127:64])

The APDBKeyHi_EL1 characteristics are:

**Purpose**

Holds bits[127:64] of key B used for authentication of data pointer values.

**Note**

The term APDBKey_EL1 is used to describe the concatenation of APDBKeyHi_EL1: APDBKeyLo_EL1.

**Configurations**

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDBKeyHi_EL1 are UNDEFINED.

**Attributes**

APDBKeyHi_EL1 is a 64-bit register.

**Field descriptions**

Bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing APDBKeyHi_EL1**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, APDBKeyHi_EL1**

D17.2.22  APIAKeyLo_EL1, Pointer Authentication Key A for Instruction (bits[63:0])

The APIAKeyLo_EL1 characteristics are:

**Purpose**

Holds bits[63:0] of key A used for authentication of instruction pointer values.

**Note**

The term APIAKey_EL1 is used to describe the concatenation of APIAKeyHi_EL1: APIAKeyLo_EL1.

**Configurations**

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APIAKeyLo_EL1 are UNDEFINED.

**Attributes**

APIAKeyLo_EL1 is a 64-bit register.

**Field descriptions**

|| 64 bit value, bits[63:0] of the 128 bit pointer authentication key value
---|---
| 01 |
| 0 |

**Bits [63:0]**

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing APIAKeyLo_EL1**

Accesses to this register use the following encodings in the System register encoding space:

D17.2.25 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

**Purpose**

Provides the information about the architecture of the currently selected cache from bits[63:32] of CCSIDR_EL1.

**Configurations**

AArch64 System register CCSIDR2_EL1 bits [31:0] are architecturally mapped to AArch32 System register CCSIDR2[31:0].

This register is present only when FEAT_CCIDX is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

In an implementation which does not support AArch32 at EL1, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

The implementation includes one CCSIDR2_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

**Attributes**

CCSIDR2_EL1 is a 64-bit register.

**Field descriptions**

**Bits [63:24]**

Reserved, RES0.

**NumSets, bits [23:0]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Accessing CCSIDR2_EL1**

If CSSELR_EL1.\{TnD, Level, InD\} is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, CCSIDR2_EL1

<table>
<thead>
<tr>

    X[t, 64] = CCSIDR2_EL1;
D17.2.26 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache.

**Configurations**

AArch64 System register CCSIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CCSIDR[31:0].

AArch64 System register CCSIDR_EL1 bits [63:32] are architecturally mapped to AArch32 System register CCSIDR2[31:0].

The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSELK_EL1 selects which Cache Size ID Register is accessible.

**Attributes**

CCSIDR_EL1 is a 64-bit register.

**Field descriptions**

*When FEAT_CCIDX is implemented:*

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:56]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[55:32]</td>
<td>NumSets, (Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.</td>
</tr>
<tr>
<td>[31:24]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[23:3]</td>
<td>Associativity, (Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.</td>
</tr>
</tbody>
</table>
| [2:0]     | LineSize, (Log2(Number of bytes in cache line)) - 4. For example:
  |   • For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
  |   • For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1. |

**Note**

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.
--- Note ---
The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

When FEAT_MTE is implemented and enabled, where a cache only holds Allocation tags, this field is RES0.

**Otherwise:**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>

</tbody>
</table>

--- Note ---
The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

---

Bits [63:32]
Reserved, RES0.

Bits [31:28]
Reserved, UNKNOWN.

NumSets, bits [27:13]
(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]
(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]
(Log2(Number of bytes in cache line)) - 4. For example:
- For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1.

--- Note ---
The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.
## Accessing CCSIDR_EL1

If `CSSELR_EL1.{TnD, Level, InD}` is programmed to a cache level that is not implemented, then on a read of the CCSIDR_EL1 the behavior is **CONSTRAINED UNPREDICTABLE**, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is **UNDEFINED**.
- The CCSIDR_EL1 read returns an **UNKNOWN** value.

Accesses to this register use the following encodings in the System register encoding space:

### MRS <Xt>, CCSIDR_EL1

```
D17.2.27  CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

**Purpose**

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Configurations**

AArch64 System register CLIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CLIDR[31:0].

**Attributes**

CLIDR_EL1 is a 64-bit register.

**Field descriptions**

![Field diagram]

**Bits [63:47]**

Reserved, RES0.

**Ttype<n>, bits [2(n-1)+34:2(n-1)+33], for n = 7 to 1**

*When FEAT_MTE2 is implemented:*

Tag cache type. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy.

- **0b00**: No Tag Cache.
- **0b01**: Separate Allocation Tag Cache.
- **0b10**: Unified Allocation Tag and Data cache, Allocation Tags and Data in unified lines.
- **0b11**: Unified Allocation Tag and Data cache, Allocation Tags and Data in separate lines.

**ICB, bits [32:30]**

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

- **0b000**: Not disclosed by this mechanism.
- **0b001**: L1 cache is the highest Inner Cacheable level.
- **0b010**: L2 cache is the highest Inner Cacheable level.
- **0b011**: L3 cache is the highest Inner Cacheable level.
- **0b100**: L4 cache is the highest Inner Cacheable level.
- **0b101**: L5 cache is the highest Inner Cacheable level.
- **0b110**: L6 cache is the highest Inner Cacheable level.
- **0b111**: L7 cache is the highest Inner Cacheable level.
LoUU, bits [29:27]
Level of Unification Uniprocessor for the cache hierarchy.
For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D7-5051.

Note
When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

LoC, bits [26:24]
Level of Coherence for the cache hierarchy.
For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D7-5051.

LoUIS, bits [23:21]
Level of Unification Inner Shareable for the cache hierarchy.
For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D7-5051.

Note
When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 7 to 1
Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>No cache.</td>
</tr>
<tr>
<td>0b001</td>
<td>Instruction cache only.</td>
</tr>
<tr>
<td>0b010</td>
<td>Data cache only.</td>
</tr>
<tr>
<td>0b011</td>
<td>Separate instruction and data caches.</td>
</tr>
<tr>
<td>0b100</td>
<td>Unified cache.</td>
</tr>
</tbody>
</table>

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing CLIDR_EL1
Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRS} \ <\text{Xt}, \ CLIDR_\text{EL1} \\
\begin{array}{cccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b11 & 0b001 & 0b0000 & 0b0000 & 0b001 \\
\end{array}
\]

if PSTATE.EL == EL0 then
if IsFeatureImplemented(FEAT_IDST) then
if EL2Enabled() && HCR_EL2.TGE == '1' then
AArch64.SystemAccessTrap(EL2, 0x18);
else
    AArch64.SystemAccessTrap(EL1, 0x18);
else
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.TID2 == '1' then

        X[t, 64] = CLIDR_EL1;
D17.2.28 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

**Purpose**

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

**Configurations**

AArch64 System register CONTEXTIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CONTEXTIDR[31:0].

**Attributes**

CONTEXTIDR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
<td>PROCID</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**PROCID, bits [31:0]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

--- **Note** ---

In AArch32 state, when TTBCR.EAE is set to 0, CONTEXTIDR.ASID holds the ASID.

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either TTBR0_EL1 or TTBR1_EL1 holds the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CONTEXTIDR_EL1**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CONTEXTIDR_EL1 or CONTEXTIDR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:
MRS \langle Xt \rangle, CONTEXTIDR_EL1

\[
\begin{array}{|c|c|c|c|c|}
\hline

D17.2.29 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

**Purpose**

Identifies the current Process Identifier for EL2.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

**Configurations**

This register is present only when FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

CONTEXTIDR_EL2 is a 64-bit register.

**Field descriptions**

D17.2.30 **CPACR_EL1, Architectural Feature Access Control Register**

The CPACR_EL1 characteristics are:

**Purpose**

Controls access to trace, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

**Configurations**

AArch64 System register CPACR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CPACR[31:0].

When EL2 is implemented and enabled in the current Security state and HCR_EL2.{E2H, TGE} == {1, 1}, the fields in this register have no effect on execution at EL0 and EL1. In this case, the controls provided by CPTR_EL2 are used.

**Attributes**

CPACR_EL1 is a 64-bit register.

</table>
System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not implemented, this bit is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

Reserved, RES0.

**SMEN, bits [25:24]**

*When FEAT_SME is implemented:*

Traps execution at EL1 and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR or SMCR_EL1 System registers to EL1, or to EL2 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1.

When instructions that directly access the SVCR System register are trapped with reference to this control, the MSR, SVCSR, MSR, SVCRZA, and MSR, SVCRSZ, instructions are also trapped.

The exception is reported using ESR_ELx.EC value of 0x1D, with an ISS code of 0x0000000.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPACR_EL1.SMEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

- **0b00** This control causes execution of these instructions at EL1 and EL0 to be trapped.
- **0b01** This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
- **0b10** This control causes execution of these instructions at EL1 and EL0 to be trapped.
- **0b11** This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Bits [23:22]**

Reserved, RES0.

**FPEN, bits [21:20]**

Traps execution at EL1 and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL1, reported using ESR_ELx.EC value 0x07, or to EL2 reported using ESR_ELx.EC value 0x00 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to FPCR, FPSR, any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
- In AArch32 state, FPSCR, and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers.

Traps execution at EL1 and EL0 of SME and SVE instructions to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPACR_EL1.SMEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.
A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

0b00  This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b01  This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
0b10  This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b11  This control does not cause execution of any instructions to be trapped.

Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

Note
• Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
• Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.FPEN is not 0b11.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:18]
Reserved, RES0.

ZEN, bits [17:16]

When FEAT_SVE is implemented:
Traps execution at EL1 and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL1 System register to EL1, or to EL2 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1.
The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

0b00  This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b01  This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
0b10  This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b11  This control does not cause execution of any instructions to be trapped.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [15:0]
Reserved, RES0.

### D17.2.31 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

**Purpose**

Controls trapping to EL2 of accesses to CPACR, CPACR_EL1, trace, Activity Monitor, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

**Configurations**

AArch64 System register CPTR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HCPTR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

CPTR_EL2 is a 64-bit register.

**Field descriptions**

*When FEAT_VHE is implemented and HCR_EL2.E2H == 1:*

<table>
<thead>
<tr>
<th>Field</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCPAC, bit [31]</td>
<td>In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x18.</td>
</tr>
<tr>
<td>In AArch32 state, traps accesses to CPACR from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x03.</td>
<td></td>
</tr>
<tr>
<td>0b0</td>
<td>This control does not cause any instructions to be trapped.</td>
</tr>
<tr>
<td>0b1</td>
<td>EL1 accesses to CPACR_EL1 and CPACR are trapped to EL2, when EL2 is enabled in the current Security state.</td>
</tr>
</tbody>
</table>

**TCPAC, bit [31]**

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x18.

In AArch32 state, traps accesses to CPACR from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to CPACR_EL1 and CPACR are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

---

**Note**

CPACR_EL1 and CPACR are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
TAM, bit [30]

When FEAT_AMUv1 is implemented:

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x18:
  - AMUSERENR_EL0, AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0,
    AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0,
    AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0,
    AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.

- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 and reported using ESR_ELx.EC value 0x03:
  - AMUSERENR, AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1,
    AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<n>, and
    AMEVTYPER1<n>.

- In AArch32 state, MRRC or MCRR accesses to AMEVCNTR0<n> and AMEVCNTR1<n>, are trapped to EL2, reported using ESR_ELx.EC value 0x04.

0b0 Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.

0b1 Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [29]

Reserved, RES0.

TTA, bit [28]

Traps System register accesses to all implemented trace registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x18.

- In AArch64 state, MRC or MCR accesses to trace registers with cpnum=14, opc1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt at EL0, EL1 or EL2, to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state, unless HCR_EL2.TGE is 0 and it is trapped by CPACR.NSTRCDIS or CPACR_EL1.TTA. When HCR_EL2.TGE is 1, any attempt at EL0 or EL2 to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state.

Note

The ETMv4 architecture and ETE do not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4 or ETE, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.

EL2 does not provide traps on trace register accesses through the optional Memory-mapped interface.
System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

Reserved, RES0.

**SMEN, bits [25:24]**

*When FEAT_SME is implemented:*

Traps execution at EL2, EL1, and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR, SMCR_EL1, or SMCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

When instructions that directly access the SVCR System register are trapped with reference to this control, the MSR SVCRSM, MSR SVCRZA, and MSR SVCRSMZA instructions are also trapped.

The exception is reported using ESR_EL2.EC value of 0x1D, with an ISS code of 0x0000000.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL2.SMEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

- **0b00** This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
- **0b01** When HCR_EL2:TGE is 0, this control does not cause execution of any instructions to be trapped.
  
  When HCR_EL2:TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.
- **0b10** This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
- **0b11** This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Bits [23:22]**

Reserved, RES0.

**FPEN, bits [21:20]**

Traps execution at EL2, EL1, and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x87.

Traps execution at EL2, EL1, and EL0 of SME and SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x87.

A trap taken as a result of CPTR_EL2.SMEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

- **0b00** This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
- **0b01** When HCR_EL2:TGE is 0, this control does not cause execution of any instructions to be trapped.
When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.

0b10 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b11 This control does not cause execution of any instructions to be trapped.

Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.FPEN is not 0b11.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:18]
Reserved, RES0.

ZEN, bits [17:16]

When FEAT_SVE is implemented:

Traps execution at EL2, EL1, and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL1 or ZCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

The exception is reported using ESR_ELx.ec value 0x19.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

0b00 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b01 When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped.

When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.

0b10 This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b11 This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [15:0]
Reserved, RES0.
Otherwise:

This format applies in all Armv8.0 implementations.

**Bits [63:32]**

Reserved, RES0.

**TCPAC, bit [31]**

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x18.

In AArch32 state, traps accesses to CPACR from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x03.

0b0 This control does not cause any instructions to be trapped.

0b1 EL1 accesses to the following registers are trapped to EL2, when EL2 is enabled in the current Security state:

- CPACR_EL1.
- CPACR.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

--- **Note** ---

CPACR_EL1 and CPACR are not accessible at EL0.

--- The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**TAM, bit [30]**

*When FEAT_AMUv1 is implemented:*

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitor registers to EL2, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x18:

  - AMUSERENR_EL0, AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.

- In AArch32 state, MCR or MRC accesses to the following registers are trapped to EL2 and reported using ESR_ELx.EC value 0x03:

  - AMUSERENR, AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<n>, and AMEVTYPER1<n>.

- In AArch32 state, MCRR or MRRC accesses to AMEVCNTR0<n> and AMEVCNTR1<n>, are trapped to EL2, reported using ESR_ELx.EC value 0x04.

0b0 Accesses from EL1 and EL0 to Activity Monitor registers are not trapped.
Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [29:21]**

Reserved, RES0.

**TTA, bit [20]**

Traps System register accesses to all implemented trace registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRC or MCR accesses to trace registers with cpnum=14, opc1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x05.

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state, unless it is trapped by one of the following controls:

- CPACR_EL1.TTA
- CPACR.TRCDIS

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [19:14]**

Reserved, RES0.

**Bit [13]**

Reserved, RES1.

**TSM, bit [12]**

*When FEAT_SME is implemented:*

Traps execution at EL2, EL1, and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR, SMCR_EL1, or SMCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

When instructions that directly access the SVCR System register are trapped with reference to this control, the MSR SVECSR, MSR SVCRZA, and MSR SVCRSMZA instructions are also trapped.
The exception is reported using ESR_EL2.EC value of 0x1D, with an ISS code of 0x0000000.
This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL2.TSM has precedence over a trap taken as a result of CPTR_EL2.TFP.

0b0  This control does not cause execution of any instructions to be trapped.
0b1  This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES1.

**Bit [11]**

Reserved, RES0.

**TFP, bit [10]**

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x07:
  - FPCR, FPSR, FPEXC32_EL2, any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
- In AArch32 state, accesses to the following registers are trapped to EL2, reported using ESR_ELx.EC value 0x07:
  - MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers. For the purposes of this trap, the architecture defines a VMSR access to FPSID from EL1 or higher as an access to a SIMD and floating-point register. Otherwise, permitted VMSR accesses to FPSID are ignored.

Traps execution at the same Exception levels of SME and SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPTR_EL2.TSM has precedence over a trap taken as a result of CPTR_EL2.TFP.

A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

0b0  This control does not cause execution of any instructions to be trapped.
0b1  This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

--- **Note** ---

FPEXC32_EL2 is not accessible from EL0 using AArch64.
FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [9]**

Reserved, RES1.

**TZ, bit [8]**

*When FEAT_SVE is implemented:*

Traps execution at EL2, EL1, and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL2 or ZCR_EL1 System registers to EL2, when EL2 is enabled in the current Security state.
The exception is reported using ESR_ELx.EC value 0x19.
A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

0b0  This control does not cause execution of any instructions to be trapped.
0b1  This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES1.

Bits [7:0]

D17.2.32 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

**Purpose**

Controls trapping to EL3 of accesses to CPACR, CPACR_EL1, HCPTR, CPTR_EL2, trace, Activity Monitor, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to CPTR_EL3 are UNDEFINED.

**Attributes**

CPTR_EL3 is a 64-bit register.

**Field descriptions**

![Field descriptions diagram]

**Bits [63:32]**

Reserved, RES0.

**TCPAC, bit [31]**

Traps all of the following to EL3, from both Execution states and any Security state.

- EL2 accesses to CPTR_EL2, reported using ESR_ELx.EC value 0x18, or HCPTR, reported using ESR_ELx.EC value 0x03.
- EL2 and EL1 accesses to CPACR_EL1 reported using ESR_ELx.EC value 0x18, or CPACR reported using ESR_ELx.EC value 0x03.

When CPTR_EL3.TCPAC is:

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3, unless they are trapped by CPTR_EL2.TCPAC.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**TAM, bit [30]**

*When FEAT_AMUv1 is implemented:*

Trap Activity Monitor access. Traps EL2, EL1, and EL0 accesses to all Activity Monitor registers to EL3.
Accesses to the Activity Monitors registers are trapped as follows:

- In AArch64 state, the following registers are trapped to EL3 and reported with ESR_ELx.EC value 0x18:
  - AMUSERENR_EL0, AMCFG_R_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<\alpha> EL0, AMEVCNTR1<\alpha> EL0, AMEVTYPER0<\alpha> EL0, and AMEVTYPER1<\alpha> EL0.

- In AArch32 state, accesses with MRC or MCR to the following registers reported with ESR_ELx.EC value 0x03:
  - AMUSERENR, AMCFG, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<\alpha>, and AMEVTYPER1<\alpha>.

- In AArch32 state, accesses with MRRC or MCRR to the following registers, reported with ESR_ELx.EC value 0x04:
  - AMEVCNTR0<\alpha>, AMEVCNTR1<\alpha>.

0b0 Accesses from EL2, EL1, and EL0 to Activity Monitor registers are not trapped.
0b1 Accesses from EL2, EL1, and EL0 to Activity Monitor registers are trapped to EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Another:
Reserved, RES0.

Bits [29:21]
Reserved, RES0.

TTA, bit [20]
Traps System register accesses. Accesses to the trace registers, from all Exception levels, any Security state, and both Execution states are trapped to EL3 as follows:
- In AArch64 state, Trace registers with op0=2, op1=1, and CRn<@b100 are trapped to EL3 and reported using EC syndrome value 0x18.
- In AArch32 state, accesses using MCR or MRC to the Trace registers with cpnum=14, opc1=1, and CRn<@b100 are reported using EC syndrome value 0x05.
0b0 This control does not cause any instructions to be trapped.
0b1 Any System register access to the trace registers is trapped to EL3, unless it is trapped by CPACR.TRCDIS, CPACR_EL1.TTA, or CPTR_EL2.TTA.

If System register access to trace functionality is not supported, this bit is RES0.

Note
The ETMv4 architecture and ETE do not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than this trap exception.

EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Configurable instruction controls on page D1-4665.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:13]
Reserved, RES0.
ESM, bit [12]

When FEAT_SME is implemented:

Traps execution of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SMCR_EL1, SMCR_EL2, SMCR_EL3, SMPRI_EL1, SMPRIMAP_EL2, or SVCR System registers, from all Exception levels and any Security state, to EL3.

When instructions that directly access the SVCR System register are trapped with reference to this control, the MSR SVCRSM, MSR SVCRZA, and MSR SVCRSMZA instructions are also trapped.

When direct accesses to SMPRI_EL1 and SMPRIMAP_EL2 are trapped, the exception is reported using an ESR_EL3.EC value of 0x18. Otherwise, the exception is reported using an ESR_EL3.EC value of 0x1D, with an ISS code of 0x00000000.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL3.ESM has precedence over a trap taken as a result of CPTR_EL3.TFP.

0b0 This control causes execution of these instructions at all Exception levels to be trapped.

0b1 This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from all Exception levels, any Security state, and both Execution states, to EL3.

This includes the following registers, all reported using ESR_ELx.EC value 0x07:

- FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers.
- MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.
- VMSR accesses to FPSID.

Permitted VMSR accesses to FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

Traps execution at all Exception levels of SME and SVE instructions to EL3 from any Security state. The exception is reported using ESR_ELx.EC value 0x07.

A trap taken as a result of CPTR_EL3.ESM has precedence over a trap taken as a result of CPTR_EL3.TFP.

A trap taken as a result of CPTR_EL3.ESM has precedence over a trap taken as a result of CPTR_EL3.TFP.

Defined values are:

0b0 This control does not cause execution of any instructions to be trapped.

0b1 This control causes execution of these instructions at all Exception levels to be trapped.

Note

FPEXC32_EL2 is not accessible from EL0 using AArch64.

FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [9]**

Reserved, RES0.

**EZ, bit [8]**

*When FEAT_SVE is implemented:*

Traps execution of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL3, ZCR_EL2, or ZCR_EL1 System registers, from all Exception levels and any Security state, to EL3.

The exception is reported using ESR_ELx.EC value 0x19.

A trap taken as a result of CPTR_EL3.EZ has precedence over a trap taken as a result of CPTR_EL3.TFP.

  - 0b0       This control causes execution of these instructions at all Exception levels to be trapped.
  - 0b1       This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [7:0]**

Reserved, RES0.

**Accessing CPTR_EL3**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, CPTR_EL3**

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b1 & 0b10 & 0b0001 & 0b0001 & 0b010 \\
\end{array}
\]

  UNDEFINED;
elsif PSTATE.EL == EL3 then
  CPTR_EL3 = X[t, 64];
D17.2.33 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

**Purpose**

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

**Configurations**

AArch64 System register CSSELR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CSSELR[31:0].

**Attributes**

CSSELR_EL1 is a 64-bit register.

**Field descriptions**

![Field Diagram]

**Bits [63:5]**

Reserved, RES0.

**TnD, bit [4]**

*When FEAT_MTE2 is implemented:*

Allocation Tag not Data bit.

0b0  Data, Instruction or Unified cache.

0b1  Separate Allocation Tag cache.

When CSSELR_EL1.InD == 1, this bit is RES0.

If CSSELR_EL1. {TnD, Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Level, bits [3:1]**

Cache level of required cache.

0b000  Level 1 cache.

0b001  Level 2 cache.

0b010  Level 3 cache.

0b011  Level 4 cache.

0b100  Level 5 cache.

0b101  Level 6 cache.

0b110  Level 7 cache.

All other values are reserved.
If CSSELR_EL1.\{TnD, Level, InD\} is programmed to a cache level that is not implemented, then
the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**InD, bit [0]**

Instruction not Data bit.

0b0 Data or unified cache.

0b1 Instruction cache.

If CSSELR_EL1.\{TnD, Level, InD\} is programmed to a cache level that is not implemented, then
a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for
CSSELR_EL1.\{Level, InD\}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architectually UNKNOWN value.

**Accessing CSSELR_EL1**

Accesses to this register use the following encodings in the System register encoding space:

    CSSELRL1 = X[t, 64];
elsif PSTATE.EL == EL3 then
    CSSELRL1 = X[t, 64];
```
D17.2.34 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

