</table>
Limitations of this issue

This issue of the Arm Architecture Reference Manual contains many improvements and corrections. Validation of this document has identified the following issues that Arm will address in future issues:

- Some diagrams in the register descriptions chapter have long field names that split over several lines. These are not wrong, and the descriptions list the field name correctly.

- The Performance Monitors external register descriptions on page I5-10753 do not include updates to registers or fields that change as a result of the optional 64-bit external access feature.

- Appendix K16 Arm Pseudocode Definition requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.

- For a list of the known issues in this Manual, please refer to the Known Issues document on https://developer.arm.com/documentation/102105/latest.

Arm Architecture Reference Manual for A-profile architecture

Preface
About this Manual .......................................................... xviii
Using this Manual ........................................................................................................ xx
Conventions xxvii
Additional reading xxx
Feedback xxxii

Part A Arm Architecture Introduction and Overview

Chapter A1 Introduction to the Arm Architecture
A1.1 About the Arm architecture .......................................................... A1-36
A1.2 Architecture profiles .......................................................... A1-38
A1.3 Arm architectural concepts .......................................................... A1-39
A1.4 Supported data types .......................................................... A1-42
A1.5 Floating-point support .......................................................... A1-55
A1.6 The Arm memory model .......................................................... A1-69

Chapter A2 Armv8-A Architecture Extensions
A2.1 Armv8.0 architecture extensions .......................................................... A2-72
A2.2 Architectural features within Armv8.0 architecture .......................................................... A2-76
A2.3 The Armv8 Cryptographic Extension .......................................................... A2-80
A2.4 The Armv8.1 architecture extension .......................................................... A2-82
A2.5 The Armv8.2 architecture extension .......................................................... A2-86
A2.6 The Armv8.3 architecture extension .......................................................... A2-96
A2.7 The Armv8.4 architecture extension .......................................................... A2-101
A2.8 The Armv8.5 architecture extension .......................................................... A2-107
Chapter C5  The A64 System Instruction Class
C5.1  The System instruction class encoding space ...........................................  C5-654
C5.2  Special-purpose registers ...........................................................................  C5-671
C5.3  A64 System instructions for cache maintenance .........................................  C5-776
C5.4  A64 System instructions for address translation .........................................  C5-841
C5.5  A64 System instructions for TLB maintenance ...........................................  C5-866
C5.6  A64 System instructions for prediction restriction .........................................  C5-1146
C5.7  A64 System instructions for the Branch Record Buffer Extension ................  C5-1159

Chapter C6  A64 Base Instruction Descriptions
C6.1  About the A64 base instructions ...............................................................  C6-1166
C6.2  Alphabetical list of A64 base instructions ..................................................  C6-1169

Chapter C7  A64 Advanced SIMD and Floating-point Instruction Descriptions
C7.1  About the A64 Advanced SIMD and floating-point instructions ...............  C7-2040
C7.2  Alphabetical list of A64 Advanced SIMD and floating-point instructions ......  C7-2042

Chapter C8  SVE Instruction Descriptions
C8.1  About the SVE instructions .......................................................................  C8-2974
C8.2  Alphabetical list of SVE instructions ..........................................................  C8-2975

Chapter C9  SME Instruction Descriptions
C9.1  About the SME instructions .......................................................................  C9-4542
C9.2  Alphabetical list of SME instructions ..........................................................  C9-4543

Part D  The AArch64 System Level Architecture

Chapter D1  The AArch64 System Level Programmers’ Model
D1.1  Exception levels ..........................................................................................  D1-4632
D1.2  Registers for instruction processing and exception handling ....................  D1-4636
D1.3  Exceptions ..................................................................................................  D1-4638
D1.4  Process state, PSTATE ...............................................................................  D1-4670
D1.5  Resets and power domains ........................................................................  D1-4673
D1.6  Mechanisms for entering a low-power state ..............................................  D1-4676
D1.7  Self-hosted debug ......................................................................................  D1-4681
D1.8  Event monitors ...........................................................................................  D1-4683
D1.9  Interprocessing ...........................................................................................  D1-4684

Chapter D2  AArch64 Self-hosted Debug
D2.1  About self-hosted debug ............................................................................  D2-4692
D2.2  The debug exception enable controls ......................................................  D2-4696
D2.3  Routing debug exceptions ........................................................................  D2-4697
D2.4  Enabling debug exceptions from the current Exception level ....................  D2-4699
D2.5  The effect of powerdown on debug exceptions ........................................  D2-4701
D2.6  Summary of the routing and enabling of debug exceptions .......................  D2-4702
D2.7  Pseudocode description of debug exceptions ...........................................  D2-4704
D2.8  Breakpoint Instruction exceptions .............................................................  D2-4705
D2.9  Breakpoint exceptions ...............................................................................  D2-4707
D2.10  Watchpoint exceptions ............................................................................  D2-4726
D2.11  Vector Catch exceptions ..........................................................................  D2-4741
D2.12  Software Step exceptions ........................................................................  D2-4742
D2.13  Synchronization and debug exceptions ..................................................  D2-4755

Chapter D3  AArch64 Self-hosted Trace
D3.1  About self-hosted trace ............................................................................  D3-4758
D3.2  Prohibited regions in self-hosted trace .....................................................  D3-4759
Chapter D4 The Embedded Trace Extension
D4.1 About the Embedded Trace Extension ................................................................. D4-4764
D4.2 Programmers’ model ......................................................................................... D4-4771
D4.3 Trace elements ................................................................................................. D4-4775
D4.4 Instruction and exception classification ............................................................ D4-4791
D4.5 About the ETE trace unit .................................................................................. D4-4800
D4.6 Resource operation ......................................................................................... D4-4843

Chapter D5 ETE Protocol Descriptions
D5.1 About the ETE protocol ..................................................................................... D5-4874
D5.2 Summary list of ETE packets ............................................................................. D5-4877
D5.3 Alphabetical list of ETE packets ....................................................................... D5-4880

Chapter D6 The Trace Buffer Extension
D6.1 About the Trace Buffer Extension ................................................................. D6-5004
D6.2 The trace buffer ............................................................................................... D6-5006
D6.3 Trace buffer management ............................................................................... D6-5018
D6.4 Synchronization and the Trace Buffer Unit ..................................................... D6-5026
D6.5 Trace synchronization and memory barriers ................................................. D6-5031
D6.6 Trace of Speculative execution ....................................................................... D6-5032
D6.7 Trace in Debug state ...................................................................................... D6-5033
D6.8 Detailed synchronization litmus tests ............................................................. D6-5034
D6.9 UNPREDICTABLE behavior .......................................................................... D6-5038

Chapter D7 The AArch64 System Level Memory Model
D7.1 About the memory system architecture ......................................................... D7-5040
D7.2 Address space ................................................................................................. D7-5041
D7.3 Mixed-endian support .................................................................................... D7-5042
D7.4 Cache support ................................................................................................. D7-5043
D7.5 External aborts ............................................................................................... D7-5072
D7.6 Memory barrier instructions ......................................................................... D7-5074
D7.7 Pseudocode description of general memory System instructions ................. D7-5075

Chapter D8 The AArch64 Virtual Memory System Architecture
D8.1 Address translation ......................................................................................... D8-5080
D8.2 Translation process ....................................................................................... D8-5093
D8.3 Translation table descriptor formats ............................................................. D8-5123
D8.4 Memory access control .................................................................................. D8-5132
D8.5 Memory region attributes ............................................................................ D8-5151
D8.6 Other descriptor fields .................................................................................. D8-5158
D8.7 Address tagging ............................................................................................. D8-5162
D8.8 Pointer authentication .................................................................................... D8-5164
D8.9 Virtualization Host Extensions ..................................................................... D8-5168
D8.10 Nested virtualization .................................................................................... D8-5173
D8.11 Memory aborts ............................................................................................ D8-5180
D8.12 Translation Lookaside Buffers .................................................................... D8-5193
D8.13 TLB maintenance ....................................................................................... D8-5197
D8.14 Caches .......................................................................................................... D8-5215
D8.15 Pseudocode description of VMSAv8-64 address translation ......................... D8-5217

Chapter D9 The Memory Tagging Extension
D9.1 Introduction .................................................................................................... D9-5220
D9.2 Allocation Tags ............................................................................................... D9-5221
D9.3 Tag checking .................................................................................................. D9-5223
D9.4 Tagged and Untagged Addresses ................................................................... D9-5224
Chapter D17 AArch64 System Register Descriptions

D17.1 About the AArch64 System registers ............................................................. D17-5546
D17.2 General system control registers ................................................................. D17-5555
D17.3 Debug registers ......................................................................................... D17-6393
D17.4 Trace registers ......................................................................................... D17-6519
D17.5 Performance Monitors registers ............................................................... D17-6740
D17.6 Activity Monitors registers ...................................................................... D17-6816
D17.7 Statistical Profiling Extension registers .................................................... D17-6858
D17.8 Branch Record Buffer Extension registers .............................................. D17-6912
D17.9 RAS registers ......................................................................................... D17-6956
D17.10 Realm Management Extension registers ................................................. D17-7004
D17.11 Generic Timer registers ......................................................................... D17-7014

Part E The AArch32 Application Level Architecture

Chapter E1 The AArch32 Application Level Programmers’ Model

E1.1 About the Application level programmers’ model ...................................... E1-7128
E1.2 The Application level programmers’ model in AArch32 state ................. E1-7129
E1.3 Advanced SIMD and floating-point instructions ...................................... E1-7140
E1.4 About the AArch32 System register interface .......................................... E1-7158
E1.5 Exceptions .................................................................................................. E1-7159

Chapter E2 The AArch32 Application Level Memory Model

E2.1 About the Arm memory model ................................................................. E2-7162
E2.2 Atomicity in the Arm architecture ............................................................ E2-7164
E2.3 Definition of the memory model ............................................................... E2-7168
E2.4 Ordering of translation table walks ......................................................... E2-7187
E2.5 Caches and memory hierarchy ............................................................... E2-7188
E2.6 Alignment support .................................................................................. E2-7193
E2.7 Endian support ......................................................................................... E2-7195
E2.8 Memory types and attributes ................................................................. E2-7198
E2.9 Mismatched memory attributes .............................................................. E2-7208
E2.10 Synchronization and semaphores ......................................................... E2-7211

Part F The AArch32 Instruction Sets

Chapter F1 About the T32 and A32 Instruction Descriptions

F1.1 Format of instruction descriptions ......................................................... F1-7224
F1.2 Standard assembler syntax fields ........................................................... F1-7228
F1.3 Conditional execution ............................................................................ F1-7229
F1.4 Shifts applied to a register ...................................................................... F1-7231
F1.5 Memory accesses .................................................................................. F1-7233
F1.6 Encoding of lists of general-purpose registers and the PC .................... F1-7234
F1.7 General information about the T32 and A32 instruction descriptions ...... F1-7235
F1.8 Additional pseudocode support for instruction descriptions ................. F1-7248
F1.9 Additional information about Advanced SIMD and floating-point instructions .. F1-7249

Chapter F2 The AArch32 Instruction Sets Overview

F2.1 Support for instructions in different versions of the Arm architecture .... F2-7256
F2.2 Unified Assembler Language ................................................................. F2-7257
F2.3 Branch instructions .............................................................................. F2-7259
F2.4 Data-processing instructions .................................................................. F2-7260
F2.5 PSTATE and banked register access instructions .................................. F2-7268
F2.6 Load/store instructions .......................................................................... F2-7269
F2.7 Load/store multiple instructions ............................................................... F2-7272
F2.8 Miscellaneous instructions .................................................................. F2-7273
Chapter F3  T32 Instruction Set Encoding
F3.1  T32 instruction set encoding ................................................................. F3-7296
F3.2  About the T32 Advanced SIMD and floating-point instructions and their encoding  F3-7371

Chapter F4  A32 Instruction Set Encoding
F4.1  A32 instruction set encoding ................................................................. F4-7374
F4.2  About the A32 Advanced SIMD and floating-point instructions and their encoding  F4-7440

Chapter F5  T32 and A32 Base Instruction Set Instruction Descriptions
F5.1  Alphabetical list of T32 and A32 base instruction set instructions ............... F5-7442
F5.2  Encoding and use of banked register transfer instructions ....................... F5-8160

Chapter F6  T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions
F6.1  Alphabetical list of Advanced SIMD and floating-point instructions .......... F6-8166

Part G  The AArch32 System Level Architecture

Chapter G1  The AArch32 System Level Programmers’ Model
G1.1  About the AArch32 System level programmers’ model ......................... G1-8898
G1.2  Exception levels .......................................................... G1-8899
G1.3  Exception terminology .......................................................... G1-8900
G1.4  Execution state .......................................................... G1-8902
G1.5  Instruction Set state .......................................................... G1-8904
G1.6  Security state .......................................................... G1-8905
G1.7  Security state, Exception levels, and AArch32 execution privilege .......... G1-8908
G1.8  Virtualization .......................................................... G1-8910
G1.9  AArch32 state PE modes, and general-purpose and Special-purpose registers G1-8912
G1.10  Process state, PSTATE .......................................................... G1-8921
G1.11  Instruction set states .......................................................... G1-8927
G1.12  Handling exceptions that are taken to an Exception level using AArch32 ... G1-8929
G1.13  Routing of aborts taken to AArch32 state ........................................ G1-8948
G1.14  Exception return to an Exception level using AArch32 ......................... G1-8951
G1.15  Asynchronous exception behavior for exceptions taken from AArch32 state .. G1-8956
G1.16  AArch32 state exception descriptions ........................................... G1-8964
G1.17  Reset into AArch32 state .......................................................... G1-8986
G1.18  Mechanisms for entering a low-power state ....................................... G1-8988
G1.19  The AArch32 System register interface ............................................ G1-8993
G1.20  Advanced SIMD and floating-point support ....................................... G1-8996
G1.21  Configurable instruction enables and disables, and trap controls .......... G1-9001

Chapter G2  AArch32 Self-hosted Debug
G2.1  About self-hosted debug .......................................................... G2-9038
G2.2  The debug exception enable controls ........................................... G2-9042
G2.3  Routing debug exceptions .......................................................... G2-9043
G2.4  Enabling debug exceptions from the current Privilege level and Security state G2-9045
G2.5  The effect of powerdown on debug exceptions ................................... G2-9047
G2.6  Summary of permitted routing and enabling of debug exceptions .......... G2-9048
G2.7  Pseudocode description of debug exceptions ..................................... G2-9050
G2.8  Breakpoint Instruction exceptions ........................................... G2-9051
G2.9  Breakpoint exceptions .......................................................... G2-9054
# External Debug

   K10.1  Save Debug registers .................................................. K10-11736
   K10.2  Restore Debug registers ............................................... K10-11738

Appendix K11  Recommended Upload and Download Processes for External Debug
   K11.1  Using memory access mode in AArch64 state ...................... K11-11742

Appendix K12  Software Usage Examples
   K12.1  Use of the Advanced SIMD complex number instructions .......... K12-11746
   K12.2  Use of the Armv8.2 extensions to the Cryptographic Extension .... K12-11748

Appendix K13  Barrier Litmus Tests
   K13.1  Introduction ............................................................. K13-11756
   K13.2  Load-Acquire, Store-Release and barriers ........................ K13-11759
   K13.3  Load-Acquire Exclusive, Store-Release Exclusive and barriers .... K13-11763
   K13.4  Using a mailbox to send an interrupt ............................. K13-11768
   K13.5  Cache and TLB maintenance instructions and barriers ............ K13-11769
   K13.6  Armv7 compatible approaches for ordering, using DMB and DSB barriers K13-11781

Appendix K14  Random Number Generation
   K14.1  Properties of the generated random number ....................... K14-11796
Preface

This preface introduces the Arm Architecture Reference Manual, for A-profile architecture. It contains the following sections:

- *About this Manual* on page xviii.
- *Using this Manual* on page xx.
- *Conventions* on page xxvii.
- *Additional reading* on page xxx.
- *Feedback* on page xxxii.
About this Manual

This Manual describes the Arm® architecture v8, Armv8, and the Arm® architecture v9, Armv9. The architecture describes the operation of an Armv8-A and an Armv9-A Processing element (PE), and this Manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
  - In AArch32 state, the A32 and T32 instruction sets, which are compatible with earlier versions of the Arm architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This Manual covers the Arm A architecture profile, both Armv8-A and Armv9-A, that defines a Virtual Memory System Architecture (VMSA). This Manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this Manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a very basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This Manual is organized into parts:

**Part A**
Provides an introduction to the Arm architecture, and an overview of the AArch64 and AArch32 Execution states.

**Part B**
Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers’ model and the memory model.

**Part C**
Describes the A64 instruction set, which is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as unprivileged execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

**Part D**
Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers’ model and the memory model. This part includes the description of self-hosted debug.
Part E  Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers’ model and the memory model.

——— Note ————
In AArch32 state, execution at EL0 is execution in User mode.

Part F  Describes the T32 and A32 instruction sets, which are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the Arm architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

——— Note ————
User mode is the only mode where software execution is unprivileged.

Part G  Describes the system level view of the AArch32 Execution state, which is generally compatible with earlier versions of the Arm architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers’ model and the memory model.

Part H  Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part I  Describes additional features of the architecture that are not closely coupled to a *processing element* (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are optional.

Part J  Provides pseudocode that describes various features of the Arm architecture.

Part K, Appendixes
Provide additional information. Some appendixes give information that is not part of the A-profile architectural requirements. The cover page of each appendix indicates its status.

Glossary  Defines terms used in this Manual that have a specialized meaning.

——— Note ————
Terms that are generally well understood in the microelectronics industry are not included in the Glossary.
Using this Manual

The information in this Manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-A and Armv9-A architecture profiles, including its relationship to the other Arm PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapters:

Chapter A1 Introduction to the Arm Architecture
Read this for an introduction to the Arm architecture.

Chapter A2 Armv8-A Architecture Extensions
Read this for an introduction to the Armv8 architecture extensions.

Chapter A3 Armv9 Architecture Extensions
Read this for an introduction to the Armv9 architecture extensions.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

Chapter B1 The AArch64 Application Level Programmers' Model
Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 The AArch64 Application Level Memory Model
Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, which is used in AArch64 state. It contains the following chapters:

Chapter C1 The A64 Instruction Set
Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 About the A64 Instruction Descriptions
Read this to understand the format of the A64 instruction descriptions.

Chapter C3 A64 Instruction Set Overview
Read this for an overview of the A64 instructions.

Chapter C4 A64 Instruction Set Encoding
Read this for a description of the A64 instruction set encoding.

Chapter C5 The A64 System Instruction Class
Read this for a description of the AArch64 System instructions and register descriptions, and the System instruction class encoding space.

Chapter C6 A64 Base Instruction Descriptions
Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.
Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions
Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C8 SVE Instruction Descriptions
Read this for information on key aspects of the SVE instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C9 SME Instruction Descriptions
Read this for information on key aspects of the SME instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Part D, The AArch64 System Level Architecture
Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

Chapter D1 The AArch64 System Level Programmers’ Model
Read this for a description of the AArch64 state system level view of the programmers’ model.

Chapter D2 AArch64 Self-hosted Debug
Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter D3 AArch64 Self-hosted Trace
Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

Chapter D4 The Embedded Trace Extension
Read this for a description of the Embedded Trace Extension.

Chapter D5 ETE Protocol Descriptions
Read this for a description of the ETE packets.

Chapter D6 The Trace Buffer Extension
Read this for a description of the Trace Buffer Extension.

Chapter D7 The AArch64 System Level Memory Model
Read this for a description of the AArch64 state system level view of the general features of the memory system.

Chapter D8 The AArch64 Virtual Memory System Architecture
Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an Armv8 or Armv9 implementation executing in AArch64 state.

Chapter D9 The Memory Tagging Extension
Read this for a description of the Memory Tagging Extension.

Chapter D10 The Generic Timer in AArch64 state
Read this for a description of the AArch64 view of the Arm Generic Timer.

Chapter D11 The Performance Monitors Extension
Read this for a description of the Arm Performance Monitors, an optional non-invasive debug component.

Chapter D12 The Activity Monitors Extension
Read this for a description of the Arm Activity Monitors.
Chapter D13 The Statistical Profiling Extension
Read this for a description of the Statistical Profiling Extension, an optional AArch64 state
non-invasive debug component.

Chapter D14 Statistical Profiling Extension Sample Record Specification
Read this for a description of the sample records generated by the Statistical Profiling Extension.

Chapter D15 The Branch Record Buffer Extension
Read this for a description of the Branch Record Buffer Extension.

Chapter D16 AArch64 System Register Encoding
Read this for a description of the encoding of the AArch64 System registers, and the other uses of
the AArch64 System registers encoding space.

Chapter D17 AArch64 System Register Descriptions
Read this for an introduction to, and description of, each of the AArch64 System registers.

Part E, The AArch32 Application Level Architecture
Part E describes the AArch32 state application level view of the architecture. It contains the following chapters:

Chapter E1 The AArch32 Application Level Programmers’ Model
Read this for an application level description of the programmers’ model for software executing in
AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

Chapter E2 The AArch32 Application Level Memory Model
Read this for an application level description of the memory model for software executing in
AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32
state. It includes information about Arm memory types, attributes, and memory access controls.

Part F, The AArch32 Instruction Sets
Part F describes the T32 and A32 instruction sets, which are used in AArch32 state. It contains the following
chapters:

Chapter F1 About the T32 and A32 Instruction Descriptions
Read this to understand the format of the T32 and A32 instruction descriptions.

Chapter F2 The AArch32 Instruction Sets Overview
Read this for an overview of the T32 and A32 instruction sets.

Chapter F3 T32 Instruction Set Encoding
Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of
the Advanced SIMD and floating-point instructions.

Chapter F4 A32 Instruction Set Encoding
Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of
the Advanced SIMD and floating-point instructions.

Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions
Read this for a description of each of the T32 and A32 base instructions.

Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions
Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point
instructions.
Part G, The AArch32 System Level Architecture

Part G describes the AArch32 state system level view of the architecture. It contains the following chapters:

Chapter G1 The AArch32 System Level Programmers’ Model
Read this for a description of the AArch32 state system level view of the programmers’ model for execution in an Exception level that is using AArch32.

Chapter G2 AArch32 Self-hosted Debug
Read this for an introduction to, and a description of, self-hosted debug in AArch32 state.

Chapter G3 AArch32 Self-hosted Trace
Read this for an introduction to, and a description of, self-hosted trace in AArch32 state.

Chapter G4 The AArch32 System Level Memory Model
Read this for a system level view of the general features of the memory system.

Chapter G5 The AArch32 Virtual Memory System Architecture
Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G6 The Generic Timer in AArch32 state
Read this for a description of the AArch32 view of an implementation of the Arm Generic Timer.

Chapter G7 AArch32 System Register Encoding
Read this for a description of the encoding of the AArch32 System registers, including the System instructions that are part of the AArch32 System registers encoding space.

Chapter G8 AArch32 System Register Descriptions
Read this for a description of each of the AArch32 System registers.

Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

Chapter H1 About External Debug
Read this for an introduction to external debug, and a definition of the scope of this part of the Manual.

Chapter H2 Debug State
Read this for a description of Debug state, which the PE might enter as the result of a Halting debug event.

Chapter H3 Halting Debug Events
Read this for a description of the external debug events referred to as Halting debug events.

Chapter H4 The Debug Communication Channel and Instruction Transfer Register
Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

Chapter H5 The Embedded Cross-Trigger Interface
Read this for a description of the embedded cross-trigger interface.

Chapter H6 Debug Reset and Powerdown Support
Read this for a description of reset and powerdown support in the Debug architecture.

Chapter H7 The PC Sample-based Profiling Extension
Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an Armv8 or Armv9 implementation.
Part I, Memory-mapped Components of the Arm architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Chapter 11 Requirements for Memory-mapped Components
Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Arm architecture.

Chapter 12 System Level Implementation of the Generic Timer
Read this for a definition of a system level implementation of the Generic Timer.

Chapter 13 Recommended External Interface to the Performance Monitors
Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Chapter 14 Recommended External Interface to the Activity Monitors
Read this for a description of the recommended memory-mapped interface to the Activity Monitors.

Chapter 15 External System Control Register Descriptions
Read this for a description of each memory-mapped system control register.

Part J, Architectural Pseudocode

Part J contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

Chapter J1 Armv8 Pseudocode
Read this for the pseudocode definitions that describe various features of the Arm architecture, for operation in AArch64 state and in AArch32 state.

Part K, Appendixes

Note
Some of the descriptions in the following appendixes are not part of the Arm architecture specification. They are included here as supplementary information, for the convenience of developers and users who might require this information.

This Manual contains the following appendixes:

Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors
Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Arm architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix K2 Recommendations for Reporting Memory Attributes on an Interconnect
Read this for the Arm recommendations about how the architectural memory attributes are reported on an interconnect.

Appendix K3 ETE Recommended Configurations
Read this for a description of the ETE recommended configurations.
Appendix K4 ETE and TRBE Software Usage Examples
Read this for software examples that help understanding of ETE and TRBE.

Appendix K5 Stages of execution
Read this for a description of the stages of execution.

Appendix K6 Recommended External Debug Interface
Read this for a description of the recommended external debug interface.

Appendix K7 Additional Information for Implementations of the Generic Timer
Read this for additional information about implementations of the Arm Generic Timer. This information does not form part of the architectural definition of the Generic Timer.

Appendix K8 Legacy Instruction Syntax for AArch32 Instruction Sets
Read this for information about the pre-UAL syntax of the AArch32 instruction sets, which can still be valid for the A32 instruction set.

Appendix K9 Address Translation Examples
Read this for examples of translation table lookups using the translation regimes described in Chapter D8 The AArch64 Virtual Memory System Architecture and Chapter G5 The AArch32 Virtual Memory System Architecture.

Appendix K10 Example OS Save and Restore Sequences
Read this for software examples that perform the OS Save and Restore sequences for an Armv8 or Armv9 debug implementation.

——— Note ————
Chapter H6 Debug Reset and Powerdown Support describes the OS Save and Restore mechanism.

Appendix K11 Recommended Upload and Download Processes for External Debug
Read this for information about implementing and using the Arm architecture.

Appendix K12 Software Usage Examples
Read this for software examples that help understanding of some aspects of the Arm architecture.

Appendix K13 Barrier Litmus Tests
Read this for examples of the use of barrier instructions provided by the Arm architecture.

Appendix K14 Random Number Generation
Read this for information on the generation of random numbers using FEAT_RNG.

Appendix K15 Legacy Feature Naming Convention
Read this for an understanding of how the current feature names map to the legacy naming convention.

Appendix K16 Arm Pseudocode Definition
Read this for definitions of the Arm pseudocode.

Appendix K17 Registers Index
Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.
Glossary

Defines terms used in this Manual that have a specialized meaning.

——— Note ————

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.
Conventions

The following sections describe conventions that this book can use:

- **Typographic conventions.**
- **Rules-based writing on page xxviii.**
- **Signals on page xxix.**
- **Numbers on page xxix.**
- **Pseudocode descriptions on page xxix.**
- **Assembler syntax descriptions on page xxix.**

**Typographic conventions**

The typographical conventions are:

**italic** Introduces special terminology, and denotes citations.

**bold** Denotes signal names, and is used for terms in descriptive lists, where appropriate.

**monospace** Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

**SMALL CAPITALS**

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

**Colored text** Indicates a link. This can be:

- A URL, for example https://developer.arm.com.
- A cross-reference that includes the page number of the referenced information if it is not on the current page, for example, Assembler syntax descriptions on page xxix.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the Manual that defines the colored term, for example Simple sequential execution or SCTLR.

**{ and }** Braces, { and }, have two distinct uses:

**Optional items**

In syntax descriptions braces enclose optional items. In the following example they indicate that the <shift> parameter is optional:

```
ADD <Wd>|<Wsp>, <Wn>|<Wsp>, #<imm>{, <shift>}
```

Similarly they can be used in generalized field descriptions, for example TCR_ELx.{I}PS refers to a field in the TCR_ELx registers that is called either IPS or PS.

**Sets of items**

Braces can be used to enclose sets. For example, HCR_EL2.{E2H, TGE} refers to a set of two register fields, HCR_EL2.E2H and HCR_EL2.TGE.

**Notes**

Notes are formatted as:

```markdown
--- Note ---

This is a Note.
```

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note may repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.
Rules-based writing

Some sections of this Manual use rules-based writing. Rules-based writing consists of a set of individual content items. A content item is classified as one of the following:

- **Rule.**
- **Information.**

Rules are normative statements. An implementation that is compliant with this specification must conform to all Rules in this Manual that apply to that implementation.

Rules must not be read in isolation. Where a particular feature is specified by multiple Rules, these are generally grouped into sections and subsections that provide context. Where appropriate, these sections begin with a short introduction.

Arm strongly recommends that implementers read all chapters and sections of this Manual to ensure that an implementation is compliant.

Content items other than Rules are informative statements. These are provided as an aid to understanding this Manual.

Content item identifiers

A content item may have an associated identifier which is unique among content items in this Manual. After content reaches beta status, a given content item has the same identifier across subsequent versions of this Manual.

Content item rendering

In this Manual, a content item is rendered with a token of the following format in the left margin: \texttt{Liiii}. \texttt{L} is a label that indicates the content class of the content item.

\texttt{iii} is the identifier of the content item.

Content item classes

Each of the content item classes has a different function in this Manual.

**Rule**

A Rule is a statement that describes the behavior of a compliant implementation.

A Rule explains what happens in a particular situation.

A Rule does not define concepts or terminology.

A Rule is rendered with the label \texttt{R}.

**Information**

An Information statement provides information and guidance as an aid to understanding the Manual.

An Information statement is rendered with the label \texttt{I}.

**Software usage**

A Software usage statement provides guidance on how software can make use of the features defined by the specification.

A Software usage statement is rendered with the label \texttt{S}. 
Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

**Signal level**

The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- **HIGH** for active-HIGH signals.
- **LOW** for active-LOW signals.

**Lowercase n**

At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a monospace font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This Manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in monospace font, and is described in Appendix K16 Arm Pseudocode Definition.

Assembler syntax descriptions

This Manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a monospace font, and use the conventions described in Structure of the A64 assembler language on page C1-228, and Appendix K16 Arm Pseudocode Definition.
Additional reading

This section lists relevant publications from Arm and third parties.

See Arm Developer, https://developer.arm.com, for access to Arm documentation.

Arm publications

- Arm® Reliability, Availability, and Serviceability (RAS) Specification, for A-profile architecture (ARM DDI 0587).
- Arm® Architecture Reference Manual Supplement, Armv8, for R-profile AArch64 architecture (ARM DDI 600).
- ARM® Debug Interface Architecture Specification, ADIv6.0 (ARM IHI 0074).
- ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2 (ARM IHI 0031).
- ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).
- ARM® CoreSight™ Architecture Specification (ARM IHI 0029).
- ARM® Procedure Call Standard for the ARM 64-bit Architecture (ARM IHI 0055).

Other publications

The following publications are referred to in this Manual, or provide more information:

• *SM3 Cryptographic Hash Algorithm*, China Internet Network Information Center (CNNIC).

• *SM4 Block Cipher Algorithm*, China Internet Network Information Center (CNNIC).

Feedback

Arm welcomes feedback on its documentation.

Feedback on this Manual

If you have comments on the content of this Manual, send email to errata@arm.com. Give:

• The number, ARM DDI 0487I.a.
• The section name to which your comments refer.
• The page numbers to which your comments refer.
• A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Note

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader.

Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact terms@arm.com.
Part A

Arm Architecture Introduction and Overview
Chapter A1
Introduction to the Arm Architecture

This chapter introduces the Arm architecture. It contains the following sections:

• About the Arm architecture on page A1-36.
• Supported data types on page A1-42.
• Floating-point support on page A1-55.
• The Arm memory model on page A1-69.
A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a processing element, often abbreviated to PE. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The Arm Architecture Reference Manual also describes rules for software to use the processing element.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
  - Chapter D2 AArch64 Self-hosted Debug.
  - Chapter G2 AArch32 Self-hosted Debug.

- Associated trace architectures that define trace units that implementers can implement with the associated processor hardware. For more information, see:
  - The Embedded Trace Macrocell Architecture Specification.
  - Chapter D3 AArch64 Self-hosted Trace.
  - Chapter D4 The Embedded Trace Extension.
  - Chapter D6 The Trace Buffer Extension.
  - Chapter G3 AArch32 Self-hosted Trace.

The Arm architecture is a Reduced Instruction Set Computer (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A load/store architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Arm architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The Arm architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the Arm architecture.

Features that are optional are explicitly defined as such in this Manual.

**Note**

The presence of an ID register field for a feature does not imply that the feature is optional.

Both Execution states support floating-point instructions:

- AArch32 state provides:
  - SIMD instructions in the base instruction sets that operate on the 32-bit general-purpose registers.
— Advanced SIMD instructions that operate on registers in the SIMD and floating-point register (SIMD&FP register) file.
— Scalar floating-point instructions that operate on registers in the SIMD&FP register file.

• AArch64 state provides:
  — Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
  — Scalar floating-point instructions that operate on registers in the SIMD&FP register file.

  **Note**
  The A64 instruction set does not include SIMD instructions that operate on the general-purpose registers, therefore, some AArch64 instructions descriptions use SIMD as a synonym for Advanced SIMD.

  **Note**
  SVE instructions that operate on registers in the SVE register file.

See *Conventions on page xxvii* for information about conventions used in this Manual, including the use of small capitals for particular terms that have Arm-specific meanings that are defined in the *Glossary*.
A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Nine major versions of the architecture have been defined to date, denoted by the version numbers 1 to 9. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

**AArch64** Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

**AArch32** Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

--- Note ---
The Base instruction set comprises the supported instructions other than the floating-point instructions.

---

Arm defines three architecture profiles:

**A** Application profile, described in this Manual:

- Supports a Virtual Memory System Architecture (VMSA) based on a Memory Management Unit (MMU).
  