**Purpose**

Provides information about the architecture of the caches.

**Configurations**

AArch64 System register CTR_EL0 bits [31:0] are architecturally mapped to AArch32 System register CTR[31:0].

**Attributes**

CTR_EL0 is a 64-bit register.

**Field descriptions**

![Field descriptions diagram]

**Bits [63:38]**

Reserved, RES0.

**TminLine, bits [37:32]**

*When FEAT_MTE2 is implemented:*

Tag minimum Line. $\log_2$ of the number of words covered by Allocation Tags in the smallest cache line of all caches which can contain Allocation tags that are controlled by the PE.

**Note**

- For an implementation with cache lines containing 64 bytes of data and 4 Allocation Tags, this will be $\log_2(64/4) = 4$.
- For an implementation with Allocations Tags in separate cache lines of 128 Allocation Tags per line, this will be $\log_2(128*16/4) = 9$.

**Otherwise:**

Reserved, RES0.

**Bit [31]**

Reserved, RES1.

**Bit [30]**

Reserved, RES0.

**DIC, bit [29]**

Instruction cache invalidation requirements for data to instruction coherence.

- **0b0** Instruction cache invalidation to the Point of Unification is required for data to instruction coherence.
- **0b1** Instruction cache invalidation to the Point of Unification is not required for data to instruction coherence.
IDC, bit [28]

Data cache clean requirements for instruction to data coherence. The meaning of this bit is:

- **0b0** Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR_EL1.LoC == 0b000 or (CLIDR_EL1.LoUIS == 0b000 && CLIDR_EL1.LoUU == 0b000).
- **0b1** Data cache clean to the Point of Unification is not required for instruction to data coherence.

CWG, bits [27:24]

Cache writeback granule. \(\log_2\) of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified. A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

Arm recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches.

ERG, bits [23:20]

Exclusives reservation granule, and, if FEAT_TME is implemented, transactional reservation granule. \(\log_2\) of the number of words of the maximum size of the reservation granule for the Load-Exclusive and Store-Exclusive instructions, and, if FEAT_TME is implemented, for detecting transactional conflicts.

A value of 0b0000 indicates that this register does not provide granule information and the architectural maximum of 512 words (2KB) must be assumed.

Value 0b0001 and values greater than 0b1001 are reserved.

DminLine, bits [19:16]

\(\log_2\) of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- **0b0** *When FEAT_VPIPT is implemented:*
  VMID aware Physical Index, Physical tag (VPIPT).
- **0b1** ASID-tagged Virtual Index, Virtual Tag (AIVIVT).
- **0b10** Virtual Index, Physical Tag (VIPT).
- **0b11** Physical Index, Physical Tag (PIPT).

From Armv8, the value 0b01 is reserved.