  --- Note ---
  An Armv8-A implementation can be called an AArchv8-A implementation and an Armv9-A implementation can be called an AArchv9-A implementation.

- Supports the A64, A32, and T32 instruction sets.

**R** Real-time profile:

- Supports a Protected Memory System Architecture (PMSA) based on a Memory Protection Unit (MPU).
  - Supports an optional VMSA based on an MMU.
  - Supports the A64, A32, and T32 instruction sets.

**M** Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

This Manual describes only Armv8-A and Armv9-A. For information about the R and M architecture profiles, and earlier Arm architecture versions, see:

- The *Arm®v8-M Architecture Reference Manual*.
- The *Arm®v7-M Architecture Reference Manual*.
- The *Arm®v6-M Architecture Reference Manual*. 
A1.3 Arm architectural concepts

This section introduces architectural concepts and the associated terminology.

The following subsections describe key architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:
- **Execution state.**
- **The instruction sets** on page A1-40.
- **System registers** on page A1-40.
- **Arm Debug** on page A1-41.

### A1.3.1 Execution state

The Execution state defines the PE execution environment, including:
- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The Exception model.
  - The **Virtual Memory System Architecture (VMSA)**.
  - The programmers' model.

The Execution states are:

**AArch64**

The 64-bit Execution state. This Execution state:
- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit Program Counter (PC), stack pointers (SPs), and Exception Link Registers (ELRs).
- Provides 32 128-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see **The instruction sets** on page A1-40.
- Defines the Armv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an execution privilege hierarchy, see **Exception levels** on page D1-4632.
- Provides support for 64-bit virtual addressing. For more information, including the limits on address ranges, see Chapter D8 The **AArch64 Virtual Memory System Architecture**.
- Defines a number of Process state (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.

**AArch32**

The 32-bit Execution state. This Execution state:
- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and Link Register (LR). The LR is used as both an ELR and a procedure link register. Some of these registers have multiple banked instances for use in different PE modes.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, A32 and T32. For more information, see **The instruction sets** on page A1-40.
- Supports the Armv7-A Exception model, based on PE modes, and maps this onto the Armv8 Exception model, that is based on the Exception levels.
- Provides support for 32-bit virtual addressing.
Introduction to the Arm Architecture
A1.3 Arm architectural concepts

- Defines a number of Process state (PSTATE) elements that hold PE state. The A32 and T32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the Application Program Status Register (APSR) or the Current Program Status Register (CPSR).

Later subsections give more information about the different properties of the Execution states.

Transferring control between the AArch64 and AArch32 Execution states is known as interprocessing. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in Interprocessing on page D1-4684. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The instruction sets

The possible instruction sets depend on the Execution state:

AArch64
AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.
For information on the A64 instruction set, see Chapter C3 A64 Instruction Set Overview.
If FEAT_SVE is implemented, the instruction set also supports scalable vector instructions. See About the SVE instructions on page C8-2974.

AArch32
AArch32 state supports the following instruction sets:
- A32 This is a fixed-length instruction set that uses 32-bit instruction encodings.
- T32 This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. Armv8 and Armv9 extend each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.
For information on the A32 and T32 instruction sets, see Chapter F2 The AArch32 Instruction Sets Overview.

The instruction sets support SIMD and scalar floating-point instructions. See Floating-point support on page A1-55.

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:
- <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see Exception levels on page D1-4632.

The System registers comprise:
- The following registers that are described in this Manual:
  - General system control registers.
  - Debug registers.
  - Generic Timer registers.
  - Optionally, Performance Monitor registers.
  - Optionally, the Activity Monitors registers.
— Optionally, the Scalable Vector Extension registers.
— Optionally, in Armv9, Trace System registers.

- Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:
  - Trace System registers, as defined in the Embedded Trace Macrocell Architecture Specification, ETMv4.
  - Generic Interrupt Controller (GIC) System registers, see The Arm Generic Interrupt Controller System registers.

- RAS Extension System registers, as defined in the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

For information about the AArch64 System registers, see Chapter D17 AArch64 System Register Descriptions.
For information about the AArch32 System registers, see Chapter G8 AArch32 System Register Descriptions.

### The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this Manual include these registers, see:

- About the GIC System registers on page D16-5542, for more information about the AArch64 GIC System registers.
- About the GIC System registers on page G7-9319, for more information about the AArch32 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).

--- Note

The programmers’ model for earlier versions of the GIC architecture is wholly memory-mapped.

### A1.3.4 Arm Debug

Armv8 and later architectures support the following:

#### Self-hosted debug

In this model, the PE generates debug exceptions. Debug exceptions are part of the Armv8 Exception model.

#### External debug

In this model, debug events cause the PE to enter Debug state. In Debug state, the PE is controlled by an external debugger.

All Armv8 and later implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:
- In AArch64 state, see Chapter D2 AArch64 Self-hosted Debug.
- In AArch32 state, see Chapter G2 AArch32 Self-hosted Debug.

For more information about external debug, see Part H External Debug on page Part H-10225.
A1.4 **Supported data types**

The Arm architecture supports the following integer data types:

- **Byte**
  - 8 bits.
- **Halfword**
  - 16 bits.
- **Word**
  - 32 bits.
- **Doubleword**
  - 64 bits.
- **Quadword**
  - 128 bits.

The architecture also supports the following floating-point data types:

- Double-precision, see *Double-precision floating-point format* on page A1-51 for details.
- BFloat16, see *BFloat16 floating-point format* on page A1-52 for details.

It also supports:

- Vectors, where a register holds multiple elements, each of the same data type. See *Advanced SIMD vector formats* on page A1-43 for details.

The architecture provides the following register files:

- A general-purpose register file.
- A SIMD&FP register file.
- If FEAT_SVE is implemented, an SVE scalable vector register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD&FP register file contains 128-bit registers:
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see *Instruction Mnemonics* on page C1-229.
- An SVE scalable vector register file contains registers of an *IMPLEMENTATION DEFINED* width:
  - An SVE scalable vector register has an *IMPLEMENTATION DEFINED* width that is a multiple of 128 bits, up to a maximum of 2048 bits.
  - All SVE scalable vector registers in an implementation are the same width.
- An SVE predicate register file contains registers of an *IMPLEMENTATION DEFINED* width:
  - An SVE predicate register has an *IMPLEMENTATION DEFINED* width that is a multiple of 16 bits, up to a maximum of 256 bits.

For more information on the register files in AArch64 state, see *Registers in AArch64 Execution state* on page B1-137.

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see *Figure A1-4* on page A1-46.
- A SIMD&FP register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.
A1.4 Supported data types

--- Note ---
Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see The general-purpose registers, and the PC, in AArch32 state on page E1-7131.

A1.4.1 Advanced SIMD vector formats

In an implementation that includes the Advanced SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. In AArch32 state, the combination of a register and a data type describes a vector of elements, where the number of elements in the vector is implied by the size of the data type and the size of the register. In AArch64 state, the explicit combination of a register, number of elements, and element size describes a vector of elements. The vector is considered to be a one-dimensional array of elements of the data type specified in the instruction.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant bits of the vector.

For more information on the Advanced SIMD and floating-point registers in AArch32 state, see The SIMD and floating-point register file on page E1-7140.

Advanced SIMD vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as Vn, where n is a value from 0 to 31.

The SIMD&FP registers support three data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register.
- A 64-bit vector of byte, halfword, word, or doubleword elements.
- A 128-bit vector of byte, halfword, word, or doubleword elements.

The element sizes are defined in Table A1-1 on page A1-43 with the vector format described as:

- For a 128-bit vector: Vn{.2D, .4S, .8H, .16B}.
- For a 64-bit vector: Vn{.1D, .2S, .4H, .8B}.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Size</th>
</tr>
</thead>

<tr>
<td>D</td>
<td>64 bits</td>
</tr>
</tbody>
</table>

Table A1-1: SIMD elements in AArch64 state

Figure A1-1 on page A1-44 shows the SIMD vectors in AArch64 state.
A1.4 Supported data types

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

<table>
<thead>
<tr>
<th>Data type specifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.&lt;size&gt;</td>
<td>Any element of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.F&lt;size&gt;</td>
<td>Floating-point number of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.I&lt;size&gt;</td>
<td>Signed or unsigned integer of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.P&lt;size&gt;</td>
<td>Polynomial over {0, 1} of degree less than &lt;size&gt;</td>
</tr>
<tr>
<td>.S&lt;size&gt;</td>
<td>Signed integer of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.U&lt;size&gt;</td>
<td>Unsigned integer of &lt;size&gt; bits</td>
</tr>
</tbody>
</table>

Polynomial arithmetic over \{0, 1\} on page A1-54 describes the polynomial data type.

The .F16 data type is the half-precision data type selected by the FPSCR.AHP bit, see Half-precision floating-point formats on page A1-48.
The `.F32` data type is the Arm standard single-precision floating-point data type, see *Single-precision floating-point format* on page A1-50.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 shows the hierarchy of the Advanced SIMD data types.

![Figure A1-2 Advanced SIMD data type hierarchy in AArch32 state](image)

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 on page A1-46 shows the Advanced SIMD vectors in AArch32 state.

---

*Note*

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.
Figure A1-3 Advanced SIMD vectors in AArch32 state

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

Figure A1-4 Vector formatting in AArch32 state

A1.4.2 SVE vector format

In an implementation that includes the AArch64 SVE instructions, an SVE register can hold one or more packed or unpacked elements, all of the same size and type. The combination of a register and an element size describes a vector of elements. The vector is considered to be a one-dimensional array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the Effective SVE vector length of the register.

Vector indexes are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant bits of the vector.
Scalable vector format in AArch64 state

In AArch64 state, the SVE registers can be referred to as $Z_n$, where $n$ is a value from 0 to 31. For a full description of the SVE scalable vector registers, see *SVE vector registers on page B1-140*.

The element sizes are defined in Table A1-3 with the vector format described as:

### Table A1-3 SVE elements in AArch64 state

<table>
<thead>
<tr>
<th>Mnemonic</th>

<tr>
<td>Q</td>
<td>128 bits</td>
</tr>
</tbody>
</table>

SVE configurable vector length

Privileged Exception levels can use the ZCR_ELx.LEN System register fields to constrain the vector length at that Exception level and at less privileged Exception levels.

An implementation allows the vector length to be constrained to any power of two that is less than the maximum implemented vector length.

An implementation is permitted to allow the vector length to be constrained to multiples of 128 that are not a power of two. It is IMPLEMENTATION DEFINED which of the permitted multiples of 128 are supported.

The following table shows the SVE configurable vector lengths:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
A1.4 Supported data types

### A1.4.3 Half-precision floating-point formats

The Arm architecture supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.
- Arm alternative half-precision format.

--- **Note** ---

BFloat16 is not a half-precision floating-point format, see *BFloat16 floating-point format on page A1-52.*

Both formats can be used for conversions to and from other floating-point formats. FPCR.AHP controls the format in AArch64 state and FPSCR.AHP controls the format in AArch32 state. FEAT_FP16 adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an *Effective value* of 0. The FEAT_SVE half-precision data-processing instructions ignore the value of FPCR.AHP, and behave as if it has an *Effective value* of 0.

The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.
For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

```
  15 14  10  9           0
 S | exponent | fraction
```

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

**0 < exponent < 0x1F**

The value is a normalized number and is equal to:

\[ (-1)^S \times 2^{(\text{exponent}-15)} \times (1.fraction) \]

The minimum positive normalized number is \(2^{-14}\), or approximately \(6.104 \times 10^{-5}\).

The maximum positive normalized number is \((2 - 2^{-10}) \times 2^{15}\), or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == 0x1F.

**exponent == 0**

The value is either a zero or a denormalized number, depending on the fraction bits:

- **fraction == 0**
  
  The value is a zero. There are two distinct zeros:
  
  +0 when S==0.
  
  -0 when S==1.

- **fraction != 0**
  
  The value is a denormalized number and is equal to:
  
  \[ (-1)^S \times 2^{-14} \times (0.fraction) \]
  
  The minimum positive denormalized number is \(2^{-24}\), or approximately \(5.960 \times 10^{-8}\).

Half-precision denormalized numbers are not flushed to zero by default. When FEAT_FP16 is implemented, the FPCR.FZ16 bit controls whether flushing denormalized numbers to zero is enabled for half-precision data-processing instructions. For details, see [Flushing denormalized numbers to zero](#) on page A1-58.

**exponent == 0x1F**

The value depends on which half-precision format is being used:

- **IEEE half-precision**
  
  The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:
  
  - **fraction == 0**
    
    The value is an infinity. There are two distinct infinities:
    
    +infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.
    
    -infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.
  
  - **fraction != 0**
    
    The value is a NaN, and is either a quiet NaN or a signaling NaN.
    
    The two types of NaN are distinguished by their most significant fraction bit, bit[9]:
    
    bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.
    
    bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.
Alternative half-precision
The value is a normalized number and is equal to:
\(-1^S \times 2^{16} \times (1.\text{fraction})\)
The maximum positive normalized number is \((2-2^{-10}) \times 2^{16}\) or 131008.

A1.4.4 Single-precision floating-point format
The single-precision floating-point format is as defined by the IEEE 754 standard.
This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>23</th>
<th>22</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td></td>
<td></td>
<td>fraction</td>
</tr>
</tbody>
</table>

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < 0xFF

The value is a normalized number and is equal to:
\((-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})\)
The minimum positive normalized number is \(2^{-126}\), or approximately \(1.175 \times 10^{-38}\).
The maximum positive normalized number is \((2 - 2^{-23}) \times 2^{127}\), or approximately \(3.403 \times 10^{38}\).

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:
+0 When S==0.
–0 When S==1.
These usually behave identically. In particular, the result is equal if +0 and –0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:
\((-1)^S \times 2^{-126} \times (0.\text{fraction})\)
The minimum positive denormalized number is \(2^{-149}\), or approximately \(1.401 \times 10^{-45}\).

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see Flushing denormalized numbers to zero on page A1-58.

exponent == 0xFF

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:
+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.
-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.
fraction != 0

The value is a NaN, and is either a quiet NaN or a signaling NaN. The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the default NaN, see The Default NaN on page A1-60.

--- Note ---

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as unordered with everything, including itself.

A1.4.5 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:

```
S  exponent  fraction
```

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < 0x7FF

The value is a normalized number and is equal to:

\((-1)^S \times 2^{(exponent-1023)} \times (1.fraction)\)

The minimum positive normalized number is \(2^{-1022}\), or approximately \(2.225 \times 10^{-308}\).

The maximum positive normalized number is \((2 - 2^{-52}) \times 2^{1023}\), or approximately \(1.798 \times 10^{308}\).

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0.

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

\((-1)^S \times 2^{-1022} \times (0.fraction)\)

The minimum positive denormalized number is \(2^{-1074}\), or approximately \(4.941 \times 10^{-324}\).
Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see Flushing denormalized numbers to zero on page A1-58.

\[
\begin{align*}
\text{exponent} &= \text{0xFF} \\
\text{fraction} &= \text{0} \\
\text{fraction} &
\end{align*}
\]

The value is either an infinity or a NaN, depending on the fraction bits:

\[
\begin{align*}
\text{fraction} &= \text{0} \\
\text{fraction} &
\end{align*}
\]

The value is an infinity. As for single-precision, there are two infinities:

\[
\begin{align*}
+\text{infinity} &\quad \text{When S==0.} \\
-\text{infinity} &\quad \text{When S==1.}
\end{align*}
\]

The value is a NaN, and is either a quiet NaN or a signaling NaN.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

\[
\begin{align*}
\text{bit}[51] &= \text{0} \\
\text{bit}[51] &
\end{align*}
\]

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

\[
\begin{align*}
\text{bit}[51] &= \text{1} \\
\text{bit}[51] &
\end{align*}
\]

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the default NaN, see The Default NaN on page A1-60.

---

**Note**

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as unordered with everything, including itself.

---

### A1.4.6 BFloat16 floating-point format

BFloat16, or BF16, is a 16-bit floating-point storage format. The BF16 format inherits many of its properties and behaviors from the single-precision format defined by the IEEE 754 standard, as described in Single-precision floating-point format on page A1-50.

For the BFloat16 floating-point format, the layout is:

\[
\begin{array}{c|c|c|c}
15 & 14 & 7 & 6 & 0 \\
\hline
S & \text{exponent} & \text{fraction} &
\end{array}
\]

\[
0 < \text{exponent} < \text{0xFF}
\]

The value is a normalized number and is equal to:

\[
(-1)^S \times 2^{(\text{exponent}-127)} \times (\text{1.fraction})
\]

The minimum positive normalized number is $2^{-126}$, or approximately $1.175 \times 10^{-38}$.

The maximum positive normalized number is $(2 - 2^{-7}) \times 2^{127}$, or approximately $3.390 \times 10^{38}$.

\[
\text{exponent} == \text{0}
\]

The value is either a zero or a denormalized number, depending on the fraction bits:

\[
\begin{align*}
\text{fraction} &= \text{0} \\
\text{fraction} &
\end{align*}
\]

The value is a zero. There are two distinct zeros:

\[
\begin{align*}
+0 &\quad \text{when S==0.} \\
-0 &\quad \text{when S==1.}
\end{align*}
\]
These usually behave identically. However, they yield different results in some circumstances. For example, the sign of the result produced as the result of multiplying by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer bitwise comparison of the two halfwords.

\[
\text{fraction} \neq 0
\]

The value is a denormalized number and is equal to:

\[
(-1)^S \times 2^{-126} \times (0.\text{fraction})
\]

The minimum positive denormalized number is \(2^{-133}\), or approximately \(9.184 \times 10^{-41}\).

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see Flushing denormalized numbers to zero on page A1-58.

\[
exponent == 0xFF
\]

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

\[
\text{fraction} == 0
\]

The value is an infinity. There are two distinct infinities:

**+infinity** When \(S==0\). This represents all positive numbers that are too big to be represented accurately as a normalized number.

**-infinity** When \(S==1\). This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

\[
\text{fraction} \neq 0
\]

The value is a NaN, and is either a quiet NaN or a signaling NaN.

The two types of NaN are distinguished by their most significant fraction bit, bit[6]:

\[
\text{bit}[6] == 0 \quad \text{The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.}
\]

\[
\text{bit}[6] == 1 \quad \text{The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.}
\]

In the arithmetic instructions that accept BF16 inputs, there is no distinction between quiet and signaling input NaNs, since these instructions cannot signal a floating-point exception, and any type of input NaN generates the same Default NaN result.

BF16 values are 16-bit halfwords that software can convert to single-precision format, by appending 16 zero bits, so that single-precision arithmetic instructions can be used. A single-precision value can be converted to BF16 format if required, either by:

- Truncating, by removing the least significant 16 bits.
- Using the BFloat16 conversion instructions, see Floating-point single-precision to BFloat16 conversion instruction on page C3-313.

### A1.4.7 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

### A1.4.8 Conversion between floating-point and fixed-point values

The Arm architecture supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument \#fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.
More specifically:
- For a 64-bit register \( X_d \):
  - The integer part is \( X_d[63:#fbits] \).
  - The fractional part is \( X_d[(#fbits-1):0] \).
- For a 32-bit register \( W_d \) or \( R_d \):
  - The integer part is \( W_d[31:#fbits] \) or \( R_d[31:#fbits] \).
  - The fractional part is \( W_d[(#fbits-1):0] \) or \( R_d[(#fbits-1):0] \).

These instructions can cause the following floating-point exceptions:

- **Invalid Operation**
  - When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.
- **Inexact**
  - When the numeric result differs from the input value.
- **Input Denormal**
  - When flushing denormalized numbers to zero is enabled and the denormal input is replaced by a zero, see Flushing denormalized numbers to zero on page A1-58 and Input Denormal exceptions on page A1-65.

---

Note
An out of range fixed-point result is saturated to the destination size.

For more information, see Floating-point exceptions and exception traps on page A1-64.

### A1.4.9 Polynomial arithmetic over \{0, 1\}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over \{0, 1\}, see Supported data types on page A1-42. The polynomial data type represents a polynomial in \( x \) of the form \( b_{n-1}x^{n-1} + \ldots + b_1x + b_0 \) where \( b_k \) is bit\([k]\) of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:
- \( 0 + 0 = 1 + 1 = 0 \).
- \( 0 + 1 = 1 + 0 = 1 \).
- \( 0 \times 0 = 0 \times 1 = 1 \times 0 = 0 \).
- \( 1 \times 1 = 1 \).

That is:
- Adding two polynomials over \{0, 1\} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over \{0, 1\} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32, and T32 provide instructions for performing polynomial multiplication of 8-bit values.
- For AArch32, see VMUL (integer and polynomial) on page F6-8575 and VMULL (integer and polynomial) on page F6-8581.
- For AArch64, see PMUL on page C7-2535 and PMULL, PMULL2 on page C7-2537.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See PMULL, PMULL2 on page C7-2537.

#### Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the PolynomialMult() function defined in Chapter J1 Armv8 Pseudocode.
A1.5 Floating-point support

Note

The architecture includes the following types of floating-point instructions:

- Scalar floating-point instructions that operate on the lowest numbered element of the SIMD&FP registers.
- Advanced SIMD floating-point instructions that operate on multiple elements of the SIMD&FP registers.
- If FEAT_SVE is implemented, AArch64 SVE instructions that operate on multiple elements of the scalable vector registers, in which the SIMD&FP registers occupy the least significant 128 bits.

The architecture can support the following levels of support for Advanced SIMD and floating-point instructions:

- Full Advanced SIMD and floating-point support without floating-point exception trapping.
- Full Advanced SIMD and floating-point support with floating-point exception trapping.
- No Advanced SIMD or floating-point support. This option is licensed only for implementations targeting specialized markets.

Note

All Armv8-A systems that support standard operating systems with rich application environments provide hardware support for Advanced SIMD and floating-point instructions. All Armv9-A systems that support standard operating systems with rich application environments also provide hardware support for SVE2 instructions. It is a requirement of the ARM Procedure Call Standard for AArch64, see Procedure Call Standard for the Arm 64-bit Architecture.

The Arm architecture supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types. When FEAT_FP16 is implemented, it also supports the half-precision floating-point data type for data-processing operations.

The SIMD instructions provide packed Single Instruction Multiple Data (SIMD) and single-element scalar operations, and support:

- Single-precision and double-precision arithmetic in AArch64 state.
- Single-precision arithmetic only in AArch32 state.
- When FEAT_FP16 is implemented, half-precision arithmetic is supported in AArch64 and AArch32 states.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

- Configurable rounding modes.
- Configurable Default NaN behavior.
- Configurable flushing to zero of denormalized numbers.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from Armv7. A32 and T32 Advanced SIMD floating-point always uses Arm standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see Flushing denormalized numbers to zero on page A1-58.
- Only default NaNs are supported, see The Default NaN on page A1-60.
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, floating-point exceptions, such as Overflow or Divide by Zero, can be handled without trapping. This applies to both SIMD and floating-point operations. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about floating-point exceptions, see Floating-point exceptions and exception traps on page A1-64.
In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, FPCR, controls:
  - The half-precision format where applicable, FPCR.AHP bit.
  - Default NaN behavior, FPCR.DN bit.
  - Flushing of denormalized numbers to zero, FPCR.{FZ, FZ16} bits. If FEAT_FP16 is not implemented, FPCR.FZ16 is RES0.
  - Rounding mode support, FPCR.Rmode field.
  - Len and Stride fields associated with execution in AArch32 state, and only supported for a context save and restore from AArch64 state. These fields are obsolete in Armv8 and can be implemented as RAZ/WI. If they are implemented as RW and are programmed to a nonzero value, they make some AArch32 floating-point instructions UNDEFINED.
  - Floating-point exception trap controls, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits, see Floating-point exceptions and exception traps on page A1-64.

- The Floating-Point Status Register, FPSR, provides:
  - Cumulative floating-point exceptions flags, FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}.
  - The AArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not implemented.

**Note**

In AArch64 state, the process state flags, PSTATE.{N,Z,C,V} are used for all data-processing compares and any associated conditional execution.

If FEAT_FlagM2 is implemented, the instructions AXFLAG and XFLAG convert between the Arm condition flag format and an alternative format shown in Relationship between ARM format and alternative format PSTATE condition flags on page C6-1168.

AArch32 state provides a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

For system level information about the SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-8996.

### A1.5.1 Instruction support

The floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

**Note**

Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements for both integer and floating-point data types.
- When FEAT_FCMA is implemented, complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point, fixed-point integer, and integer data types.
- Floating-point rounding.

For more information on floating-point instructions in AArch64 state, see Chapter C3 A64 Instruction Set Overview.

For more information on floating-point instructions in AArch32 state, see Chapter F2 The AArch32 Instruction Sets Overview.
A1.5.2 Floating-point standards, and terminology

The Arm architecture includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this Manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-4 on page A1-57 shows how the terminology in this Manual differs from that used in IEEE 754-2008.

<table>

* Normalized number is used in preference to normal number, because of the other specific uses of normal in this Manual.

A1.5.3 Arm standard floating-point input and output values

The Arm architecture provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to *Arm standard floating-point operation*, regardless of the selected rounding mode in the FPSCR. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the FPCR.

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see *Flushing denormalized numbers to zero on page A1-58*.
- NaNs.
- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see *Flushing denormalized numbers to zero on page A1-58*.
- NaNs produced in floating-point operations are always the default NaN, see *The Default NaN on page A1-60*.
- Infinities.
A1.5.4 Flushing denormalized numbers to zero

For this section if FEAT_AFP is not implemented, the behavior is the same as if FPCR.AH == 0, FPCR.FZ == 0 and FPCR.NEP == 0.

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and Intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization.

If a number value satisfies the condition 0 < Abs(value) < MinNorm, it is treated as a denormalized number.

MinNorm is defined as follows:
- For half-precision numbers, MinNorm is $2^{-14}$.
- For single-precision and BFloat16 numbers, MinNorm is $2^{-126}$.
- For double-precision numbers, MinNorm is $2^{-1022}$.

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:
- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has an input denormalized number that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For floating-point instructions, if the instruction processes half-precision inputs, flushing denormalized inputs to zero can be controlled as follows:
- If FPCR.FZ16 == 0, denormalized half-precision inputs are not flushed to zero.
- If FPCR.FZ16 == 1, for half-precision data-processing instructions, flushing of input denormalized numbers to zero occurs as follows:
  - If an instruction does not convert a half-precision input to a higher precision output, all input denormalized numbers are flushed to zero.
  - If an instruction converts a half-precision input to a higher precision output, input denormalized numbers are not flushed to zero.

If FPCR.FIZ == 1, or both FPCR.AH == 0 and FPCR.FZ == 1, for Advanced SIMD and floating-point instructions other than FABS and FNEG, all single-precision, double-precision and BF16 input operands that are denormalized numbers are flushed to zero. Half-precision input operands are not flushed to zero.

If FPCR.FZ == 0, for Advanced SIMD, floating-point and BF16 instructions, the FPCR.FZ setting does not cause denormalized inputs to be flushed to zero, although other factors might cause denormalized numbers to be flushed to zero.

If FPCR.AH == 1, regardless of the value of FPCR.FIZ, all of the following instructions flush all input denormal numbers to zero:
- BFloat instructions: BFCVT, BFCVTN, BFCVTN2, BFMLALB, BFMLALT (by element), BFMLALB, BFMLALT (vector), and BFCVTNT.
• Single-precision and double-precision instructions: FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

**Flushing to zero of denormalized numbers as Intermediate results of some BF16 instructions**

BF16 arithmetic instructions BFDOT (by element), BFDOT (vector), BFMMMLA in AArch64, and VDOT (by element), VDOT (vector), VMMMLA in AArch32 when working with BF16 inputs, convert BF16 input values to IEEE single-precision format, and calculate N-way dot-products, accumulating the products in single-precision accumulators.

If a BF16 arithmetic instruction processes an intermediate result that is a single-precision denormalized number, the Intermediate result is unconditionally flushed to zero.

**Flushing denormalized outputs to zero**

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If FPCR.AH == 0, for half-precision, single-precision and double-precision numbers, the test for a denormalized number for the purpose of flushing the output to zero occurs before rounding.

If FPCR.AH == 1, and if output flushing is caused by FPCR.FZ == 1 or FPCR.FZ16 == 1, for half-precision, single-precision and double-precision numbers, the test for a denormalized number for the purpose of flushing the output to zero occurs after rounding using an unbounded exponent.

If FPCR.AH == 1, and if FPCR.FZ == 0, Advanced SIMD, floating-point and BF16 instructions, for single-precision, double-precision and BF16 outputs, the FPCR.FZ setting does not cause denormalized outputs to be flushed to zero, although other factors might cause denormalized outputs to be flushed to zero.

BFDOT (by element), BFDOT (vector), and BFMMMLA instructions unconditionally flush denormalized output numbers to zero.

If FPCR.AH == 0, for Advanced SIMD, floating-point, and BF16 instructions, for single-precision, double-precision and BF16 outputs, flushing denormalized numbers to zero can be controlled as follows:

- If FPCR.FZ == 0, the FPCR.FZ setting does not cause denormalized output numbers to be flushed to zero, although other factors might cause denormalized output numbers to be flushed to zero.
- If FPCR.FZ == 1, for all Advanced SIMD, floating-point and BF16 instructions other than FABS and FNEG, all single-precision, double-precision, and BF16 outputs that are denormalized numbers are flushed to zero.

If FPCR.FZ16 == 0 denormalized half-precision output numbers are not flushed to zero.

If FPCR.FZ16 == 1, for floating-point instructions other than FABS, FNEG, FMAX*, and FMIN*, if the instruction processes half-precision numbers, flushing denormalized output numbers to zero can be controlled as follows:

- Instructions that convert between half-precision and single-precision numbers do not flush denormalized half-precision output numbers to zero.
- Instructions that convert between half-precision and double-precision numbers do not flush denormalized half-precision output numbers to zero.
- All other half-precision data-processing instructions flush all denormalized half-precision output numbers to zero.

If FPCR.AH == 1 and FPCR.FZ == 1, for Advanced SIMD, floating-point and BF16 instructions, all of the following apply:

- For all floating-point operations other than FABS, FNEG, FMAX*, and FMIN*, all single-precision and double-precision denormalized output operands are flushed to zero.
- For FABS, FNEG, FMAX*, and FMIN*, denormalized output operands are not flushed to zero.
If \( \text{FPCR.AH} = 1 \), regardless of the value of \( \text{FPCR.FZ} \) bit, for both Advanced SIMD and SVE, all of the following instructions flush all output denormal numbers to zero:

- BFloat instructions: \( \text{BFCVT} \), \( \text{BFCVTN} \), \( \text{BFCVTN2} \), \( \text{BFMLALB} \), \( \text{BFMLALT} \) (by element), \( \text{BFMLALB} \), \( \text{BFMLALT} \) (vector), and \( \text{BFCVTNT} \).
- Single-precision and double-precision instructions: \( \text{FRECPE} \), \( \text{FRECPS} \), \( \text{FRECPX} \), \( \text{FRSQRTS} \), and \( \text{FRSQRT} \).

### A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa. The Arm architecture additionally defines a Default NaN which does not follow this format.

The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a speculative result of a floating-point calculation not involving NaN inputs.

#### The Default NaN

The Default NaN is encoded as described in Table A1-5 on page A1-60.

<table>
<thead>
<tr>
<th>Table A1-5 Default NaN encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign bit</td>
</tr>
<tr>
<td>( \text{If FPCR.AH} = 0 )</td>

<tr>
<td>( \text{If FPCR.AH} = 1 )</td>
</tr>
<tr>
<td>Exponent</td>
</tr>
<tr>
<td>Fraction</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

IF \( \text{FPCR.DN} = 1 \), for floating-point instructions other than \( \text{FABS} \), \( \text{FMAX} \), \( \text{FMIN} \), and \( \text{FNEG} \), if any input to a floating-point operation performed by the instruction is a NaN, the output of the floating-point operation is the Default NaN.

For \( \text{FABS} \), \( \text{FNEG} \), \( \text{FMAX} \), \( \text{FMIN} \), Default NaN behavior is explained in the instruction description.

If \( \text{FPCR.DN} = 0 \), for floating-point processing the Default NaN is not used for NaN propagation.

If a floating-point instruction performs a floating-point operation, and that instruction generates an untrapped Invalid Operation floating-point exception for a reason other than one of the inputs being a signaling NaN, the output is the Default NaN.

#### NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and a different number of fraction bits from its source. See instruction descriptions for details.
**NaN propagation**

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN.
- If the input NaN is a signaling NaN, the output NaN is derived as follows:
  - If the handling of a signaling NaN by the instruction generates an Invalid Operation exception, the output NaN is the quieted version of the input NaN.
  - If the handling of a signaling NaN by the instruction does not generate an Invalid Operation exception, the output NaN is the same as the input NaN. This case applies for FABS, FNEG, and FTSSEL instructions.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, the term “first operand” and “second operand” relate to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

If $\text{FPCR.DN} = 0$, for Advanced SIMD, floating-point, or BF16 instructions that perform a floating-point operation, other than $\text{FABS}$, $\text{FNEG}$, $\text{FMAX}$, and $\text{FMIN}$, NaN outputs that derive from NaN inputs are derived as follows:

- If all of the following apply, an instruction outputs a quiet NaN derived from the first signaling NaN operand:
  - $\text{FPCR.AH} = 0$.
  - At least one operand is a signaling NaN.
  - The instruction is not trapped.
- If all of the following apply, an instruction outputs a quiet NaN derived from the first NaN operand:
  - $\text{FPCR.AH} = 0$.
  - At least one operand is a NaN, but none of the operands is a signaling NaN.
  - The instruction is not trapped.
- If all of the following apply, the output is a quiet NaN derived from the NaN operand:
  - $\text{FPCR.AH} = 1$.
  - The operation has two floating-point inputs.
  - The operation has only one NaN operand.
- If all of the following apply, the output is a NaN derived from the $\langle Vn \rangle$, $\langle Hn \rangle$, $\langle Sn \rangle$, or $\langle Dn \rangle$ register:
  - $\text{FPCR.AH} = 1$.
  - The operation has two floating-point inputs.
  - The operation has two NaN operands.
• If all of the following apply, the output is a NaN derived from the NaN held in the <Vn>, <Hn>, <Sn>, or <Dn> register:
  — FPCR.AH == 1
  — The instruction is one of: BFMLALB, BFMLALT (by element), BFMLALB, BFMLALT (vector),
    FCMLA, FMADD, FMLA (by element), FMLA (vector), FMLAL, FMLAL2 (by element), FMLAL,
    FMLAL2 (vector), FMLS (by element), FMLS (vector), FMLSL, FMLSL2 (by element), FMLSL,
    FMLSL2 (vector), FMSUB, FNADD, and FNMSUB.
  — One of the following applies:
    — The operation has three NaN operands.
    — The operation has two NaN operands and the <Vn>, <Hn>, <Sn> or <Dn> register holds a NaN.