The value 0b00 is permitted only in an implementation that includes FEAT_VPIPT.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

\(\log_2\) of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.
Accessing CTR_EL0

```
D17.2.35 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 DACR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register DACR32_EL2 bits [31:0] are architecturally mapped to AArch32 System register DACR[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DACR32_EL2 are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

Attributes

DACR32_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

D<n>, bits [2n+1:2n], for n = 15 to 0

Domain n access permission, where n = 0 to 15. Permitted values are:

0b00 No access. Any access to the domain generates a Domain fault.

0b01 Client. Accesses are checked against the permission bits in the translation tables.

0b11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 0b10 is reserved.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DACR32_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DACR32_EL2

<table>

D17.2.36 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

**Purpose**

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Address) System instruction.

If FEAT_MTE is implemented, this register also indicates the granularity at which the DC GVA and DC GZVA instructions write.

**Configurations**

There are no configuration notes.

**Attributes**

DCZID_EL0 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:5]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DZP, bit [4]</td>
<td>Data Zero Prohibited. This field indicates whether use of DC ZVA instructions is permitted or prohibited.</td>
</tr>
<tr>
<td>BS, bits [3:0]</td>
<td>Log2 of the block size in words. The maximum size supported is 2KB (value == 9).</td>
</tr>
</tbody>
</table>

**Accessing DCZID_EL0**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, DCZID_EL0**

<table>
<thead>
<tr>

elsif PSTATE_EL == EL3 then
    X[t, 64] = DCZID_EL0;
D17.2.37 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL1.

**Configurations**

AArch64 System register ESR_EL1 bits \([31:0]\) are architecturally mapped to AArch32 System register DFSR[31:0].

**Attributes**

ESR_EL1 is a 64-bit register.

**Field descriptions**

ESR_EL1 is made **UNKNOWN** as a result of an exception return from EL1.

When an **UNPREDICTABLE** instruction is treated as **UNDEFINED**, and the exception is taken to EL1, the value of ESR_EL1 is **UNKNOWN**. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Bits [63:37]**

Reserved, **RES0**.

**ISS2, bits [36:32]**

*When FEAT_LS64 is implemented:*

When FEAT_LS64 V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort exception for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort exception for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

Otherwise, this field is **RES0**.

*Otherwise:*

Reserved, **RES0**.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 0b00000000**

Unknown reason.

See **ISS encoding for exceptions with an unknown reason**.
EC == 0b000001
Trapped WF* instruction execution.
Conditional WF* instructions that fail their condition code check do not cause an exception.
See ISS encoding for an exception from a WF* instruction.

EC == 0b000011
When AArch32 is supported:
Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.
See ISS encoding for an exception from an MCR or MRC access.

EC == 0b000100
When AArch32 is supported:
Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 0b000101
When AArch32 is supported:
Trapped MCRR or MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 0b000110
When AArch32 is supported:
Trapped LDC or STC access.
The only architected uses of these instruction are:
• An STC to write data to memory from DBGDTRRXint.
• An LDC to read data from memory to DBGDTRTXint.
See ISS encoding for an exception from an LDC or STC instruction.

EC == 0b000111
Access to SME, SVE, Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.
Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.
See ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps.

EC == 0b001010
When FEAT_LS64 is implemented:
Trapped execution of an LD64B or ST64B* instruction.
See ISS encoding for an exception from an LD64B or ST64B* instruction.

EC == 0b001100
When AArch32 is supported:
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 0b001101
When FEAT_BTI is implemented:
Branch Target Exception.
See ISS encoding for an exception from Branch Target Identification instruction.

EC == 0b001110
Illegal Execution state.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.
EC == 0b010001
When AArch32 is supported:
SVC instruction execution in AArch32 state.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b010101
When AArch64 is supported:
SVC instruction execution in AArch64 state.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b011000
When AArch64 is supported:
Trapped MSR, MRS or System instruction execution in AArch64 state, that is not
reported using EC 0b000000, 0b000001, or 0b000111.
This includes all instructions that cause exceptions that are part of the encoding space
defined in System instruction class encoding overview on page C5-655, except for those
exceptions reported using EC values 0b000000, 0b000001, or 0b000111.
See ISS encoding for an exception from MSR, MRS, or System instruction execution in
AArch64 state.

EC == 0b011001
When FEAT_SVE is implemented:
Access to SVE functionality trapped as a result of CPACR_EL1.ZEN,
CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC
0b000000.
See ISS encoding for an exception from an access to SVE functionality, resulting from
CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ.

EC == 0b011011
When FEAT_TME is implemented:
Exception from a TSTART instruction at EL0 when SCTLR_EL1.TME0
== 0, EL0 when SCTLR_EL2.TME0 == 0, at EL1 when SCTLR_EL1.TME == 0, at
EL2 when SCTLR_EL2.TME == 0 or at EL3 when SCTLR_EL3.TME == 0.
See ISS encoding for an exception from a TSTART instruction.

EC == 0b011100
When FEAT_FPAC is implemented:
Exception from a Pointer Authentication instruction authentication failure
See ISS encoding for an exception from a Pointer Authentication instruction
authentication failure.

EC == 0b011101
When FEAT_SME is implemented:
Access to SME functionality trapped as a result of CPACR_EL1.SMEN,
CPTR_EL2.SMEN, CPTR_EL2.TSM, CPTR_EL3.ESM, or an attempted execution of
an instruction that is illegal because of the value of PSTATE.SM or PSTATE.ZA, that is
not reported using EC 0b000000.
See ISS encoding for an exception due to SME functionality.

EC == 0b011110
When FEAT_RME is implemented:
Exception from a Granule Protection Check
See ISS encoding for an exception from a Granule Protection Check.

EC == 0b100000
Instruction Abort from a lower Exception level.
Used for MMU faults generated by instruction accesses and synchronous External
aborts, including synchronous parity or ECC errors. Not used for debug-related
exceptions.
See ISS encoding for an exception from an Instruction Abort.

**EC == 0b100001**

Instruction Abort taken without a change in Exception level.  
Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.  
See ISS encoding for an exception from an Instruction Abort.

**EC == 0b100010**

PC alignment fault exception.  
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.

**EC == 0b100100**

Data Abort exception from a lower Exception level.  
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.  
See ISS encoding for an exception from a Data Abort.

**EC == 0b100101**

Data Abort exception taken without a change in Exception level.  
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.  
See ISS encoding for an exception from a Data Abort.

**EC == 0b100110**

SP alignment fault exception.  
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.

**EC == 0b100111**

*When FEAT_MOPS is implemented:*  
Memory Operation Exception.  
See ISS encoding for an exception from the Memory Copy and Memory Set instructions.

**EC == 0b101000**

*When AArch32 is supported:*  
Trapped floating-point exception taken from AArch32 state.  
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.  
See ISS encoding for an exception from a trapped floating-point exception.

**EC == 0b101100**

*When AArch64 is supported:*  
Trapped floating-point exception taken from AArch64 state.  
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.  
See ISS encoding for an exception from a trapped floating-point exception.

**EC == 0b101111**

SError interrupt.  
See ISS encoding for an SError interrupt.

**EC == 0b110000**

Breakpoint exception from a lower Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.

EC == 0b1100001
Breakpoint exception taken without a change in Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.

EC == 0b110010
Software Step exception from a lower Exception level.
See ISS encoding for an exception from a Software Step exception.

EC == 0b110011
Software Step exception taken without a change in Exception level.
See ISS encoding for an exception from a Software Step exception.

EC == 0b110100
Watchpoint exception from a lower Exception level.
See ISS encoding for an exception from a Watchpoint exception.

EC == 0b110101
Watchpoint exception taken without a change in Exception level.
See ISS encoding for an exception from a Watchpoint exception.

EC == 0b111000
When AArch32 is supported:
BKPT instruction execution in AArch32 state.
See ISS encoding for an exception from execution of a Breakpoint instruction.

EC == 0b111000
When AArch64 is supported:
BRK instruction execution in AArch64 state.
See ISS encoding for an exception from execution of a Breakpoint instruction.

All other EC values are reserved by Arm, and:
- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]
Instruction Length for synchronous exceptions. Possible values of this bit are:

0b0  16-bit instruction trapped.
0b1  32-bit instruction trapped. This value is also used when the exception is one of the following:
    - An SError interrupt.
    - An Instruction Abort exception.
    - A PC alignment fault exception.
    - An SP alignment fault exception.
    - A Data Abort exception for which the value of the ISV bit is 0.
    - An Illegal Execution state exception.
    - Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
      — 0b0: 16-bit T32 BKPT instruction.
— 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see Mapping of the general-purpose registers between the Execution states on page D1-4684.

If the AArch32 register descriptor is 0b1111, then:

• If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.

• If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  — The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  — The value 0b11111.

ISS encoding for exceptions with an unknown reason

<table>
<thead>
<tr>
<th>Bits [24:0]</th>
<th>Reserved, RES0</th>
</tr>
</thead>
</table>

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

• The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  — A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  — A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  — Instruction encodings that are unallocated.
  — Instruction encodings for instructions or System registers that are not implemented in the implementation.

• In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.

• In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.

• In AArch32 state, attempted execution of a short vector floating-point instruction.
• In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.

• An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.

• Attempted execution of:
  — An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  — An SMC instruction when disabled by SCR_EL3.SMD.
  — An HLT instruction when disabled by EDSCR.HDE.

• Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.

• Attempted execution of an MSR or MRS instruction using a _EL12 register name when HCR_EL2.E2H == 0.

• Attempted execution, in Debug state, of:
  — A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  — A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  — A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.

• When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon.

• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

• In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.

• An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0b000111.

• In Non-transactional state, attempted execution of a TCOMMIT instruction.

**ISS encoding for an exception from a WF* instruction**

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>RES0</th>
<th>RN</th>
<th>RES0</th>
<th>RV</th>
<th>TI</th>
</tr>
</thead>
</table>

CV, bit [24]

Condition code valid.

0b0  The COND field is not valid.

0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.

• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT is implemented:

Register Number. Indicates the register number supplied for a WFET or WFIT instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT is implemented:

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped WFET or WFIT instruction.

- 0b0 Register field invalid.
- 0b1 Register field valid.

If TI[1] == 0, then this field is RES0.

This field is set to 1 on a trap on WFET or WFIT.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**TI, bits [1:0]**
Trapped instruction. Possible values of this bit are:
- 0b00 WFI trapped.
- 0b01 WFE trapped.
- 0b10 *When FEAT_WFxT is implemented:* WFIT trapped.
- 0b11 *When FEAT_WFxT is implemented:* WFET trapped.

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating this exception:
- SCTLR_EL1.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.
- SCR_EL3.{TWE, TWI}.

```

**CV, bit [24]**
Condition code valid.
- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.
For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**
For exceptions taken from AArch64, this field is set to 0b1110.
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to \texttt{0b1110}.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to \texttt{0b1110}, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is \textbf{IMPLEMENTATION DEFINED} whether:
  - CV is set to 0 and COND is set to an \textbf{UNKNOWN} value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is \textbf{IMPLEMENTATION DEFINED} whether the COND field is set to \texttt{0b1110}, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textbf{UNKNOWN} value.

\textbf{Opc2, bits [19:17]}

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value \texttt{0b000}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textbf{UNKNOWN} value.

\textbf{Opc1, bits [16:14]}

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value \texttt{0b111}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textbf{UNKNOWN} value.

\textbf{CRn, bits [13:10]}

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textbf{UNKNOWN} value.

\textbf{Rt, bits [9:5]}

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not \texttt{0b1111}, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt value is \texttt{0b1111}:

- If the instruction that generated the exception is not \textbf{UNPREDICTABLE}, then the register specifier takes the value \texttt{0b11111}.

- If the instruction that generated the exception is \textbf{UNPREDICTABLE}, then the register specifier takes an \textbf{UNKNOWN} value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value \texttt{0b11111}.
See *Mapping of the general-purpose registers between the Execution states* on page D1-4684.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**CRm, bits [4:1]**
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value **0b0000**.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Direction, bit [0]**
Indicates the direction of the trapped instruction.
- **0b0** Write to System register space. MCR instruction.
- **0b1** Read from System register space. MRC or VMRS instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

The following fields describe configuration settings for generating exceptions that are reported using EC value **0b000011**:
- If `FEAT_TIDCP1` is implemented, `SCTLR_EL1.TIDCP`, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL1.
- `CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}`, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL1 or EL2.
- `PMUSERENR_EL0.{ER, CR, SW, EN}`, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL1 or EL2.
- `AMUSERENR_EL0.EN`, for accesses to Activity Monitors registers from EL0 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL1 or EL2.
- `HCR_EL12.TTLB`, for execution of TLB maintenance instructions at EL1 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `HCR_EL2.TSVT, TPC, TPU` for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `HCR_EL2.TACR`, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `HCR_EL2.TIDCP`, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- If `FEAT_TIDCP1` is implemented, `SCTLR_EL2.TIDCP`, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `HCR_EL22.TID1, TID2, TID3`, for accesses to ID registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `CPTR_EL2.TCPAC`, for accesses to CPACR_EL1 or CPACR using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
- `HSTR_EL2.T<n>`, for accesses to System registers using AArch32 state, MCR or MRC access (coproc == **0b1111**), trapped to EL2.
• **CNTHCTL_EL2.EL1PCEN**, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **MDCR_EL2.[TPM, TPMCR]**, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL2.TAM**, for accesses to Activity Monitors registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL3.TCPAC**, for accesses to CPACR from EL1 and EL2, and accesses to HCPTP from EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.

• **CPTR_EL3.TAM**, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.

• If **FEAT_FGT** is implemented, MCR or MRC access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000101:

• **CPACR_EL1.TTA** for accesses to trace registers, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.

• **MDSCR_EL1.TDCC**, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.

• If **FEAT_FGT** is implemented, **MDCR_EL2.TDCC** for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

• **HCR_EL2.TID0**, for accesses to the JIDR register in the ID group 0 at EL0 and EL1 using AArch32, MRC access (coproc == 0b1110) trapped to EL2.

• **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDRA**, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDOSA**, for accesses to powerdown debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDA**, for accesses to other debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

• **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

• **MDCR_EL3.TDA**, for accesses to other debug registers, using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001000:

• **HCR_EL2.TID0**, for accesses to the FPSID register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.

• **HCR_EL2.TID3**, for accesses to registers in ID group 3 including MVFR0, MVFR1 and MVFR2, VMRS access trapped to EL2.
**ISS encoding for an exception from an LD64B or ST64B* instruction**

</table>

All other values are reserved.

**ISS encoding for an exception from an MCRR or MRRC access**

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]
The Opc1 value from the issued instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]
Reserved, RES0.

Rt2, bits [14:10]
The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.
If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is 0b1111:
- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b1111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value 0b1111.

See Mapping of the general-purpose registers between the Execution states on page D1-4684.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]
The Rt value from the issued instruction, the first general-purpose register used for the transfer.
If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is 0b1111:
- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b1111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value 0b1111.

See Mapping of the general-purpose registers between the Execution states on page D1-4684.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
CRm, bits [4:1]
The CRm value from the issued instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction.
0b0 Write to System register space. MCRR instruction.
0b1 Read from System register space. MRRC instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000100:

• CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.

• PMUSERENR_EL0.{CR, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.

• AMUSERENR_EL0.{EN}, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.

• HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

• HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

• CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

• MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

• CPTR_EL2.TAM, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.

• MDCR_EL3.TPM, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.

• CPTR_EL3.TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.

• IF FEAT_FGT is implemented, HDFGRTR_EL2.PMCCNTR_EL0 for MRRC access and HDFGWTR_EL2.PMCCNTR_EL0 for MCRR access to PMCCNTR at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001100:

• MDSCR_EL1.TDCC, for accesses to the Debug ROM registers DBGDSAR and DBGDRAR at EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.

• MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.

• MDCR_EL3.TDA, for accesses to debug registers, using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.
• **CPACR_EL1.TTA** for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.

• **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.

• **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.

--- **Note**

If the Armv8-A architecture is implemented with an ETMv4 implementation, MCRR and MRRC accesses to trace registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

**CV, bit [24]**

Condition code valid.
- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:
- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IR field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \texttt{0b1110}, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

\textbf{imm8, bits \([19:12]\)}

The immediate value from the issued instruction.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

\textbf{Bits \([11:10]\)}

Reserved, \texttt{RES0}.

\textbf{Rn, bits \([9:5]\)}

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not \texttt{0b1111}, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rn value is \texttt{0b1111}:
• If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value \texttt{0b1111}.
• If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  — The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  — The value \texttt{0b1111}.

See \textit{Mapping of the general-purpose registers between the Execution states on page D1-4684.}

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

\textbf{Offset, bit \([4]\)}

Indicates whether the offset is added or subtracted:
\begin{itemize}
  \item \texttt{0b0} Subtract offset.
  \item \texttt{0b1} Add offset.
\end{itemize}

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

\textbf{AM, bits \([3:1]\)}

Addressing mode. The permitted values of this field are:
\begin{itemize}
  \item \texttt{0b000} Immediate unindexed.
  \item \texttt{0b001} Immediate post-indexed.
  \item \texttt{0b010} Immediate offset.
  \item \texttt{0b011} Immediate pre-indexed.
  \item \texttt{0b100} For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
  \item \texttt{0b110} For a trapped STC instruction, this encoding is reserved.
\end{itemize}
The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-11600.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction.

0b0 Write to memory. STC instruction.

0b1 Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000110:

- **MDSCR_EL1.TDCC**, for accesses using AArch32 state, LDC access to DBGDTRXint or STC access to DBGDTRXint trapped to EL1 or EL2.

- **MDCR_EL2.TDA**, for accesses using AArch32 state, LDC access to DBGDTRXint or STC access to DBGDTRXint MCR or MRC access trapped to EL2.

- **MDCR_EL3.TDA**, for accesses using AArch32 state, LDC access to DBGDTRXint or STC access to DBGDTRXint MCR or MRC access trapped to EL3.

- If FEAT_FGT is implemented, **MDCR_EL2.TDCC** for LDC and STC accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

**ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps**

```
   28  23  20  19  0
   CV  COND RES0
```

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.

- Accesses to the Advanced SIMD and floating-point System registers.

- Execution of SME instructions.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

**CV, bit [24]**

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.
The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:
• When an A32 instruction is trapped, CV is set to 1 and:
  — If the instruction is conditional, COND is set to the condition code field value from the instruction.
  — If the instruction is unconditional, COND is set to 0b1110.
• A conditional A32 instruction that is known to pass its condition code check can be presented either:
  — With COND set to 0b1110, the value for unconditional.
  — With the COND value held in the instruction.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  — CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  — CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]
Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:
• CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
• CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
• CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The accesses covered by this trap include:
• Execution of SVE instructions when the PE is not in Streaming SVE mode.
• Accesses to the SVE System registers, ZCR_ELx.
For an implementation that does not include SVE, the exception is reported using the EC value 0b000000.

**Bits [24:0]**

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b011001:

- **CPACR_EL1.ZEN**, for execution of SVE instructions and accesses to SVE registers at EL0 or EL1, trapped to EL1.
- **CPTR_EL2.ZEN and CPTR_EL2.TZ**, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- **CPTR_EL3.EZ**, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

**ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

![ISS encoding diagram]

**Bits [24:0]**

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see [PC alignment checking](#) on page D1-4668.

**SP alignment checking** on page D1-4668 describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from the Memory Copy and Memory Set instructions**

![ISS encoding diagram]

**MemInst, bit [24]**

Indicates the memory instruction class causing the exception.

- 0b0: CPYFE*, CPYFM*, CPYE*, and CPYM* instructions.
- 0b1: SETE*, SETM*, SETGE*, and SETGM* instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**isSETG, bit [23]**

Indicates whether the instruction belongs to SETGM* or SETGE* class of instruction.

- 0b0: Not a SETGM* or SETGE* instruction.
- 0b1: SETGM* or SETGE* instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Options, bits [22:19]
Options : the Options field of the instruction.
For Memory Copy instructions, bits[22:19] forms the Options field, which holds the bits[15:12] of the instruction.
For Memory Set instructions:
- Bits[22:21] are RES0.
- Bits[20:19] form the Options field, which holds the bits[13:12] of the instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FromEpilogue, bit [18]
Indicates whether the instruction belongs to the epilogue class of Memory Copy or Memory Set instructions.
0b0 Not an epilogue instruction.
0b1 CPYE*, CPYFE*, SETE*, or SETGE* instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WrongOption, bit [17]
Algorithm option.
0b0 WrongOption is false.
0b1 WrongOption is true.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OptionA, bit [16]
Algorithm type indicated by the PSTATE.C bit.
0b0 OptionB indicated by PSTATE.C is 0.
0b1 OptionA indicated by PSTATE.C is 1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]
Reserved, RES0.

destreg, bits [14:10]
The destination register value from the issued instruction, containing the destination address.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

srcreg, bits [9:5]
The source register value from the issued instruction, containing either the source address or the source data.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

sizereg, bits [4:0]
The size register value from the issued instruction, containing the number of bytes to be transfered or set.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from HVC or SVC instruction execution**

<table>
<thead>
<tr>
<th>Bits [24:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:
- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see SVC and HVC.

For A64 instructions, see SVC and HVC.

If FEAT_FGT is implemented, HFGITR_EL2.[SVC_EL1, SVC_EL0] control fine-grained traps on SVC execution.

**ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state**

<table>
<thead>
<tr>
<th>Bits [24:22]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Op0, bits [21:20]**

The Op0 value from the issued instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Op2, bits [19:17]**

The Op2 value from the issued instruction.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Op1, bits [16:14]**

The Op1 value from the issued instruction.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**CRn, bits [13:10]**

The CRn value from the issued instruction.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the general-purpose register used for the transfer.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction.
0b0   Write access, including MSR instructions.
0b1   Read access, including MRS instructions.
The reset behavior of this field is:
   • On a Warm reset, this field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see *System instructions on page C4-539* for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- If **FEAT_TIDCP1** is implemented, **SCTLR_EL1.TIDCP**, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL1.
- **SCTLR_EL1.UCI**, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- **SCTLR_EL1.UCT**, for accesses to **CTR_EL0** using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- **SCTLR_EL1.DZE**, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- **SCTLR_EL1.UMA**, for accesses to the **PSTATE** interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- **CPACR_EL1.TTA**, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- **MDSCR_EL1.TDCC**, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
• If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

• CNTKCTL_EL1.\{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN\} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• PMUSERENR_EL0.\{ER, CR, SW, EN\}, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• AMUSERENR_EL0.EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• HCR_EL2.\{TRVM, TVM\}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.\{TSW, TPC, TPU\}, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.

• If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.\{TID1, TID2, TID3\}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.

• CNTHTCTL_EL2.\{EL1PCEN, EL1PCTEN\}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.\{TPM, TPMCR\}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.APK, for accesses to Pointer authentication key registers. using AArch64 state, MSR or MRS access trapped to EL2.
• `HCR_EL2.{NV, NV1}`, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.

• `HCR_EL2.AT`, for execution of AT S1E* instructions, using AArch64 state, MSR or MRS access, trapped to EL2.

• `HCR_EL2.{TERR, FIEN}`, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.

• `SCR_EL3.APK`, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `SCR_EL3.ST`, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `SCR_EL3.{TERR, FIEN}`, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `CPTR_EL3.TTCPAC`, for accesses to `CPTR_EL2` and `CPACR_EL1` using AArch64 state, MSR or MRS access trapped to EL3.

• `CPTR_EL3.TTA`, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `MDCR_EL3.TTRF`, for accesses to the trace filter control registers, `TRFCR_EL1` and `TRFCR_EL2`, using AArch64 state, MSR or MRS access trapped to EL3.

• `MDCR_EL3.TDA`, for accesses to debug registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `MDCR_EL3.TDOSA`, for accesses to powerdown debug registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `MDCR_EL3.TPM`, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL3.

• `CPTR_EL3.TAM`, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.

• If `FEAT_EVT` is implemented, the following registers control traps for EL1 and EL0 Cache controls that use this EC value:
  — `HCR_EL2.{TTLBOS, TTLBIS, TICAB, TOCU, TID4}`.
  — `HCR2.{TTLBIS, TICAB, TOCU, TID4}`.

• If `FEAT_FGT` is implemented:
  — `SCR_EL3.FGTEn`, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  — `HFGRTR_EL2` for reads and `HFGWTR_EL2` for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
  — `HFGITR_EL2` for execution of system instructions, MSR or MRS access trapped to EL2
  — `HDFGRTR_EL2` for reads and `HDFGWTR_EL2` for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
  — `HAFGRTR_EL2` for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.

• If `FEAT_RNG_TRAP` is implemented:
  — `SCR_EL3.TRNDR` for reads of `RNDR` and `RNDRRS` using AArch64 state, MRS access trapped to EL3.

• If `FEAT_SME` is implemented:
  — `CPTR_EL3.ESM`, for MSR or MRS accesses to `SMPRI_EL1` at EL1, EL2, and EL3, trapped to EL3.
— CPTR_EL3.ESM, for MSR or MRS accesses to SMPRIMAP_EL2 at EL2 and EL3, trapped to EL3.
— SCTLR_EL1.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL1 or EL2.
— SCTLR_EL2.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL2.
— SCR_EL3.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, EL1, and EL2, trapped to EL3.

• If FEAT_NMI is implemented, HCRX_EL2.TALLINT, for MSR writes of ALLINT at EL1, trapped to EL2.

**ISS encoding for an exception from an Instruction Abort**

![ISS encoding diagram]

**Bits [24:13]**

Reserved, RES0.

**SET, bits [12:11]**

*When FEAT_RAS is implemented:*

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the
Instruction Abort exception.

0b00 Recoverable state (UER).
0b10 Uncontainable (UC).
0b11 Restartable state (UEO).

All other values are reserved.

--- **Note** ---

Software can use this information to determine what recovery might be possible. Taking a
synchronous External Abort exception might result in a PE state that is not recoverable.

---

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

* • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**FnV, bit [10]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a
translation table walk.

0b0 FAR is valid.
0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

* • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External
aborts.

For any abort other than an External abort this bit returns a value of 0.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [8]**

Reserved, RES0.

**S1PTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code.

- 0b000000 Address size fault, level 0 of translation or translation table base register.
- 0b000001 Address size fault, level 1.
- 0b000010 Address size fault, level 2.
- 0b000011 Address size fault, level 3.
- 0b000100 Translation fault, level 0.
- 0b000101 Translation fault, level 1.
- 0b000110 Translation fault, level 2.
- 0b000111 Translation fault, level 3.
- 0b001001 Access flag fault, level 1.
- 0b001010 Access flag fault, level 2.
- 0b001011 Access flag fault, level 3.
- 0b001100 When FEAT_LP A2 is implemented:
  Access flag fault, level 0.
- 0b001101 When FEAT_LP A2 is implemented:
  Permission fault, level 0.
- 0b001110 Permission fault, level 1.
- 0b001111 Permission fault, level 2.
- 0b010000 Synchronous External abort, not on translation table walk or hardware update of translation table.
- 0b010011 When FEAT_LP A2 is implemented:
  Synchronous External abort on translation table walk or hardware update of translation table, level -1.
- 0b010100 Synchronous External abort on translation table walk or hardware update of translation table, level 0.
- 0b010101 Synchronous External abort on translation table walk or hardware update of translation table, level 1.
- 0b010110 Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b01011  Synchronous External abort on translation table walk or hardware update of translation table, level 3.

0b01100  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access, not on translation table walk.

0b01101  When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.

0b01110  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.

0b01101  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.

0b01110  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.

0b01111  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.

0b10001  When FEAT_RME is implemented and FEAT_LPA2 is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level -1.

0b10010  When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 0.

0b10011  When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 1.

0b10010  When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 2.

0b10011  When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 3.

0b10100  When FEAT_RME is implemented:
Granule Protection Fault, not on translation table walk or hardware update of translation table.

0b10101  When FEAT_LPA2 is implemented:
Address size fault, level -1.

0b10111  When FEAT_LPA2 is implemented:
Translation fault, level -1.

0b11000  TLB conflict abort.

0b11001  When FEAT_HAFDBS is implemented:
Unsupported atomic hardware update fault.

All other values are reserved.

For more information about the lookup level associated with a fault, see The lookup level associated with MMU faults on page D8-5190.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception due to SME functionality**

The accesses covered by this trap include:
- Execution of SME instructions.
- Execution of SVE and Advanced SIMD instructions, when the PE is in Streaming SVE mode.
- Direct accesses of SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3.

**Bits [24:3]**
- Reserved, RES0.

**SMTC, bits [2:0]**
- SME Trap Code. Identifies the reason for instruction trapping.
  - 0b000: Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, or CPTR_EL3.ESM, that is not reported using EC 0b000000.
  - 0b001: Advanced SIMD, SVE, or SVE2 instruction trapped because PSTATE.SM is 1.
  - 0b010: SME instruction trapped because PSTATE.SM is 0.
  - 0b011: SME instruction trapped because PSTATE.ZA is 0.
- All other values are reserved.

The following fields describe the configuration settings for the traps that are reported using the EC value 0b011101:
- **CPACR_EL1.SMEN**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR and SMCR_EL1 System registers at EL1 and EL0, trapped to EL1 or EL2.
- **CPTR_EL2.SMEN and CPTR_EL2.TSM**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2 at EL2, EL1, or EL0, trapped to EL2.
- **CPTR_EL3.ESM**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3 from all Exception levels and any Security state, trapped to EL3.