• If all of the following apply, the output is a NaN derived from the NaN held in the <Vm>, <Hm>, <Sm>, or <Dm> register:
  — FPCR.AH == 1
  — The instruction is one of: BFMLALB, BFMLALT (by element), BFMLALB, BFMLALT (vector),
    FCMLA, FMADD, FMLA (by element), FMLA (vector), FMLAL, FMLAL2 (by element), FMLAL,
    FMLAL2 (vector), FMLS (by element), FMLS (vector), FMLSL, FMLSL2 (by element), FMLSL,
    FMLSL2 (vector), FMSUB, FNADD, and FNMSUB.
  — The operation has two NaN operands and the <Vn>, <Hn>, <Sn> or <Dn> register does not hold a NaN.

If FPCR.AH == 0, and an output NaN is derived from an input NaN, the pseudocode functions FPAbs(), FPNeg(),
FPTrigMAdd(), and FPTrigSSel() can change the sign of the NaN.

If FPCR.AH == 1, and an output NaN is derived from an input NaN, for all cases, the sign bit of the NaN is unchanged.

For FMAX* and FMIN*, the NaN handling is described in the instruction.

A1.5.6 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field FPCR.RMode or by the instruction.

If FPCR.AH == 1, for any value of FPCR.RMode, the following instructions use Round to Nearest on outputs:

• BF16 instructions BFCVT, BFCVTN, BFCVTN2, BFMLALB, BFMLALT (by element), BFMLALB,
  BFMLALT (vector), and the SVE instruction BFCVNT.

• Single-precision and double-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTE, and
  FRSQRTS.

• Half-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTE, and FRSQRTS.

The rounding mode control field FPCR.RMode can select the following rounding modes:

• Round to Nearest (RN) mode.
• Round towards Plus Infinity (RP) mode.
• Round towards Minus Infinity (RM) mode.
• Round towards Zero (RZ) mode.

The following two additional rounding modes are not selected by FPCR.RMode, but are used by some instructions:

• Round to Odd mode.
• Round to Nearest with ties to away mode.
Round to Nearest mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round towards Plus Infinity mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

Round towards Minus Infinity mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

Round towards Zero mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounding mode is used by the FCVTAS (scalar), FCVTAS (vector), FCVTAU (scalar), FCVTAU (vector), FRINTA (scalar), and FRINTA (vector) instructions.

Round to Nearest with Ties to Away rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity, the sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the larger number.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round to Odd mode

Round to Odd mode is not defined by IEEE 754, and differs between the FCVTXN, FCVTXN2 instructions, and the BFDO (by element), BFDO (vector), and BFMMMLA instructions.

The FCVTXN, FCVTXN2 instructions use Round to Odd rounding mode. If the result of the rounding is inexact, the least significant bit of the mantissa is forced to 1.
Round to Odd rounding mode can avoid double rounding errors when a floating-point value is converted to a lower precision destination format through an intermediate precision format.

**Example A1-1 Converting 64-bit floating-point format to 16-bit floating-point format**

A 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value using the following steps:

1. Use an FCVTXN instruction to produce a 32-bit value.
2. Use another instruction with the required rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

For BFDOT (by element), BFDOT (vector), and BFMM MLA instructions, if the intermediate format has at least two more bits of precision than the result format, Round to Odd mode is used and operates as follows:

- If the rounded value is inexact, the least significant bit of the fraction is set to 1.
- If the value is too large to represent in the single-precision format, the rounded value is a single-precision Infinity, the sign of the rounded value is the same as the sign of the value before rounding.

### A1.5.7 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*. Predicated SVE floating-point instructions only generate floating-point exceptions in response to floating-point operations performed on *Active elements*.

**Note**

In AArch64 state, an Advanced SIMD or SVE instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an operation, rather than on an instruction.

The architecture does not support asynchronous reporting of floating-point exceptions.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements about synchronous exception generation from that floating-point exception do not apply to the implementation.

Synchronous exception generation by floating-point exceptions is enabled using the FPCR as follows:

- For each floating-point exception that supports synchronous exception generation, the relevant control bit chosen from FPCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} is used to enable synchronous exception generation.
- For each floating-point exception that does not support synchronous exception generation, the relevant bit chosen from FPCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} is RAZ/WI.
**Input Denormal exceptions**

The cumulative floating-point exception bit FPSR.IDC, and the trap enable bit FPCR.IDE both relate to Input Denormal exceptions.

If an input denormalized number is flushed to zero, the occurrence of the Input Denormal exception is determined using the value before flushing.

If an input denormalized number is flushed to zero, and FPCR.AH is 0, the occurrence of all floating-point exceptions, except Input Denormal, is determined treating the input value that is flushed to zero as zero.

If an input denormalized number is flushed to zero, and FPCR.AH is 1, the occurrence of all floating-point exceptions is determined treating the input value that is flushed to zero as zero.

If FPCR.AH is 0, when a single-precision or double-precision floating-point input is flushed to zero, an Input Denormal exception is generated.

If FPCR.AH is 1, and FPCR.FIZ is 0, if and only if none of the following apply, any operation that unpacks a denormalized floating-point input, other than unpacking a BFloat or half-precision value, generates an Input Denormal exception:

- One of the other operands of the instruction is a NaN.
- The operation generates an Invalid Operation floating-point exception.
- The operation generates a Divide-by-Zero floating-point exception.
- The instruction that generated the operation was one of: BFCVTN, BFCVTN2, BFCVT, and BFCVTNT.
- The denormalized floating-point input is flushed to zero.

When a half-precision floating-point value is flushed to zero, an Input Denormal exception is not generated.

If FPCR.AH is 1, or FPCR.FZ is 0, when FPCR.FIZ causes flushing of a denormalized number, an Input Denormal Exception is not generated.

**Inexact exceptions**

The cumulative floating-point exception bit FPSR.IXC and the trap enable bit FPCR.IXE both relate to Inexact exceptions.

If a denormalized output is flushed to zero, all of the following apply:

- If FPCR.AH is 1, an Inexact exception is generated.
- If FPCR.AH is 0, an Inexact exception is not generated.

If a result is not flushed to zero, and the result does not equal the result computed with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

**Underflow exceptions**

The cumulative floating-point exception bit FPSR.UFC, and the trap enable bit FPCR.UFE both relate to Underflow exceptions.

If FPCR.AH is 1, for all floating points other than BFu1H() and BFu1AdH() which are used by BF00T and BFMLA, for the purpose of underflow floating-point exception generation, a denormalized number is detected after rounding with an unbounded exponent.

If FPCR.AH is 0, for the purpose of underflow floating-point exception generation, a denormalized number is detected before rounding is applied.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then:

- If FPCR.UFE is 0, and the result is inexact, then the underflow floating-point exception is generated.
- If FPCR.UFE is 1, then the underflow floating-point exception is generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is not generated.
Overflow exceptions

The cumulative floating-point exception bit FPSR.OFC, and the trap enable bit FPCR.OFE both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the rounding mode and the sign of the result before rounding as follows:

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision’s largest finite number with the sign of the result before rounding.

Divide by Zero exceptions

The cumulative floating-point exception bit FPSR.DZC, and the trap enable bit FPCR.DZE both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

Invalid Operation exceptions

The cumulative floating-point exception bit FPSR.IOC, and the trap enable bit FPCR.IOE both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN.
- Magnitude subtraction of infinities.
- Multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Square root of an operand that is less than zero.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation floating-point exception.

For the signaling compare instructions FCMPE and FCCMPE, if either of the source operands is any type of NaN, the instruction generates an Invalid Operation floating-point exception.

If FPCR.AH is 1, for FMAX (vector), FMAX (scalar), FMAXP (scalar), FMAXP (vector), FMAXV, FMIN (vector), FMIN (scalar), FMINP (scalar), FMINP (vector), and FMINV, if either input is any type of NaN, then an Invalid Operation floating-point exception is generated.

Operations that do not generate floating point exceptions

BFDOT (by element), BFDOT (vector), and BFMMMLA do not generate floating-point exceptions.
If FPCR.AH is 1, all of the following instructions do not generate any floating-point exceptions regardless of their input values:

- BF16 instructions BFMLALB, BFMLALT (by element), BFMLALB, BFMLALT (vector), BFCVT, BFCVTN, BFCVTN2, and BFCVTNT.
- Single-precision, double-precision and half-precision instructions FRECPE, FRECPS, FRECPX, FRSQRTN, and FRSQRTE.
- Floating-point to integer and integer to floating-point rounding instructions: FCVTMS (scalar), FCVTMS (vector), FCVTMU (scalar), FCVTMU (vector), FCVTNS (scalar), FCVTNS (vector), FCVTNU (scalar), FCVTNU (vector), FCVTPS (scalar), FCVTPS (vector), FCVPUS (scalar), FCVPUS (vector), FCVTZS (scalar, fixed-point), FCVTZS (scalar), integer), FCVTZS (vector, fixed-point), FCVTZS (vector, integer), FCVTZU (scalar, fixed-point), FCVTZU (scalar, integer), FCVTZU (vector, fixed-point), FCVTAS (scalar), FCVTAS (vector), FCVTZU (vector, fixed-point), FCVTZS (vector, scalar), FCVTZS (vector, integer), FRINTA (scalar), FRINTA (vector), FRINTZ (scalar), FRINTZ (vector), FRINTM (scalar), FRINTM (vector), FRINTP (scalar), FRINTP (vector), FRINTN (scalar), FRINTN (vector), FRINTX (scalar), FRINTX (vector), FRINTI (scalar), FRINTI (vector), FRINT32X (scalar), FRINT32X (vector), FRINT32Z (scalar), FRINT32Z (vector), FRINT64X (scalar), FRINT64X (vector), FRINT64Z (scalar), and FRINT64Z (vector).

FPAbs() and FPNeg() are not classified as floating-point operations and all of the following apply to them:

- They cannot generate floating-point exceptions.
- The floating-point behavior described in the Flushing denormalized numbers to zero on page A1-58 does not apply to them.
- The floating-point behavior described in the section NaN handling and the Default NaN on page A1-60 does not apply to them.

Handling floating-point exceptions

If an implementation supports synchronous exception generation for floating-point exceptions, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception and that is not at a lower Exception level than where the exception was generated.

If an implementation supports synchronous exception generation for floating-point exceptions in AArch64 state, all of the following apply:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception, except that an implementation is permitted to not restore the cumulative floating-point exception bits in the event of such an exception.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported.

The AArch64.FPTrappedException() and FPProcessException() pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

Combinations of floating-point exceptions

More than one floating-point exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- If FPCR.AH is 0, Input Denormal with any other floating-point exceptions.
- If FPCR.AH is 1, Input Denormal with Inexact, Underflow, or Overflow.

If two floating-point exceptions occur on the same operation, the Input Denormal exception is treated as highest priority and the Inexact exception is treated as lowest priority.
Some floating-point instructions specify more than one floating-point operation, this is indicated by the pseudocode descriptions of the instruction. In these cases, it is possible for one instruction to generate multiple exceptions. Multiple exceptions from one instruction are prioritized as follows:

- If an exception generating operation outputs a result that is used by a second exception generating operation, the exception generated by the operation that outputs the result is treated as higher priority than the exception generated by the second operation that uses the result.

- If exception generating operations do not use the outputs of other exception generating operations, it is constrained unpredictable which floating-point exception is treated as higher priority. The exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

- A trapped Underflow exception has priority over a trapped inexact exception.

If none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative exception flag bit in the FPSR to be set to 1.

When a floating-point exception is trapped, all of the following apply:

- When the trapped floating-point exception is taken, it is implementation defined whether the FPSR is restored to the value of the FPSR immediately before the instruction that generated the trapped floating-point exception.

When the trapped floating-point exception is taken, if the FPSR is not restored, it is constrained unpredictable which untrapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative exception flag bits having the value 1.

- In the ESR_ELx to which the trapped exception is taken all of the following apply:
  - The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
  - If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
  - If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is constrained unpredictable whether the floating-point exception trapped bit is set to 1.

The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD or SVE operation. For trapped floating-point exceptions from Advanced SIMD or SVE instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction.
A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating virtual addresses (VAs) provided by executing instructions to physical addresses (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

VA support depends on the Execution state, as follows:

**AArch64 state**

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

**AArch32 state**

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported PA space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the Virtual Memory System Architecture (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

**For execution in AArch64 state**

- Chapter B2 The AArch64 Application Level Memory Model.
- Chapter D7 The AArch64 System Level Memory Model.
- Chapter D8 The AArch64 Virtual Memory System Architecture.

**For execution in AArch32 state**

- Chapter E2 The AArch32 Application Level Memory Model.
- Chapter G4 The AArch32 System Level Memory Model.
- Chapter G5 The AArch32 Virtual Memory System Architecture.
Chapter A2
Armv8-A Architecture Extensions

This chapter introduces the Arm architecture versions and extensions. It contains the following sections:

- Armv8.0 architecture extensions on page A2-72.
- Architectural features within Armv8.0 architecture on page A2-76.
- The Armv8 Cryptographic Extension on page A2-80.
- The Armv8.1 architecture extension on page A2-82.
- The Armv8.2 architecture extension on page A2-86.
- The Armv8.3 architecture extension on page A2-96.
- The Armv8.4 architecture extension on page A2-101.
- The Armv8.5 architecture extension on page A2-107.
- The Armv8.6 architecture extension on page A2-111.
- The Armv8.7 architecture extension on page A2-113.
- The Armv8.8 architecture extension on page A2-117.
- The Performance Monitors Extension on page A2-121.
- The Reliability, Availability, and Serviceability Extension on page A2-122.
- The Statistical Profiling Extension (SPE) on page A2-123.
- The Scalable Vector Extension (SVE) on page A2-124.
- The Activity Monitors Extension (AMU) on page A2-125.
- The Memory Partitioning and Monitoring (MPAM) Extension on page A2-126.
A2.1 Armv8.0 architecture extensions

The original Armv8-A architecture is called Armv8.0. The following sections of this manual describe or summarize permitted extensions to Armv8.0:

- The Armv8 Cryptographic Extension on page A2-80.
- The Reliability, Availability, and Serviceability Extension on page A2-122.
- Event monitors on page D1-4683.
- The IVIPT Extension described Instruction caches on page D8-5215.
- Chapter H7 The PC Sample-based Profiling Extension.

Note

The naming convention of features in the Arm architecture has been redefined. For more information on how these names map to the legacy convention, see Appendix K15 Legacy Feature Naming Convention.

In addition to describing Armv8.0, this manual describes the following architectural extensions:

Features added to Armv8.0 in later releases

Architectural features and architectural requirements have been added to the original Armv8-A architecture. For more information, see:

- Additional functionality added to Armv8.0 in later releases on page A2-76.
- Architectural requirements within Armv8.0 architecture on page A2-79.

For more information, see Architectural features within Armv8.0 architecture on page A2-76.

The Armv8.1 architectural extension

The Armv8.1 architecture extension adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.1 compliant if all of the following apply:

- It includes all of the Armv8.1 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.1 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.1 on page A2-82 for all of the Armv8.1 architectural features.
- It includes all of the Armv8.1 architectural requirements. Additional requirements of Armv8.1 on page A2-84 lists these requirements.

For more information, see The Armv8.1 architecture extension on page A2-82.

The Armv8.2 architectural extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.2 compliant if all of the following apply:

- It is Armv8.1 compliant.
- It includes all of the Armv8.2 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.2 compliant implementation includes the optional architecture component or extension. The features are listed at: Architectural features added by Armv8.2 on page A2-86, which lists the original Armv8.2 architectural features.
The Armv8.2 architecture extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.2 compliant if all of the following apply:

- It includes all of the Armv8.2 architectural requirements. Additional requirements of Armv8.2 on page A2-93 lists these requirements.

For more information, see The Armv8.2 architecture extension on page A2-86.

The Armv8.3 architectural extension

The Armv8.3 architecture extension is an extension to Armv8.2. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.3 compliant if all of the following apply:

- It is Armv8.2 compliant.
- It includes all of the Armv8.3 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.3 compliant implementation includes the optional architecture component or extension. The features are listed at:
  - Architectural features added by Armv8.3 on page A2-96, which lists the original Armv8.3 architectural features.
  - Features added to the Armv8.3 extension in later releases on page A2-98, which lists additional Armv8.3 architectural features.
- It includes all of the Armv8.3 architectural requirements. Additional requirements of Armv8.3 on page A2-98 lists these requirements.

For more information, see The Armv8.3 architecture extension on page A2-96.

The Armv8.4 architectural extension

The Armv8.4 architecture extension is an extension to Armv8.3. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.4 compliant if all of the following apply:

- It is Armv8.3 compliant.
- It includes all of the Armv8.4 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.4 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.4 on page A2-101 for all of the Armv8.4 architectural features.

For more information, see The Armv8.4 architecture extension on page A2-101.

The Armv8.5 architectural extension

The Armv8.5 architecture extension is an extension to Armv8.4. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.5 compliant if all of the following apply:

- It is Armv8.4 compliant.
- It includes all of the Armv8.5 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.5 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.5 on page A2-107 for all of the Armv8.5 architectural features.
- It includes all of the Armv8.5 architectural requirements. Additional requirements of Armv8.5 on page A2-109 lists these requirements.

For more information, see The Armv8.5 architecture extension on page A2-107.
The Armv8.6 architectural extension

The Armv8.6 architecture extension is an extension to Armv8.5. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.6 compliant if all of the following apply:

- It is Armv8.5 compliant.
- It includes all of the Armv8.6 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.6 compliant implementation includes the optional architecture component or extension. See "Architectural features added by Armv8.6" on page A2-111 for all of the Armv8.6 architectural features.
- It includes all of the Armv8.6 architectural requirements. "Additional requirements of Armv8.6" on page A2-112 lists these requirements.

For more information, see "The Armv8.6 architecture extension" on page A2-111.

The Armv8.7 architectural extension

The Armv8.7 architecture extension is an extension to Armv8.6. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.7 compliant if all of the following apply:

- It is Armv8.6 compliant.
- It includes all of the Armv8.7 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.7 compliant implementation includes the optional architecture component or extension. See "Architectural features added by Armv8.7" on page A2-113 for all of the Armv8.7 architectural features.
- It includes all of the Armv8.7 architectural requirements. "Additional requirements of Armv8.7" on page A2-116 lists these requirements.

For more information, see "The Armv8.7 architecture extension" on page A2-113.

The Armv8.8 architectural extension

The Armv8.8 architecture extension is an extension to Armv8.7. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.8 compliant if all of the following apply:

- It is Armv8.7 compliant.
- It includes all of the Armv8.8 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.8 compliant implementation includes the optional architecture component or extension. See "Architectural features added by Armv8.8" on page A2-117 for all of the Armv8.8 architectural features.
- It includes all of the Armv8.8 architectural requirements. "Additional requirements of Armv8.8" on page A2-120 lists these requirements.

For more information, see "The Armv8.8 architecture extension" on page A2-117.

The Statistical Profiling Extension (SPE)

SPE is an optional extension to Armv8.2. That is, SPE requires the implementation of Armv8.2.

For more information, see "The Statistical Profiling Extension (SPE)" on page A2-123.

The Scalable Vector Extension (SVE)

SVE is an optional extension to Armv8.2. That is, SVE requires the implementation of Armv8.2.

For more information, see "The Scalable Vector Extension (SVE)" on page A2-124.

The Activity Monitors Extension (AMU)

AMU is an optional extension to Armv8.4. That is, AMU requires the implementation of Armv8.4.
For more information, see *The Activity Monitors Extension (AMU)* on page A2-125.

**The Memory Partitioning and Monitoring Extension (MPAM)**

MPAM is an optional extension to Armv8.2. That is, MPAM requires the implementation of Armv8.2.

For more information, see *The Memory Partitioning and Monitoring (MPAM) Extension* on page A2-126.

See also *Permitted implementation of subsets of Armv8.x and Armv8.(x+1) architectural features*.

---

**A2.1.1 Permitted implementation of subsets of Armv8.x and Armv8.(x+1) architectural features**

An Armv8.x compliant implementation can include any arbitrary subset of the architectural features of Armv8.(x+1), subject only to those constraints that require that certain features be implemented together.

Unless this manual permits otherwise, an Armv8.x compliant implementation does not include any features of Armv8.(x+2) or later.

---

**Note**

The addition of Armv8.(x+1) features to an Armv8.x compliant implementation is permitted only if the implementer has a license to Armv8.(x+1) in addition to the license to Armv8.x.
A2.2 Architectural features within Armv8.0 architecture

This includes architectural features and architectural requirements that have been added to the Armv8.0 architecture since the initial release, that were not part of the original Armv8-A architecture, see:

- Additional functionality added to Armv8.0 in later releases.
- Architectural requirements within Armv8.0 architecture on page A2-79.

A2.2.1 Additional functionality added to Armv8.0 in later releases

An implementation of Armv8.0 can include any or all of the features that this section describes.

The Armv8.0 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**FEAT_SB, Speculation Barrier**

FEAT_SB introduces a barrier to control speculation.

This instruction is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

The following fields identify the presence of FEAT_SB:

- ID_AA64ISAR1_EL1.SB.
- ID_ISAR6_EL1.SB.
- ID_ISAR6.SB.

For more information, see:

- Speculation Barrier (SB) on page B2-176.
- Barriers and CLREX instructions on page C3-251.
- Speculation Barrier (SB) on page E2-7183.
- Miscellaneous instructions on page F2-7273.

**FEAT_SSBS, FEAT_SBSS2, Speculative Store Bypass Safe**

FEAT_SSBS allows software to indicate whether hardware is permitted to load or store speculatively in a manner that could give rise to a cache timing side channel, which in turn could be used to derive an address from values loaded to a register from memory.

FEAT_SSBS2 provides controls for the MSR and MRS instructions to read and write the PSTATE.SSBS field.

FEAT_SSBS is supported in both AArch64 and AArch32 states. FEAT_SBSS2 is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_SSBS and FEAT_SSBS2:

- ID_AA64PFR1_EL1.SSBS.
- ID_PFR2_EL1.SSBS.
- ID_PFR2.SSBS.

For more information, see:

- Speculative Store Bypass Safe (SSBS) on page B2-172.
- Speculative Store Bypass Safe (SSBS) on page E2-7179.

**FEAT_CSV2, FEAT_CSV2_2, and FEAT_CSV2_3, Cache Speculation Variant 2**

FEAT_CSV2 adds a mechanism to identify if hardware cannot disclose information about whether branch targets trained in one hardware described context can control speculative execution in a different hardware described context.

FEAT_CSV2_2 adds the SCXTNUM_ELx registers, which provide a number that can be used to separate out different context numbers within their respective Exception levels for the purpose of protecting against side-channels using branch prediction and similar resources.
FEAT_CSV2_3 adds a mechanism to identify if hardware cannot disclose information about whether branch targets and branch history trained in one hardware described context can control speculative execution in a different hardware described context.

FEAT_CSV2 is supported in both AArch64 and AArch32 states.

FEAT_CSV2_2 and FEAT_CSV2_3 are supported in AArch64 state only.

FEAT_CSV2 is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

FEAT_CSV2_2 and FEAT_CSV2_3 are OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_CSV2:
- ID_AA64PFR0_EL1.CSV2.
- ID_PFR0_EL1.CSV2.
- ID_PFR0.CSV2.

The ID_AA64PFR0_EL1.CSV2 field identifies the presence of FEAT_CSV2_2 and FEAT_CSV2_3.

For more information, see:
- Restrictions on the effects of speculation on page E2-7179.

**FEAT_CSV2_1p1 and FEAT_CSV2_1p2, Cache Speculation Variant 2**

For each of these features, within a hardware-described context, branch targets trained for branches situated at one address can control speculative execution of branches situated at different addresses only in a hard-to-determine way.

FEAT_CSV2_1p1 does not support the SCXTNUM_ELx registers, and the contexts do not include the SCXTNUM_ELx register contexts.

FEAT_CSV2_1p2 adds the SCXTNUM_ELx registers, but the contexts do not include the SCXTNUM_ELx register contexts.

FEAT_CSV2_1p1 is supported in both AArch64 and AArch32 states.

FEAT_CSV2_1p2 is supported in AArch64 state only.

These features are OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_CSV2_1p1:
- ID_AA64PFR1_EL1.CSV2_frac.
- ID_PFR0_EL1.CSV2.
- ID_PFR0.CSV2.

The ID_AA64PFR1_EL1.CSV2_frac field identifies the presence of FEAT_CSV2_1p2.

For more information, see:
- Restrictions on the effects of speculation on page E2-7179.

**FEAT_CSV3, Cache Speculation Variant 3**

FEAT_CSV3 adds a mechanism to identify if hardware cannot disclose information about whether data loaded under speculation with a permission or domain fault can be used to form an address, generate condition codes, or generate SVE predicate values, to be used by instructions newer than the load in the speculative sequence.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations and mandatory in Armv8.5 implementations.

This feature is mandatory when FEAT_E0PD is implemented.

The following fields identify the presence of FEAT_CSV3:
- ID_AA64PFR0_EL1.CSV3.
- ID_PFR2_EL1.CSV3.
- ID_PFR2.CSV3.
FEAT_SPECRES, Speculation restriction instructions
FEAT_SPECRES adds the CFP RCTX, CPP RCTX, DVP RCTX, CFPRCTX, CPPRCTX, and DVP RCTX System instructions. These instructions prevent predictions based on information gathered from earlier execution within a particular execution context from affecting the later speculative execution within that context, to the extent that the speculative execution is observable through side channels.

This feature is supported in both AArch64 and AArch32 states.
This feature is optional in Armv8.0 implementations and mandatory in Armv8.5 implementations.

The following fields identify the presence of FEAT_SPECRES:
- ID_AA64ISAR1_EL1.SPECRES.
- ID_ISAR6_EL1.SPECRES.
- ID_ISAR6.SPECRES.

For more information, see:
- Prediction restriction instructions on page C5-661.
- Execution, data prediction and prefetching restriction System instructions on page D7-5070.
- Execution and data prediction restriction System instructions on page G4-9134.

FEAT_CP15SDISABLE2, CP15SDISABLE2
FEAT_CP15SDISABLE2 provides an implementation-defined mechanism, the CP15SDISABLE2 signal, which when asserted HIGH prevents writes to a set of Secure CP15 registers. This signal is analogous to the existing CP15SDISABLE signal.

This feature is supported only when EL3 is executing in AArch32 state.
This feature is optional in Armv8.0 implementations.

For more information, see The CP15SDISABLE and CP15SDISABLE2 input signals on page G5-9285.

FEAT_DoubleLock, Double Lock
FEAT_DoubleLock is the mnemonic used for the OS Double Lock.

If FEAT_DoPD is not implemented and FEAT_Debugv8p2 is implemented, this feature is optional.
If FEAT_DoPD is not implemented and FEAT_Debugv8p2 is not implemented, this feature is mandatory.
If FEAT_DoPD is implemented, this feature is not implemented.
The ID_AA64DFR0_EL1.DoubleLock field identifies that the OS Double Lock has been implemented.

FEAT_DGH, Data Gathering Hint
FEAT_DGH adds the Data Gathering Hint instruction to the hint space.

This instruction is added to the A64 instruction set only.
This feature is optional in Armv8.0 implementations.

The ID_AA64ISAR1_EL1.DGH field identifies the presence of FEAT_DGH.

For more information, see Hint instructions on page C3-251.

FEAT_ETS, Enhanced Translation Synchronization
FEAT_ETS adds support for enhanced memory access ordering requirements for translation table walks.

This feature is supported in both AArch64 and AArch32 states.
This feature is optional in Armv8.0 implementations and mandatory in Armv8.7 implementations.
The following fields identify the presence of FEAT_ETS:
- ID_AA64MMFR1_EL1.ETS.
- ID_MMFR5_EL1.ETS.
A2.2 Architectural features within Armv8.0 architecture

- ID_MMFR5.ETS.
  For more information, see:
  - Ordering of memory accesses from translation table walks on page D8-5099.
  - Ordering of translation table walks on page E2-7187.

**FEAT_nTLBPA, Intermediate caching of translation table walks**

FEAT_nTLBPA adds a mechanism to identify if the intermediate caching of translation table walks does not include non-coherent caches of previous valid translation table entries since the last completed TLBI applicable to the PE.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_nTLBPA:
- ID_AA64MMFR1_EL1.nTLBPA.
- ID_MMFR5_EL1.nTLBPA.
- ID_MMFR5.nTLBPA.

For more information, see:
- TLB maintenance on page D8-5197.
- General TLB maintenance requirements on page G5-9220.

**FEAT_PCSRv8, PC Sample-based Profiling Extension**

FEAT_PCSRv8 adds support for PC Sample-based Profiling Extension that provides coarse-grained, non-invasive profiling by an external debugger.

This feature is OPTIONAL in Armv8.0 implementations.

The following fields identify the presence of FEAT_PCSRv8:
- EDDEVID.PCSample.
- DBGDEVID.PCSample.
- EDDEVID1.PCSROffset.
- DBGDEVID1.PCSROffset.
- PMDEVID.PCSample.

For more information, see About the PC Sample-based Profiling Extension on page H7-10352.

**A2.2.2 Architectural requirements within Armv8.0 architecture**

The Armv8.0 architecture includes some mandatory changes, that have been added to the architecture at a later date, that are not associated with a feature. These are:

**Prefetch speculation protection**

When substituting a direct branch with another direct branch, or a NOP with a direct branch, by the modified PE, at around the time that the executing PE is executing the software being modified, prefetch speculation protection prevents the old instructions from accidentally being fetched to the executing PE. For further information on implementation of these requirements, see:

- Ordering of instruction fetches on page B2-170.
- Ordering of instruction fetches on page E2-7178.

An implementation of the Armv8.0 architecture must comply with all of the additional requirements. When combined with the mandatory architectural features that have been added to the Armv8.0 architecture, such an implementation is also called an implementation of the Armv8.0 architecture.
A2.3 The Armv8 Cryptographic Extension

The Armv8.0 Cryptographic Extension provides instructions for the acceleration of encryption and decryption, and includes the following features:

- **FEAT_AES**, which includes the **AESD** and **AESE** instructions.
- **FEAT_PMULL**, which includes the **PMULL**, **PMULL2** instructions.
- **FEAT_SHA1**, which includes the **SHA1+** instructions.
- **FEAT_SHA256**, which includes the **SHA256+** instructions.

From Armv8.2, an implementation of the Armv8.0 Cryptographic Extension can include either or both of:

- The AES functionality, including support for multiplication of 64-bit polynomials. The **ID_AA64ISAR0_EL1.AES** field indicates whether this functionality is supported.
- The SHA1 and SHA2-256 functionality. The **ID_AA64ISAR0_EL1.{SHA2, SHA1}** fields indicate whether this functionality is supported.

The presence of the Cryptographic Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file.

The Cryptographic Extension also provides multiply instructions that operate on long polynomials.

The Cryptographic Extension provides this functionality in AArch64 state and AArch32 state, and an implementation that supports both AArch64 state and AArch32 state provides the same Cryptographic Extension functionality in both states.

For more information, see *The Cryptographic Extension on page C3-334 or The Cryptographic Extension in AArch32 state on page F2-7290.*

A2.3.1 Armv8.2 extensions to the Cryptographic Extension

Armv8.2 adds optional extensions to the Armv8 Cryptographic Extension, that provide cryptographic functionality in AArch64 state only. These optional features are:

**FEAT_SHA512, Advanced SIMD SHA512 instructions**

FEAT_SHA512 adds Advanced SIMD instructions that support SHA2-512 functionality.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SHA512 requires implementation of the Armv8.0 Cryptographic Extension FEAT_SHA1 and FEAT_SHA256 functionality.

The **ID_AA64ISAR0_EL1.SHA2** field identifies the presence of FEAT_SHA512.

For more information, see *FEAT_SHA512, SHA2-512 functionality on page C3-335.*

**FEAT_SHA3, Advanced SIMD SHA3 instructions**

FEAT_SHA3 adds Advanced SIMD instructions that support SHA3 functionality.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SHA3 requires implementation of the Armv8.0 Cryptographic Extension FEAT_SHA1 and FEAT_SHA256 functionality.

The **ID_AA64ISAR0_EL1.SHA3** field identifies the presence of FEAT_SHA3.

For more information, see *FEAT_SHA3, SHA3 functionality on page C3-336.*

**FEAT_SM3, Advanced SIMD SM3 instructions**

FEAT_SM3 adds Advanced SIMD instructions that support the Chinese cryptography algorithm SM3.

These instructions are added to the A64 instruction set only.

Implementation of FEAT_SM3 is independent of the implementation of any SHA functionality.

The **ID_AA64ISAR0_EL1.SM3** field identifies the presence of FEAT_SM3.
For more information, see *FEAT_SM3, SM3 functionality on page C3-337.*

**FEAT_SM4, Advanced SIMD SM4 instructions**

FEAT_SM4 adds Advanced SIMD instructions that support the Chinese cryptography algorithm SM4.

Implementation of FEAT_SM4 is independent of the implementation of any SHA functionality. These instructions are added to the A64 instruction set only.

The ID_AA64ISAR0_EL1.SM4 field identifies the presence of FEAT_SM4.

For more information, see *FEAT_SM4, SM4 functionality on page C3-337.*
A2.4 The Armv8.1 architecture extension

The Armv8.1 architecture extension adds both architectural features and architectural requirements, see:

- Architectural features added by Armv8.1.
- Additional requirements of Armv8.1 on page A2-84.
- Features added to the Armv8.1 extension in later releases on page A2-85.
- Features made optional in Armv8.1 implementations on page A2-85.

A2.4.1 Architectural features added by Armv8.1

An implementation of the Armv8.1 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.1, is also called an implementation of the Armv8.1 architecture.

The Armv8.1 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**FEAT_LSE, Large System Extensions**

FEAT_LSE introduces a set of atomic instructions:

- Compare and Swap instructions, CAS and CASP.
- Atomic memory operation instructions, LD<OP> and ST<OP>, where <OP> is one of ADD, CLR, EOR, SET, SMAX, SMIN, UMAX, and UMIN.
- Swap instruction, SWP.

These instructions are added only to the A64 instruction set.

This feature is mandatory in Armv8.1 implementations.

Implementations of FEAT_VHE require the implementation of FEAT_LSE.

The ID_AA64ISAR0_EL1.Atomic field identifies the presence of FEAT_LSE.

For more information, see:

- Atomic memory operations on page C3-268.
- Swap on page C3-272.
- Compare and Swap on page C3-272.

**FEAT_RDM, Advanced SIMD rounding double multiply accumulate instructions**

FEAT_RDM introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions.

For more information, see:

For the A64 instruction set

- SQRDMLAH (by element) on page C7-2698.
- SQRDMLAH (vector) on page C7-2701.
- SQRDMLSH (by element) on page C7-2704.
- SQRDMLSH (vector) on page C7-2707.

For the T32 and A32 instruction sets

- VQRDMLAH on page F6-8658.
- VQRDMLSH on page F6-8662.

This feature is mandatory in Armv8.1 implementations.

The following fields identify the presence of FEAT_RDM:

- ID_AA64ISAR0_EL1.RDM.
- ID_ISAR5_EL1.RDM.
- ID_ISAR5.RDM.
FEAT_LOR, Limited ordering regions
Limited ordering regions allow large systems to perform special Load-Acquire and Store-Release instructions that provide order between the memory accesses to a region of the PA map as observed by a limited set of observers.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.1 implementations.
The ID_AA64MMFR1_EL1.LO field identifies the presence of FEAT_LOR.
For more information, see:
• Limited ordering regions on page B2-182.

FEAT_HPDS, Hierarchical permission disable
FEAT_HPDS introduces the facility to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.
This feature is mandatory in Armv8.1 implementations.
This feature is added only to the VMSAv8-64 translation regimes. Armv8.2 extends this to the AArch32 translation regimes, see FEAT_AA32HPD.
The ID_AA64MMFR1_EL1.HPDS field identifies the presence of FEAT_HPDS.

FEAT_HAFDBS, Hardware management of the Access flag and dirty state
In Armv8.0, all updates to the translation tables are performed by software. From Armv8.1, for the VMSAv8-64 translation regimes only, hardware can perform updates to the translation tables in two contexts:
• Hardware management of the Access flag.
• Hardware management of dirty state, with updates to a dirty state in the translation tables.
The dirty state is introduced in Armv8.1.
Hardware management of dirty state can be enabled only when hardware management of the Access flag is also enabled.
This feature is OPTIONAL in Armv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.
The ID_AA64MMFR1_EL1.HAFDBS field identifies the presence of FEAT_HAFDBS.
For more information, see:
• Hardware management of the Access flag on page D8-5144.
• Hardware management of the dirty state on page D8-5145.

FEAT_PAN, Privileged access never
FEAT_PAN adds a bit to PSTATE. When the value of this PAN state bit is 1, any privileged data access from EL1, or EL2 when HCR_EL2.E2H is 1, to a virtual memory address that is accessible to data accesses at EL0, generates a Permission fault.
This feature is mandatory in Armv8.1 implementations.
This feature is supported in both AArch64 and AArch32 states.
The following fields identify the presence of FEAT_PAN:
• ID_AA64MMFR1_EL1.PAN.
• ID_MMFR3_EL1.PAN.
• ID_MMFR3.PAN.
For more information, see:
• PSTATE.PAN on page D8-5132.
• About the PAN bit on page G5-9195.

FEAT_VMID16, 16-bit VMID
In an Armv8.1 implementation, when EL2 is using AArch64, the virtual machine identifier (VMID) size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.
This feature is OPTIONAL in Armv8.1 implementations. When implemented, this feature is supported only when EL2 is using AArch64. The ID_AA64MMFR1_EL1.VMIDBits field identifies the supported VMID size. For more information, see:

- VMID size on page D8-5196.

**FEAT_VHE, Virtualization Host Extensions**

Armv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state. This feature is mandatory in Armv8.1 implementations. An implementation that includes FEAT_VHE requires FEAT_LSE to be implemented. The ID_AA64MMFR1_EL1.VH field identifies the presence of FEAT_VHE. The following fields indicate the presence of the Virtualization Host Extensions for debug, including the changes for the PC Sample-based Profiling Extension and the Performance Monitors Extension:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.{CopSDbg, CopDbg}.

For more information, see:

- Virtualization Host Extensions on page D8-5168.

**FEAT_PMUv3p1, PMU Extensions v3.1**

Armv8.1 makes the following enhancements to the Performance Monitors Extension:

- The event number space is extended to 16 bits to allow additional IMPLEMENTATION DEFINED event types, and the reserved space for future additions to the architecturally-defined event types is extended.
- The HPMD bit is added to MDCR_EL2. This bit disables event counting at EL2.
- The STALL_FRONTEND and STALL_BACKEND events are required to be implemented. For more information, see Required events on page D11-5425.

The Performance Monitors Extension is an optional feature, but if it is implemented, an Armv8.1 implementation must include FEAT_PMUv3p1. The following fields identify the presence of FEAT_PMUv3p1:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.

**A2.4.2 Additional requirements of Armv8.1**

The Armv8.1 architecture includes some mandatory changes that are not associated with a feature. These are:

**FEAT_CRC32, Changes to CRC32 instructions**

All implementations of the Armv8.1 architecture are required to implement the CRC32* instructions. These are OPTIONAL in Armv8.0. The following fields identify the presence of the CRC32* instructions:

- ID_AA64ISAR0_EL1.CRC32.
- ID_ISAR5_EL1.CRC32.
- ID_ISAR5.CRC32.

An implementation of the Armv8.1 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.1, is also called an implementation of the Armv8.1 architecture.
A2.4.3 Features added to the Armv8.1 extension in later releases

FEAT_PAN3, Support for SCTLR_ELx.EPAN

FEAT_PAN3 adds a bit to SCTLR_EL1 and SCTLR_EL2, EPAN, to support using Privileged Access Never with instruction accesses for stage 1 translation regimes. This feature is supported in AArch64 state only. This feature is OPTIONAL in Armv8.1 implementations and mandatory in Armv8.7 implementations. The ID_AA64MMFR1_EL1.PAN field identifies the presence of FEAT_PAN3. For more information, see PSTATE.PAN on page D8-5132.

A2.4.4 Features made OPTIONAL in Armv8.1 implementations

The feature that has been made OPTIONAL in Armv8.1 implementations is FEAT_PAN2 on page A2-86.
A2.5 The Armv8.2 architecture extension

The Armv8.2 architecture extension adds both architectural features and architectural requirements, see:

- Architectural features added by Armv8.2.
- Additional requirements of Armv8.2 on page A2-93.
- Features added to the Armv8.2 extension in later releases on page A2-93.
- Features made optional in Armv8.2 implementations on page A2-95.

The Armv8.2 architecture extension also adds functionality to the Cryptographic Extension, see Armv8.2 extensions to the Cryptographic Extension on page A2-80.

A2.5.1 Architectural features added by Armv8.2

An implementation of the Armv8.2 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.2, is also called an implementation of the Armv8.2 architecture.

The Armv8.2 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**FEAT_ASMv8p2, Armv8.2 changes to the A64 ISA**

FEAT_ASMv8p2 adds the BFC instruction to the A64 instruction set as an alias of BFM. It also requires that the BFC instruction and the A64 pseudo-instruction REV64 are implemented by assemblers.

--- Note ---

- In Armv8.0 and Armv8.1, the A64 pseudo-instruction REV64 is OPTIONAL.
- Because this feature relates to support for an instruction alias and for a pseudo-instruction, there are no corresponding feature ID register fields.

This change to the instruction set and assembler requirements is mandatory in an Armv8.2 implementation.

For more information, see:

- **BFC** on page C6-1217.
- **REV64** on page C6-1762.

**FEAT_PAN2, AT S1E1R and AT S1E1W instruction variants affected by PSTATE.PAN**

FEAT_PAN2 adds variants of the AArch64 AT S1E1R and AT S1E1W instructions and the AArch32 ATS1CPWP instructions. These instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a Permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions

- **AT S1E1RP, Address Translate Stage 1 EL1 Read PAN** on page C5-856.
- **AT S1E1WP, Address Translate Stage 1 EL1 Write PAN** on page C5-860.

For the AArch32 System instructions

- **ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN** on page G8-9360.
- **ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN** on page G8-9362.

This feature is OPTIONAL in Armv8.1 implementations and mandatory in Armv8.2 implementations. These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of FEAT_PAN2:

- **ID_AA64MMFR1_EL1.PAN**.
- **ID_MMFR3_EL1.PAN**.
- **ID_MMFR3.PAN**.
Feat_fp16, Half-precision floating-point data processing

Feat_fp16 supports:
- Half-precision data-processing instructions for Advanced SIMD and floating-point in both AArch64 and AArch32 states.
- The FPSCR.FZ16 and FPSCR.FZ16 bits, which enables flushing of denormalized numbers to zero for half-precision data-processing instructions.

This feature is optional in Armv8.2 implementations, unless one of the following is implemented:
- The Scalable Vector Extension (SVE).
- Feat_fhm.

If SVE or Feat_fhm is implemented, Feat_fp16 is implemented. From Armv8.4, if Feat_fhm is not implemented, Feat_fp16 is not implemented.

When this feature is implemented it is implemented in both Advanced SIMD and floating-point, and in AArch64 and AArch32 states.

The following fields identify the presence of Feat_fp16:
- ID_AA64PFR0_EL1.{FP, AdvSIMD}.
- MVFR1_EL1.{FHPH, SIMDHP}.
- MVFR1.{FHPH, SIMDHP}.

For more information, see:
- Flushing denormalized numbers to zero on page A1-58.
- Modified immediate constants in A64 instructions on page C2-244.

Feat_dotprod, Advanced SIMD dot product instructions

Feat_DOTProd provides instructions to perform the dot product of two 32-bit vectors, accumulating the result in a third 32-bit vector. This can be performed using signed or unsigned arithmetic.

This feature is optional in Armv8.2 implementations and mandatory in Armv8.4 implementations. These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of Feat_DOTProd:
- ID_AA64ISAR0_EL1.DP.
- ID_ISAR6_EL1.DP.
- ID_ISAR6.DP.

For more information, see:
- SIMD integer dot product on page C3-331.
- Advanced SIMD dot product instructions on page F2-7287.

Feat_fhm, Floating-point half-precision multiplication instructions

Feat_fhm adds floating-point multiplication instructions.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is optional in Armv8.2 implementations, and can be implemented only when Feat_fp16 is implemented. This feature is mandatory in Armv8.4 implementations when Feat_fp16 is implemented. This feature is not implemented in Armv8.4 implementations when Feat_fp16 is not implemented.

The following fields identify the presence of Feat_fhm:
- ID_AA64ISAR0_EL1.FHM.
- ID_ISAR6_EL1.FHM.
• ID_ISAR6.FHM.
For more information, see:
• SIMD arithmetic on page C3-318.
• SIMD by element arithmetic on page C3-325.
• Advanced SIMD multiply instructions on page F2-7286.

FEAT_LSMAOC, AArch32 Load/Store Multiple instruction atomicity and ordering controls
FEAT_LSMAOC adds controls that disable legacy behavior of AArch32 load multiple and store multiple instructions, and provide a trap of one aspect of this legacy behavior.
Implementation of FEAT_LSMAOC is OPTIONAL. When implemented it provides:
• LSMAOE fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can have the following effects on the behavior of AArch32 load multiple and store multiple instructions:
  — An interrupt can be taken between two memory accesses made by a single load multiple or store multiple instruction.
  — The memory accesses made by a single load multiple or store multiple instruction to Device memory with the non-Reordering attribute can be reordered.
• nTLSMD fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can cause an access to Device-nGRE, Device-nGnRE, or Device-nGnRnE memory by an AArch32 load multiple and store multiple instruction to generate an Alignment fault.

Note
Armv8.2 deprecates software dependence on the legacy behavior of AArch32 load multiple and store multiple instructions, and these fields disable this behavior.

The following fields identify the presence of FEAT_LSMAOC:
• ID_AA64MMFR2_EL1.LSM.
• ID_MMFR4_EL1.LSM.
• ID_MMFR4.LSM.
For more information, see the register field descriptions and:
• Generation of Alignment faults by load/store multiple accesses to Device memory on page E2-7194.
• Multi-register loads and stores that access Device memory on page E2-7206.
• Taking an interrupt or other exception during a multiple-register load or store on page G1-8963.

FEAT_UAO, Unprivileged Access Override control
Armv8.2 adds a bit to PSTATE. When the value of PSTATE.UAO is 1, and when executed at EL1 or at EL2 with HCR_EL2.{E2H, TGE} == {1, 1}, the memory accesses made by the load/store unprivileged instructions behave as if they were made by the load/store register instructions. See Load/store unprivileged on page C3-260 and Load/store register on page C3-256.
This feature is mandatory in Armv8.2 implementations.
This feature is supported in AArch64 state only.
The ID_AA64MMFR2_EL1.UAO field identifies the presence of FEAT_UAO.
For more information, see PSTATE_UAO on page D8-5133.

FEAT_DPB, DC CVAP instruction
FEAT_DPB introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the DC CVAP instruction.
This feature is mandatory in Armv8.2 implementations.
This feature is supported in AArch64 state only.
The ID_AA64ISAR1_EL1.DPB field identifies the presence of FEAT_DPB.
For more information about FEAT_DPB, see Memory hierarchy on page B2-184.

**FEAT_VPIPT, VMID-aware PIPT instruction cache**

FEAT_VPIPT supports a instruction cache type, described as the VMID-aware PIPT (VPIPT) instruction cache.

--- Note ---

Armv8.2 adds VPIPT to the set of supported cache types, meaning an Armv8.2 implementation is permitted to implement VPIPT caches, but is not required to do so.

---

This feature is supported in both AArch64 and AArch32 states.

The CTR_EL0.L1Ip and CTR.L1Ip fields identify the presence of FEAT_VPIPT.

For more information, see:
- VMID-aware PIPT instruction caches on page D8-5216.
- VPIPT (VMID-aware PIPT) instruction caches on page G5-9236.

**FEAT_AA32HPD, AArch32 hierarchical permission disables**

FEAT_HPDS introduced the ability to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the VMSA8v8-64 translation regimes. FEAT_AA32HPD extends this functionality to the VMSA8v8-32 translation regimes when those regimes are using the Long descriptor Translation Table format.

This feature is OPTIONAL in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

The ID_MMFR4_EL1.HPDS and ID_MMFR4.HPDS fields identify the presence of FEAT_AA32HPD.

For more information, see Attribute fields in VMSA8-32 Long-descriptor translation table format descriptors on page G5-9176.

**FEAT_HPDS2, Translation table page-based hardware attributes**

Armv8.2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of Translation Table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

This functionality is available for all translation regimes in AArch64 state and for stages of translation in AArch32 state that use the Long descriptor Translation Table format.

FEAT_HPDS2 is OPTIONAL in Armv8.2 implementations, but implementation of FEAT_HPDS2 requires implementation of both:
- FEAT_HPDS.
- FEAT_AA32HPD, if any Exception level higher than EL0 can use AArch32.

--- Note ---

For stage 1 translations, page-based hardware attributes can be used only for a stage of translation for which the Hierarchical permission disables field has a value of 1.

---

The following fields identify the presence of FEAT_HPDS2:
- ID_AA64MMFR1_EL1.HPDS.
- ID_MMFR4_EL1.HPDS.
- ID_MMFR4.HPDS.

For more information, see:
- Page Based Hardware attributes on page D8-5159.
- Attribute fields in VMSA8-32 Long-descriptor translation table format descriptors on page G5-9176.
FEAT_LPA, Large PA and IPA support

FEAT_LPA:

- Allows a larger intermediate physical address (IPA) and PA space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

This is an OPTIONAL feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

This feature is supported in AArch64 state only.

The ID_AA64MMFR0_EL1.PARange field identifies the presence of FEAT_LPA.

For more information about FEAT_LPA, see:
- Implemented physical address size on page D8-5088.
- Output address size configuration on page D8-5088.
- Intermediate physical address size configuration on page D8-5091.
- Translation using the 64KB granule on page D8-5112.
- Table descriptor format on page D8-5123.
- Block descriptor and Page descriptor formats on page D8-5126.

FEAT_LVA, Large VA support

FEAT_LVA supports a larger VA space for each translation table base register of up to 52 bits when using the 64KB translation granule.

This feature is supported in AArch64 state only.

This is an OPTIONAL feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

If FEAT_LVA is implemented, then any implemented trace macrocell must be at least ETMv4.2 for Armv8-A, and FEAT_ETE for Armv9-A.

The ID_AA64MMFR2_EL1.VARange field identifies the presence of FEAT_LVA.

For more information about FEAT_LVA, see:
- Supported virtual address ranges on page D8-5089.
- Input address size configuration on page D8-5090.
- Translation using the 64KB granule on page D8-5112.
- Table descriptor format on page D8-5123.
- Block descriptor and Page descriptor formats on page D8-5126.

FEAT_TTCNP, Translation table Common not private translations

FEAT_TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This feature is mandatory in Armv8.2 implementations.

This facility is available for all VMSAv8-64 translation regimes and for VMSAv8-32 translation stages that use the Long descriptor Translation Table format.

The following fields identify the presence of FEAT_TTCNP:

- ID_AA64MMFR2_EL1.CnP.
- ID_MIMFR4_EL1.CnP.
- ID_MIMFR4.CnP.

For more information, see:
- Common not private translations on page D8-5196.
- Common not private translations in VMSAv8-32 on page G5-9225.
FEAT_XNX, Translation table stage 2 Unprivileged Execute-never

FEAT_XNX extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This feature is mandatory in Armv8.2 implementations that implement EL2.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

The following fields identify the presence of FEAT_XNX:

- ID_AA64MMFR1_EL1.XNX.
- ID_MMFR4_EL1.XNX.
- ID_MMFR4.XNX.

For more information, see:

- Instruction execution permissions on page D8-5138.
- Access permissions for instruction execution on page G5-9196.

FEAT_Debugv8p2, Debug v8.2

FEAT_Debugv8p2 covers a selection of mandatory changes, including:

- If the Core power domain is powered up and DoubleLockStatus() == TRUE, EDPRSR.{DLK,SPD,PU} is only permitted to read {UNKNOWN, 0, 0}.
- The definition of Exception Catch debug events is extended to include reset entry.
- All CONSTRAINED UNPREDICTABLE cases that generate Exception Catch debug events are removed.
- Controls are added to EDECCR to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to OSLAR_EL1 is removed.
- ExternalSecureNoninvasiveDebugEnabled() cannot override software controls of counting attributable events in Secure state.

If FEAT_Debugv8p2 is implemented, FEAT_DoubleLock is OPTIONAL.

The fields that identify the presence of FEAT_Debugv8p2 are:

- ID_AA64DFR0_EL1.DebugVer and DBGDIDR.Version.
- ID_DFR0_EL1.{CopSDbg, CopDbg} and ID_DFR0.{CopSDbg, CopDbg}.
- EDDEVARCH.ARCHID.

For more information, see:

- Exception Catch debug event on page H3-10287.
- EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-10342.
- Interaction with EL3 on page D11-5245.
- External access disabled on page H8-10364.

FEAT_PCSRv8p2, PC Sample-based profiling

In Armv8.2, the control and implementation of the OPTIONAL PC Sample-based Profiling extension is moved from ED*SR Debug registers to PM*SR registers in the Performance Monitors address space. See Chapter H7 The PC Sample-based Profiling Extension.

The PC Sample-based Profiling Extension is an OPTIONAL feature. If it is implemented, an Arm8.2 implementation must also include FEAT_PCSRv8p2.

If Secure EL2 and PC Sample-based Profiling are both implemented, FEAT_PCSRv8p2 is mandatory.

The following fields identify the presence of FEAT_PCSRv8p2:

- EDDEVID.PCSample.
- DBGDEVID.PCSample.
- EDDEVID1.PCSROffset.
- DBGDEVID1.PCSROffset.
FEAT_IESB, Implicit Error Synchronization event

FEAT_IESB adds an implicit error synchronization event at exception entry and return, controlled by the added SCTLR_ELx.IESB fields. An IESB field is added to the ESR_ELx syndrome registers. The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the ESB instruction, see The Reliability, Availability, and Serviceability Extension on page A2-122.

This feature is OPTIONAL in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR2_EL1.IESB field identifies the presence of FEAT_IESB.

For more information, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

FEAT_F32MM, Single-precision Matrix Multiplication

FEAT_F32MM adds support for the SVE FP32 single-precision floating-point matrix multiplication variant of the FMMLA instruction.

This feature is OPTIONAL in Armv8.2 implementations.

This feature is supported in AArch64 state only.

FEAT_F32MM requires FEAT_SVE.

The ID_AA64ZFR0_EL1.F32MM field identifies the presence of FEAT_F32MM.

FEAT_F64MM, Single-precision Matrix Multiplication

FEAT_F64MM adds support for the following SVE instructions:

- FMMLA (FP64 double-precision variant).
- LD1ROB (scalar plus immediate).
- LD1ROB (scalar plus scalar).
- LD1ROD (scalar plus immediate).
- LD1ROD (scalar plus scalar).
- LD1ROH (scalar plus immediate).
- LD1ROH (scalar plus scalar).
- LD1ROW (scalar plus immediate).
- LD1ROW (scalar plus scalar).
- TRN1, TRN2 (vectors) (128-bit variant).
- UZP1, UZP2 (vectors) (128-bit variant).
- ZIP1, ZIP2 (vectors) (128-bit variant).

This feature is OPTIONAL in Armv8.2 implementations.

This feature is supported in AArch64 state only.

FEAT_F64MM requires FEAT_SVE.

The ID_AA64ZFR0_EL1.F64MM field identifies the presence of FEAT_F64MM.

Extensions to the Arm Cryptographic Extensions

See the description of the FEAT_SHA512 and FEAT_SM3 features in Armv8.2 extensions to the Cryptographic Extension on page A2-80.
A2.5.2 Additional requirements of Armv8.2

The Armv8.2 architecture includes some mandatory changes that are not associated with a feature. These are:

**Change to ACTLR2 and HCTLR2 registers**

In AArch32 state, the ACTLR2 and HACTLR2 registers become mandatory.

**Implementation of RAS Extension**

The RAS Extension must be implemented, see *The Reliability, Availability, and Serviceability Extension* on page A2-122.

An implementation of the Armv8.2 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.2, is also called an implementation of the Armv8.2 architecture.

If FEAT_PMUv3 is implemented, the feature FEAT_PMUv3p4 is optional in Armv8.2 implementations.

A2.5.3 Features added to the Armv8.2 extension in later releases

**FEAT_EVT, Enhanced Virtualization Traps**

FEAT_EVT introduces additional traps for EL1 and EL0 Cache controls. These traps are independent of existing controls.

This feature is supported in both AArch64 and AArch32 states.

This feature is optional in Armv8.2 implementations and is mandatory in Armv8.5.

ID_AA64MMFR2_EL1.EVT identifies the presence of the AArch64 traps controls.

ID_MMFR4_EL1.EVT and ID_MMFR4.EVT identify the presence of the AArch32 traps.

For more information, see:

• HCR_EL2.{TTLBIS, TTLBOS, TICAB, TOCU, TID4}.
• HCR2.{TTLBIS, TICAB, TOCU, TID4}.

**FEAT_DPB2, DC CVADP instruction**

FEAT_DPB2 allows two levels of cache clean to the Point of Persistence by:

• Redefining Point of Persistence, which changes the scope of DC CVAP.
• Defining a Point of Deep Persistence.
• Adding the DC CVADP System instruction.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.2 implementations and is mandatory in Armv8.5 implementations.

The ID_AA64ISAR1_EL1.DPB field identifies the presence of FEAT_DPB2.

For further information, see *Terminology for Clean, Invalidate, and Clean and Invalidate instructions* on page D7-5051.

**FEAT_BF16, AArch64 BFloat16 instructions**

FEAT_BF16 supports the BFloat16, or BF16, 16-bit floating-point storage format in AArch64 state. This format supports:

• The BFloat16 floating-point data type.
• Arithmetic instructions to accelerate dot products and matrix multiplications of BF16 values.
• Instructions to convert single-precision floating-point values to BF16 format.
• Arithmetic instructions to multiply BFloat16 values and accumulate into single-precision results.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.2 implementations and mandatory in Armv8.6 implementations.

The ID_AA64ISAR1_EL1.BF16 field identifies the presence of FEAT_BF16.
When both Advanced SIMD and SVE are implemented, the ID_AA64ISAR1_EL1.BF16 and ID_AA64ZFR0_EL1.BF16 fields must return the same value.

For further information, see:
- Floating-point single-precision to BFloat16 conversion instruction on page C3-313.
- SIMD BFloat16 on page C3-332.
- SVE BFloat16 floating-point multiply-add on page C3-353.
- SVE BFloat16 floating-point dot product on page C3-353.
- SVE BFloat16 floating-point matrix multiply on page C3-354.
- SVE BFloat16 floating-point convert on page C3-355.

FEAT_AA32BF16, AArch32 BFloat16 instructions
FEAT_AA32BF16 supports the BFloat16, or BF16, 16-bit floating-point storage format in AArch32 state. This format supports:
- The BFloat16 floating-point data type.
- Arithmetic instructions to accelerate dot products and matrix multiplications of BF16 values.
- Instructions to convert single-precision floating-point values to BF16 format.

This feature is supported in AArch32 state only.

This feature is OPTIONAL in Armv8.2 implementations.

The ID_ISAR6_EL1.BF16 and ID_ISAR6.BF16 fields identify the presence of FEAT_AA32BF16.

For further information, see:
- Advanced SIMD BFloat16 instructions on page F2-7288.
- Floating-point data-processing on page F3-7329.

FEAT_I8MM, AArch64 Int8 matrix multiplication instructions
FEAT_I8MM introduces integer matrix multiply-accumulate instructions and mixed sign dot product instructions.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.6 implementations.

The ID_AA64ISAR1_EL1.I8MM field identifies the presence of FEAT_I8MM.

When both Advanced SIMD and SVE are implemented, the ID_AA64ISAR1_EL1.I8MM and the ID_AA64ZFR0_EL1.I8MM fields must return the same value.

For further information, see:
- SIMD integer dot product on page C3-331.
- SIMD integer matrix multiply-accumulate on page C3-334.
- SVE Integer dot product on page C3-342.
- SVE Integer matrix multiply operations on page C3-342.

FEAT_AA32I8MM, AArch32 Int8 matrix multiplication instructions
FEAT_AA32I8MM introduces integer matrix multiply-accumulate instructions and mixed sign dot product instructions.

This feature is supported in AArch32 state only.

This feature is OPTIONAL in Armv8.2 implementations.

The ID_ISAR6_EL1.I8MM and ID_ISAR6.I8MM fields identify the presence of FEAT_AA32I8MM.

For further information, see:
- Advanced SIMD dot product instructions on page F2-7287.
- Advanced SIMD matrix multiply instructions on page F2-7288.
A2.5.4 Features made OPTIONAL in Armv8.2 implementations

The features that have been made OPTIONAL in Armv8.2 implementations are:

- \textit{FEAT\_FlagM} on page A2-101.
- \textit{FEAT\_LSE2} on page A2-101.
- \textit{FEAT\_LRCPC2} on page A2-101.
A2.6 The Armv8.3 architecture extension

The Armv8.3 architecture extension adds both architectural features and additional requirements, see:

- Architectural features added by Armv8.3.
- Additional requirements of Armv8.3 on page A2-98.
- Features added to the Armv8.3 extension in later releases on page A2-98.

A2.6.1 Architectural features added by Armv8.3

An implementation of the Armv8.3 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.3 architecture.

The Armv8.3 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_FCMA, Floating-point complex number instructions

FEAT_FCMA introduces instructions for floating-point multiplication and addition of complex numbers.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in Armv8.3 implementations.

The half-precision versions of these instructions are implemented only if FEAT_FP16 is implemented. Otherwise they are UNDEFINED.

The fields that identify the presence of FEAT_FCMA are:

- ID_AA64ISAR1_EL1.FCMA.
- ID_ISAR5_EL1.VCMA.
- ID_ISAR5.VCMA.

For more information, see:

- SIMD complex number arithmetic on page C3-332.
- Advanced SIMD complex number arithmetic instructions on page F2-7287.

FEAT_JSCVT, JavaScript conversion instructions

FEAT_JSCVT introduces instructions that perform a conversion from a double-precision floating point value to a signed 32-bit integer, with rounding to zero. For more information, see:

For the A64 instruction set

- FJCVTZS on page C7-2269.

For the A32/T32 instruction set

- VJCVT on page F6-8419.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in Armv8.3 implementations.

The fields that identify the presence of FEAT_JSCVT are:

- ID_AA64ISAR1_EL1.JSCVT.
- ID_ISAR6_EL1.JSCVT.
- ID_ISAR6.JSCVT.

For more information, see:

- Floating-point conversion on page C3-313.
- About the A64 Advanced SIMD and floating-point instructions on page C7-2040.
- Advanced SIMD and floating-point instructions on page E1-7140.
- Floating-point data-processing instructions on page F2-7292.
FEAT_LRCPC, Load-Acquire RCpc instructions

FEAT_LRCPC introduces three instructions to support the weaker *Release Consistency processor consistent* (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address:

- `LDAPR` on page C6-1520.
- `LDAPRB` on page C6-1522.
- `LDAPRH` on page C6-1524.

These instructions are added to the A64 instruction set.

The feature is mandatory in Armv8.3 implementations.

The ID_AA64ISAR1_EL1.LRCPC field identifies the presence of FEAT_LRCPC.

For more information, see:

FEAT_NV, Nested virtualization support

FEAT_NV provides support for a Guest Hypervisor to run in Non-secure EL1 and ensures that the Guest Hypervisor is unaware that it is running at that Exception level. A Guest Hypervisor is supported regardless of the value of HCR_EL2.E2H.

This feature is supported in AArch64 state only.

The feature is *optional* in Armv8.3 implementations. This feature must be implemented if FEAT_NV2 is implemented.

The ID_AA64MMFR2_EL1.NV field identifies the presence of FEAT_NV.

For more information, see *Nested virtualization* on page D8-5173.

FEAT_CCIDX, Extended cache index

FEAT_CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of CCSIDR_EL1.
- CCSIDR2_EL1.
- CCSIDR2.

This feature is supported in both AArch64 and AArch32 states.

This feature is *optional* in Armv8.3 implementations.

The following fields identify the presence of FEAT_CCIDX:

- ID_AA64MMFR2_EL1.CCIDX.
- ID_MMFR4_EL1.CCIDX.
- ID_MMFR4.CCIDX.

For more information, see:
- *Possible formats of the Cache Size Identification Register, CCSIDR_EL1* on page D7-5045.
- *Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2* on page G4-9115.

FEAT_PAuth and FEAT_EPAC, Pointer authentication and Enhanced Pointer authentication

FEAT_PAuth adds functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

FEAT_EPAC adds functionality that permits setting the *Pointer Authentication Code* (PAC) field to 0 on performing a PAC operation on a non-canonical address.

These features are supported in AArch64 state only.

FEAT_PAuth is mandatory in Armv8.3 implementations.

FEAT_EPAC is *optional* in Armv8.3 implementations.
When FEAT_PAuth is implemented, one of the following must be true:

- Exactly one of the PAC algorithms is implemented.
- If the PACGA instruction and other Pointer authentication instructions use different PAC algorithms, exactly two PAC algorithms are implemented.

The PAC algorithm features are:

- FEAT_PACQARMA5.
- FEAT_PACIMP.
- FEAT_PACQARMA3.

The following fields identify the presence of FEAT_PAuth:

- ID_AA64ISAR1_EL1.{GPI, GPA, API, APA}.
- ID_AA64ISAR2_EL1.{GPA3, APA3}.

The following fields identify the presence of FEAT_EPAC:

- ID_AA64ISAR1_EL1.{API, APA}.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication on page D8-5164.

**FEAT_PACQARMA5, Pointer authentication - QARMA5 algorithm**

FEAT_PACQARMA5 adds the QARMA5 cryptographic algorithm for PAC calculation.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.3 implementations, and can be implemented only if FEAT_PAuth is implemented.

The ID_AA64ISAR1_EL1.{GPA, APA} fields identify the support for FEAT_PACQARMA5.

For more information, see Pointer authentication on page D8-5164.