**ISS encoding for an exception from a Granule Protection Check**

**Bits [24:22]**
- Reserved, RES0.
S2PTW, bit [21]
Indicates whether the Granule Protection Check exception was on an access made for a stage 2 translation table walk.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Fault not on a stage 2 translation table walk.</td>
</tr>
<tr>
<td>0b1</td>
<td>Fault on a stage 2 translation table walk.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

InD, bit [20]
Indicates whether the Granule Protection Check exception was on an instruction or data access.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Data access.</td>
</tr>
<tr>
<td>0b1</td>
<td>Instruction access.</td>

<tr>
<td>0b1</td>
<td>The fault was generated by the use of <strong>VNCR_EL2</strong>, by an MRS or MSR instruction executed at EL1.</td>
</tr>
</tbody>
</table>

This field is 0 in ESR_EL1.

When InD is '1', this field is **RES0**.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*
Reserved, **RES0**.

**Bits [12:9]**
Reserved, **RES0**.
CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

<table>
<thead>
<tr>
<th>CM Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.</td>
</tr>
<tr>
<td>0b1</td>
<td>The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

Indicates whether the Granule Protection Check exception was on an access for stage 2 translation for a stage 1 translation table walk:

<table>
<thead>
<tr>
<th>S1PTW Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Fault not on a stage 2 translation for a stage 1 translation table walk.</td>
</tr>
<tr>
<td>0b1</td>
<td>Fault on the stage 2 translation of an access for a stage 1 translation table walk.</td>
</tr>
</tbody>
</table>

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

<table>
<thead>
<tr>
<th>WnR Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Abort caused by an instruction reading from a memory location.</td>
</tr>
<tr>
<td>0b1</td>
<td>Abort caused by an instruction writing to a memory location.</td>
</tr>
</tbody>
</table>

When InD is '1', this field is RES0.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

xFSC, bits [5:0]

Instruction or Data Fault Status Code.

<table>
<thead>
<tr>
<th>xFSC Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b100011</td>
<td>When FEAT_RME is implemented and FEAT_LPA2 is implemented: Granule Protection Fault on translation table walk or hardware update of translation table, level -1.</td>
</tr>
<tr>
<td>0b100100</td>
<td>When FEAT_RME is implemented: Granule Protection Fault on translation table walk or hardware update of translation table, level 0.</td>
</tr>
</tbody>
</table>
When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 1.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 2.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 3.

When FEAT_RME is implemented:
Granule Protection Fault, not on translation table walk or hardware update of translation table.

All other values are reserved.

For more information about the lookup level associated with a fault, see *The lookup level associated with MMU faults on page D8-5190.*

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a Data Abort**

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

**ISV, bit [24]**

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

0b0 No valid instruction syndrome. ISS[23:14] are RES0.

0b1 ISS[23:14] hold a valid instruction syndrome.

In ESR_EL2, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

In ESR_EL2, ISV is 1 when FEAT_LS64_V is implemented and a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

In ESR_EL2, ISV is 1 when FEAT_LS64_ACCDATA is implemented and a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.
For other faults reported in ESR_EL2, ISV is 0 except for the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with \texttt{0b11111}, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
  - Is an LDR, LDA, LDRT, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDBA, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLHB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using R15 as a source or destination register.

For these stage 2 aborts, ISV is \texttt{UNKNOWN} if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64_V is implemented and a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64_ACCE is implemented and a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When FEAT_MOPS is implemented, for a synchronous Data Abort on a Memory Copy and Memory Set instruction, ISV is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \texttt{UNKNOWN} value.

\textbf{SAS, bits [23:22]}

\textit{When ISV == 1:}

\textbf{Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.}

\begin{itemize}
\item \texttt{0b00}  \textbf{Byte}
\item \texttt{0b01}  \textbf{Halfword}
\item \texttt{0b10}  \textbf{Word}
\item \texttt{0b11}  \textbf{Doubleword}
\end{itemize}

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is \texttt{0b11}.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is \texttt{0b11}.

When FEAT_LS64_ACCE is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is \texttt{0b11}.

This field is \texttt{UNKNOWN} when the value of ISV is \texttt{UNKNOWN}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \texttt{UNKNOWN} value.
SSE, bit [21]

**When ISV == 1:**
Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

- **0b0** Sign-extension not required.
- **0b1** Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

SRT, bits [20:16]

**When ISV == 1:**
Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states](#) on page D1-4684.

This field is **UNKNOWN** when the value of ISV is **UNKNOWN**.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**
Reserved, RES0.

SF, bit [15]

**When ISV == 1:**

**SF**
Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

- **0b0** Instruction loads/stores a 32-bit general-purpose register.
- **0b1** Instruction loads/stores a 64-bit general-purpose register.

--- **Note** ---
This field specifies the register width identified by the instruction, not the Execution state.
When `FEAT_LS64` is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When `FEAT_LS64_V` is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When `FEAT_LS64_ACCDATA` is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is `UNKNOWN` when the value of ISV is `UNKNOWN`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally `UNKNOWN` value.

**When `ISV == 0` and `FEAT_SME` is implemented:**

FnP

FAR not Precise.

0b0 The FAR holds the faulting virtual address that generated the Data Abort.

0b1 The FAR holds any virtual address within the naturally-aligned granule that contains the faulting virtual address that generated a Data Abort due to an SVE contiguous vector load/store instruction in Streaming SVE mode, or an SME load/store instruction.

For more information about the naturally-aligned fault granule, see FAR_ELx (for example, FAR_EL1).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally `UNKNOWN` value.

**Otherwise:**

Reserved, RES0.

**AR, bit [14]**

**When `ISV == 1`:**

Acquire/Release.

0b0 Instruction did not have acquire/release semantics.

0b1 Instruction did have acquire/release semantics.

When `FEAT_LS64` is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When `FEAT_LS64_V` is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When `FEAT_LS64_ACCDATA` is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is `UNKNOWN` when the value of ISV is `UNKNOWN`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally `UNKNOWN` value.

**Otherwise:**

Reserved, RES0.
VNCR, bit [13]

When FEAT_NV2 is implemented:

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

0b0    The fault was not generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

0b1    The fault was generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LST, bits [12:11]

When (DFSC == 0b00xxxx || DFSC == 0b101011) && DFSC != 0b0000xx:

LST
Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort.

0b00    The instruction that generated the Data Abort is not specified.

0b01    When FEAT_LS64_V is implemented:
An ST64BV instruction generated the Data Abort.

0b10    When FEAT_LS64 is implemented:
An LD64B or ST64B instruction generated the Data Abort.

0b11    When FEAT_LS64_ACCDATA is implemented:
An ST64BV0 instruction generated the Data Abort.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and DFSC == 0b010000:

SET
Synchronous Error Type. Used when a Synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

0b00    Recoverable state (UER).

0b10    Uncontainable (UC).

0b11    Restartable state (UEO).

All other values are reserved.

Note
Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0  FAR is valid.
0b1  FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:
•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:
•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0  The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1  The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:
•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0  Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:
•  On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0  Abort caused by an instruction reading from a memory location.
0b1  Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.
This field is **UNKNOWN** for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of \(0b110101\) or \(0b110001\), indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**DFSC, bits [5:0]**

Data Fault Status Code.

- \(0b000000\) Address size fault, level 0 of translation or translation table base register.
- \(0b000001\) Address size fault, level 1.
- \(0b000010\) Address size fault, level 2.

All other values are reserved.

For more information about the lookup level associated with a fault, see The lookup level associated with MMU faults on page D8-5190.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
ISS encoding for an exception from a trapped floating-point exception

Bit [24]
Reserved, RES0.

TFV, bit [23]
Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.

0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see Floating-point exceptions and exception traps on page A1-64.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note
This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]
Reserved, RES0.

VECITR, bits [10:8]
For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.
For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]
Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0 Input denormal floating-point exception has not occurred.
0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
D17.2 General system control registers

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0    Inexact floating-point exception has not occurred.
0b1    Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0    Underflow floating-point exception has not occurred.
0b1    Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0    Overflow floating-point exception has not occurred.
0b1    Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0    Divide by Zero floating-point exception has not occurred.
0b1    Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0b0    Invalid Operation floating-point exception has not occurred.
0b1    Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR. {IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
• From an Exception level using AArch32, the FPSCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} bits enable each of the floating-point exception traps.

**ISS encoding for an SError interrupt**

![ISS encoding diagram]

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

0b0 Bits [23:0] of the ISS field holds the fields described in this encoding.

--- Note ---

If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

--- Note ---

0b1 Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

--- Note ---

This field was previously called ISV.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

*When FEAT_IESB is implemented and DFSC == 0b010001:*

Implicit error synchronization event.

0b0 The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.

0b1 The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

AET, bits [12:10]

*When FEAT_RAS is implemented and DFSC == 0b010001:*

Asynchronous Error Type.

Describes the PE error state after taking the SError interrupt exception.

0b000 Uncontainable (UC).

0b001 Unrecoverable state (UEU).

0b010 Restartable state (UEO).

0b011 Recoverable state (UER).

0b110 Corrected (CE).

All other values are reserved.
If multiple errors are taken as a single SError interrupt exception, the overall PE error state is reported.

--- Note ---

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and DFSC == 0b010001:
External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:
Data Fault Status Code.
- 0b000000 Uncategorized error.
- 0b010001 Asynchronous SError interrupt.
All other values are reserved.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

<table>
<thead>
<tr>
<th>24</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>IFSC</td>
</tr>
</tbody>
</table>

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.
- 0b100010 Debug exception.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
For more information about generating these exceptions:

- For exceptions from AArch64, see *Breakpoint exceptions* on page D2-4707.
- For exceptions from AArch32, see *Breakpoint exceptions* on page G2-9054 and *Vector Catch exceptions* on page G2-9093.

**ISS encoding for an exception from a Software Step exception**

<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISV</td>
<td>RES0</td>
<td>EX</td>
<td>IFSC</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

- 0b0  EX bit is RES0.
- 0b1  EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [23:7]**

Reserved, RES0.

**EX, bit [6]**

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

- 0b0  An instruction other than a Load-Exclusive instruction was stepped.
- 0b1  A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IFSC, bits [5:0]**

Instruction Fault Status Code.

- 0b100010  Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Software Step exceptions* on page D2-4742.

**ISS encoding for an exception from a Watchpoint exception**

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-4756.
Bit [24]
Reserved, RES0.

WPT, bits [23:18]

When FEAT_SME is implemented:
Watchpoint number, 0 to 15 inclusive.
All other values are reserved.

Otherwise:
Reserved, RES0.

WPTV, bit [17]

When FEAT_SME is implemented:
Watchpoint number Valid.
0b0 The WPT field is invalid, and holds an UNKNOWN value.
0b1 The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

When a Watchpoint exception is triggered by a watchpoint match:
• If the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
• If the PE sets all of FnV, FnP, and WPF to 0, then the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:
Reserved, RES0.

WPF, bit [16]

When FEAT_SME is implemented:
Watchpoint might be false-positive.
0b0 The watchpoint matched the original access or set of contiguous accesses.
0b1 The watchpoint matched an access or set of contiguous accesses where the lowest accessed address was rounded down to the nearest multiple of 16 bytes and the highest accessed address was rounded up to the nearest multiple of 16 bytes minus 1, but the watchpoint might not have matched the original access or set of contiguous accesses.

Otherwise:
Reserved, RES0.

FnP, bit [15]

When FEAT_SME is implemented:
FAR not Precise.
This field only has meaning if the FAR is valid; that is, when the FnV field is 0. If the FnV field is 1, the FnP field is 0.
0b0 If the FnV field is 0, the FAR holds the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.
0b1 The FAR holds any address within the smallest implemented translation granule that contains the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.

Otherwise:
Reserved, RES0.

Bit [14]
Reserved, RES0.
**VNCR, bit [13]**

*When FEAT_NV2 is implemented:*

Indicates that the watchpoint came from use of VNCR_EL2 register by EL1 code.

0b0  The watchpoint was not generated by the use of VNCR_EL2 by EL1 code.

0b1  The watchpoint was generated by the use of VNCR_EL2 by EL1 code.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNDEFINED value.

**Bits [12:11]**

Reserved, RES0.

**FnV, bit [10]**

*When FEAT_SME is implemented:*

FAR not Valid.

0b0  The FAR is valid, and its value is as described by the FnP field.

0b1  The FAR is invalid, and holds an UNDEFINED value.

**Otherwise:**

Reserved, RES0.

**Bit [9]**

Reserved, RES0.

**CM, bit [8]**

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

0b0  The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.

0b1  The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as a cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNDEFINED value.

**Bit [7]**

Reserved, RES0.

**WnR, bit [6]**

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0  Watchpoint exception caused by an instruction reading from a memory location.

0b1  Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DFSC, bits [5:0]**

Data Fault Status Code.

0b100010 Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-4726.

**ISS encoding for an exception from execution of a Breakpoint instruction**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Comment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:16]**

Reserved, RES0.

**Comment, bits [15:0]**

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For more information about generating these exceptions, see *Breakpoint Instruction exceptions* on page D2-4705.

**ISS encoding for an exception from a TSTART instruction**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>5</th>
<th>4</th>
<th>0</th>

<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:10]**

Reserved, RES0.

**Rd, bits [9:5]**

The Rd value from the issued instruction, the general purpose register used for the destination.

**Bits [4:0]**

Reserved, RES0.

**ISS encoding for an exception from Branch Target Identification instruction**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>10</th>
<th>9</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>BTYPE</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:2]**

Reserved, RES0.
BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

For more information about generating these exceptions, see Chapter B1 The AArch64 Application Level Programmers’ Model.

ISS encoding for an exception from a Pointer Authentication instruction authentication failure

<table>
<thead>
<tr>
<th>Bit [24:2]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Exception as a result of an Instruction key or a Data key</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit [1]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Instruction Key</td>
</tr>
<tr>
<td>0b1</td>
<td>Data Key</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

<table>
<thead>
<tr>
<th>Bit [0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>A key</td>
</tr>
<tr>
<td>0b1</td>
<td>B key</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following instructions generate an exception when the Pointer Authentication Code (PAC) is incorrect:
- AUTIASP, AUTIAZ, AUTIA1716.
- AUTIBSP, AUTIBZ, AUTIB1716.
- AUTIA, AUTDA, AUTIB, AUTDB.
- AUTiza, AUTIZB, AUTDZA, AUTDZB.