**FEAT_PACIMP, Pointer authentication - IMPLEMENTATION DEFINED algorithm**

FEAT_PACIMP permits an IMPLEMENTATION DEFINED cryptographic algorithm to be used for PAC calculation.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.3 implementations, and can be implemented only if FEAT_PAuth is implemented.

The ID_AA64ISAR1_EL1.{GPI, API} fields identify the support for FEAT_PACIMP.

For more information, see Pointer authentication on page D8-5164.

### A2.6.2 Additional requirements of Armv8.3

If FEAT_PMUv3 is implemented, FEAT_PMUv3p4 is optional in Armv8.3 implementations.

### A2.6.3 Features added to the Armv8.3 extension in later releases

**FEAT_SPEv1p1, Armv8.3 Statistical Profiling Extensions**

FEAT_SPEv1p1 adds an Alignment Flag in the Events packet and filtering on this event using PMSEVFR_EL1, together with support for the profiling of Scalable Vector Extension operations.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.3 implementations. An Armv8.5 implementation that includes the Statistical Profiling Extension must include FEAT_SPEv1p1.

The fields in ID_AA64DFR0_EL1.PMSVer identify the presence of FEAT_SPEv1p1.

For more information, see Chapter D13 The Statistical Profiling Extension and Chapter D14 Statistical Profiling Extension Sample Record Specification.
FEAT_DoPD, Debug over Powerdown

FEAT_DoPD provides a debug programmers’ model where all debug and PMU registers are in the Core power domain, all CTI registers are in the Debug power domain. Power control is provided by a CoreSight Granular Power Requester (GPR) component.

When the OPTIONAL powerup mechanism is implemented and this feature is implemented, the debugger makes power control requests for the Core power domain using a CoreSight Class 0x9 ROM Table block, instead of using EDRCR.COREPURQ. EDRCR.COREPURQ is not implemented. Refer to the ARM® CoreSight Architecture Specification for more information.

This feature is OPTIONAL in Armv8.3 implementations.

When FEAT_DoPD is implemented:

- FEAT_DoubleLock is not implemented.
- FEAT_Debugv8p2 must be implemented.
- If PC Sample-based profiling is implemented, FEAT_PCSRv8p2 must be implemented.
- The optional Software Lock is not implemented by the architecturally defined debug components in the PE Core power domain.
- If an ETMv4 trace unit is implemented, the ETM must implement:
  - ETMv4.2 or later.
  - The Unified Power Domain Model.
- If FEAT_ETE is implemented, the trace unit always implements a single power domain.

The fields that identify the presence of FEAT_DoPD are:

- EDDEVID.DebugPower.
- CTIDEVARCH.REVISION.

For more information, see Chapter H6 Debug Reset and Powerdown Support.

FEAT_PAuth2, Enhancements to pointer authentication

FEAT_PAuth2 adds enhanced pointer authentication functionality that changes the mechanism by which a PAC is added to the pointer.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations and mandatory in Armv8.6 implementations.

The fields that identify the support for FEAT_PAuth2 are:

- ID_AA64ISAR1_EL1.{API, APA}.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication on page D8-5164.

FEAT_FPAC and FEAT_FPACCOMBINE, Faulting on AUT* instructions and combined pointer authentication instructions

FEAT_FPAC introduces faulting on an AUT* instruction.

FEAT_FPACCOMBINE introduces faulting on the combined instructions that perform pointer authentication.

FEAT_FPAC is added as a further extension to FEAT_PAuth2.

FEAT_FPACCOMBINE is added as a further extension to FEAT_FPAC.

These features are supported in AArch64 state only.

FEAT_FPAC is OPTIONAL in Armv8.3 implementations, and can be implemented only if FEAT_PAuth2 is implemented.

FEAT_FPACCOMBINE is OPTIONAL in Armv8.3 implementations, and can be implemented only if FEAT_FPAC is implemented.

The fields that identify the support for FEAT_FPAC and FEAT_FPACCOMBINE are:

- ID_AA64ISAR1_EL1.{API, APA}.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Faulting on pointer authentication on page D8-5167.
FEAT_PACQARMA3, Pointer authentication - QARMA3 algorithm

FEAT_PACQARMA3 adds the QARMA3 cryptographic algorithm for PAC calculation.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations, and can be implemented only if FEAT_PAuth is implemented.

The ID_AA64ISAR2_EL1.{GPA3, APA3} fields identify the support for FEAT_PACQARMA3.

For more information, see Pointer authentication on page D8-5164.

FEAT_CONSTPACFIELD, PAC algorithm enhancement

FEAT_CONSTPACFIELD introduces functionality that permits an implementation with pointer authentication to use the value of bit[55] in the virtual address to determine the size of the PAC field, even when the top byte is not being ignored.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in Armv8.3 implementations, and can be implemented only if FEAT_PAuth2 is implemented.

The ID_AA64ISAR2_EL1.PAC_frac field identifies the support for FEAT_CONSTPACFIELD.

For more information, see PAC field on page D8-5164.
A2.7 The Armv8.4 architecture extension

The Armv8.4 architecture extension adds architectural features, see Architectural features added by Armv8.4. It also adds features to earlier architecture extensions, see Features added to earlier extensions on page A2-106.

A2.7.1 Architectural features added by Armv8.4

An implementation of the Armv8.4 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.4 architecture.

The Armv8.4 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_DIT, Data Independent Timing instructions
FEAT_DIT provides independent timing for data processing instructions with the addition of the PSTATE.DIT and CPSR.DIT fields.
This feature is supported in both AArch64 and AArch32 states.
This feature is mandatory in Armv8.4 implementations.
The following fields identify the presence of FEAT_DIT:
• ID_AA64PFR0_EL1.DIT.
• ID_PFR0_EL1.DIT.
• ID_PFR0.DIT.
For more information, see:
• About PSTATE.DIT on page B1-147.
• About the DIT bit on page E1-7139.

FEAT_FlagM, Flag manipulation instructions v2
FEAT_FlagM provides instructions which manipulate the PSTATE.{N,Z,C,V} flags.
These instructions are added to the A64 instruction set only.
This feature is OPTIONAL in Armv8.2 implementations.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64ISAR0_EL1.TS field identifies the presence of FEAT_FlagM.
For more information, see Flag manipulation instructions on page C3-305.

FEAT_LRCPC2, Load-Acquire RCpc instructions v2
FEAT_LRCPC2 provides versions of LDAPR and STLlR with a 9-bit unscaled signed immediate offset.
These instructions are added to the A64 instruction set only.
This feature is OPTIONAL in Armv8.2 implementations.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64ISAR1_EL1.LRCPC field identifies the presence of FEAT_LRCPC2.
For more information, see:
• Changes to single-copy atomicity in Armv8.4 on page B2-155.
• Non-exclusive Load-Acquire and Store-Release instructions on page C3-262.
• A64 instructions that are changed in Debug state on page H2-10243.

FEAT_LSE2, Large System Extensions v2
FEAT_LSE2 introduces changes to single-copy atomicity requirements for loads and stores, and changes to alignment requirements for loads and stores.
This feature is supported in AArch64 state only.
This feature is OPTIONAL in Armv8.2 implementations.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.AT field identifies the presence of FEAT_LSE2.
For more information, see:
  • Requirements for single-copy atomicity on page B2-154.
  • Alignment of data accesses on page B2-189.

FEAT_TLBIOs, TLB invalidate instructions in Outer Shareable domain
FEAT_TLBIOs provides TLBI maintenance instructions that extend to the Outer Shareable domain.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.4 implementations.
The field ID_AA64ISAR0_EL1.TLB identifies the presence of FEAT_TLBIOs.
For more information, see:
  • TLB maintenance instructions on page D8-5201.

FEAT_TLBIRANGE, TLB invalidate range instructions
FEAT_TLBIRANGE provides TLBI maintenance instructions that apply to a range of input addresses. FEAT_TLBIRANGE being implemented implies that FEAT_TLBIOs is implemented.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.4 implementations.
The field ID_AA64ISAR0_EL1.TLB identifies the presence of FEAT_TLBIRANGE.
For more information, see:
  • TLB maintenance instructions on page D8-5201.
  • TLB maintenance instructions that apply to a range of addresses on page D8-5203.

FEAT_TTL, Translation Table Level
FEAT_TTL provides the TTL field to indicate the level of translation table walk holding the leaf entry for the address that is being invalidated. This field is provided in all TLB maintenance instructions that take a VA or an IPA argument.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.4 implementations.
The field ID_AA64MMFR2_EL1.TTL identifies the presence of FEAT_TTL.
For more information, see:
  • TLB maintenance instructions on page D8-5201.
  • TLB maintenance instructions that apply to a range of addresses on page D8-5203.

FEAT_S2FWB, Stage 2 forced Write-Back
FEAT_S2FWB reduces the requirement of additional cache maintenance instructions in systems where the data Cacheability attributes used by the Guest operating system are different from those expected by the Hypervisor. If this feature is implemented, there is no meaningful distinction between the Inner and Outer Shareability domains for accesses to Normal Cacheable memory.
This feature is supported in AArch64 state.
This feature is mandatory in Armv8.4 implementations that implement EL2.
The ID_AA64MMFR2_EL1.FWB field identifies the presence of FEAT_S2FWB.
For more information, see:
  • Block descriptor and Page descriptor formats on page D8-5126.
  • Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled on page D8-5155.
FEAT_TTST, Small translation tables

FEAT_TTST relaxes the lower limit on the size of translation tables, by increasing the maximum permitted value of the T1SZ and T0SZ fields in TCR_EL1, TCR_EL2, TCR_EL3, VTCR_EL2 and VSTCR_EL2.

This feature is supported in AArch64 state only.

This feature is mandatory if FEAT_SEL2 is implemented.

This feature is optional if FEAT_SEL2 is not implemented.

The ID_AA64MMFR2_EL1.ST field identifies the presence of FEAT_TTST.

For more information, see:

• Input address size configuration on page D8-5090.
• Translation using the 4KB granule on page D8-5100.
• Translation using the 16KB granule on page D8-5106.
• Translation using the 64KB granule on page D8-5112.

FEAT_BBM, Translation table break-before-make levels

FEAT_BBM provides support to identify the requirements of hardware to have break-before-make sequences when changing between block size for a translation.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.BBM field identifies the presence of FEAT_BBM.

For more information, see:

• Block descriptor and Page descriptor formats on page D8-5126.
• Block translation entry on page D8-5160.
• Support levels for changing block size on page D8-5199.

FEAT_SEL2, Secure EL2

FEAT_SEL2 permits EL2 to be implemented in Secure state. When Secure EL2 is enabled, a translation regime is introduced that follows the same format as the other Secure translation regimes.

This feature is not supported if EL2 is using AArch32.

This feature is mandatory in Armv8.4 implementations that implement both EL2 and Secure state.

The ID_AA64PFR0_EL1.SEL2 field identifies the presence of FEAT_SEL2.

For more information, see:

• Translation regimes on page D8-5082.

FEAT_NV2, Enhanced nested virtualization support

FEAT_NV2 supports nested virtualization by redirecting register accesses that would be trapped to EL1 and EL2 to access memory instead. The address of the memory access depends on information held in introduced register, VNCR_EL2.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.NV field identifies the presence of FEAT_NV2.

For more information, see Enhanced support for nested virtualization on page D8-5175.

FEAT_IDST, ID space trap handling

FEAT_IDST causes all AArch64 read accesses to the feature ID space when exceptions are generated to be reported in ESR_ELx using the EC code 0x18.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.IDS field identifies the presence of FEAT_IDST.

**FEAT_CNTSC, Generic Counter Scaling**

FEAT_CNTSC adds a scaling register to the memory-mapped counter module that allows the frequency of the counter that is generated to be scaled from the basic frequency reported in the counter ID mechanisms.

This feature is supported in both AArch64 and AArch32 states.

This feature is **OPTIONAL** in Armv8.4 implementations.

The CNTID.CNTSC field identifies the presence of FEAT_CNTSC.

For more information, see:

- *CNTCR, Counter Control Register* on page 15-10878.

**FEAT_Debugv8p4, Debug v8.4**

FEAT_Debugv8p4 covers a selection of mandatory changes:

- The fields MDCR_EL3.{EPMAD, EDAD} control Non-secure access to the debug and PMU registers. The bus Requester is responsible for other debug authentication.
- The Software Lock is obsolete.
- Non-invasive Debug controls are relaxed.
- Secure and Non-secure views of the debug registers are enabled.

This feature is mandatory if FEAT_SEL2 is implemented.

The fields that identify the presence of FEAT_Debugv8p4 are:

- ID_AA64DFR0_EL1.DebugVer.
- DBGDIDR.Version.
- ID_DFR0_EL1.{CopSDbg, CopDbg}.
- ID_DFR0.{CopSDbg, CopDbg}.
- EDDEV ARCH.ARCHID.

For more information, see:

- *Definition and constraints of a debugger in the context of external debug* on page H1-10228
- *External debug interface register access permissions* on page H8-10364

**FEAT_TRF, Self-hosted Trace Extensions**

FEAT_TRF adds controls of trace in a self-hosted system through System registers.

The feature provides:

- Control of Exception levels and Security states where trace generation is prohibited.
- Control of whether an offset is used for the timestamp recorded with trace information.
- A barrier instruction `TSB CSYNC` which can be used to prevent reordering of trace operation accesses with respect to other accesses of the same System registers.

If Armv8.4 and an ETM Architecture trace unit is implemented, this feature is mandatory. If this feature is implemented, the trace unit must include System register access to its control registers.

The reset state of the PE has prohibited regions controlled by the feature and not the external authentication signals. An external trace controller must override the internal controls before enabling trace, including trace from reset. This is a change from previous trace architectures and is not backwards-compatible.

The fields that identify the presence of FEAT_TRF are:

- ID_AA64DFR0_EL1.TraceFilt.
- ID_DFR0_EL1.TraceFilt.
- ID_DFR0.TraceFilt.
- EDDFR.TraceVer.
- ID_AA64DFR0_EL1.TraceVer.
For more information, see:

- Chapter D3 AArch64 Self-hosted Trace.
- Chapter G3 AArch32 Self-hosted Trace.

**FEAT_PMUv3p4, PMU Extensions v3.4**

FEAT_PMUv3p4 introduces the PMMIR_EL1 and PMMIR registers.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.4 implementation must include FEAT_PMUv3p4.

The fields that identify the presence of FEAT_PMUv3p4 are:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see *PMU events and event numbers* on page D11-5266.

**FEAT_RASv1p1, RAS Extension v1.1**

FEAT_RASv1p1 implements RAS System Architecture v1.1 and adds support for:

- Simplifications to ERR<n>STATUS.
- Additional ERR<n>MISC<m> registers.
- The OPTIONAL RAS Common Fault Injection Model Extension.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.2 implementations and mandatory in Armv8.4 implementations.

The following fields identify the complete or partial presence of FEAT_RASv1p1:

- ID_AA64PFR0_EL1.RAS.
- ID_AA64PFR1_EL1.RAS_frac.
- ID_PFR0_EL1.RAS.
- ID_PFR2_EL1.RAS_frac.
- ID_PFR0.RAS.
- ID_PFR2.RAS_frac.

For more information, see:

- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

**FEAT_DoubleFault, Double Fault Extension**

FEAT_DoubleFault provides two controls:

- SCR_EL3.EASE.
- SCR_EL3.NMEA.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations if EL3 is implemented and EL3 uses AArch64. Otherwise, it is not implemented.

This feature is implemented if ID_AA64PFR0_EL1.RAS >= 0b0010 and the implementation includes EL3 using AArch64.

For more information, see:

- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.
A2.7.2 Features added to earlier extensions

The existing functionality of OS Double Lock is added as a feature mnemonic in Armv8.0, see `FEAT_DoubleLock` on page A2-78.
A2.8  The Armv8.5 architecture extension

The Armv8.5 architecture extension adds architectural features and additional requirements, see:

• Architectural features added by Armv8.5.
• Additional requirements of Armv8.5 on page A2-109.
• Features added to earlier extensions on page A2-110.
• Architectural requirements added to earlier extensions on page A2-110.
• Features added to the Armv8.5 extension in later releases on page A2-110.

A2.8.1  Architectural features added by Armv8.5

An implementation of the Armv8.5 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.5 architecture.

The Armv8.5 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**FEAT_FlagM2, Enhancements to flag manipulation instructions**

FEAT_FlagM2 provides instructions that convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format described in *Relationship between ARM format and alternative format PSTATE condition flags* on page C6-1168.

These instructions are added to the A64 instruction set only.

This feature is mandatory in Armv8.5 implementations.

The ID_AA64ISAR0_EL1.TS field identifies the presence of FEAT_FlagM2.

For more information, see:

• Flag manipulation instructions on page C3-305.
• Relationship between ARM format and alternative format PSTATE condition flags on page C6-1168.

**FEAT_FRINTTS, Floating-point to integer instructions**

FEAT_FRINTTS provides instructions that round a floating-point number to an integral valued floating-point number that fits in a 32-bit or 64-bit integer number range.

These instructions are added to the A64 instruction set only.

This feature requires SIMD&FP, and is mandatory in Armv8.5 implementations when SIMD&FP is implemented.

The ID_AA64ISAR1_EL1.FRINTTS identifies the presence of FEAT_FRINTTS.

For more information, see *Floating-point round to integral value* on page C3-314.

**FEAT_ExS, Context synchronization and exception handling**

FEAT_ExS provides a mechanism to control whether exception entry and exception return are context synchronization events. Fields in the SCTLR_ELx registers enable and disable context synchronization at exception entry and return at an Exception level.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.5 implementations.

The ID_AA64MMFR0_EL1.ExS identifies the presence of FEAT_ExS.

For more information, see:

• SCTLR_EL1, System Control Register (EL1) on page D17-6169, SCTLR_EL2 and SCTLR_EL3.
• Context synchronization event on page Glossary-11933

**FEAT_GTG, Guest translation granule size**

FEAT_GTG allows a hypervisor to support different granule sizes for stage 2 and stage 1 translation, and allows a nested hypervisor to determine what stage 2 granule sizes are available.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.5 implementations.

The ID_AA64MMFR0_EL1.{TGran16_2, TGran64_2, TGran4_2} fields identify whether each of
the granule sizes is supported for stage 2 translation. The ID_AA64MMFR0_EL1.{TGran16,
TGran64, TGran4} fields identify whether each of the granule sizes is supported for stage 1
translations.

For more information, see Translation granules on page D8-5081.

FEAT_BTI, Branch Target Identification

FEAT_BTI allows memory pages to be guarded against the execution of instructions that are not the intended target of a branch. To do this, it introduces:

• The GP field, which denotes the blocks and pages in stage 1 translation tables that are guarded pages.
• The PSTATE.BTYPE field, which is used to determine whether an access to a guarded memory region will generate a Branch Target exception.
• The BTI instruction, which is used to guard against the execution of instructions that are not the intended target of a branch.

This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.5 implementations.
The ID_AA64PFR1_EL1.BT field identifies the presence of FEAT_BTI.
For more information, see:
• Exception entry on page D1-4641.
• Synchronous exception types on page D1-4646.
• Table descriptor format on page D8-5123.
• PSTATE.BTYPE on page D8-5133.
• Effect of entering Debug state on PSTATE on page H2-10240.

FEAT_E0PD, Preventing EL0 access to halves of address maps

FEAT_E0PD prevents access at EL0 to half of the addresses in the memory map.
This feature is supported in AArch64 state only. When EL1 is using AArch64 state, this feature affects access to EL0, in either Execution state.
This feature is mandatory in Armv8.5 implementations.
Implementations that support FEAT_E0PD must also support FEAT_CSV3.
The ID_AA64MMFR2_EL1.E0PD field identifies presence of FEAT_E0PD.
For more information, see:
• Preventing EL0 access to halves of the address map on page D8-5097.
• TCR_EL1.{E0PD0, E0PD1}.
• TCR_EL2.{E0PD0, E0PD1}.

FEAT_RNG, Random number generator

FEAT_RNG introduces the RNDR and RNDRRS registers. Reads to these registers return a 64-bit random number. A read to RNDRRS will cause a reseeding of the random number before the generation of the random number that is returned.
This feature is supported in AArch64 state only.
This feature is OPTIONAL in Armv8.5 implementations.
The ID_AA64ISRAR0_EL1.RNDR field identifies presence of FEAT_RNG.
• Effect of random number generation instructions on Condition flags on page C6-1168.
• Appendix K14 Random Number Generation.
FEAT_MTE and FEAT_MTE2, Memory Tagging Extension

FEAT_MTE and FEAT_MTE2 provide architectural support for runtime, always-on detection of various classes of memory error to aid with software debugging to eliminate vulnerabilities arising from memory-unsafe languages.

These features are supported in AArch64 state only.

These features are optional in Armv8.5 implementations.

The ID_AA64FPFR1_EL1.MTE field identifies the presence of FEAT_MTE and FEAT_MTE2.

For more information, see:
• Chapter D9 The Memory Tagging Extension.
• Chapter B2 The AArch64 Application Level Memory Model.
• PMU events and event numbers on page D11-5266.
• Chapter D13 The Statistical Profiling Extension.
• Chapter H2 Debug State.

FEAT_PMUv3p5, PMU Extensions v3.5

FEAT_PMUv3p5 extends event counters to 64-bit event counters, and adds mechanisms to disable the cycle counter in Secure state and in EL2.

FEAT_PMUv3p5 relaxes the behavior of PMCR.{IMP, IDCODE}, and deprecates use of these fields.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an optional feature, but if it is implemented, an Armv8.5 implementation must include FEAT_PMUv3p5.

The fields that identify the presence of FEAT_PMUv3p5 are:
• ID_AA64DFR0_EL1.PMUVer.
• ID_DFR0_EL1.PerfMon.
• ID_DFR0.PerfMon.
• EDDFR.PMUVer.

For more information, see:
• Behavior on overflow on page D11-5250
• Controlling the PMU counters on page D11-5254.
• PMU events and event numbers on page D11-5266.

A2.8.2 Additional requirements of Armv8.5

The Armv8.5 architecture includes some mandatory changes that are not associated with a feature. These are:

Restrictions on effects of speculation

Further restrictions are placed on execution for:
• Execution prediction instructions that predict addresses or register values.
• Data loaded under speculation with a permission or domain fault.
• Any System register read under speculation to a register that is not architecturally accessible from the current Exception level.

For more information, see:
• Restrictions on the effects of speculation on page B2-171.
• Restrictions on the effects of speculation on page E2-7179.

Changes to CTIDEVAR, CTIDEVAFF0, and CTIDEVAFF1

CTIDEVAR, CTIDEVAFF0, and CTIDEVAFF1 must be implemented.

Changes to the input channel gate function
If the Cross Trigger Matrix (CTM) is implemented, the input channel gate function must be implemented.

Deprecation of EDPRCR.CWRR

EDPRCR.CWRR is deprecated.

Mandatory changes are also made to earlier architectural extensions, see Architectural requirements added to earlier extensions.

A2.8.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- FEAT_SB on page A2-76.
- FEAT_SSBS on page A2-76.
- FEAT_CSV2 on page A2-76.
- FEAT_CSV3 on page A2-77.
- FEAT_SPECRES on page A2-78.
- FEAT_CP15SDISABLE2 on page A2-78.
- FEAT_EVT on page A2-93.
- FEAT_DPB2 on page A2-93.
- FEAT_SPEv1p1 on page A2-98.

A2.8.4 Architectural requirements added to earlier extensions

The additional architectural requirement that has been added to earlier extensions is Prefetch speculation protection on page A2-79.

A2.8.5 Features added to the Armv8.5 extension in later releases

FEAT_MTE3, MTE Asymmetric Fault Handling

FEAT_MTE3 introduces support for asymmetric Tag Check Fault handling.
This feature is optional in Armv8.5 implementations.
This feature is mandatory from Armv8.7 when FEAT_MTE2 is implemented.
This feature is supported in AArch64 state.
The ID_AA64PFR1_EL1.MTE field identifies the presence of FEAT_MTE3.
For more information, see Chapter D9 The Memory Tagging Extension.

FEAT_RNG_TRAP, Trapping support for RNDR/RNDRRS

FEAT_RNG_TRAP introduces support for EL3 trapping of reads of the RNDR and RNDRRS registers.
This feature is supported in AArch64 state.
This feature is optional in Armv8.5 implementations.
The ID_AA64PFR1_EL1.RNDR_trap field identifies the presence of FEAT_RNG_TRAP.
A2.9 The Armv8.6 architecture extension

The Armv8.6 architecture extension adds architectural features and additional requirements, see:

- Architectural features added by Armv8.6.
- Additional requirements of Armv8.6 on page A2-112.

Features are also added to earlier architecture extensions, see Features added to earlier extensions on page A2-112.

A2.9.1 Architectural features added by Armv8.6

An implementation of the Armv8.6 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.6 architecture.

The Armv8.6 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_ECV, Enhanced Counter Virtualization

FEAT_ECV enhances the Generic Timer architecture.

When executing in AArch64 state or AArch32 state, FEAT_ECV provides:

- Self-synchronizing views of the virtual and physical timers in AArch64 and AArch32 state.
- The ability to scale the generation of the event stream.

When EL2 is using AArch64 state, FEAT_ECV provides:

- An optional offset between the EL1 or EL0 view of physical time, and the EL2 or EL3 view of physical time.
- Traps configurable in CNTHCTL_EL2 that trap EL0 and EL1 access to the virtual counter or timer registers, and accesses to the physical timer registers when they are accessed using an EL02 descriptor.

The optional offset to views of physical time, and the configurable traps in CNTHCTL_EL2, both apply to EL1 and EL0 whether EL1 and EL0 are in AArch64 state or AArch32 state.

This feature is mandatory in Armv8.6 implementations.

The ID_AA64MMFR0_EL1.ECV field identifies the presence of FEAT_ECV. The ID_PFR1_EL1.GenTimer and ID_PFR1.GenTimer fields identify support for self-synchronized counter views in AArch32 state.

For more information, see:

- Self-hosted trace timestamps on page D3-4761.
- The profiling data on page D13-5446.
- The AArch64 view of the Generic Timer on page D10-5236.
- The AArch32 view of the Generic Timer on page G6-9292.

FEAT_FGT, Fine Grain Traps

FEAT_FGT introduces additional traps to EL2 of EL1 and EL0 access to individual or small groups of System registers and instructions, and traps to EL3 and EL2 of the Debug Communications Channel registers. The traps are independent of existing controls.

This feature is supported in AArch64, and when EL1 is using AArch64, EL0 accesses using AArch32 are also trapped.

This feature is mandatory in Armv8.6 implementations.

The ID_AA64MMFR0_EL1.FGT field identifies the presence of FEAT_FGT.

For more information, see Configurable instruction controls on page D1-4665.

FEAT_TWED, Delayed Trapping of WFE

FEAT_TWED introduces support for configurable delayed trapping of the WFE instruction.

This feature is supported in both AArch64 and AArch32 states.

This feature is OPTIONAL in Armv8.6 implementations.
The ID_AA64MMFR1_EL1.TWED field identifies the presence of FEAT_TWED.
For more information, see the Wait for Event and Wait for Event with Timeout instructions on page D1-4677.

FEAT_AMUv1p1, AMU Extensions v1.1
FEAT_AMUv1p1 introduces support for virtualization of Activity Monitors event counters, and introduces controls to disable access to auxiliary event counters below the highest Exception level.
This feature is supported in AArch32 state and AArch64 state, if the hypervisor is using AArch64.
This feature is optional in Armv8.6 implementations if the optional FEAT_AMUv1 is implemented.
The fields ID_AA64PFR0_EL1.AMU, ID_PFR0_EL1.AMU, and ID_PFR0.AMU identify the presence of FEAT_AMUv1p1.
For more information, see Chapter D12 The Activity Monitors Extension.

FEAT_MTPMU, Multi-threaded PMU Extensions
FEAT_MTPMU introduces controls to disable PMEVTYPE<n>_EL0.MT.
This feature requires at least one of EL2 and EL3. If neither is implemented, this feature is not implemented.
If EL2 or EL3 is implemented, the feature is optional if FEAT_PMUv3 is implemented.
Multithreaded Armv8.6 implementations with FEAT_PMUv3 implemented must implement FEAT_MTPMU to enable any multithreaded event counting.
This feature is supported in both AArch64 and AArch32 states.
The fields ID_AA64DFR0_EL1.MTPMU and ID_DFR1.MTPMU identify the presence of FEAT_MTPMU.
For more information, see:
- Multithreaded implementations on page D11-5258.
- MDACR_EL3.MTPME, SDCR.MTPME, MDACR_EL2.MTPME, and HDACR.MTPME.
- Common event numbers on page D11-5306.

A2.9.2 Additional requirements of Armv8.6
The Armv8.6 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to the frequency of the physical counter
The frequency of CNTFRQ_EL0 is standardized to a frequency of 1GHz. This means that the system counter must be implemented at 64 bits. For more information, see:
- The system counter on page D10-5234.
- The system counter on page G6-9290.

A2.9.3 Features added to earlier extensions
The features that have been added to earlier architectural extensions are:
- FEAT_DGH on page A2-78.
- FEAT_ETS on page A2-78.
- FEAT_BF16 on page A2-93.
- FEAT_AA32BF16 on page A2-94.
- FEAT_I8MM on page A2-94.
- FEAT_AA32I8MM on page A2-94.
- FEAT FPAC on page A2-99.
A2.10 The Armv8.7 architecture extension

The Armv8.7 architecture extension adds architectural features and additional requirements, see:

- Architectural features added by Armv8.7.
- Additional requirements of Armv8.7 on page A2-116.

Features are also added to earlier architecture extensions, see Features added to earlier extensions on page A2-116.

A2.10.1 Architectural features added by Armv8.7

An implementation of the Armv8.7 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.7 architecture.

The Armv8.7 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

- **FEAT_AFP, Alternate floating-point behavior**
  
  FEAT_AFP allows alternate behavior for specified floating-point instructions including:
  - Flushing of denormalized numbers to zero can be controlled separately on inputs and outputs.
  - Alternate NaN propagation rules can apply.
  - Output elements for specified scalar Advanced SIMD instructions can be determined using alternate rules.
  - Changes to floating-point exception generation.
  
  This feature is supported in AArch64 state only.
  
  This feature is mandatory in Armv8.7 implementations that implement floating-point support.
  
  The ID_AA64MMFR1_EL1.AFP field identifies the presence of FEAT_AFP.
  
  For more information, see:
  - Flushing denormalized numbers to zero on page A1-58.
  - NaN handling and the Default NaN on page A1-60.
  - Floating-point exceptions and exception traps on page A1-64.

- **FEAT_RPRES, Increased precision of Reciprocal Estimate and Reciprocal Square Root Estimate**
  
  FEAT_RPRES allows an increase in the precision of the Reciprocal Estimate and Reciprocal Square Root Estimate from an 8-bit mantissa to a 12-bit mantissa.
  
  This feature is supported in AArch64 state only.
  
  This feature is OPTIONAL in Armv8.7 implementations. This feature requires implementation of FEAT_AFP.
  
  The ID_AA64ISAR2_EL1.RPRES field identifies the presence of FEAT_RPRES.
  
  For more information, see RecipEstimate() and RecipSqrtEstimate().

- **FEAT_LS64, FEAT_LS64_V, FEAT_LS64_ACCDATA, Support for 64 byte loads/stores**
  
  FEAT_LS64 introduces support for atomic single-copy 64-byte loads and stores without return. For more information, see:
  - LD64B on page C6-1512.
  - ST64B on page C6-1837.
  
  FEAT_LS64_V introduces support for atomic single-copy 64-byte stores with return. For more information, see:
  - ST64BV on page C6-1838.
  
  FEAT_LS64_ACCDATA introduces support for atomic single-copy 64-byte EL0 stores with return. For more information, see:
  - ST64BV0 on page C6-1840.
  - ACCDATA_EL1, Accelerator Data on page D17-5556.
These features are supported in AArch64 state only.
FEAT_LS64 is OPTIONAL in Armv8.7 implementations.
FEAT_LS64_V is OPTIONAL in Armv8.7 implementations, and can be implemented only if 
FEAT_LS64 is implemented.
FEAT_LS64_ACCDATA is OPTIONAL in Armv8.7 implementations, and can be implemented only 
if FEAT_LS64_V is implemented.

--- Note ---

The meaning of any values being returned by the ST64BV and ST64BV0 instructions are 
retrospectively relaxed such that they are defined by the peripheral providing the response.

The ID_AA64ISAR1_EL1.LS64 field identifies the presence of FEAT_LS64, FEAT_LS64_V, and 
FEAT_LS64_ACCDATA.

For more information, see Single-copy atomic 64-byte load/store on page C3-271.

FEAT_WFxT, WFE and WFI instructions with timeout

FEAT_WFxT introduces WFET and WFIT. These instructions support the generation of a local timeout 
event to act as a wake-up event for the PE when the virtual count in CNTVCT_EL0 equals or 
exceeds the value supplied by the instruction for the first time. The register number that holds the 
timeout value for trapped WFET and WFIT instructions is reported in ESR_ELx.

These instructions are added to the A64 instruction set only.

FEAT_WFxT is mandatory in Armv8.7 implementations.
The ID_AA64ISAR2_EL1.WFxT field identifies the presence of FEAT_WFxT.

For more information, see:
• Instructions with register argument on page C3-250.
• Wait for Event on page D1-4676.
• Wait for Interrupt mechanism on page D1-4678.

FEAT_HCX, Support for the HCRX_EL2 register

FEAT_HCX introduces the Extended Hypervisor Configuration Register, HCRX_EL2, that 
provides configuration controls for virtualization in addition to those provided by HCR_EL2, 
including defining whether various operations are trapped to EL2.

This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.7 implementations.
The ID_AA64MMFR1_EL1.HCX field identifies the presence of FEAT_HCX.

For more information, see Configurable instruction controls on page D1-4665.

FEAT_LPA2, Larger physical address for 4KB and 16KB translation granules

FEAT_LPA2:
• Allows a larger VA space for each translation table base register of up to 52 bits when using 
  the 4KB or 16KB translation granules.
• Allows a larger intermediate physical address (IPA) and PA space of up to 52 bits when using 
  the 4KB or 16KB translation granules.
• Allows a level 0 block size where the block covers a 512GB address range for the 4KB 
  translation granule if the implementation supports 52 bits of PA.
• Allows a level 1 block size where the block covers a 64GB address range for the 16KB 
  translation granule if the implementation supports 52 bits of PA.

This feature is supported in AArch64 state only.
This feature is OPTIONAL in Armv8.7 implementations. This feature requires implementation of 
FEAT_LPA and FEAT_LVA.
The ID_AA64MMFR0_EL1.{TGRAN4_2, TGRAN16_2, TGRAN4, TGRAN16} fields identify the presence of FEAT_LPA2.

For more information, see:
- Implemented physical address size on page D8-5088.
- Output address size configuration on page D8-5088.
- Supported virtual address ranges on page D8-5089.
- Input address size configuration on page D8-5090.
- Intermediate physical address size configuration on page D8-5091.
- Translation using the 4KB granule on page D8-5100.
- Translation using the 16KB granule on page D8-5106.
- Table descriptor format on page D8-5123.
- Block descriptor and Page descriptor formats on page D8-5126.

**FEAT_XS, XS attribute**

FEAT_XS introduces the XS attribute for memory to indicate that an access could take a long time to complete. This feature provides variants of DSB instructions and TLB maintenance instructions, the completion of which does not depend on the completion of memory accesses with the XS attribute.

FEAT_XS adds:
- A mechanism to define the XS attribute for memory.
- An optional nXS variant to the AArch64 DSB instruction and optional nXS qualifier to each AArch64 TLBI instruction to handle memory accesses with the XS attribute.
- The FGTnXS bit to HCRX_EL2 to determine the behavior of fine-grained traps in HFGITR_EL2 for TLB maintenance instructions with the nXS qualifier.
- The FnXS bit to HCRX_EL2 to determine the behavior of pre-existing TLB maintenance instructions in relation to the XS attribute.

This feature is supported in AArch64 state only, but the XS attribute also impacts AArch32 state execution.

This feature is mandatory in Armv8.7 implementations.

The ID_AA64ISAR1_EL1.XS field identifies the presence of FEAT_XS.

For more information, see:
- Data Synchronization Barrier (DSB) on page B2-178.
- Behavior when stage 1 address translation is disabled on page D8-5118.
- Block descriptor and Page descriptor formats on page D8-5126.
- Stage 1 memory type and Cacheability attributes on page D8-5151.
- XS attribute modifier on page D8-5160.
- Data Synchronization Barrier (DSB) on page E2-7182.
- Overview of memory region attributes for stage 1 translations on page G5-9203.
- Ordering and completion of TLB maintenance instructions on page G5-9223.

**FEAT_PMUv3p7, Armv8.7 PMU extensions**

FEAT_PMUv3p7 adds the following features to the Performance Monitors Extension:
- PMU counters can be frozen when an event counter has an unsigned overflow.
- Event counters can be prohibited from counting events at EL3 without affecting the rest of Secure state.
- The cycle counter can be prohibited from counting cycles at EL3 without affecting the rest of Secure state.

This feature is supported in both AArch64 and AArch32 states.
The Performance Monitors Extension is an **optional** feature, but if it is implemented, an Armv8.7 implementation must include **FEAT_PMUv3p7**.

The fields that identify the presence of **FEAT_PMUv3p7** are:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see:
- *Controlling the PMU counters* on page D11-5254.
- *Freezing event counters* on page D11-5255.
- *Common microarchitectural events* on page D11-5317.
- *PMMIR_EL1, Performance Monitors Machine Identification Register* on page D17-6788.

**FEAT_SPEv1p2, Armv8.7 SPE features**

**FEAT_SPEv1p2** adds the following features to the Statistical Profiling Extension, **FEAT_SPE**:

- Adds an inverse event filter control.
- Adds controls to freeze the PMU event counters after an SPE buffer management event occurs.
- Adds a discard mode that allows all SPE data to be discarded rather than written to memory.

This feature is mandatory from Armv8.7 when **FEAT_SPE** is implemented.

This feature is supported in AArch64 state.

**FEAT_SPEv1p2** optionally enables support for a packet for each taken branch that provides the target address for the previous taken branch.

**ID_AA64DFR0_EL1.PMSVer** identifies the presence of **FEAT_SPEv1p2**.

If **FEAT_SPEv1p2** is implemented, **PMSIDR_EL1.PBT** indicates support for the previous branch target packet.

For more information, see:
- *Freezing event counters* on page D11-5255.
- *Common event numbers* on page D11-5306.
- *Filtering sample records* on page D13-5444.
- *Previous branch target* on page D13-5447.
- *About the Statistical Profiling Extension sample records* on page D14-5472.
- *Address packet* on page D14-5476.

### A2.10.2 Additional requirements of Armv8.7

The Armv8.7 architecture includes some mandatory changes that are not associated with a feature. These are:

**FEAT_ETS, Enhanced Translation Synchronization**

All implementations of the Armv8.7 architecture are required to implement **FEAT_ETS**.

For more information, see **FEAT_ETS on page A2-78**.

### A2.10.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- **FEAT_PAN3** on page A2-85.
- **FEAT_MTE3** on page A2-110
A2.11 The Armv8.8 architecture extension

The Armv8.8 architecture extension adds architectural features and additional requirements, see:

- Architectural features added by Armv8.8
- Additional requirements of Armv8.8 on page A2-120.

Features are also added to earlier architecture extensions, see Features added to earlier extensions on page A2-120.

A2.11.1 Architectural features added by Armv8.8

An implementation of the Armv8.8 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.8 architecture.

The Armv8.8 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

FEAT_MOPS, Standardization of memory operations

FEAT_MOPS provides instructions that perform a memory copy or memory set, and adds Memory Copy and Memory Set exceptions.

FEAT_MOPS also adds the HCRX_EL2.{MSCEn, MCE2}, SCTLR_EL1.MSCEn, and SCTLR_EL2.MSCEn control bits.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.8 implementations.

The ID_AA64ISAR2_EL1.MOPS field identifies the presence of FEAT_MOPS.

For more information, see:
- Memory Copy and Memory Set exceptions on page D1-4654.

FEAT_HBC, Hinted conditional branches

FEAT_HBC provides the BC.cond instruction to give a conditional branch with a hint to branch prediction logic that this branch will consistently and is highly unlikely to change direction.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.8 implementations.

The ID_AA64ISAR2_EL1.BC field identifies the presence of FEAT_HBC.

For more information, see:
- Conditional branch on page C3-248.

FEAT_NMI, Non-maskable Interrupts

FEAT_NMI provides a mechanism to support non-maskable interrupts (NMI) and less-masked interrupts (LMI). In addition to legacy behavior, the feature includes the following:

- A mode for supporting an LMI interrupt mask that is distinct from PSTATE.{I, F}.
- A mode for supporting a limited NMI, where the value when PSTATE.SP is 1 is taken as an interrupt mask for all interrupts targeting that Exception level, and where the LMI interrupt mask can also be used.

FEAT_NMI adds:
- The AllIntMask variable.
- An optional Superpriority attribute to denote virtual and physical IRQ and FIQ interrupts as non-maskable.
- The SCTLR_EL{x}.{NMI, SPINTMASK} control bits.
- The PSTATE.ALLINT bit and associated instructions.
- The HCRX_EL2.TALLINT bit to enable trapping of ALLINT instructions at EL1.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.8 implementations.

The ID_AA64PFR1_EL1.NMI field identifies the presence of FEAT_NMI.
FEAT_TIDCP1, EL0 use of IMPLEMENTATION DEFINED functionality

FEAT_TIDCP1 adds a control at EL1 and EL2 to enable trapping of EL0 accesses to registers that might control IMPLEMENTATION DEFINED functions.

This feature adds controls only in AArch64 state, and controls IMPLEMENTATION DEFINED execution at EL0 in both AArch32 and AArch64 states.

This feature is mandatory in Armv8.8 implementations.

The ID_AA64MMFR1_EL1.TIDCP1 field identifies the presence of FEAT_TIDCP1.

For more information, see Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.

FEAT_CMOW, Control for cache maintenance permission

FEAT_CMOW introduces support for cache maintenance instructions that controls whether:

- Cache maintenance instructions executed at EL0 require stage 1 read and write permission to prevent the instructions from generating a Permission fault.
- Cache maintenance instructions executed at EL1 or EL0 require stage 2 read and write permission to prevent the instructions from generating a Permission fault.

This feature is supported in AArch64 state only, but also impacts AArch32 instructions.

This feature is mandatory in Armv8.8 implementations.

The ID_AA64MMFR1_EL1.CMOW field identifies the presence of FEAT_CMOW.

For more information, see:
- A64 Cache maintenance instructions on page D7-5054.
- Permission fault on page D8-5183.

FEAT_PMUv3p8, Armv8.8 PMU extensions

FEAT_PMUv3p8 adds the following features to the Performance Monitors Extension:

- The Common event number space is extended to include the ranges 0x0040-0x00BF and 0x4040-0x40BF.
- For an event counter n, if any reserved or unimplemented PMU event number is written to PMEVTYPE<\textit{n}\.evtCount, the event counter \textit{n} does not count, and a read of PMEVTYPE<\textit{n}\.evtCount returns the value written.

This feature is supported in both AArch64 and AArch32 states.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.8 implementation must include FEAT_PMUv3p8.

The fields that identify the presence of FEAT_PMUv3p8 are:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.
- EDDFR.PMUVer.

For more information, see:
- The PMU event number space and common events on page D11-5275.
- Common event numbers on page D11-5306.
- PMEVTYPE<\textit{n}>_EL0, Performance Monitors Event Type Registers, \textit{n} = 0 - 30 on page D17-6773.
- PMEVTYPE<\textit{n}>, Performance Monitors Event Type Registers, \textit{n} = 0 - 30 on page G8-10006.
FEAT_HPMN0, Setting of MDCR_EL2.HPMN to zero

FEAT_HPMN0 permits a hypervisor to provide zero PMU event counters for a guest operating system by setting MDCR_EL2.HPMN to zero.

This feature is supported in both AArch64 and AArch32 states.

This feature is mandatory in Armv8.8 implementations that include FEAT_PMUv3 and EL2. Otherwise, this feature is optional in implementations that include FEAT_PMUv3, FEAT_FGT, and EL2.

The fields that identify the presence of FEAT_HPMN0 are:
- ID_AA64DFR0_EL1.HPMN0.
- ID_DFR1_EL1.HPMN0.
- ID_DFR1.HPMN0.

For more information, see:
- Interaction with EL2 on page D11-5245.
- Controlling the PMU counters on page D11-5254.
- The Performance Monitors Extension on page K1-11569.
- The Performance Monitors Extension on page K1-11586.

FEAT_PMUv3_TH, Event counting threshold

FEAT_PMUv3_TH adds threshold condition controls to each PMEVTYPER<n>_EL0 register. This feature permits the counter to count only when PMEVTYPER<n>_{MT, evtCount} describes an event whose count meets a specified threshold condition.

This feature is supported in both AArch64 and AArch32 states. The threshold condition controls are only accessible in AArch64 state. However, threshold conditions still apply in AArch32 state.

This feature is optional in Armv8.8 implementations.

This feature requires FEAT_PMUv3 to be implemented, and AArch64 state to be supported.

The fields that identify the presence of FEAT_PMUv3_TH are:
- PMMIR_EL1.THWIDTH.
- PMMIR.THWIDTH.
- If the external debug interface to the PMU registers is implemented, PMMIR.THWIDTH.

For more information, see Event counting threshold on page D11-5262.

FEAT_SPEv1p3, Armv8.8 Statistical Profiling Extensions

FEAT_SPEv1p3 adds the following features to the Statistical Profiling Extension:
- Support for sampling Tag operations.
- Support for sampling Memory Copy and Set operations.

This feature is supported in both AArch64 and AArch32 states.

This feature is mandatory from Armv8.8 when FEAT_SPE is implemented.

The ID_AA64DFR0_EL1.PMSVer field identifies the presence of FEAT_SPEv1p3.

For more information, see:
- Additional information for each profiled memory access operation on page D13-5448.
- About the Statistical Profiling Extension sample records on page D14-5472.
- Address packet on page D14-5476.

FEAT_Debugv8p8, Debug v8.8

FEAT_Debugv8p8 adds support to allow an asynchronous exception to be taken after an exception generates an Exception Catch debug event, but before the PE halts.

This feature is supported in both AArch64 and AArch32 states.

This feature is mandatory in Armv8.8 implementations.

The fields that identify the presence of FEAT_Debugv8p8 are:
- ID_AA64DFR0_EL1.DebugVer,
A2.11.2 Additional requirements of Armv8.8

The Armv8.8 architecture includes the following mandatory changes that are associated with FEAT_SPE:

**Access Flag and dirty state management by SPE**

Removal of the option for the Access Flag and dirty state to behave as if always disabled for accesses made by the SPU. For more information, see *Hardware management of dirty state and the Access flag by the Statistical Profiling Extension* on page D13-5465.

**External abort handling by SPE**

External aborts on writes made by the SPU must generate SError interrupt exceptions. For more information, see *External aborts* on page D13-5466.

The Armv8.8 architecture includes the following optional change that is associated with FEAT_PMUv3:

**64-bit external PMU programmers’ model extension**

The 64-bit external PMU programmers’ model extension extends the Performance Monitors registers to 64 bits, except the 32-bit CoreSight management registers.

This extension is supported in both AArch64 and AArch32 states.

This extension is optional when the external debug interface to the Performance Monitors is implemented.

This extension requires the external debug interface to the Performance Monitors to be implemented, and AArch64 state to be supported.

The PMDEVARCH.ARCHPART field indicates the presence of the 64-bit external PMU programmers’ model extension.

For more information, see *Chapter I3 Recommended External Interface to the Performance Monitors*.

A2.11.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- **FEAT_PACQARMA3** on page A2-100.
- **FEAT_CONSTPACFIELD** on page A2-100.
- **FEAT_RNG_TRAP** on page A2-110.
The Performance Monitors Extension

The Performance Monitors Extension, FEAT_PMUv3, is an OPTIONAL extension but Arm strongly recommends that Armv8-A implementations include version 3 of the Performance Monitors Extension.

ID_AA64DFR0_EL1.PMUVer indicates whether the Performance Monitors Extension is implemented.

For more information, see Chapter D11 *The Performance Monitors Extension*.

Armv8.1 introduces the following architectural feature to the Performance Monitors Extension:
- FEAT_PMUv3p1.

Armv8.4 introduces the following architectural feature to the Performance Monitors Extension:
- FEAT_PMUv3p4.

Armv8.5 introduces the following architectural feature to the Performance Monitors Extension:
- FEAT_PMUv3p5.

Armv8.6 introduces the following architectural feature to the Performance Monitors Extension:
- FEAT_MTPMU.

Armv8.7 introduces the following architectural feature to the Performance Monitors Extension:
- FEAT_PMUv3p7.

Armv8.8 introduces the following architectural features to the Performance Monitors Extension:
- FEAT_PMUv3p8.
- FEAT_HPMN0.
- FEAT_PMUv3_TH.
A2.13 The Reliability, Availability, and Serviceability Extension

The RAS Extension, FEAT_RAS, is a mandatory extension to the Armv8.2 architecture, and an OPTIONAL extension to the Armv8.0 and the Armv8.1 architectures.

The RAS Extension improves the dependability of a system by providing:

- Reliability, that is, the continuity of correct service.
- Availability, that is, the readiness for correct service.
- Serviceability, that is, the ability to undergo modifications and repairs.

ID_AA64PFR0_EL1.RAS in AArch64 state, and ID_PFR0.RAS in AArch32 state, indicate whether the RAS Extension is implemented.

The RAS Extension introduces a barrier instruction, the Error Synchronization Barrier (ESB), to the A32, T32, and A64 instruction sets.

System registers introduced by the RAS Extension are described in:

- For AArch64, RAS registers on page D17-6956.
- For AArch32, RAS registers on page G8-10083.

In addition, the RAS Extension introduces a number of memory-mapped registers. These are described in the Arm® Architecture Reference Manual Supplement: Reliability, Availability, and Serviceability (RAS), for Armv8-A.

Armv8.2 introduces the following architectural features to the RAS Extension:

- FEAT_IESB.

Armv8.4 introduces the following architectural features to the RAS Extension:

- FEAT_RASv1p1.
- FEAT_DoubleFault.
A2.14 The Statistical Profiling Extension (SPE)

The Statistical Profiling Extension, FEAT_SPE, is an OPTIONAL extension introduced by the Armv8.2 architecture. Implementation of the Statistical Profiling Extension requires implementation of at least Armv8.1 of the Armv8-A architecture profile. The Statistical Profiling Extension is supported only in AArch64 state.

The Statistical Profiling Extension provides a non-invasive method of sampling software and hardware using randomized sampling of either architectural instructions, as defined by the instruction set architecture, or by microarchitectural operations.

ID_AA64DFR0_EL1.PMSVer indicates whether the Statistical Profiling Extension is implemented.

For more information, see Chapter D13 The Statistical Profiling Extension.

Armv8.3 introduces the following architectural feature to the SPE:
• FEAT_SPEv1p1.

Armv8.7 introduces the following architectural feature to the SPE:
• FEAT_SPEv1p2.

Armv8.8 introduces the following architectural feature to the SPE:
• FEAT_SPEv1p3.
A2.15 The Scalable Vector Extension (SVE)

The Scalable Vector Extension, FEAT_SVE, is an OPTIONAL extension introduced by the Armv8.2 architecture. SVE is supported in AArch64 state only.

The Scalable Vector Extension includes the following functionality:

- Configurable vector length with scalable vector lengths from 128 bits up to 2048 bits.
- Predication using scalable predicate registers from 16 bits up to 256 bits.
- Instructions that operate on scalable size vectors and predicates.
- Gather-load and scatter-store.
- Software-managed speculative vectorization.
- System registers and fields to configure the Effective SVE vector length and traps.

ID_AAA64PFR0_EL1.SVE indicates whether the Scalable Vector Extension is implemented.

The Scalable Vector Extension complements the AArch64 Advanced SIMD and floating-point functionality. SVE does not replace the AArch64 Advanced SIMD and floating-point functionality.

Implementation of FEAT_SVE requires implementation of FEAT_FCMA and FEAT_FP16.
A2.16 The Activity Monitors Extension (AMU)

The Activity Monitors Extension is an OPTIONAL extension introduced by the Armv8.4 architecture. AMU is supported in AArch64 and AArch32 states.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, FEAT_AMUv1, which provides a function similar to a subset of the existing Performance Monitors Extension functionality, intended for system management use rather than debugging and profiling.

The Activity Monitors Extension implements a System register interface to the Activity Monitors registers, and supports an optional external memory-mapped interface.

The fields that identify the presence of the Activity Monitors Extension are:

- ID_AA64PFR0_EL1.AMU.
- ID_PFR0_EL1.AMU.
- ID_PFR0.AMU.
- EDPFR.AMU.

For more information, see Chapter D12 The Activity Monitors Extension.

Armv8.6 introduces the following architectural feature to the Activity Monitors Extension:

- FEAT_AMUv1p1.
A2.17 The Memory Partitioning and Monitoring (MPAM) Extension

The MPAM Extension, FEAT_MPAM, is an optional extension introduced by the Armv8.4 architecture and requires implementation of at least Armv8.2 of the Armv8-A architecture profile. MPAM is supported in AArch64 state only.

The MPAM Extension provides a framework for memory-system component controls that partition one or more of the performance resources of the component.

The fields that identify the presence of the MPAM Extension are:

- ID_AA64PFR0_EL1.MPAM.
- EDPFR.MPAM.

For more information, see Arm® Architecture Reference Manual Supplement, Memory System Resource Partitioning and Monitoring (MPAM), for A-profile architecture.
Chapter A3

Armv9 Architecture Extensions

This chapter introduces the Armv9 architecture versions and extensions. It contains the following sections:

• *Armv9-A architecture extensions* on page A3-128.
A3.1 Armv9-A architecture extensions

An implementation of the Armv9-A architecture must include all of the extensions that this section describes as mandatory. Such an implementation is also called an implementation of the Armv9-A architecture.

The AArch32 state might optionally be implemented at EL0. The AArch32 state is not implemented at EL1, EL2, and EL3.

The implementation of FEAT_DoubleLock in an Armv9 implementation is prohibited.

An implementation of the Armv9-A architecture cannot include an ETM.

The Armv9 architecture adds the following features, which are identified by the architectural feature name and a short description of the feature:

**FEAT_SVE2, Scalable Vector Extension version 2**

The Scalable Vector Extension version 2 (SVE2) is a superset of SVE that incorporates functionality similar to Advanced SIMD, and other enhancements. In this Manual, unless stated otherwise, when SVE is used, the behavior also applies to SVE2.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in an Armv9.0 implementation, standard Armv9-A software platforms support FEAT_SVE2.

This feature requires FEAT_SVE.

The following fields indicate the presence of FEAT_SVE2:

- ID_AA64PFR0_EL1.SVE.
- ID_AA64ZFR0_EL1.SVEver.

For more information, see:

- *The Scalable Vector Extension (SVE)* on page A2-124.
- *Data processing - SVE2* on page C3-368.

**FEAT_SVE_AES, Scalable Vector AES instructions**

FEAT_SVE_AES provides the following SVE AES cryptographic instructions:

- AESD.
- AESE.
- AESIMC.
- AESMC.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in an Armv9.0 implementation.

FEAT_SVE_AES requires FEAT_SVE2.

The ID_AA64ZFR0_EL1.AES field identifies support for FEAT_SVE_AES.

**FEAT_SVE_BitPerm, Scalable Vector Bit Permutes instructions**

FEAT_SVE_BitPerm provides the following SVE bit permute instructions:

- BEXT.
- BDEP.
- BGRP.

This feature is supported in AArch64 state only.

This feature is OPTIONAL in an Armv9.0 implementation.

FEAT_SVE_BitPerm requires FEAT_SVE2.

The ID_AA64ZFR0_EL1.BitPerm field identifies support for FEAT_SVE_BitPerm.
FEAT_SVE_PMULL128, Scalable Vector PMULL instructions
FEAT_SVE_PMULL128 provides the following SVE 128-bit polynomial multiply instructions:
- PMULLB.
- PMULLT.
This feature is supported in AArch64 state only.
This feature is optional in an Armv9.0 implementation.
FEAT_SVE_PMULL128 requires FEAT_SVE2.
The ID_AA64ZFR0_EL1.AES field identifies support for FEAT_SVE_PMULL128.

FEAT_SVE_SHA3, Scalable Vector SHA3 instructions
FEAT_SVE_SHA3 provides the following SVE SHA3 cryptographic instruction:
- RAX1.
This feature is supported in AArch64 state only.
This feature is optional in an Armv9.0 implementation.
FEAT_SVE_SHA3 requires FEAT_SVE2.
The ID_AA64ZFR0_EL1.SHA3 field identifies support for FEAT_SVE_SHA3.

FEAT_SVE_SM4, Scalable Vector SM4 instructions
FEAT_SVE_SM4 provides the following SVE SM4 cryptographic instructions:
- SM4E.
- SM4EKEY.
This feature is supported in AArch64 state only.
This feature is optional in an Armv9.0 implementation.
FEAT_SVE_SM4 requires FEAT_SVE2.
The ID_AA64ZFR0_EL1.SM4 field identifies support for FEAT_SVE_SM4.

FEAT_ETE, Embedded Trace Extension
FEAT_ETE provides a trace unit that records details about software control flow running on a PE, which can be used to aid debugging or optimizing. The trace unit provides filtering functionality to allow the targeting of the information to specific code regions or periods of operation.
This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.
This feature is optional in an Armv9.0 implementation.
This feature requires FEAT_TRBE and FEAT_TRF.
The ID_AA64DFR0_EL1.TraceVer field identifies the presence of FEAT_ETE.
For more information, see Chapter D4 The Embedded Trace Extension.

FEAT_TME, Transactional Memory Extension
FEAT_TME introduces a set of instructions to support hardware transaction memory, which means a group of instructions can appear to be collectively executed as a single atomic operation. For more information on these instructions, see:
- TCANCEL.
- TCOMMIT.
- TSTART.
- TTEST.
This feature is supported in AArch64 state only.
This feature is optional in an Armv9.0 implementation.
The ID_AA64ISAR0_EL1.TME field identifies the presence of FEAT_TME.
For more information on FEAT_TME, see Arm® Architecture Reference Manual Supplement, Transactional Memory Extension (TME), for A-profile architecture (ARM DDI 0617).

**FEAT_TRBE, Trace Buffer Extension**

FEAT_TRBE enables support for a Trace Buffer Unit within a PE. When the Trace Buffer Unit is enabled, program-flow trace generated by a trace unit is written directly to memory by the Trace Buffer Unit, rather than routing trace data to a trace sink.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

This feature is **OPTIONAL** in an Armv9.0 implementation.

FEAT_TRBE requires FEAT_ETE and FEAT_TRF.

The ID_AA64DFR0_EL1.TraceBuffer field identifies support for FEAT_TRBE.

For more information, see Chapter D6 The Trace Buffer Extension.

**FEAT_ETEv1p1, Embedded Trace Extension**

FEAT_ETEv1p1 extends FEAT_ETE to support FEAT_FGT.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

This feature is **OPTIONAL** in an Armv9.1 implementation.

This feature requires FEAT_ETE.

The TRCDEVARCH.REVISION field identifies the presence of FEAT_ETEv1p1.

For more information, see Chapter D4 The Embedded Trace Extension.

**FEAT_BRBE, Branch Record Buffer Extension**

FEAT_BRBE provides a Branch record buffer for capturing control path history.

This feature is supported in AArch64 state only.

This feature is **OPTIONAL** in an Armv9.2 implementation.

The ID_AA64DFR0_EL1.BRBE field identifies the presence of FEAT_BRBE.

For more information, see Chapter D15 The Branch Record Buffer Extension.

**FEAT_ETEv1p2, Embedded Trace Extension**

FEAT_ETEv1p2 extends FEAT_ETE to support FEAT_RME.

This feature is supported in AArch64 state, and performs trace in both AArch64 and AArch32 states.

This feature is **OPTIONAL** in an Armv9.2 implementation.

This feature requires FEAT_ETEv1p1.

This feature is required if FEAT_RME is implemented and FEAT_ETE is implemented.

The TRCDEVARCH.REVISION field identifies the presence of FEAT_ETEv1p2.

For more information, see Arm® Architecture Reference Manual Supplement, The Realm Management Extension (RME), for Armv9-A (ARM DDI 0615).

**FEAT_BRBEv1p1, Branch Record Buffer Extension**

FEAT_BRBEv1p1 enables branch recording at EL3.

This feature is supported in AArch64 state only.

This feature requires FEAT_BRBE.

If FEAT_BRBE is implemented, an Armv9.3-compliant implementation includes the FEAT_BRBEv1p1 feature.

The ID_AA64DFR0_EL1.BRBE field identifies the presence of FEAT_BRBEv1p1.

For more information, see Chapter D15 The Branch Record Buffer Extension.
FEAT_RME, Realm Management Extension

FEAT_RME is one component of the Arm Confidential Compute Architecture (Arm CCA). Together with the other components of the Arm CCA, RME enables support for dynamic, attestable, and trusted execution environments (Realms) to be run on an Arm PE.

This feature is supported in AArch64 state only.
This feature is OPTIONAL in an Armv9.2 implementation.
FEAT_RME requires FEAT_RNG or FEAT_RNG_TRAP.
If the Trace Architecture is implemented, a PE that implements FEAT_RME also implements FEAT_ETEv1p2.
For more information, see Arm® Architecture Reference Manual Supplement, The Realm Management Extension (RME), for Armv9-A (ARM DDI 0615).

FEAT_SME, Scalable Matrix Extension

FEAT_SME introduces two AArch64 execution modes that can be enabled and disabled by application software:

- In ZA mode, scalable, two-dimensional, architectural ZA tile storage becomes available and instructions are defined to load, store, extract, insert, and clear rows and columns of the ZA tiles.
- In Streaming SVE mode, the Effective SVE vector length changes to match the Effective ZA tile width, support for a substantial subset of the SVE2 instruction set is available, and, when ZA mode is also enabled, instructions are defined that accumulate the matrix outer product of two SVE vectors into a ZA tile.

This feature is supported in AArch64 state only.
This feature is OPTIONAL from Armv9.2.
The ID_AA64PFR1_EL1.SME field identifies the presence of FEAT_SME.
For more information, see Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

FEAT_SME_FA64, Full Streaming SVE mode instructions

FEAT_SME_FA64 supports the full A64 instruction set in Streaming SVE mode.
This feature is supported in AArch64 state only.
This feature is OPTIONAL in an Armv9.2 implementation.
FEAT_SME_FA64 requires FEAT_SME.
The ID_AA64SMFR0_EL1.FA64 field identifies support for FEAT_SME_FA64.
For more information, see Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

FEAT_EBF16, AArch64 Extended BFloat16 instructions

FEAT_EBF16 supports the Extended BFloat16 mode.
This feature is supported in AArch64 state only.
This feature is OPTIONAL in an Armv9.2 implementation.
FEAT_EBF16 requires FEAT_SME.
The ID_AA64ISAR1_EL1.BF16 and ID_AA64ZFR0_EL1.BF16 fields identify the presence of FEAT_EBF16, and must return the same value.
For more information, see Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

FEAT_SME_F64F64, Double-precision floating-point outer product instructions

FEAT_SME_F64F64 indicates SME support for instructions that accumulate into FP64 double-precision floating-point elements in the ZA array.
This feature is supported in AArch64 state only.
This feature is OPTIONAL in an Armv9.2 implementation. FEAT_SME_F64F64 requires FEAT_SME.
The ID_AA64SMFR0_EL1.F64F64 field identifies support for FEAT_SME_F64F64. For more information, see Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

**FEAT_SME_I16I64, 16-bit to 64-bit integer widening outer product instructions**

FEAT_SME_I16I64 indicates SME support for instructions that accumulate into 64-bit integer elements in the ZA array. This feature is supported in AArch64 state only. This feature is OPTIONAL in an Armv9.2 implementation. FEAT_SME_I16I64 requires FEAT_SME.
The ID_AA64SMFR0_EL1.I16I64 field identifies support for FEAT_SME_I16I64. For more information, see Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

### A3.1.1 Architectural requirements within Armv9-A architecture

An Armv9 compliant implementation must also be Armv8.5 compliant.

An Armv9.1 compliant implementation must also be Armv8.6 and Armv9.0 compliant.

An Armv9.2 compliant implementation must also be Armv8.7 and Armv9.1 compliant.

An Armv9.3 compliant implementation must also be Armv8.8 and Armv9.2 compliant.
Part B
The AArch64 Application Level Architecture
Chapter B1
The AArch64 Application Level Programmers’ Model

This chapter describes the AArch64 application level programmers’ model. It contains the following sections:

- About the Application level programmers’ model on page B1-136.
- Registers in AArch64 Execution state on page B1-137.
- Software control features and EL0 on page B1-146.
B1.1 About the Application level programmers’ model

This chapter contains the programmers’ model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers’ model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different Exception levels that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information, see Exception levels on page D1-4632.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to Chapter D1 The AArch64 System Level Programmers’ Model.
B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- Registers in AArch64 state
- Process state, PSTATE on page B1-142
- System registers on page B1-144

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an Arm processing element has:

**R0-R30**

31 general-purpose registers, R0 to R30. Each register can be accessed as:
- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

See the register name mapping in Figure B1-1.

**Note**

In instruction encodings, the value 0b11111 (31) is used to indicate the ZR (zero register). This indicates that the argument takes the value zero, but does not indicate that the ZR is implemented as a physical register.

**SP**

A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack pointer can be accessed using the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

**Note**

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information, see the Procedure Call Standard for the Arm 64-bit Architecture.

**PC**

A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can be updated only on a branch, exception entry or exception return.

**Note**

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see PC alignment checking on page D1-4668.

**V0-V31**

32 SIMD&FP registers, V0 to V31. Each register can be accessed as:
- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.
- A 128-bit vector of elements.
A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See Figure B1-2.

**FPCR, FPSR** Two SIMD and floating-point control and status registers, FPCR and FPSR.

**Z0-Z31** 32 scalable vector registers, Z0 to Z31. Each register can be accessed as:

- A vector of elements with an IMPLEMENTATIONDEFINED maximum length of 128 to 2048 bits.
- A fixed-length 128-bit vector of elements named V0 to V31.
- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.

**P0-P15** 16 SVE scalable predicate registers, P0 to P15. See SVE predicate registers on page B1-141.

**FFR** The dedicated SVE First Fault Register that has the same size and format as the predicate registers, P0-P15. See FFR, First Fault Register on page B1-142.

For more information on SVE registers, see SVE vector registers on page B1-140 and SVE writes to scalar registers on page B1-141.

For more information about data types and vector formats, see Supported data types on page A1-42.
Pseudocode description of registers in AArch64 state

In the pseudocode functions that access registers:

• The assignment form is used for register writes.
• The non-assignment for register reads.

The uses of the X[] function are:

• Reading or writing X0-X30, using n to index the required register.
• Reading the zero register ZR, accessed as X[31].

Note

The pseudocode use of X[31] to represent the zero register does not indicate that hardware must implement this register.

The AArch64 SP[] function is used to read or write the current SP.

The AArch64 PC[] function is used to read the PC.

The AArch64 V[] function is used to read or write the Advanced SIMD and floating-point registers V0-V31, using a parameter n to index the required register.

The AArch64 Vpart[] function is used to read or write a part of one of V0-V31, using a parameter n to index the required register, and a parameter part to indicate the required part of the register, see the function description for more information.