It is IMPLEMENTATION DEFINED whether the following instructions generate an exception directly from the authorization failure, rather than changing the address in a way that will generate a Translation fault when the address is accessed:
- RETAA, RETAB.
- BRAA, BRAB, BLRAA, BLRAB.
- BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.
Accessing ESR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic ESR_EL1 or ESR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, ESR_EL1**

<table>

D17.2.38  ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL2.

**Configurations**

AArch64 System register ESR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HSR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

ESR_EL2 is a 64-bit register.

**Field descriptions**

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Bits [63:37]**

Reserved, RES0.

**ISS2, bits [36:32]**

*When FEAT_LS64 is implemented:*

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort exception for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort exception for a Translation fault, Access flag fault, or Permission fault, then this field holds register specifier, Xs.

Otherwise, this field is RES0.

*Otherwise:*

Reserved, RES0.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.
Possible values of the EC field are:

**EC == 0b000000**
- Unknown reason.
  - See ISS encoding for exceptions with an unknown reason.

**EC == 0b000001**
- Trapped WF* instruction execution.
  - Conditional WF* instructions that fail their condition code check do not cause an exception.
  - See ISS encoding for an exception from a WF* instruction.

**EC == 0b000011**
- When AArch32 is supported:
  - Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.
  - See ISS encoding for an exception from an MCR or MRC access.

**EC == 0b000100**
- When AArch32 is supported:
  - Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.
  - See ISS encoding for an exception from an MCRR or MRRC access.

**EC == 0b000101**
- When AArch32 is supported:
  - Trapped MCR or MRC access with (coproc==0b1110).
  - See ISS encoding for an exception from an MCR or MRC access.

**EC == 0b000110**
- When AArch32 is supported:
  - Trapped LDC or STC access.
  - The only architected uses of these instruction are:
    - An STC to write data to memory from DBGDTRRXint.
    - An LDC to read data from memory to DBGDTRTXint.
  - See ISS encoding for an exception from an LDC or STC instruction.

**EC == 0b000111**
- Access to SME, SVE, Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.
  - Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.
  - See ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps.

**EC == 0b001000**
- When AArch32 is supported:
  - Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.
  - See ISS encoding for an exception from an MCR or MRC access.

**EC == 0b001001**
- When FEAT_P Auth is implemented:
  - Trapped use of a Pointer authentication instruction because HCR_EL2.API == 0 || SCR_EL3.API == 0.
  - See ISS encoding for an exception from a Pointer Authentication instruction when HCR_EL2.API == 0 || SCR_EL3.API == 0.

**EC == 0b001010**
- When FEAT_LS64 is implemented:
An exception from an LD64B or ST64B* instruction.
See ISS encoding for an exception from an LD64B or ST64B* instruction.

EC == 0b0001100
When AArch32 is supported:
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 0b0001101
When FEAT_BTI is implemented:
Branch Target Exception.
See ISS encoding for an exception from Branch Target Identification instruction.

EC == 0b010001
When AArch32 is supported:
SVC instruction execution in AArch32 state.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b010010
When AArch32 is supported:
HVC instruction execution in AArch32 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b010011
When AArch32 is supported:
SMC instruction execution in AArch32 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch32 state.

EC == 0b010101
When AArch64 is supported:
SVC instruction execution in AArch64 state.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b010110
When AArch64 is supported:
HVC instruction execution in AArch64 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 0b010111
When AArch64 is supported:
SMC instruction execution in AArch64 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.
See ISS encoding for an exception from SMC instruction execution in AArch64 state.

EC == 0b011000
When AArch64 is supported:
Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.
This includes all instructions that cause exceptions that are part of the encoding space defined in System instruction class encoding overview on page C5-655, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

See ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state.

**EC == 0b011001**

*When FEAT_SVE is implemented:*

Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC 0b000000.

See ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ.

**EC == 0b011010**

*When FEAT_PAuth is implemented and FEAT_NV is implemented:*

Trapped ERET, ERETTA, or ERETB instruction execution.

See ISS encoding for an exception from an ERET, ERETTA, or ERETB instruction.

**EC == 0b011011**

*When FEAT_TME is implemented:*

Exception from an access to a TSTART instruction at EL0 when SCTLR_EL1.TME0 == 0, EL0 when SCTLR_EL2.TME0 == 0, at EL1 when SCTLR_EL1.TME == 0, at EL2 when SCTLR_EL2.TME == 0 or at EL3 when SCTLR_EL3.TME == 0.

See ISS encoding for an exception from a TSTART instruction.

**EC == 0b011100**

*When FEAT_FPAC is implemented:*

Exception from a Pointer Authentication instruction authentication failure

See ISS encoding for an exception from a Pointer Authentication instruction authentication failure.

**EC == 0b011101**

*When FEAT_SME is implemented:*

Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, CPTR_EL3.ESM, or an attempted execution of an instruction that is illegal because of the value of PSTATE.SM or PSTATE.ZA, that is not reported using EC 0b000000.

See ISS encoding for an exception due to SME functionality.

**EC == 0b011110**

*When FEAT_RME is implemented:*

Exception from a Granule Protection Check

See ISS encoding for an exception from a Granule Protection Check.

**EC == 0b100000**

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See ISS encoding for an exception from an Instruction Abort.

**EC == 0b100001**

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.

See ISS encoding for an exception from an Instruction Abort.
EC == 0b100010
PC alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.

EC == 0b100100
Data Abort exception from a lower Exception level, excluding Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.
These Data Abort exceptions might be generated from Exception levels in any Execution state.
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
See ISS encoding for an exception from a Data Abort.

EC == 0b100101
Data Abort exception without a change in Exception level, or Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.
Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
See ISS encoding for an exception from a Data Abort.

EC == 0b100110
SP alignment fault exception.
See ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault.

EC == 0b100111
When FEAT_MOPS is implemented:
Memory Operation Exception.
See ISS encoding for an exception from the Memory Copy and Memory Set instructions.

EC == 0b101000
When AArch32 is supported:
Trapped floating-point exception taken from AArch32 state.
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped floating-point exception.

EC == 0b101111
When AArch64 is supported:
Trapped floating-point exception taken from AArch64 state.
This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped floating-point exception.

EC == 0b101100
SError interrupt.
See ISS encoding for an SError interrupt.

EC == 0b110000
Breakpoint exception from a lower Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.
EC == 0b110001
Breakpoint exception taken without a change in Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.

EC == 0b110010
Software Step exception from a lower Exception level.
See ISS encoding for an exception from a Software Step exception.

EC == 0b110011
Software Step exception taken without a change in Exception level.
See ISS encoding for an exception from a Software Step exception.

EC == 0b110100
Watchpoint from a lower Exception level, excluding Watchpoint Exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.
These Watchpoint Exceptions might be generated from Exception levels using any Execution state.
See ISS encoding for an exception from a Watchpoint exception.

EC == 0b110101
Watchpoint exceptions without a change in Exception level, or Watchpoint exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.
See ISS encoding for an exception from a Watchpoint exception.

EC == 0b111000
When AArch32 is supported:
BKPT instruction execution in AArch32 state.
See ISS encoding for an exception from execution of a Breakpoint instruction.

EC == 0b111010
When AArch32 is supported:
Vector Catch exception from AArch32 state.
The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception.

EC == 0b111100
When AArch64 is supported:
BRK instruction execution in AArch64 state.
See ISS encoding for an exception from execution of a Breakpoint instruction.

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]
Instruction Length for synchronous exceptions. Possible values of this bit are:
0b0 16-bit instruction trapped.
0b1 32-bit instruction trapped. This value is also used when the exception is one of the following:

- An SError interrupt.
- An Instruction Abort exception.
- A PC alignment fault exception.
- An SP alignment fault exception.
- A Data Abort exception for which the value of the ISV bit is 0.
- An Illegal Execution state exception.
- Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
  — 0b0: 16-bit T32 BKPT instruction.
  — 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
- An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS, bits [24:0]**

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see *Mapping of the general-purpose registers between the Execution states on page D1-4684.*

If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  — The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  — The value 0b11111.

**ISS encoding for exceptions with an unknown reason**

![ISS encoding diagram]

**Bits [24:0]**

Reserved, RES0.

When an exception is reported using this EC code the IL field is set to 1.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  — A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
— A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
— Instruction encodings that are unallocated.
— Instruction encodings for instructions or System registers that are not implemented in the implementation.

• In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
• In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
• In AArch32 state, attempted execution of a short vector floating-point instruction.
• In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
• An exception generated because of the value of one of the SCTRL_EL1.{ITD, SED, CP15BEN} control bits.
• Attempted execution of:
  — An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  — An SMC instruction when disabled by SCR_EL3.SMD.
  — An HLT instruction when disabled by EDSCR.HDE.
• Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.
• Attempted execution of an MSR or MRS instruction using a _EL12 register name when HCR_EL2.E2H == 0.
• Attempted execution, in Debug state, of:
  — A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  — A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  — A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
• When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon.
• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
• In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
• An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0b000111.
• In Non-transactional state, attempted execution of a TCOMMIT instruction.

**ISS encoding for an exception from a WF* instruction**

CV, bit [24]
Condition code valid.
0b0    The COND field is not valid.
0b1    The COND field is valid.
For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:
  • When an A32 instruction is trapped, CV is set to 1.
  • When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or
    set to 0. See the description of the COND field for more information.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
For exceptions taken from AArch64, this field is set to 0b1110.
The condition code for the trapped instruction. This field is valid only for exceptions taken from
AArch32, and only when the value of CV is 1.
For exceptions taken from AArch32:
  • When an A32 instruction is trapped, CV is set to 1 and:
    — If the instruction is conditional, COND is set to the condition code field value from the
      instruction.
    — If the instruction is unconditional, COND is set to 0b1110.
  • A conditional A32 instruction that is known to pass its condition code check can be presented
    either:
    — With COND set to 0b1110, the value for unconditional.
    — With the COND value held in the instruction.
  • When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
    — CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the
      SPSR.IT field to determine the condition, if any, of the T32 instruction.
    — CV is set to 1 and COND is set to the condition code for the condition that applied to
      the instruction.
  • For an implementation that, for both A32 and T32 instructions, takes an exception on a
    trapped conditional instruction only if the instruction passes its condition code check, these
    definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND
    field is set to 0b1110, or to the value of any condition that applied to the instruction.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]
Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT is implemented:
Register Number. Indicates the register number supplied for a WFET or WFIT instruction.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
Bits [4:3]

Reserved, RES0.

RV, bit [2]

*When FEAT_WFxT is implemented:*

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped WFET or WFIT instruction.

- 0b0 Register field invalid.
- 0b1 Register field valid.

If TI[1] == 0, then this field is RES0.

This field is set to 1 on a trap on WFET or WFIT.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

- 0b00 WFI trapped.
- 0b01 WFE trapped.
- 0b10 *When FEAT_WFxT is implemented:* WFIT trapped.
- 0b11 *When FEAT_WFxT is implemented:* WFET trapped.

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating this exception:

- SCTLR_EL1.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.
- SCR_EL3.{TWE, TWI}.

**ISS encoding for an exception from an MCR or MRC access**

```
+---------+---------+---------+---------+---------+--------+--------+--------+--------+--------+--------+
| CV      | COND    | Opc2    | Opc1    | Cn      | Rt     | Crm    | Direction |
+---------+---------+---------+---------+---------+--------+--------+---------+---------+---------+---------+
```

CV, bit [24]

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.
For a trapped VMRS access, holds the value 0b000.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.
For a trapped VMRS access, holds the value 0b111.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.
For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Rt, bits [9:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register.
Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value 0b11111.

See Mapping of the general-purpose registers between the Execution states on page D1-4684.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value 0b0000.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction.

0b0   Write to System register space. MCR instruction.
0b1   Read from System register space. MRC or VMRS instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- PMUSERENR_EL0.{ER, CR, SW, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors registers from EL0 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- HCR_EL2.{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
- HCR_EL2.TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.
• **HCR_EL2.TIDCP**, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **If FEAT_TIDCP1** is implemented, **SCTLR_EL2.TIDCP**, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **HCR_EL2.TID1, TID2, TID3**, for accesses to ID registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL2.TCPAC**, for accesses to CPACR_EL1 or CPACR using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **HSTR_EL2.T<n>**, for accesses to System registers using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CNTHCTL_EL2.EL1PCEN**, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **MDCR_EL2.TPM, TPMCR**, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL2.TAM**, for accesses to Activity Monitors registers from EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL3.TCPAC**, for accesses to CPACR from EL1 and EL2, and accesses to HCPTR from EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.

• **MDCR_EL3.TPM**, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.

• **CPTR_EL3.TAM**, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCR or MRC access (coproc == 0b1111) trapped to EL3.

• **If FEAT_FGT** is implemented, MCR or MRC access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b0008101:

• **CPACR_EL1.TTA** for accesses to trace registers, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.

• **MDSCR_EL1.TDCC**, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL1 or EL2.

• **If FEAT_FGT** is implemented, **MDCR_EL2.TDCC** for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

• **HCR_EL2.TID0**, for accesses to the JIDR register in the ID group 0 at EL0 and EL1 using AArch32, MRC access (coproc == 0b1111) trapped to EL2.

• **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDRA**, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDOSA**, for accesses to powerdown debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **MDCR_EL2.TDA**, for accesses to other debug registers, using AArch32 state, MCR or MRC access (coproc == 0b1110) trapped to EL2.

• **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.
• **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

• **MDCR_EL3.TDA**, for accesses to other debug registers, using AArch32, MCR or MRC access (coproc == 0b1110) trapped to EL3.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001000:

• **HCR_EL2.TID0**, for accesses to the FPSID register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.

• **HCR_EL2.TID3**, for accesses to registers in ID group 3 including MVFR0, MVFR1 and MVFR2, VMRS access trapped to EL2.

**ISS encoding for an exception from an LD64B or ST64B* instruction**

**CV, bit [24]**

Condition code valid.

0b0 The COND field is not valid.

0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.

• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [15]**

Reserved, RES0.

**Rt2, bits [14:10]**

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt2 value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value 0b11111.

See *Mapping of the general-purpose registers between the Execution states on page D1-4684*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

If the Rt value is not 0b1111, then the reported value gives the AArch64 view of the register.

Otherwise, if the Rt value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
• If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  — The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  — The value 0b11111.

See Mapping of the general-purpose registers between the Execution states on page D1-4684.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction.
0b0 Read to System register space. MCRR instruction.
0b1 Write from System register space. MRRC instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe configuration settings for generating exceptions that are reported using EC value 0b000100:
• CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
• PMUSERENR_EL0.{CR, EN}, for accesses to Performance Monitor registers from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
• AMUSERENR_EL0.{EN}, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL1 or EL2.
• HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
• HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
• CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
• MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor registers from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
• CPTR_EL2.TAM, for accesses to Activity Monitors registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL2.
• MDCR_EL3.TPM, for accesses to Performance Monitor registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
• CPTR_EL3.TAM, for accesses to Activity Monitors registers from EL0, EL1 and EL2 using AArch32 state, MCRR or MRRC access (coproc == 0b1111) trapped to EL3.
• If FEAT_FGT is implemented, HDFGRTR_EL2.PMCCNTR_EL0 for MRRC access and HDFGWTR_EL2.PMCCNTR_EL0 for MCRR access to PMCCNTR at EL0, trapped to EL2.
The following fields describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- **MDSCR_EL1.TDCC**, for accesses to the Debug ROM registers DBGDSAR and DBGDRAR at EL0 using AArch32 state, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **MDCR_EL2.TDRA**, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- **MDCR_EL3.TDA**, for accesses to debug registers, using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.
- **CPACR_EL1.TTA** for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL1 or EL2.
- **CPTR_EL2.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL2.
- **CPTR_EL3.TTA**, for accesses to trace registers using AArch32, MCRR or MRRC access (coproc == 0b1110) trapped to EL3.

**Note**

If the Armv8-A architecture is implemented with an ETMv4 implementation, MCRR and MRRC accesses to trace registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

**ISS encoding for an exception from an LDC or STC instruction**

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>imm8</th>
<th>RES0</th>
<th>Rn</th>
<th>AM</th>
<th>Offset</th>
<th>Direction</th>
</tr>
</thead>
</table>

**CV, bit [24]**

Condition code valid.

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
• A conditional A32 instruction that is known to pass its condition code check can be presented either:
  — With COND set to 0b1110, the value for unconditional.
  — With the COND value held in the instruction.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  — CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  — CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**imm8, bits [19:12]**

The immediate value from the issued instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [11:10]**

Reserved, RES0.

**Rn, bits [9:5]**

The Rn value from the issued instruction, the general-purpose register used for the transfer.
If the Rn value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is 0b1111:
• If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.
• If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  — The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  — The value 0b11111.

See *Mapping of the general-purpose registers between the Execution states* on page D1-4684.
This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Offset, bit [4]**

Indicates whether the offset is added or subtracted:
0b0 Subtract offset.
0b1 Add offset.
This bit corresponds to the U bit in the instruction encoding.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- 0b000  Immediate unindexed.
- 0b001  Immediate post-indexed.
- 0b010  Immediate offset.
- 0b011  Immediate pre-indexed.
- 0b100  For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
- 0b110  For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-11600.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

- 0b0  Write to memory. STC instruction.
- 0b1  Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000110:

- **MDSCR_EL1.TDCC**, for accesses using AArch32 state, LDC access to DBGDTRTXint or STC access to DBGDTRRXint trapped to EL1 or EL2.
- **MDCR_EL2.TDA**, for accesses using AArch32 state, LDC access to DBGDTRTXint or STC access to DBGDTRRXint MCR or MRC access trapped to EL2.
- **MDCR_EL3.TDA**, for accesses using AArch32 state, LDC access to DBGDTRTXint or STC access to DBGDTRRXint MCR or MRC access trapped to EL3.

- If FEAT_FGT is implemented, **MDCR_EL2.TDCC** for LDC and STC accesses to the DCC registers at EL0 and EL1 trapped to EL2, and **MDCR_EL3.TDCC** for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.

**ISS encoding for an exception from an access to SVE, Advanced SIMD or floating-point functionality, resulting from the FPEN and TFP traps**

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>23</td>
<td>20</td>
</tr>
</tbody>
</table>

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.
- Execution of SME instructions.
For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

**CV**, bit [24]

Condition code valid.

- 0b0       The COND field is not valid.
- 0b1       The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND**, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [19:0]**

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- **CPACR_EL1.FPEN**, for accesses to SIMD and floating-point registers trapped to EL1.
- **CPTR_EL2.FPEN** and **CPTR_EL2.TFP**, for accesses to SIMD and floating-point registers trapped to EL2.
- **CPTR_EL3.TFP**, for accesses to SIMD and floating-point registers trapped to EL3.
**ISS encoding for an exception from an access to SVE functionality, resulting from**

*CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ*

The accesses covered by this trap include:

- Execution of SVE instructions when the PE is not in Streaming SVE mode.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value `0b000000`.

**Bits [24:0]**

Reserved, RES0.

The following fields describe the configuration settings for the traps that are reported using EC value `0b011001`:

- **CPACR_EL1.ZEN**, for execution of SVE instructions and accesses to SVE registers at EL0 or EL1, trapped to EL1.
- **CPTR_EL2.ZEN** and **CPTR_EL2.TZ**, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- **CPTR_EL3.EZ**, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

**ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

**Bits [24:0]**

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see [PC alignment checking](#) on page D1-4668.

[SP alignment checking](#) on page D1-4668 describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from the Memory Copy and Memory Set instructions**

**MemInst, bit [24]**

Indicates the memory instruction class causing the exception.

- `0b0` CPYFE*, CPYFM*, CPYE*, and CPYM* instructions.
- `0b1` SETE*, SETM*, SETGE*, and SETGM* instructions.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**isSETG, bit [23]**
Indicates whether the instruction belongs to SETGM* or SETGE* class of instruction.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Not a SETGM* or SETGE* instruction.</td>
</tr>
<tr>
<td>0b1</td>
<td>SETGM* or SETGE* instruction.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Options, bits [22:19]**
Options : the Options field of the instruction.

For Memory Copy instructions, bits[22:19] forms the Options field, which holds the bits[15:12] of the instruction.

For Memory Set instructions:

- Bits[22:21] are RES0.
- Bits[20:19] form the Options field, which holds the bits[13:12] of the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**FromEpilogue, bit [18]**
Indicates whether the instruction belongs to the epilogue class of Memory Copy or Memory Set instructions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Not an epilogue instruction.</td>
</tr>
<tr>
<td>0b1</td>
<td>CPYE*, CPYFE*, SETE*, or SETGE* instruction.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**WrongOption, bit [17]**
Algorithm option.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>WrongOption is false.</td>
</tr>
<tr>
<td>0b1</td>
<td>WrongOption is true.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**OptionA, bit [16]**
Algorithm type indicated by the PSTATE.C bit.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>OptionB indicated by PSTATE.C is 0.</td>
</tr>
<tr>
<td>0b1</td>
<td>OptionA indicated by PSTATE.C is 1.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [15]**
Reserved, RES0.

**destreg, bits [14:10]**
The destination register value from the issued instruction, containing the destination address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
**srcreg, bits [9:5]**

The source register value from the issued instruction, containing either the source address or the source data.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**sizereg, bits [4:0]**

The size register value from the issued instruction, containing the number of bytes to be transferred or set.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from HVC or SVC instruction execution**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>imm16</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:
- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see SVC and HVC.

For A64 instructions, see SVC and HVC.

If FEAT_FGT is implemented, HFGITR_EL2 {{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

**ISS encoding for an exception from SMC instruction execution in AArch32 state**

<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CV</td>
<td>COND</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

CCKOWNPASS
For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

**CV, bit [24]**

Condition code valid.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The COND field is not valid.</td>
</tr>
<tr>
<td>0b1</td>
<td>The COND field is valid.</td>
</tr>
</tbody>
</table>

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**CCKNOWNPASS, bit [19]**

Indicates whether the instruction might have failed its condition code check.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The instruction was unconditional, or was conditional and passed its condition code check.</td>
</tr>
<tr>
<td>0b1</td>
<td>The instruction was conditional, and might have failed its condition code check.</td>
</tr>
</tbody>
</table>
In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [18:0]**

Reserved, RES0.

**HCR_EL2.TSC** describes the configuration settings for trapping SMC instructions to EL2.

**ISS encoding for an exception from SMC instruction execution in AArch64 state**

```plaintext
  +-----+-----+-----+-----+
  | RES0| RES0| imm16| RES0 |
  +-----+-----+-----+-----+
      24 16 15 0
```

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The value of ISS[24:0] described here is used both:
- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

**HCR_EL2.TSC** describes the configuration settings for trapping SMC from EL1 modes.

**ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state**

```plaintext
  +-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
  | RES0| Op0 | Op2 | Op1 | CRn | Rt  | CRm |
  +-----+-----+-----+-----+-----+-----+-----+
      24 22 21 20 19 17 16 14 13 10 9 5 4 1 0
```

**Bits [24:22]**

Reserved, RES0.

**Op0, bits [21:20]**

The Op0 value from the issued instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Op2, bits [19:17]**

The Op2 value from the issued instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Op1, bits [16:14]
The Op1 value from the issued instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]
The CRn value from the issued instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction.
0b0 Write access, including MSR instructions.
0b1 Read access, including MRS instructions.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

For exceptions caused by System instructions, see System instructions on page C4-539 for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:
- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL1.
- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
• CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• PMUSERENR_EL0.{ER, CR, SW, EN}, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• AMUSERENR_EL0.EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

• HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TS, for accesses to HD_CCR registers using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.

• If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.TID1, TID2, TID3, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.

• CNTKCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.

• MDCR_EL2.TPM, TPMCR, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.

• CPTR_EL2.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.APK, for accesses to Pointer authentication key registers. using AArch64 state, MSR or MRS access trapped to EL2.

• HCR_EL2.NV, NV1, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
• **HCR_EL2.AT**, for execution of AT S1E* instructions, using AArch64 state, MSR or MRS access, trapped to EL2.

• **HCR_EL2.{TERR, FIEN}**, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.

• **SCR_EL3.APK**, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **SCR_EL3.ST**, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **SCR_EL3.{TERR, FIEN}**, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **CPTR_EL3.TCPAC**, for accesses to **CPTR_EL2** and **CPACR_EL1** using AArch64 state, MSR or MRS access trapped to EL3.

• **CPTR_EL3.TTA**, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **MDCR_EL3.TTRF**, for accesses to the trace filter control registers, **TRFCR_EL1** and **TRFCR_EL2**, using AArch64 state, MSR or MRS access trapped to EL3.

• **MDCR_EL3.TDA**, for accesses to debug registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **MDCR_EL3.TDOSA**, for accesses to powerdown debug registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **MDCR_EL3.TPM**, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL3.

• **CPTR_EL3.TAM**, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.

• If **FEAT_EVT** is implemented, the following registers control traps for EL1 and EL0 Cache controls that use this EC value:
  — **HCR_EL2.{TTLBOS, TTLBIS, TICAB, TOCU, TID4}**.
  — **HCR2.{TTLBIS, TICAB, TOCU, TID4}**.

• If **FEAT_FGT** is implemented:
  — **SCR_EL3.FGTEn**, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  — **HFGTR_EL2** for reads and **HFGWTR_EL2** for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
  — **HFGITR_EL2** for execution of system instructions, MSR or MRS access trapped to EL2
  — **HDFGRTR_EL2** for reads and **HDFGWTR_EL2** for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
  — **HAFGRTR_EL2** for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.

• If **FEAT_RNG_TRAP** is implemented:
  — **SCR_EL3.TRNDR** for reads of **RNDR** and **RNDRRS** using AArch64 state, MRS access trapped to EL3.

• If **FEAT_SME** is implemented:
  — **CPTR_EL3.ESM**, for MSR or MRS accesses to **SMPRI_EL1** at EL1, EL2, and EL3, trapped to EL3.
  — **CPTR_EL3.ESM**, for MSR or MRS accesses to **SMPRIMAP_EL2** at EL2 and EL3, trapped to EL3.
  — **SCTL_EL1.EnTP2**, for MSR or MRS accesses to **TPIDR2_EL0** at EL0, trapped to EL1 or EL2.
— SCTLR_EL2.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL2.
— SCR_EL3.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, EL1, and EL2, trapped to EL3.

• If FEAT_NMI is implemented, HCRX_EL2.TALLINT, for MSR writes of ALLINT at EL1, trapped to EL2.

**ISS encoding for an exception from an Instruction Abort**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>Reserved, RES0.</td>

<td>S1PTW</td>
</tr>
</tbody>
</table>

**Bits [24:13]**

Reserved, RES0.

**SET, bits [12:11]**

*When FEAT_RAS is implemented:*

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

- 0b00: Recoverable state (UER).
- 0b10: Uncontainable (UC).
- 0b11: Restartable state (UEO).

All other values are reserved.

**Note**

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**FnV, bit [10]**

Far not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0: Far is valid.
- 0b1: Far is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- **0b0** Fault not on a stage 2 translation for a stage 1 translation table walk.
- **0b1** Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

- **0b000000** Address size fault, level 0 of translation or translation table base register.
- **0b000001** Address size fault, level 1.
- **0b000010** Address size fault, level 2.
- **0b000011** Address size fault, level 3.
- **0b000100** Translation fault, level 0.
- **0b000101** Translation fault, level 1.
- **0b000110** Translation fault, level 2.
- **0b000111** Translation fault, level 3.
- **0b001001** Access flag fault, level 1.
- **0b001010** Access flag fault, level 2.
- **0b001011** Access flag fault, level 3.
- **0b001100** When FEAT_LPA is implemented:
  Access flag fault, level 0.
- **0b001101** When FEAT_LPA is implemented:
  Permission fault, level 0.
- **0b001110** Permission fault, level 1.
- **0b001111** Permission fault, level 2.
- **0b010000** Permission fault, level 3.
- **0b010001** Synchronous External abort, not on translation table walk or hardware update of translation table.
- **0b010011** When FEAT_LPA is implemented:
  Synchronous External abort on translation table walk or hardware update of translation table, level -1.
- **0b010100** Synchronous External abort on translation table walk or hardware update of translation table, level 0.
- **0b010101** Synchronous External abort on translation table walk or hardware update of translation table, level 1.
- **0b010110** Synchronous External abort on translation table walk or hardware update of translation table, level 2.
- **0b010111** Synchronous External abort on translation table walk or hardware update of translation table, level 3.
When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access, not on translation table walk.

When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or
hardware update of translation table, level -1.

When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or
hardware update of translation table, level 0.

When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or
hardware update of translation table, level 1.

When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or
hardware update of translation table, level 2.

When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk or
hardware update of translation table, level 3.

When FEAT_RME is implemented and FEAT_LPA2 is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level -1.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level 0.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level 1.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level 2.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level 3.

When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation
table, level 2.

When FEAT_RME is implemented:
Granule Protection Fault, not on translation table walk or hardware update of translation
table.

When FEAT_LPA2 is implemented:
Address size fault, level -1.

When FEAT_LPA2 is implemented:
Translation fault, level -1.

TLB conflict abort.

When FEAT_HAFDBS is implemented:
Unsupported atomic hardware update fault.

All other values are reserved.

For more information about the lookup level associated with a fault, see The lookup level associated
with MMU faults on page D8-5190.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a
stage 1 translation walk.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
ISS encoding for an exception due to SME functionality

The accesses covered by this trap include:

- Execution of SME instructions.
- Execution of SVE and Advanced SIMD instructions, when the PE is in Streaming SVE mode.
- Direct accesses of SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3.

Bits [24:3]

Reserved, RES0.

SMTC, bits [2:0]

SME Trap Code. Identifies the reason for instruction trapping.

0b000  Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, or CPTR_EL3.ESM, that is not reported using EC 0b000000.

0b001  Advanced SIMD, SVE, or SVE2 instruction trapped because PSTATE.SM is 1.

0b010  SME instruction trapped because PSTATE.SM is 0.

0b011  SME instruction trapped because PSTATE.ZA is 0.

All other values are reserved.

The following fields describe the configuration settings for the traps that are reported using the EC value 0b011101:

- **CPACR_EL1.SMEN**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR and SMCR_EL1 System registers at EL1 and EL0, trapped to EL1 or EL2.

- **CPTR_EL2.SMEN** and **CPTR_EL2.TSM**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2 at EL2, EL1, or EL0, trapped to EL2.

- **CPTR_EL3.ESM**, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3 from all Exception levels and any Security state, trapped to EL3.

ISS encoding for an exception from a Granule Protection Check

Bits [24:22]

Reserved, RES0.

S2PTW, bit [21]

Indicates whether the Granule Protection Check exception was on an access made for a stage 2 translation table walk.

0b0  Fault not on a stage 2 translation table walk.

0b1  Fault on a stage 2 translation table walk.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**InD, bit [20]**

Indicates whether the Granule Protection Check exception was on an instruction or data access.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Data access.</td>
</tr>
<tr>
<td>0b1</td>
<td>Instruction access.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**GPCSC, bits [19:14]**

Granule Protection Check Status Code.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000000</td>
<td>GPT address size fault at level 0.</td>
</tr>
<tr>
<td>0b000100</td>
<td>GPT walk fault at level 0.</td>
</tr>
<tr>
<td>0b000101</td>
<td>GPT walk fault at level 1.</td>
</tr>
<tr>
<td>0b001100</td>
<td>Granule protection fault at level 0.</td>
</tr>
<tr>
<td>0b001101</td>
<td>Granule protection fault at level 1.</td>
</tr>
<tr>
<td>0b010100</td>
<td>Synchronous External abort on GPT fetch at level 0.</td>
</tr>
<tr>
<td>0b010101</td>
<td>Synchronous External abort on GPT fetch at level 1.</td>
</tr>
</tbody>
</table>

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**VNCR, bit [13]**

When **FEAT_NV2** is implemented:

Indicates that the fault came from use of **VNCR_EL2** register by EL1 code.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The fault was not generated by the use of <strong>VNCR_EL2</strong>, by an MRS or MSR instruction executed at EL1.</td>
</tr>
<tr>
<td>0b1</td>
<td>The fault was generated by the use of <strong>VNCR_EL2</strong>, by an MRS or MSR instruction executed at EL1.</td>
</tr>
</tbody>
</table>

This field is 0 in ESR_EL1.

When InD is '1', this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

**Bits [12:9]**

Reserved, RES0.

**CM, bit [8]**

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.</td>
</tr>
<tr>
<td>0b1</td>
<td>The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The <strong>DC ZVA</strong>, <strong>DC GVA</strong>, and <strong>DC GZVA</strong> instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.</td>
</tr>
</tbody>
</table>
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**S1PTW, bit [7]**

Indicates whether the Granule Protection Check exception was on an access for stage 2 translation for a stage 1 translation table walk:

- 0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**WnR, bit [6]**

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

- 0b0 Abort caused by an instruction reading from a memory location.
- 0b1 Abort caused by an instruction writing to a memory location.

When InD is '1', this field is RES0.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:
- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b111010 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**xFSC, bits [5:0]**

Instruction or Data Fault Status Code.

- 0b100011 *When FEAT_RME is implemented and FEAT_LPA2 is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level -1.
- 0b100100 *When FEAT_RME is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level 0.
- 0b100101 *When FEAT_RME is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level 1.
- 0b100110 *When FEAT_RME is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level 2.
- 0b100111 *When FEAT_RME is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level 3.
- 0b101000 *When FEAT_RME is implemented*: Granule Protection Fault on translation table walk or hardware update of translation table, level 3.
Granule Protection Fault, not on translation table walk or hardware update of translation table.

All other values are reserved.

For more information about the lookup level associated with a fault, see The lookup level associated with MMU faults on page D8-5190.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a Data Abort**

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this ISS encoding includes ISS2, bits[36:32].

**ISV, bit [24]**

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0: No valid instruction syndrome. ISS[23:14] are RES0.

In ESR_EL2, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

In ESR_EL2, ISV is 1 when FEAT_LS64_V is implemented and a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

In ESR_EL2, ISV is 1 when FEAT_LS64_ACCDATA is implemented and a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For other faults reported in ESR_EL2, ISV is 0 except for the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- AArch32 instructions where the instruction:
  - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using R15 as a source or destination register.

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.
For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64 is implemented and a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64_V is implemented and a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

For faults reported in ESR_EL1 or ESR_EL3, ISV is 1 when FEAT_LS64_ACCDATA is implemented and a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When FEAT_MOPS is implemented, for a synchronous Data Abort on a Memory Copy and Memory Set instruction, ISV is 0.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == 1:
Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

0b00  Byte
0b01  Halfword
0b10  Word
0b11  Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0b11.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSE, bit [21]

When ISV == 1:
Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

0b0  Sign-extension not required.
0b1  Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.
When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**SRT, bits [20:16]**

*When ISV == 1:*

Syndrome Register Transfer. The register number of the Wu/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states on page D1-4684.*

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**SF, bit [15]**

*When ISV == 1:*

SF

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

- 0b0 Instruction loads/stores a 32-bit general-purpose register.
- 0b1 Instruction loads/stores a 64-bit general-purpose register.

--- **Note**

This field specifies the register width identified by the instruction, not the Execution state.

---

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
When ISV == 0 and FEAT_SME is implemented:

FnP

FAR not Precise.

0b0 The FAR holds the faulting virtual address that generated the Data Abort.

0b1 The FAR holds any virtual address within the naturally-aligned granule that contains the faulting virtual address that generated a Data Abort due to an SVE contiguous vector load/store instruction in Streaming SVE mode, or an SME load/store instruction.

For more information about the naturally-aligned fault granule, see FAR_ELx (for example, FAR_EL1).

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AR, bit [14]

When ISV == 1:

Acquire/Release.

0b0 Instruction did not have acquire/release semantics.

0b1 Instruction did have acquire/release semantics.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

When FEAT_NV2 is implemented:

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

0b0 The fault was not generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

0b1 The fault was generated by the use of VNCR_EL2, by an MRS or MSR instruction executed at EL1.

This field is 0 in ESR_EL1.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
LST, bits [12:11]

When (DFSC == 0b00xxxx || DFSC == 0b101011) && DFSC != 0b0000xx:

LST
Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort.

0b00 The instruction that generated the Data Abort is not specified.

0b01 When FEAT_LS64_V is implemented:
An ST64BV instruction generated the Data Abort.

0b10 When FEAT_LS64 is implemented:
An LD64B or ST64B instruction generated the Data Abort.

0b11 When FEAT_LS64_ACCDATA is implemented:
An ST64BV0 instruction generated the Data Abort.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and DFSC == 0b010000:

SET
Synchronous Error Type. Used when a Syncronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

0b00 Recoverable state (UER).

0b10 Uncontainable (UC).

0b11 Restartable state (UEO).

All other values are reserved.

Note
Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 FAR is valid.

0b1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
CM, bit [8]
Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

0b0 The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]
For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]
Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

0b0 Abort caused by an instruction reading from a memory location.
0b1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:
- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]
Data Fault Status Code.

0b000000 Address size fault, level 0 of translation or translation table base register.
0b000001 Address size fault, level 1.
0b000010 Address size fault, level 2.
0b000011 Address size fault, level 3.
0b000100 Translation fault, level 0.
0b000101 Translation fault, level 1.
0b000110 Translation fault, level 2.
0b00011  Translation fault, level 3.
0b001001  Access flag fault, level 1.
0b001010  Access flag fault, level 2.
0b001011  Access flag fault, level 3.
0b001000  When FEAT_LPA2 is implemented:
          Access flag fault, level 0.
0b001100  When FEAT_LPA2 is implemented:
          Permission fault, level 0.
0b001101  Permission fault, level 1.
0b001110  Permission fault, level 2.
0b001111  Permission fault, level 3.
0b010000  Synchronous External abort, not on translation table walk or hardware update of translation table.
0b010001  When FEAT_MTE2 is implemented:
          Synchronous Tag Check Fault.
0b010011  When FEAT_LPA2 is implemented:
          Synchronous External abort on translation table walk or hardware update of translation table, level -1.
0b010100  Synchronous External abort on translation table walk or hardware update of translation table, level 0.
0b010101  Synchronous External abort on translation table walk or hardware update of translation table, level 1.
0b010110  Synchronous External abort on translation table walk or hardware update of translation table, level 2.
0b010111  Synchronous External abort on translation table walk or hardware update of translation table, level 3.
0b011000  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access, not on translation table walk.
0b011011  When FEAT_LPA2 is implemented and FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.
0b011100  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.
0b011101  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.
0b011110  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.
0b011111  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.
0b100001  Alignment fault.
0b100011  When FEAT_RME is implemented and FEAT_LPA2 is implemented:
          Granule Protection Fault on translation table walk or hardware update of translation table, level -1.
0b100100  When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 0.

0b100101 When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 1.

0b100110 When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 2.

0b100111 When FEAT_RME is implemented:
Granule Protection Fault on translation table walk or hardware update of translation table, level 3.

0b101000 When FEAT_RME is implemented:
Granule Protection Fault, not on translation table walk or hardware update of translation table.

0b101001 When FEAT_LPA2 is implemented:
Address size fault, level -1.

0b101011 When FEAT_LPA2 is implemented:
Translation fault, level -1.

0b110000 TLB conflict abort.

0b110001 When FEAT_HAFDBS is implemented:
Unsupported atomic hardware update fault.

0b110100 IMPLEMENTATION DEFINED fault (Lockdown).

0b110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).

All other values are reserved.

For more information about the lookup level associated with a fault, see The lookup level associated with MMU faults on page D8-5190.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ISS encoding for an exception from a trapped floating-point exception**

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

0b0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see Floating-point exceptions and exception traps on page A1-64.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

--- Note ---

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
- 0b0 Input denormal floating-point exception has not occurred.
- 0b1 Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
- 0b0 Inexact floating-point exception has not occurred.
- 0b1 Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
- 0b0 Underflow floating-point exception has not occurred.
- 0b1 Underflow floating-point exception occurred during execution of the reported instruction.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**OFF, bit [2]**

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0  Overflow floating-point exception has not occurred.
- 0b1  Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DZF, bit [1]**

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0  Divide by Zero floating-point exception has not occurred.
- 0b1  Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IOF, bit [0]**

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0b0  Invalid Operation floating-point exception has not occurred.
- 0b1  Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} bits enable each of the floating-point exception traps.

**ISS encoding for an SError interrupt**

![ISS encoding diagram]

**IDS, bit [24]**

IMPLEMENTATION DEFINED syndrome.

- 0b0  Bits [23:0] of the ISS field holds the fields described in this encoding.

**Note**

If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

- 0b1  Bits [23:0] of the ISS field hold IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.
Note
This field was previously called ISV.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]
Reserved, RES0.

IESB, bit [13]
When FEAT_IESB is implemented and DFSC == 0b010001:
Implicit error synchronization event.
0b0  The SError interrupt was either not synchronized by the implicit error synchronization event or not taken immediately.
0b1  The SError interrupt was synchronized by the implicit error synchronization event and taken immediately.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

AET, bits [12:10]
When FEAT_RAS is implemented and DFSC == 0b010001:
Asynchronous Error Type.
Describes the PE error state after taking the SError interrupt exception.
0b000  Uncontainable (UC).
0b001  Unrecoverable state (UEU).
0b010  Restartable state (UEO).
0b011  Recoverable state (UER).
0b100  Corrected (CE).
All other values are reserved.
If multiple errors are taken as a single SError interrupt exception, the overall PE error state is reported.

Note
Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EA, bit [9]
When FEAT_RAS is implemented and DFSC == 0b010001:
External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherweise:
Reserved, RES0.

Bits [8:6]