The AArch64 Z[] function is used to read or write the SVE scalable vector registers Z0-Z31, using a parameter n to index the required register.

The Z[], V[] and Vpart[] functions access the same underlying vector register file.

The X[], SP[], PC[], V[], Vpart[], and Z[] functions are defined in Chapter J1 Armv8 Pseudocode.
### SVE vector registers

SVE has 32 scalable vector registers named Z0-Z31.

All SVE scalable vector registers are the same size.

The size of an SVE scalable vector register is an IMPLEMENTATION DEFINED multiple of 128 bits.

The maximum size of an SVE scalable vector register is 2048 bits.

The minimum size of an SVE scalable vector register is 128 bits.

Unless stated otherwise in an instruction description, SVE instructions treat an SVE scalable vector register as containing one or more vector elements that are equal in size.

Unless stated otherwise in an instruction description, vector elements can be processed in parallel by SVE instructions.

When an SVE scalable vector register is divided into vector elements by an instruction, the size of the vector elements is encoded in the opcode of the instruction. The size of the vector elements is 8, 16, 32, 64, or 128 bits.

When the order of operations performed by an SVE instruction on vector or predicate elements has observable significance, elements are processed in increasing element number order.

The layouts of an SVE 256-bit vector register and a SIMD&FP vector in AArch64 state are:

![Figure B1-4 SVE vectors in AArch64 state](image-url)
Bits[127:0] of each of the SVE scalable vector registers, Z0-Z31, hold the correspondingly numbered AArch64 SIMD&FP register, V0-V31.

When the accessible SVE vector length at the current Exception level is greater than 128 bits, any AArch64 instruction that writes to V0-V31 sets all the accessible bits above bit [127] of the corresponding SVE scalable vector register to zero.

**SVE writes to scalar registers**

Certain SVE instructions generate a scalar result that is written to an AArch64 general-purpose register or to element[0] of a vector register.

When an SVE instruction generates a scalar result of width N bits, the instruction places the result in bits [N-1:0] of the destination register.

When an instruction generates a scalar result of width N bits, and N is less than the maximum accessible destination register width RW, the instruction sets bits [RW-1:N] of the destination register to zero.

**B1.2.3 SVE predicate registers**

SVE has 16 scalable predicate registers named P0-P15.

Each SVE predicate register holds one bit for each byte of a vector register.

The size of an SVE predicate register is an IMPLEMENTATION DEFINED multiple of 16 bits.

The maximum size of an SVE predicate register is 256 bits.

The minimum size of an SVE predicate register is 16 bits.

Unless stated otherwise in the instruction description, SVE instructions treat an SVE predicate register as containing one or more predicate elements of equal size.

Each predicate register can be subdivided into a number of 1-bit, 2-bit, 4-bit, or 8-bit elements.

Each predicate element in a predicate register corresponds to a vector element.

When a predicate register is divided into predicate elements by an instruction, the size of the predicate elements is encoded in the opcode of the instruction.

If the lowest-numbered bit of a predicate element is 1, the value of the predicate element is TRUE.

If the lowest-numbered bit of a predicate element is 0, the value of the predicate element is FALSE.

For all SVE instructions, if all of the following are true, all bits except the lowest-numbered bit of each predicate element are ignored on reads:

- The instructions are not used to move and permute predicate elements.
- The instructions are not predicate logical operations.

For all SVE instructions, if all of the following are true, all bits except the lowest-numbered bit of each predicate element are set to zero on writes:

- The instructions are not used to move and permute predicate elements.
- The instructions are not predicate logical operations.
B1.2.4 FFR, First Fault Register

SVE has a dedicated First Fault Register named FFR.

The FFR captures the cumulative fault status of a sequence of SVE First-fault and Non-fault vector load instructions.

The FFR and the predicate registers have the same size and format.

The FFR is a Special-purpose register.

All bits in the FFR that are accessible at the current Exception level are initialized to 1 by using the `SETFFR` instruction.

Bits in the FFR are indirectly set to 0 as a result of a suppressed access or fault generated in response to an Active element of an SVE First-fault or Non-fault vector load.

Bits in the FFR are never set to 1 as a result of a vector load instruction.

After a sequence of one or more SVE First-fault or Non-fault loads that follow a `SETFFR` instruction, the FFR contains a sequence of zero or more TRUE elements, followed by zero or more FALSE elements.

The TRUE elements in the FFR indicate the shortest sequence of consecutive elements that could contain valid data loaded from memory.

The only instructions that directly read the FFR are:
- `RDFFR` (predicated).
- `RDFFRS`.

The only instructions that directly write the FFR are:
- `WRFFR`.
- `SETFFR`.

All direct and indirect reads and writes to the FFR occur in program order relative to other instructions, without explicit synchronization.

B1.2.5 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N  Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
   • 1 if the result is negative.
   • 0 if the result is positive or zero.

Z  Zero Condition flag. Set to:
   • 1 if the result of the instruction is zero.
   • 0 otherwise.
   A result of zero often indicates an equal result from a comparison.

C  Carry Condition flag. Set to:
   • 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
   • 0 otherwise.
V  Overflow Condition flag. Set to:
  • 1 if the instruction results in an overflow condition, for example a signed
    overflow that is the result of an addition.
  • 0 otherwise.

Conditional instructions test the N, Z, C and V Condition flags, combining them with the Condition
code for the instruction to determine whether the instruction must be executed. In this way,
execution of the instruction is conditional on the result of a previous operation. For more
information about conditional execution, see Condition flags and related instructions on
page C6-1167.

The exception masking bits

D  Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is
    visible and can be modified. However, this bit is architecturally ignored at EL0.

A  SError interrupt mask bit.

I  IRQ interrupt mask bit.

F  FIQ interrupt mask bit.

For each bit, the values are:
0  Exception not masked.
1  Exception masked.

Access at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

See Process state, PSTATE on page D1-4670 for the system level view of PSTATE.

Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly
read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the
Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using
AArch64. All other PSTATE fields do not have direct read and write access at EL0.

Software can also use the MSR (immediate) instruction to directly write to PSTATE. {D, A, I, F}. Table B1-2 shows
the MSR (immediate) operands that can directly write to PSTATE. {D, A, I, F} when the PE is at EL0 using AArch64
state.

However, access to the PSTATE. {D, A, I, F} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

Writers to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are
guaranteed:
• Not to be visible to earlier instructions in the execution stream.
• To be visible to later instructions in the execution stream.
SVE use of PSTATE N, Z, C, and V Condition flags

This section describes the SVE-specific use of PSTATE.

PSTATE N, Z, C and V condition flags can be updated by any of the following:

- An SVE instruction that generates a predicate result and updates the PSTATE N, Z, C and V Condition flags based on the value of the result.
- An SVE instruction that updates the PSTATE N, Z, C and V Condition flags based on the value in its predicate source register or FFR:
  - PTEST.
  - RDFFR (predicated).
- An SVE instruction that updates the PSTATE N, Z, C and V Condition flags based on the values in its general-purpose source registers:
  - CTERMEQ, CTERMNE.

When setting the PSTATE N, Z, C and V Condition flags for SVE predicated flag-setting instructions, the instruction's Governing predicate determines which predicate elements are considered Active.

When setting the PSTATE N, Z, C and V Condition flags for SVE unpredicated flag-setting instructions, all predicate elements are considered Active.

Unless otherwise specified in an instruction description, the SVE flag-setting instructions update the PSTATE N, Z, C and V Condition flags as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>SVE Name</th>
<th>SVE interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>First</td>
<td>Set to 1 if the First active element was TRUE, otherwise cleared to 0.</td>
</tr>
<tr>
<td>Z</td>
<td>None</td>
<td>Cleared to 0 if any Active element was TRUE, otherwise set to 1.</td>
</tr>
<tr>
<td>C</td>
<td>Not last</td>
<td>Cleared to 0 if the Last active element was TRUE, otherwise set to 1.</td>
</tr>
<tr>
<td>V</td>
<td>-</td>
<td>Cleared to 0.</td>
</tr>
</tbody>
</table>

B1.2.6 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register with the access right disabled causes the instruction to behave as UNDEFINED. The registers that can be accessed from EL0 are:

- **Cache ID registers**: The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.
- **Debug registers**: A Debug Communications Channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0 and DBGDTRTX_EL0 registers.
- **Performance Monitors registers**: The Performance Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure some of these registers to be accessible at EL0. For more details, see Chapter D11 *The Performance Monitors Extension*.
- **Activity Monitors registers**: The Activity Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure these registers to be accessible at EL0.
For more details, see Chapter D12 *The Activity Monitors Extension*.

**Thread ID registers**
The TPIDR_EL0 and TPIDRRO_EL0 registers are two thread ID registers with different access rights.

**Timer registers**
The following operations are performed by these registers:

- Read access to the system counter clock frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0 and CNTVCT_EL0.
- Physical up-count comparison, down-count value and timer control registers, CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0.
- Virtual up-count comparison, down-count value and timer control registers, CNTV_CVAL_EL0, CNTV_TVAL_EL0, and CNTV_CTL_EL0.
B1.3 Software control features and EL0

The following sections describe the EL0 view of the software control features:

- Exception handling
- Wait for Interrupt and Wait for Event
- The YIELD instruction
- Application level cache management on page B1-147
- Instructions relating to Debug on page B1-147
- About PSTATE.DIT on page B1-123

B1.3.1 Exception handling

In the Arm architecture, an exception causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:
- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in Chapter D1 The AArch64 System Level Programmers' Model.

The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The BRK instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see Breakpoint Instruction exceptions on page D2-4705.

--- Note ---

The BRK instruction is supported only in the A64 instruction set. The equivalent instruction in the T32 and A32 instruction sets is BKPT.

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a WFI instruction indicates that no further execution is required until a WFI wake-up event occurs, see Wait for Interrupt mechanism on page D1-4678. This permits entry to a low-power state.

Issuing a WFE instruction indicates that no further execution is required until a WFE wake-up event occurs, see Wait for Event on page D1-4676. This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The YIELD instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see YIELD on page C6-2037. This mechanism can be used to improve overall performance in a Symmetric Multithreading (SMT) or Symmetric Multiprocessing (SMP) system.

Examples of when the YIELD instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The YIELD instruction permits binary compatibility between SMT and SMP systems.

The YIELD instruction is a NOP hint instruction.
The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

### B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 System register. Any access from EL0 to an operation with the access right disabled causes the instruction to behave as UNDEFINED.

About the available operations, see Application level access to functionality related to caches on page B2-185.

### B1.3.5 Instructions relating to Debug

Exception handling on page B1-146 refers to the BRK instruction, which generates a Breakpoint Instruction exception. In addition, in both AArch64 state and AArch32 state, the HLT instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see Chapter H1 About External Debug.

---

**Note**

In AArch32 state, previous versions of the architecture defined the DBG instruction, which could provide a hint to the debug system. This instruction executes as a NOP. Arm deprecates the use of the DBG instruction.

### B1.3.6 About PSTATE.DIT

When the value of PSTATE.DIT is 1:

- The instructions listed in DIT are required to have:
  - Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
  - Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.

- All loads and stores must have their timing insensitive to the value of the data being loaded or stored.

---

**Note**

- The use of value prediction for load data values when PSTATE.DIT is set, is not compatible with the requirement that the timing is insensitive to the data value being loaded.

- Arm recommends that the FEAT_PAuth instructions do not have their timing dependent on the key value used in the pointer authentication, regardless of the PSTATE.DIT bit.

- When the value of PSTATE.DIT is 0, the architecture makes no statement about the timing properties of any instructions. However, it is likely that these instructions have timing that is invariant of the data in many situations.

- If SVE2 is not implemented, the data independent timing control introduced by FEAT_DIT does not affect the timing properties of SVE instructions.

- The Operational information section of an SVE or an SVE2 instruction description indicates whether or not that instruction honors the PSTATE.DIT control. If the Operational information section of an SVE instruction description does not mention PSTATE.DIT or if the section does not exist, then the instruction timing is not affected by PSTATE.DIT.

- For SVE and SVE2 predicated instructions, it is the programmer’s responsibility to use a Governing predicate that does not reflect the values of the data being operated on.

---

A corresponding DIT bit is added to PSTATE in AArch64 state, and to CPSR in AArch32 state.
On an exception that is taken from AArch64 state to AArch64 state, PSTATE.DIT is copied to SPSR_ELx.DIT.

On an exception that is taken from AArch32 state to AArch64 state, CPSR.DIT is copied to SPSR_ELx.DIT.

On an exception return from AArch64 state:
- SPSR_ELx.DIT is copied to PSTATE.DIT, when the target Exception level is in AArch64 state.
- SPSR_ELx.DIT is copied to CPSR.DIT, when the target Exception level is in AArch32 state.

PSTATE.DIT can be written and read at all Exception levels.

--- Note ---
- PSTATE.DIT is unchanged on entry into Debug state.
- PSTATE.DIT is not guaranteed to have any effect in Debug state.
B1.4 SVE predicated instructions

IVKHDR If an instruction supports predication, it is known as a predicated instruction.

IFNFRN The predicate operand that is used to determine the Active elements of a predicated instruction is known as the Governing predicate.

ISVYXB An instruction that does not have a Governing predicate operand and implicitly treats all other vector and predicate elements as Active is known as an unpredicated instruction.

IKNKBN Many predicated instructions can only use P0-P7 as the Governing predicate.

ILZVFFJ When a Governing predicate element is TRUE, the corresponding element in other vector or predicate operands is an Active element.

ICNFLG When a Governing predicate element is FALSE, the corresponding element in other vector or predicate operands is an Inactive element.

ICBYYJH Predicated instructions process Active elements.

ILDXSF Predicated instructions do not process Inactive elements.

IGILPZ Unpredicated instructions process all elements in their vector or predicate operands.

ILWLQBD When a predicated instruction writes to a vector destination register or a predicate destination register, one of the following happens:

- The Inactive elements in the destination register are set to zero.
- The Inactive elements in the destination register retain their previous value.

IQBHRN Zeroing predication is performed when the Inactive elements in the destination register are set to zero.

IFYRF Merging predication is performed when Inactive elements in the destination register retain their previous value.
B1.4 SVE predicated instructions
Chapter B2  
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- About the Arm memory model on page B2-152.
- Definition of the Arm memory model on page B2-159.
- Caches and memory hierarchy on page B2-184.
- Alignment support on page B2-189.
- Endian support on page B2-192.
- Memory types and attributes on page B2-196.
- Synchronization and semaphores on page B2-211.

--- Note ---

In this chapter, System register names usually link to the description of the register in Chapter D17 AArch64 System Register Descriptions, for example. SCTLR_EL1.
B2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be reordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.
- If FEAT_MTE2 is implemented, the definitions of the memory model which apply to data accesses and data apply to Allocation Tag accesses and Allocation tags.

This section contains:
- Address space.
- Memory type overview.

B2.1.1 Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top eight address bits for use as a tag, as described in Address tagging on page D8-5162. If this is done, address bits[63:56]:

- Are not considered when determining whether the address is valid.
- Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Simple sequential execution of instructions might overflow the valid address range. For more information, see Virtual address space overflow on page D7-5041.

Memory accesses use the Mem[] function. This function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

The AccType{} enumeration defines the different access types.

Note

- Chapter D7 The AArch64 System Level Memory Model and Chapter D8 The AArch64 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see Basic memory access on page D7-5075, Unaligned memory access on page D7-5075, and Aligned memory access on page D7-5075.

B2.1.2 Memory type overview

The Arm architecture provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read/write and read-only operations.
The Arm architecture forbids *Speculative* reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive Locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page B2-203.
- They preserve the access order and synchronization requirements for accesses to a single peripheral. See *Reordering* on page B2-204.
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page B2-205.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page B2-196.

---

**Note**

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A Note in *Device memory* on page B2-200 describes how these memory types map onto the Armv8 memory types.

---

**B2.1.3 SVE memory model**

SVE predicated memory operations have a vector element size and a memory element access size. The vector element size specifies the data that is read from and written to the vector. The memory element access size specifies the amount of data that is read from and written to the memory.

The vector element size and the memory element access size do not need to have the same value.

For each memory element, there is an associated element address.

SVE also affects behavior in the following areas:

- *SVE memory ordering relaxations* on page B2-170.
- *Load or Store of Single or Multiple registers* on page B2-189.
- *SVE loads and stores that access Device memory* on page B2-206.
B2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The Arm architecture description refers to two types of atomicity, single-copy atomicity and multi-copy atomicity. In the Arm architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Requirements for single-copy atomicity.
- Properties of single-copy atomic accesses on page B2-156.
- Multi-copy atomicity on page B2-156.
- Requirements for multi-copy atomicity on page B2-156.
- Concurrent modification and execution of instructions on page B2-156.

For more information about the memory types, see Memory type overview on page B2-152.

B2.2.1 Requirements for single-copy atomicity

For explicit memory effects generated from an Exception level the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

Note

To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see Concurrent modification and execution of instructions on page B2-156.
- Reads to SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
- Writes from SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.
- Element or Structure Reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.
- Element or Structure Writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.
- Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.
- Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.
- Atomicity rules for SIMD load and store instructions also apply to SVE load and store instructions.
- SVE predicated load and store instructions are performed as a sequence of memory element accesses.
• If an SVE predicated load or store instruction uses an element address that is aligned to the specified memory element access size, the related element memory access is performed as a single-copy atomic access.
• SVE unpredicated load and store instructions are performed as a sequence of byte accesses.
• SVE unpredicated load and store instructions do not guarantee that any access larger than a byte will be performed as a single-copy atomic access.
• When FEAT_LS64 is implemented, a single-copy atomic load of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte read from the target address.
• When FEAT_LS64 is implemented, a single-copy atomic store of a 64-byte value that is 64-byte aligned in memory is treated as an atomic 64-byte write to the target address.
• For unaligned memory accesses, the single-copy atomicity is described in Alignment of data accesses on page B2-189.
• The reads and writes of the two words or two double-words accessed by CASP instructions are single-copy atomic at the size of the two words or double-words.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

--- Note ---
In AArch64 state, no memory accesses from a DC ZVA have single-copy atomicity of any quantity greater than individual bytes.

---

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also Taking an interrupt during a multi-access load or store on page D1-4664.

--- Note ---
The exception behavior for these multiple access instructions means that they are not suitable for use for writes to memory for the purpose of software synchronization.

---

Changes to single-copy atomicity in Armv8.4

In addition to the single-copy atomicity requirements listed above:

Instructions that are introduced in FEAT_LRCPC are single-copy atomic when all of the following conditions are true:
• All bytes being accessed are within the same 16-byte quantity aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If FEAT_LSE2 is implemented, all loads and stores are single-copy atomic when all of the following conditions are true:
• Accesses are unaligned to their data size but all bytes being accessed are within a 16-byte quantity that is aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If FEAT_LSE2 is implemented, LDP, LDNP, and STP instructions that load or store two 64-bit registers are single-copy atomic when all of the following conditions are true:
• The overall memory access is aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If FEAT_LSE2 is implemented, LDP, LDNP, and STP instructions that access fewer than 16 bytes are single-copy atomic when all of the following conditions are true:
• All bytes being accessed are within a 16-byte quantity aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.
B2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.

2. For a single-copy atomic load instruction $L_1$ that overlaps a single-copy atomic store instruction $S_2$, if one of the overlapping reads generated by $L_1$ Reads-from one of the overlapping writes generated by $S_2$, then none of the overlapping writes generated by $S_2$ are Coherence-after the corresponding overlapping reads generated by $L_1$.

For more information, see Definition of the Arm memory model on page B2-159.

B2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are multi-copy atomic if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note
Writes that are not coherent are not multi-copy atomic.

B2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Arm memory model is Other-multi-copy atomic. For more information, see External ordering constraints on page B2-166.

B2.2.5 Concurrent modification and execution of instructions

The Arm architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where each of the instruction before modification and the instruction after modification is one of a B, B.cond, BL, BRK, CBNZ, CBZ, HVIC, ISB, NOP, SMC, SVC, TBNZ or TBZ instruction.

For the B, B.cond, BL, BRK, CBNZ, CBZ, HVIC, ISB, NOP, SMC, SVC, TBNZ and TBZ instructions, the architecture guarantees that after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

   ; Coherency example for data and instruction accesses within the same Inner Shareable domain.
   ; enter this code with <Wt> containing a new 32-bit instruction,
   ; to be held in Cacheable space at a location pointed to by Xn.
   STR Wt, [Xn]
The AArch64 Application Level Memory Model
B2.2 Atomicity in the Arm architecture

DC CVAU, Xn ; Clean data cache by VA to point of unification (PoU)
DSB ISH ; Ensure visibility of the data cleaned from cache
IC IVAU, Xn ; Invalidate instruction cache by VA to PoU
DSB ISH

Note
• The DC CVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
• If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
• In a multiprocessor system, the DC CVAU and IC IVAU are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence.

3. When the modified instructions are observable, each PE that is executing the modified instructions must execute an ISB or perform a context synchronizing event to ensure execution of the modified instructions:
   ISB ; Synchronize fetched instruction stream

For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses on page B2-187.

For information about memory accesses caused by instruction fetches, see Ordering relations on page B2-163.

B2.2.6 Possible implementation restrictions on using atomic instructions

In some implementations, and for some memory types, the properties of atomicity can be met only by functionality outside the PE. Some system implementations might not support atomic instructions for all regions of the memory. In particular, this can apply to:
• Any type of memory in the system that does not support hardware cache coherency.
• Device, Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such implementations, it is defined by the system:
• Whether the atomic instructions are atomic in regard to other agents that access memory.
• If the atomic instructions are atomic in regard to other agents that access memory, which address ranges or memory types this applies to.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the atomic instructions will be atomic are:
• Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
• Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The architecture only requires that Conventional memory that is mapped in this way supports this functionality.

If the atomic instructions are not atomic in regard to other agents that access memory, then performing an atomic instruction to such a location can have one or more of the following effects:
• The instruction generates a synchronous External abort.
• The instruction generates a System Error interrupt.
• The instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = 110101.
For the EL1&0 translation regime, if the atomic instruction is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.

- The instruction is treated as a `nop`.
- The instructions are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a System Error interrupt.
B2.3 Definition of the Arm memory model

This section describes observation and ordering in the Arm memory model. It contains the following subsections:

- **Basic definitions**
- **Dependency definitions** on page B2-162.
- **Ordering relations** on page B2-163.
- **Ordering constraints** on page B2-165.
- **Internal visibility requirement** on page B2-166.

For more information about endpoint ordering of memory accesses, see *Reordering* on page B2-204.

In the Arm memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see *Memory types and attributes* on page B2-196.

The Arm architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:
- **Chapter D7 The AArch64 System Level Memory Model**.
- **Chapter D8 The AArch64 Virtual Memory System Architecture**.

See also *Mismatched memory attributes* on page B2-208.

### B2.3.1 Basic definitions

The Arm memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

**Observer**

An *Observer* refers to a processing element or mechanism in the system, such as a peripheral device, that can generate reads from, or writes to, memory.

**Common Shareability Domain**

For the purpose of this section, all *Observers* are assumed to belong to a Common Shareability Domain. All read and write effects access only Normal memory locations in a Common Shareability Domain, and excludes the situations described in *Mismatched memory attributes* on page B2-208.

**Location**

A *Location* is a byte that is associated with an address in the physical address space.

--- **Note** ---

It is expected that an operating system will present the illusion to the application programmer that is consistent with a location also being considered as a byte that is associated with an address in the virtual address space.

---

**Effects**

The *Effects* of an instruction can be:

- Register effects.
- Memory effects.
- Barrier effects.
- Tag effects.
- Branching effects.
The effects of an instruction $I_1$ are said to appear in program order before the effects of an instruction $I_2$ if and only if $I_1$ occurs before $I_2$ in the order specified by the program. Each effect generated by an instruction has a unique identifier, which characterizes it amongst the events generated by the same instruction.

**Register effect**

The *Register effects* of an instruction are register reads or register writes of that instruction. For an instruction that accesses registers, a register read effect is generated for each register read by the instruction and a register write effect is generated for each register written by the instruction. An instruction may generate both read and write Register effects.

**Memory effect**

The *Memory effects* of an instruction are the memory reads or writes generated by that instruction. For an instruction that accesses memory, a memory read effect is generated for each Location read by the instruction and a memory write effect is generated for each Location written by the instruction. An instruction may generate both read and write Memory effects.

**Tag effect**

The *Tag effects* of a Memory Tagging instruction are the memory read or write effects of that instruction that affect tag locations.

**Tag-read**

A *Tag-read* is a read of a tag location generated by an $LDG$ instruction.

**Tag-write**

A *Tag-write* is a write of a tag location generated by an $STG$ instruction.

**Tag-Check-read**

A *Tag-Check-read* is a read of a tag location that is generated by a checked memory access. All other reads and writes are considered Data accesses.

**Branching effect**

The *Branching effects* of an instruction are effects which correspond to a branching decision being taken.

Note

Conditional and compare-and-swap instructions do not create Branching effects.

**Intrinsic order**

There is a per-instruction *Intrinsic order* relation that provides a partial order over the effects of that instruction, according to the operation of that instruction.

The operation of an instruction is defined by the pseudocode in Chapter C6 *A64 Base Instruction Descriptions*.

**Reads-from-register**

The *Reads-from-register* relation couples register read and write effects to the same register such that each register read effect is paired with exactly one register write effect in the execution of a program. A register read effect $R_2$ Reads-from-register a register write effect $W_1$ to the same register if and only if $R_2$ takes its data from $W_1$. By construction $W_1$ must be in program order before $R_2$ and there must be no intervening write to the same register in program order between $W_1$ and $R_2$.

**Reads-from**

The *Reads-from* relation couples memory read and write effects to the same Location such that each memory read effect is paired with exactly one memory write effect in the execution of a program. A memory read effect $R_2$ from a Location Reads-from a memory write effect $W_1$ to the same Location if and only if $R_2$ takes its data from $W_1$.
Coherence order
There is a per-location Coherence order relation that provides a total order over all memory write effects from all coherent Observers to that Location, starting with a notional memory write effect of the initial value. The Coherence order of a Location represents the order in which memory write effects to the Location arrive at memory.

Local read successor
A memory read effect R2 of a Location is the Local read successor of a memory write effect W1 from the same Observer to the same Location if and only if W1 appears in program order before R2 and there is not a memory write effect W3 from the same Observer to the same Location appearing in program order between W1 and R2.

Local write successor
A memory write effect W2 of a Location is a Local write successor of a memory read or write effect RW1 from the same Observer to the same Location if and only if RW1 appears in program order before W2.

Coherence-after
A memory write effect W2 to a Location is Coherence-after another memory write effect W1 to the same Location if and only if W2 is sequenced after W1 in the Coherence order of the Location.
A memory write effect W2 to a Location is Coherence-after a memory read effect R1 of the same location if and only if R1 Reads-from a memory write effect W3 to the same Location and W2 is Coherence-after W3.

Observed-by
A memory read or write effect RW1 from an Observer is Observed-by a memory write effect W2 from a different Observer if and only if W2 is coherence-after RW1.
A memory write effect W1 from an Observer is Observed-by a memory read effect R2 from a different Observer if and only if R2 Reads-from W1.

Note
The Observed-by relation relates only Memory effects generated by different Observers.

Overlapping accesses
Two Memory effects overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Single-copy-atomic-ordered-before
A memory read effect R1 is Single-copy-atomic-ordered-before another memory read effect R2 if and only if all of the following statements are true:
• R1 and R2 are memory read effects generated by the same instruction.
• R1 is not a Local read successor of a memory write effect.
• R2 is a Local read successor of a memory write effect.

DMB FULL
A DMB FULL is a DMB with neither the LD or the ST qualifier.
Where this section refers to DMB without any qualification, then it is referring to all types of DMB. Unless a specific shareability domain is defined, a DMB applies to the Common Shareability Domain.
All properties that apply to DMB also apply to the corresponding DSB.

Context synchronization instruction
A Context synchronization instruction is one of the following:
• An ISB instruction.
• An instruction that generates a synchronous exception.
B2.3 Definition of the Arm memory model

B2.3.2 Dependency definitions

Dependency through registers

A Dependency through registers from a first effect E1 to a second effect E2 exists within a PE if and only if at least one of the following applies:

- E1 is a register write effect W1 which has not been generated by a Store Exclusive, E2 is a register read effect R2 and R2 Reads-from-register W1.
- E1 and E2 have been generated by the same instruction and E1 is before E2 in the Intrinsic order of that instruction.
- There is a Dependency through registers from E1 to a third effect E3, and there is a Dependency through registers from E3 to E2.

Address dependency

An Address dependency from a memory read effect R1 to a Memory effect RW2 exists if and only if there is a Dependency through registers from R1 to a Register effect E3 generated by RW2, and E3 affects the address part of RW2, and either:

- RW2 is a memory write effect W2.
- RW2 is a memory read effect R2 and there is no Branching effect D4 such that there is a Dependency through registers from R1 to D4 and from D4 to R2.

Note

An Address dependency exists from a memory read effect R1 to a Tag-Check-read R2 if and only if there is a Dependency through registers from R1 to the address part of R2.

Data dependency

A Data dependency from a memory read effect R1 to a memory write effect W2 exists if and only if there is a Dependency through registers from R1 to a Register effect E3 generated by W2, and E3 affects the data part of W2.

Control dependency

A Control dependency from a memory read effect R1 to a Memory effect RW2 exists if and only if either:

- There is a Dependency through registers from R1 to a Branching effect B3 and B3 is in program order before RW2.
- There is a Dependency through registers from R1 to the determination of a synchronous exception on an instruction generating an effect RW3, and RW2 appears in program order after RW3.

Note

This notion is under review. Arm’s intent is that a branch instruction between a read and a write, where the branch condition is dependent on the read, will provide order, regardless of whether the branch is taken. This applies only to branch instructions and not to conditional selection or other conditional data processing instructions. A formal definition of this change will be issued soon as an erratum to the Armv8 Architecture Reference Manual.

Pick Basic dependency

A Pick Basic dependency from a read Register effect or read Memory effect R1 to a Register effect or Memory effect E2 exists if and only if one of the following applies:

- There is a Dependency through registers from R1 to E2.
• There is an Intrinsic Control dependency from \( R_1 \) to \( E_2 \).
• There is a Pick Basic dependency from \( R_1 \) to an Effect \( E_3 \) and there is a Pick Basic dependency from \( E_3 \) to \( E_2 \).

### Pick Address dependency

A Pick Address dependency from a read Register effect or read Memory effect \( R_1 \) to a read or write Memory effect \( RW_2 \) exists if and only if all of the following apply:

• There is a Pick Basic dependency from \( R_1 \) to a Register effect \( E_3 \).
• There is an Intrinsic data dependency from the Register effect \( E_3 \) to \( RW_2 \).
• The Register effect \( E_3 \) affects the address of the location accessed by \( RW_2 \).

### Pick Data dependency

A Pick Data dependency from a read Register effect or read Memory effect \( R_1 \) to a write Memory effect \( W_2 \) exists if and only if all of the following apply:

• There is a Pick Basic dependency from \( R_1 \) to a Register effect \( E_3 \).
• There is an Intrinsic data dependency from the Register effect \( E_3 \) to \( RW_2 \).
• The Register effect \( E_3 \) affects the value written by \( W_2 \).

### Pick Control dependency

A Pick Control dependency from a read Register effect or read Memory effect \( R_1 \) to an effect \( E_2 \) exists if and only if all of the following apply:

• There is a Pick Basic dependency from \( R_1 \) to a Branching effect \( BR_3 \).
• The Branching effect \( BR_3 \) is in program order before \( E_2 \).

### Pick dependency

A Pick dependency from a read Register effect or read Memory effect \( R_1 \) to an effect \( E_2 \) exists if and only if one of the following applies:

• There is a Pick Basic dependency from \( R_1 \) to \( E_2 \).
• There is a Pick Address dependency from \( R_1 \) to \( E_2 \).
• There is a Pick Data dependency from \( R_1 \) to \( E_2 \).
• There is a Pick Control dependency from \( R_1 \) to \( E_2 \).

### Ordering relations

Dependency-ordered-before

A dependency creates externally-visible order between a memory read effect and another Memory effect generated by the same Observer. A memory read effect \( R_1 \) is Dependency-ordered-before a memory read or write effect \( RW_2 \) from the same Observer if and only if \( R_1 \) appears in program order before \( RW_2 \) and any of the following cases apply:

• There is an Address dependency or a Data dependency from \( R_1 \) to \( RW_2 \).
• \( RW_2 \) is a memory write effect \( W_2 \) and there is a Control dependency from \( R_1 \) to \( W_2 \).
• \( RW_2 \) is a memory read effect \( R_2 \) generated by an instruction appearing in program order after an instruction that generates a Context synchronization event \( E_3 \), and there is a Dependency through registers from \( R_1 \) to \( E_3 \).
• \( RW_2 \) is a memory write effect \( W_2 \) appearing in program order after a memory read or write effect \( RW_3 \) and there is an Address dependency on a Memory effect \( W_3 \) from \( R_1 \) to \( W_3 \).
• \( RW_2 \) is a Local read successor \( R_2 \) of a memory write effect \( W_3 \) and there is an Address dependency or a Data dependency from \( R_1 \) to \( W_3 \).
Pick-ordered-before

A read Register effect or read Memory effect $R_1$ is **Pick-ordered-before** a read or write Memory effect $RW_2$ from the same Observer if and only if $R_1$ appears in program order before $RW_2$ and any of the following cases apply:

- $RW_2$ is a write Memory effect $W_2$ and there is a Pick dependency from $R_1$ to $W_2$.
- $RW_2$ is a read Memory effect $R_2$ generated by an instruction appearing in program order after an instruction that generates a Context synchronization event $E_3$, and there is a Pick Control dependency from $R_1$ to $E_3$.
- $RW_2$ is a Memory effect generated by an instruction appearing in program order after an instruction that generates a Context synchronization event $E_3$, there is a Pick Address dependency from $R_1$ to an effect $E_4$ and $E_4$ is in program order before $E_3$.
- $RW_2$ is a write Memory effect $W_2$, there is a Pick Address dependency from $R_1$ to a read or write Memory effect $RW_3$ and $W_2$ is program-order-after $RW_3$.

Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write Memory effect $RW_1$ is **Atomic-ordered-before** a read or write Memory effect $RW_2$ from the same Observer if and only if $RW_1$ appears in program order before $RW_2$ and either of the following cases apply:

- $RW_1$ is a read Memory effect $R_1$ and $RW_2$ is a write Memory effect $W_2$ such that $R_1$ and $W_2$ are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same Location.
- $RW_1$ is a read Memory effect $R_1$ generated by an atomic instruction (resp. a Load-Exclusive instruction) and $RW_2$ is a read Memory effect $R_2$ generated by an instruction with Acquire or AcquirePC semantics such that $R_2$ is a Local read successor of the write Memory effect $W_3$ generated by the same atomic instruction as $R_1$ (resp. the successful Store-Exclusive instruction paired with the Load-Exclusive instruction that generated $R_1$).

For more information, see [Synchronization and semaphores](#) on page B2-211.

Barrier-ordered-before

Barrier instructions order prior Memory effects before subsequent Memory effects generated by the same Observer. A memory read or write effect $RW_1$ is **Barrier-ordered-before** a memory read or write effect $RW_2$ from the same Observer if and only if $RW_1$ appears in program order before $RW_2$ and any of the following cases apply:

- $RW_1$ appears in program order before a **DMB FULL** that appears in program order before $RW_2$.
- $RW_1$ is a memory write effect $W_1$ and is generated by an atomic instruction with both Acquire and Release semantics.
- $RW_1$ is a memory write effect $W_1$ generated by an instruction with Release semantics and $RW_2$ is a memory read effect $R_2$, except a Tag-Check-read, generated by an instruction with Acquire semantics.
- $RW_1$ is a memory read effect $R_1$ and appears in program order before a **DMB LD** that appears in program order before $RW_2$.
- $RW_1$ is a memory read effect $R_1$, except a Tag-Check-read, and is generated by an instruction with Acquire or AcquirePC semantics.
- $RW_1$ is a memory write effect $W_1$ and $RW_2$ is a memory write effect $W_2$ appearing in program order before a **DMB ST** that appears in program order before $W_2$.
- $RW_2$ is a memory write effect $W_2$ and is generated by an instruction with Release semantics.
Tag-ordered-before

If FEAT_MTE2 is implemented, a Tag read \( R_1 \) is Tag-ordered-before a memory read or write effect Checked data access \( RW_2 \) generated by the same instruction if and only if all of the following apply:

- \( R_1 \) is in the Intrinsic order of that instruction before \( RW_2 \).
- \( R_1 \) reads the Allocation Tag at a tag physical address and compares it with the physical address Tag of the instruction. If the result of the comparison can cause a precise exception and the result is negative, then \( RW_2 \) does not architecturally occur.

Tag-Location-Ordered

Tag-Check-reads \( R_1 \) and \( R_2 \) are Tag-Location-Ordered if and only if all the following apply:

- \( R_1 \) is Tag-ordered-before a Checked data access \( RW_3 \).
- \( R_2 \) is Tag-ordered-before a Checked data access \( RW_4 \).
- \( RW_3 \) and \( RW_4 \) are to the same Location.

Locally-ordered-before

Dependencies, Local write successor, load/store-exclusive, atomic and barrier instructions can be composed within an Observer to create externally-visible order. A memory read or write effect \( RW_1 \) is Locally-ordered-before a memory read or write effect \( RW_2 \) from the same Observer if and only if any of the following cases apply:

- \( RW_1 \) is a memory write effect \( W_1 \) and \( RW_2 \) is a memory write effect \( W_2 \) that is equal to or generated by the same instruction as a Local write successor of \( RW_1 \).
- \( RW_1 \) is Pick-ordered-before \( RW_2 \).
- \( RW_1 \) is Dependency-ordered-before \( RW_2 \).
- \( RW_1 \) is Atomic-ordered-before \( RW_2 \).
- \( RW_1 \) is Barrier-ordered-before \( RW_2 \).
- \( RW_1 \) is Tag-ordered-before \( RW_2 \).
- \( RW_1 \) is Locally-ordered-before a memory read or write effect that is Locally-ordered-before \( RW_2 \).

Pick-locally-ordered-before

A read or a write Memory effect \( RW_1 \) is Pick-locally-ordered-before a read or a write Memory effect \( RW_2 \) from the same Observer if and only if all of the following apply:

- There is a Pick Basic dependency from \( RW_1 \) to an effect \( E_3 \).
- \( RW_2 \) is a write Memory effect \( W_2 \).
- \( E_3 \) is Locally-ordered-before \( W_2 \).

B2.3.4 Ordering constraints

The Arm memory model is described as being Other-multi-copy atomic. The definition of Other-multi-copy atomic is as follows:

Other-multi-copy atomic

In an Other-multi-copy atomic system, it is required that a memory write effect from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.
The Other-multi-copy atomic property of the Arm memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be Architecturally well-formed. An implementation that is executing a program is only permitted to exhibit behavior consistent with an Architecturally well-formed execution.

Architecturally well-formed

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and any of the three alternative External ordering constraints.

B2.3.5 Internal visibility requirement

For a memory read or write effect RW₁ that appears in program order before a memory read or write effect RW₂ to the same Location:

- Where one or more of the following statements is true:
  - RW₁ is not a Tag-Check-read.
  - RW₂ is not a Tag-Check-read.
  - RW₁ and RW₂ are both Tag-Check-reads R₁ and R₂ that are Tag-Location-Ordered.

- The Internal visibility requirement requires that exactly one of the following statements is true:
  - RW₂ is a memory write effect W₂ that is Coherence-after RW₁.
  - RW₁ is a memory write effect W₁, RW₂ is a memory read effect R₂ and either:
    - R₂ Reads-from W₁.
    - R₂ Reads-from a memory write effect that is Coherence-after W₁.
  - RW₁ and RW₂ are both reads R₁, R₂, R₁ Reads-from a memory write effect W₃ and either:
    - R₂ Reads-from W₃.
    - R₂ Reads-from a memory write effect that is Coherence-after W₃.

Informally, if a Memory effect M₁ from an Observer appears in program order before a Memory effect M₂ from the same Observer, then M₁ will be seen to occur before M₂ by that Observer.

B2.3.6 External ordering constraints

The Arm memory model offers the following three alternative representations of the External ordering constraint:

- External visibility requirement.
- External completion requirement.
- External global completion requirement.

An Architecturally well-formed execution must satisfy both the Internal visibility requirement and one of the three alternative representations in the External ordering constraints.

External visibility requirement

Ordered-before

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A memory read or write effect RW₁ is Ordered-before a memory read or write effect RW₂ if and only if any of the following cases apply:

- RW₁ is Observed-by a memory read or write effect RW₃ which is generated by the same instruction as RW₂.
- RW₁ is Locally-ordered-before RW₂.
- RW₁ is Pick-locally-ordered-before RW₂.
- RW₁ is Ordered-before a memory read or write effect that is Ordered-before RW₂.
For a memory read or write effect \( \text{RW}_1 \) from an Observer that is Ordered-before a memory read or write effect \( \text{RW}_2 \) from a different Observer, the External visibility requirement requires that \( \text{RW}_2 \) is not Observed-by \( \text{RW}_1 \). This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

Informally, if a Memory effect \( \text{M}_1 \) from an Observer appears in program order before a Memory effect \( \text{M}_2 \) from the same Observer, then \( \text{M}_1 \) will be seen to occur before \( \text{M}_2 \) by all Observers in the system.

**Completes-before order**

The Completes-before order is a total order that corresponds to the order in which Memory effects complete within the system. The following effects constitute a single entry in the Completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the Completes-before order.

**Completes-before**

A memory read or write effect \( \text{RW}_1 \) Completes-before a memory read or write effect \( \text{RW}_2 \) if and only if \( \text{RW}_1 \) appears in the Completes-before order before \( \text{RW}_2 \).

**Deriving Reads-from and Coherence order from the Completes-before order**

The Completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:

- For a memory read effect \( \text{R}_1 \) of a memory location by an Observer, then:
  - If there is a memory write effect \( \text{W}_2 \) to the same Location from the same Observer and all of the following are true:
    - \( \text{W}_2 \) appears in program order before \( \text{R}_1 \).
    - \( \text{R}_1 \) Completes-before \( \text{W}_2 \).
    - There are no writes to the Location appearing in program order between \( \text{W}_2 \) and \( \text{R}_1 \) then \( \text{R}_1 \) Reads-from \( \text{W}_2 \).
  - Otherwise, \( \text{R}_1 \) Reads-from its closest preceding write in the Completes-before order to the same Location. If no such write exists, then \( \text{R}_1 \) Reads-from the initial value of the memory location.

- The Coherence order of writes to a memory location is the order in which those writes appear in the Completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

**External completion requirement**

A memory read or write effect \( \text{RW}_1 \) Completes-before a memory read or write effect \( \text{RW}_2 \) if and only if any of the following statements are true:

- \( \text{RW}_1 \) is Locally-ordered-before \( \text{RW}_2 \).
- \( \text{RW}_1 \) is Pick-locally-ordered-before \( \text{RW}_2 \).
- \( \text{RW}_1 \) is a memory read effect \( \text{R}_1 \) and \( \text{RW}_2 \) is a memory read effect \( \text{R}_2 \) and \( \text{R}_1 \) is Single-copy-atomic-ordered-before \( \text{R}_2 \).

**Globally-completes-before order**

The Globally-completes-before order is a total order that corresponds to the order in which Memory effects globally-complete within the system. The following effects constitute a single entry in the Globally-completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
• Reads from the same instruction which read from the same internal write. All other reads constitute distinct entries in the Globally-completes-before order.

**Globally-completes-before**

A memory read or write effect RW<sub>1</sub> *Globally-completes-before* a memory read or write effect RW<sub>2</sub> if and only if RW<sub>1</sub> appears in the Globally-completes-before order before RW<sub>2</sub>.

**Deriving Reads-from and Coherence order from the Globally-completes-before order**

The Globally-completes-before order can be used to resolve the Reads-from and Coherence order relations for every memory access in the system as follows:

• A memory read effect R<sub>1</sub> of a memory location by an Observer Reads-from its closest preceding write in the Globally-completes-before order to the same Location. If no such write exists, then R<sub>1</sub> Reads-from the initial value of the memory location.

• The Coherence order of writes to a memory location is the order in which those writes appear in the Globally-completes-before order. The final value of each memory location is therefore determined by the final write to each Location in the Globally-completes-before order. If no such write exists for a given Location, the final value is the initial value of that Location.

**External global completion requirement**

The External global completion requirement requires that a memory read or write effect RW<sub>1</sub> *Globally-completes-before* a memory read or write effect RW<sub>2</sub> if and only if any of the following statements are true:

• RW<sub>1</sub> is Locally-ordered-before RW<sub>2</sub> and either:
  — RW<sub>1</sub> is a memory write effect.
  — RW<sub>1</sub> is a memory read effect R<sub>1</sub> and either:
    — R<sub>1</sub> is not a Local read successor of a memory write effect.
    — R<sub>1</sub> is a Local read successor of a memory write effect that is Locally-ordered-before RW<sub>2</sub>.
    — R<sub>1</sub> is a Local read successor of a memory write effect that is Pick-locally-ordered-before RW<sub>2</sub>.
  — RW<sub>1</sub> is a memory read effect R<sub>1</sub> and RW<sub>2</sub> is a memory read effect R<sub>2</sub> and R<sub>1</sub> is Single-copy-atomic-ordered-before R<sub>2</sub>.

**B2.3.7 Completion and endpoint ordering**

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

• A memory read effect R<sub>1</sub> to a Location is complete for a shareability domain when all of the following are true:
  — Any write to the same Location by an Observer within the shareability domain will be Coherence-after R<sub>1</sub>.
  — Any translation table walks associated with R<sub>1</sub> are complete for that shareability domain.

• A memory write effect W<sub>1</sub> to a Location is complete for a shareability domain when all of the following are true:
  — Any write to the same Location by an Observer within the shareability domain will be Coherence-after W<sub>1</sub>.
— Any read to the same Location by an Observer within the shareability domain will either Reads-from \( W_1 \) or Reads-from a memory write effect that is Coherence-after \( W_1 \).
— Any translation table walks associated with the write are complete for that shareability domain.

- A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.
- A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

--- Note ---

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

---

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:
- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

--- Note ---

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

---

Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral coherence order:

Memory-mapped peripheral

A Memory-mapped peripheral occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral coherence order

The Peripheral coherence order of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

--- Note ---

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.

---

For a memory read or write effect \( RW_1 \) and a memory read or write effect \( RW_2 \) to the same peripheral, then \( RW_1 \) will appear in the Peripheral coherence order for the peripheral before \( RW_2 \) if either of the following cases apply:
- \( RW_1 \) and \( RW_2 \) are accesses using Non-cacheable or Device attributes and \( RW_1 \) is Ordered-before \( RW_2 \).
• RW₁ and RW₂ are accesses using Device-nGnRE or Device-nGnRnE attributes, with the same XS attribute value, and RW₁ appears in program order before RW₂.

Note
When FEAT_XS is implemented, if accesses marked with the Device-nGnRE or Device-nGnRnE attributes are within the same Memory-mapped peripheral, but the XS attribute is not the same on those accesses, the order of arrival at the endpoint is not defined by the architecture.

Out-of-band-ordered-before
A memory read or write effect RW₁ is Out-of-band-ordered-before a memory read or write effect RW₂ if and only if either of the following cases apply:

• RW₁ appears in program order before a DSB instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW₂.
• RW₁ is Ordered-before a memory read or write effect RW₃ and RW₃ is Out-of-band-ordered-before RW₂.

If a Memory effect M₁ is Out-of-band-ordered-before a memory read or write effect M₂, then M₁ is seen to occur before M₂ by all Observers.

Note
Arm expects that, in most systems with early acknowledgments, those acknowledgments will come from a point at or after the point that establishes global visibility. This is expected in such systems to enable the acknowledgments to be used as part of the mechanisms to implement the ordering requirements of the Arm memory model.

B2.3.8 SVE memory ordering relaxations

ICTNGV
The Arm memory model is relaxed for reads and writes generated by SVE load and store instructions.

QLIPC
When two reads generated by SVE vector load instructions have an address dependency, the dependency does not contribute to the dependency-ordered-before relation.

YMBMZ
When a pair of reads access the same location, and at least one of the reads is generated by an SVE load instruction, for a given observer, the pair of reads is not required to satisfy the internal visibility requirement.

CHWV
When a single SVE vector store instruction generates multiple writes to the same location, the instruction ensures that these writes appear in the coherence order for that location, in order of increasing vector element number. No other ordering restrictions apply to memory effects generated by the same SVE store instruction.

LVXTJ
If a single SVE load instruction generates multiple reads, the order in which the reads for different elements and registers appear is not architecturally defined.

VMDYZ
If an address dependency exists between two memory reads and an SVE non-temporal vector load instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

CCWGN
For any SVE load or store instruction that generates multiple single-copy atomic accesses to Normal or Device memory, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic memory element access sizes.

B2.3.9 Ordering of instruction fetches
For two memory locations A and B, if A has been written to with an updated value and been made coherent with the instruction fetches of the shareability domain before B has been written to with an updated value by an observer in the same shareability domain, then where, for an observer in the shareability domain, an instruction read from B appears in program order before an instruction fetched from A, if the instruction read from B contains the updated value of B then the instruction read from A appearing later in program order will contain the updated value of A.
A write has been made coherent with an instruction fetch of a shareability domain when:

**CTR_EL0.{DIC, IDC} == \{0, 0\}**

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

**CTR_EL0.{DIC, IDC} == \{1, 0\}**

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

**CTR_EL0.{DIC, IDC} == \{0, 1\}**

The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

**CTR_EL0.{DIC, IDC} == \{1, 1\}**

The write is complete for the shareability domain.

--- Note

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When **CTR_EL0.DIC == 0**, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the **IC IVAU** instructions of a different core.
  - When **CTR_EL0.DIC == 1**, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

### B2.3.10 Restrictions on the effects of speculation

The Arm architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- Each load from a location using a particular VA after an exception entry that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry.
- Any load from a location using a particular VA before an exception entry that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception entry.
- Any load from a location using a particular VA before an exception return that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception exit.
- When data is loaded under speculation with a Translation fault, it cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.
- When data is loaded under speculation from a location without a translation for the translation regime being speculated in, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.
• When data is loaded as a result of speculative accesses made after TLBI + DSB + ERET using a translation that was invalidated by the TLBI, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence. The execution timing of any other instructions in the speculative sequence is not a function of the data loaded.

• Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.

• Changes to Special-purpose registers can occur speculatively.

• Execute-never controls apply to speculative instruction fetching. See Instruction execution permissions on page D8-5138.

• When writing new instructions to memory, there is no requirement for an SB instruction to prevent speculative execution of the old code. See Instruction cache maintenance instructions on page K13-11773.

Note
The prohibition of using data loaded under speculation with faults to form addresses, condition codes or SVE predicate values does not prohibit the use of value predicted data from such locations for such purposes, so long as the training of the data value prediction was from the hardware defined context that is using the prediction. A consequence of this is that training of value prediction cannot be based on data loaded under speculation with a translation or Permission fault.

Speculative Store Bypass Safe (SSBS)
When FEAT_SSBS is implemented, PSTATE.SSBS is a control that can be set by software to indicate whether hardware is permitted to use, in a manner that is potentially speculatively exploitable, a speculative value in a register that has been loaded from memory using a load instruction that speculatively read the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

A speculative value in a register is used in a potentially speculatively exploitable manner if it is used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence or if the execution timing of any other instructions in the speculative sequence is a function of the data loaded under speculation.

When the value of PSTATE.SSBS is 0, hardware is not permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of PSTATE.SSBS is 1, hardware is permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

Note
• If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.

• Software written for architectures from Armv8.0 to Armv8.4 will set SPSR_ELx.SSBS to 0. This means that PSTATE.SSBS will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.
Restrictions on exploitative control of speculative execution

The execution of some code (code1) can exploitatively control speculative execution of some other code (code2) if and only if all of the following apply:

• The actions of code1 can influence, in a manner that is not hard-to-determine, the speculative execution of code2 to cause an irreversible change to the microarchitectural state of the PE that is indicative of some architectural state accessible to the execution context of code2.

• Code1 has control in determining the choice of the architecture state that the irreversible change to the microarchitectural state is indicative of.

• The irreversible changes to the microarchitectural state of the PE can be measured by code executing in an execution context other than that of code2 to allow the retrieval of the architectural state in a manner that is not hard-to-determine.

Note

Mechanisms to prevent the influence and the state recovery being “not hard-to-determine” are left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.

Restrictions on predictive leakage

The execution of some code (code1) can predictively leak to some other code (code2) if and only if all of the following apply:

• The execution of code1 influences, in a manner that is not hard-to-determine, the predictive micro-architectural structures of the implementation to behave in a way that is indicative of some architectural state accessible to the execution context of code1.

• The predictive micro-architectural structures of the implementation impact the timing of the speculative execution of code2 in a way that enables code2 to recover the architecture state in a manner that is not hard-to-determine.

Note

Mechanisms to prevent the influence and the state recovery being “not hard-to-determine” are left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.

Restrictions on the effects of speculation from Armv8.5

Note

If SCR_EL3.EEL2 is changed, in order to remove all VMID tagging from Secure EL1 and Secure EL0 entries, each prediction resource should be invalidated by software for:

• Secure EL0 for all ASID and VMID values.
• Secure EL1 for all VMID values.

Further restrictions on speculation are introduced by some additional architectural features as described here.

FEAT_CSV3 introduces these restrictions:

• Data loaded under speculation with a Permission or Domain fault cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence.

• Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address, to generate condition codes, or to generate SVE predicate values to be used by other instructions in the speculative sequence.
As the effects of speculation are not architecturally visible, this restriction requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

- Changes to System registers must not occur speculatively in a way that can affect a speculative memory access that can cause a change to the micro-architectural state.

- Changes to Special-purpose registers can occur speculatively.

**Note**

Changes to Special-purpose registers can occur speculatively.

**FEAT_CSV2, FEAT_CSV2_1p1, FEAT_CSV2_1p2, FEAT_CSV2_2 and FEAT_CSV2_3** introduce a range of additional restrictions.

If FEAT_CSV2 is implemented:

- Code running in one hardware-defined context (context1) cannot either exploitatively control, or predictively leak to, the speculative execution of code in a different hardware-defined context (context2), as a result of the behavior of any of the following resources:
  - Branch target prediction based on the branch targets used in context1.
    - This applies to both direct and indirect branches, but excludes the prediction of the direction of a conditional branch.
  - Data Value predictions based on data value from execution in context1.
  - Virtual address-based cache prefetch predictions generated as a result of execution in context1.
  - Any other prediction mechanisms, other than Branch, Data Value, or Cache Prefetch predictions.

In this definition, the hardware-defined context is determined by:

- The Exception level.
- The Security state.
- When executing at EL1, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0, whether the EL1&0 or the EL2&0 translation regime is in use.
- When executing at EL0 and using the EL1&0 translation regime, the address space identifier (ASID) and, if EL2 is implemented and enabled in the current Security state, the VMID.
- When executing at EL0 and using the EL2&0 translation regime, the ASID.

If FEAT_CSV2_2 is implemented, then SCXTNUM_ELx is also part of the hardware-defined context.

If either FEAT_CSV2_1p1 or FEAT_CSV2_3 is implemented, code running in one hardware-defined context (context1) cannot either exploitatively control, or predictively leak to, the speculative execution of code in a different hardware-defined context (context2) as a result of the behavior of branch target prediction based on the branch history used in context1.

If FEAT_CSV2_1p1 is implemented, branch or data values trained from one instruction address can exploitatively control, or predictively leak to, the speculative execution of code from a different address only in a hard-to-determine way.

If FEAT_CSV2_1p2 is implemented, the SCXTNUM_ELx register is implemented, but is not part of the hardware-defined context.

**B2.3.11 Memory barriers**

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the Arm architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
The following subsections describe the Arm memory barrier instructions:

- **Instruction Synchronization Barrier (ISB)**
- **Data Memory Barrier (DMB)**
- **Data Synchronization Barrier (DSB)** on page B2-178.
- **Speculation Barrier (SB)** on page B2-176.
- **Consumption of Speculative Data Barrier (CSDB)** on page B2-176.
- **Speculative Store Bypass Barrier (SSBB)** on page B2-177.
- **Profiling Synchronization Barrier (PSB CSYNC)** on page B2-177.
- **Physical Speculative Store Bypass Barrier (PSSBB)** on page B2-177.
- **Trace Synchronization Barrier (TSB CSYNC)** on page B2-177.
- **Shareability and access limitations on the data barrier operations** on page B2-179.
- **LoadLOAcquire, StoreLORelease** on page B2-181.

--- Note ---

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are available only when software execution is at EL1 or higher.

DMB and DSB instructions affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

### Instruction Synchronization Barrier (ISB)

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction.

Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction take effect only after the ISB has been executed.

The pseudocode function for the operation of an ISB is `InstructionSynchronizationBarrier()`.

See also **Memory barriers** on page D7-5077.

### Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB instruction is covered formally in the **Definition of the Arm memory model** on page B2-159 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB instruction is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are Observed-by that PE.
The use of a DMB instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The DMB instruction affects only memory accesses and the operation of data cache and unified cache maintenance instructions, see A64 Cache maintenance instructions on page D7-5054. It has no effect on the ordering of any other instructions executing on the PE.

The pseudocode function for the operation of a DMB instruction is `DataMemoryBarrier()`.

### Speculation Barrier (SB)

An SB instruction is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that a instruction that could generate an exception does not generate an exception.

Speculative execution of an SB instruction:

- Cannot be as a result of control flow speculation.
- Cannot be as a result of data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when:

- It is known that it is not speculative.
- All the predicted data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

**Note**

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after the SB instruction.

### Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:

- Data value predictions of any instructions.
- \( \text{PSTATE.}(N,Z,C,V) \) predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

For purposes of the definition of CSDB, \( \text{PSTATE.}(N,Z,C,V) \) is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB instruction.
- Speculative execution of conditional data processing instructions after the CSDB instruction, unless they use the results of data value or \( \text{PSTATE.}(N,Z,C,V) \) predictions of instructions appearing in program order before the CSDB instruction that have not been architecturally resolved.
Speculative Store Bypass Barrier (SSBB)

The SSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB instruction.
- When a load to a location appears in program order before the SSBB instruction, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB instruction.

Profiling Synchronization Barrier (PSB CSYNC)

The PSB CSYNC instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

Physical Speculative Store Bypass Barrier (PSSBB)

The PSSBB instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB instruction.
- When a load to a location appears in program order before the PSSBB instruction, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB instruction.

Note: The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

Trace Synchronization Barrier (TSB CSYNC)

The TSB CSYNC instruction is a barrier instruction that preserves the relative order of accesses to System registers due to trace operations and other accesses to the same registers.

A trace operation is an operation of the trace unit generating trace for an instruction when FEAT_TRF is implemented and enabled.
A TSB CSYNC instruction is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more Context synchronization events are required to ensure that TSB CSYNC instruction is executed in the necessary order.

If trace is generated between a Context synchronization event and a TSB CSYNC operation, these trace operations may be reordered with respect to the TSB CSYNC operation, and therefore may not be synchronized.

The following situations are synchronized using a TSB CSYNC operation:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
  - A is executed in program order before a Context synchronization event C.
  - C is in program order before a TSB CSYNC operation T.
  - B is executed in program order after T.

- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
  - A is executed in program order before a Context synchronization event C1.
  - C1 is in program order before TSB CSYNC operation T.
  - T is executed in program order before a second Context synchronization event C2.
  - B is executed in program order after C2.

A TSB CSYNC operation is not needed to ensure a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:

- A is executed in program order after a Context synchronization event C.
- B is executed in program order before C.

If FEAT_TRBE is implemented, the requirements in this section are extended. See Synchronization and the Trace Buffer Unit on page D6-5026.

The pseudocode function for the operation of a TSB CSYNC instruction is TraceSynchronizationBarrier().

Data Synchronization Barrier (DSB)

A DSB instruction is a memory barrier that ensures that memory accesses that occur before the DSB instruction have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB instruction:

- At EL2 ensures that any memory accesses caused by Speculative translation table walks from the EL1&0 translation regime have been observed.
- At EL3 ensures that any memory accesses caused by speculative translation table walks from the EL2, EL1&0 or EL2&0 translation regimes have been observed.

For more information, see Out-of-context translation regimes on page D8-5087.

A DSB instruction executed by a PE, PEe, completes when all of the following apply:

- All explicit memory effects of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, the following instructions issued by PEe before the DSB are complete for the required shareability domain:
  - All cache maintenance instructions.
  - All TLB maintenance instructions.
  - All PSB CYNC instructions.
When FEAT_XS is implemented, if the required access types of the DSB is reads and writes, completion of the DSB instruction with the nXS qualifier executed by a PE, PEe, ensures that:

- All previous TLBInXS maintenance operations generated by AArch64 TLB maintenance instructions with the nXS qualifier executed by PEe are finished for all PEs in the shareability domain of the DSB instruction.
- All previous TLBInXS maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 by PEe when HCRX_EL2.FnXS is 1 are finished for all PEs in the shareability domain of the DSB instruction.

Completion of the DSB instruction with the nXS qualifier executed by a PE, PEe, does not ensure that:

- All previous TLB maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 by PEe when HCRX_EL2.FnXS is 0 are finished for all PEs in the shareability domain of the DSB instruction.
- All previous TLB maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL2 or EL3 by PEe are finished for all PEs in the shareability domain of the DSB instruction.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes other than:

- Being fetched from memory and decoded.
- Reading the general-purpose, SIMD and floating-point, SVE vector or predicate, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.
- If FEAT_ETS is not implemented, having any virtual addresses of loads and stores translated.

If FEAT_MTE2 is implemented, on completion of a DSB instruction operating over the Non-shareable domain, all updates to TFSR_ELx.TFx or TFSRE0_EL1.TFx due to Tag Check fails caused by accesses for which the DSB operates will be complete. For more information on FEAT_MTE2, see Chapter D9 The Memory Tagging Extension.

When FEAT_XS is implemented and HCRX_EL2.FnXS is 1, an AArch64 DSB instruction executed at EL1 or EL0 behaves in the same way as the corresponding DSB instruction with the nXS qualifier executed at EL1 or EL0.

If FEAT_TRBE is implemented, the requirements in this section are extended. See Trace synchronization and memory barriers on page D6-5031.

The pseudocode function for the operation of a DSB is DataSynchronizationBarrier().

See also:
- Memory barriers on page D7-5077.
- Ordering and completion of TLB maintenance instructions on page D8-5213.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions take an argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.

  Full system applies to all the observers in the system and, as such, encompasses the Inner and Outer Shareable domains of the processor.

  __________ Note __________

  The distinction between Full system and Outer Shareable is applicable only for Normal Non-cacheable memory accesses and Device memory accesses.

  __________

- The accesses for which the instruction operates. This is one of:
  - Read and write accesses, both before and after the barrier instruction.
— Write accesses only, before and after the barrier instruction.
— Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

--- Note ---
This form of a DMB or DSB instruction can be described as a load-load/store barrier.

For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page B2-175 or Data Synchronization Barrier (DSB) on page B2-178.

Table B2-1 on page B2-180 shows how these options are encoded in the <option> field of the instruction:

<table>
<thead>
<tr>
<th>Accesses</th>
<th>Shareability domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the barrier</td>
<td>After the barrier</td>
</tr>
<tr>
<td>Reads and writes</td>
<td>Reads and writes</td>
</tr>
<tr>
<td>Writes</td>
<td>Writes</td>
</tr>
<tr>
<td>Reads</td>
<td>Reads and writes</td>
</tr>
</tbody>
</table>

See the instruction descriptions for more information:
• DMB on page C6-1485.
• DSB on page C6-1488.

--- Note ---
ISB also supports an optional limitation argument that can contain only one value that corresponds to full system operation, see ISB on page C6-1511.

**Load-Acquire, Load-AcquirePC, and Store-Release**

Arm provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the Release Consistency sequentially consistent (RCsc) model. In addition, FEAT_LRCPC provides Load-AcquirePC instructions. The combination of Load-AcquirePC and Store-Release can be used to support the weaker Release Consistency processor consistent (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the Definition of the Arm memory model on page B2-159. This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between:
• The memory access generated by the Load-Acquire or Load-AcquirePC instruction.
• The memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is Observed-by each PE to the extent that the PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are Observed-by that PE to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the Definition of the Arm memory model on page B2-159 and this introduction to the Store-Release instruction is not intended to contradict that section.
The basic principle of a Store-Release instruction is to introduce order between the following:

- A set of memory accesses, RWx, that are generated by the PE executing the Store-Release instruction and that appear in program order before the Store-Release instruction, together with those that originate from a different PE to the extent that the PE is required to observe them coherently, Observed-by the PE before executing the Store-release.

- The memory access generated by the Store-Release (Wrel), such that all of the memory accesses, RWx, are Observed-by each PE to the extent that the PE is required to observe those accesses coherently, before Wrel is Observed-by that PE to the extent that the PE is required to observe that access coherently.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Where a Load-Acquire appears in program order after a Store-Release, the memory access generated by the Store-Release instruction is Observed-by each PE to the extent that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction is Observed-by that PE, to the extent that the PE is required to observe the access coherently. In addition, the use of a Load-Acquire, Load-AcquirePC or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction has the release semantics only if the store is successful.

--- Note ---

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.

- The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB instruction.

**LoadLOAcquire, StoreLORelease**

For each PE, the Non-secure physical memory map is divided into a set of LORegions using a table that is held within the PE. Any PA in the Non-secure memory map can be a member of one LORegion. If a PA is assigned to more than one LORegion, then an implementation might treat it as if it has been assigned to fewer LORegions than that have been specified. A PA in the Secure physical memory map cannot be a member of any LORegion. For more information, see Limited ordering regions on page B2-182.

**FEAT_LOR** provides a set of instructions with Acquire semantics for loads, and Release semantics for stores that apply in relation to the defined LORegions. The new variants of the Load-Acquire and Store-Release instructions are LoadLOAcquire and StoreLORelease. See LoadLOAcquire/StoreLORelease on page C3-263.

For all memory types, these instructions have the following ordering requirements:

- LoadLOAcquire has the same semantics as Load-Acquire except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.
StoreLORelease has the same semantics as Store-Release except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

In addition, for accesses to Memory-mapped peripherals:

- LoadLOAcquire has the same semantics as Load-Acquire except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.
- StoreLORelease has the same semantics as Store-Release except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-180.

Note

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB instruction.

B2.3.12 Limited ordering regions

FEAT_LOR introduces limited ordering regions (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

This feature is supported in AArch64 state only.

Specification of the LORegions

The LORegions are defined in the Non-secure physical memory map using a set of LORegion descriptors. The number of LORegion descriptors is IMPLEMENTATION DEFINED, and can be discovered by reading the LORID_EL1 register.

Each LORegion descriptor consists of:

- A tuple of the following values:
  - A Start Address.
  - An End Address.
  - An LORegion Number.
- Valid bit which indicates whether that LORegion descriptor is valid.

A memory location lies within the LORegion identified by the LORegion Number if the PA lies between the Start Address and the End Address, inclusive. The Start Address must be defined to be aligned to 64KB and the End Address must be defined as the top byte of a 64KB block of memory.

The LORegion descriptors are programmed using the LORSA_EL1, LOREA_EL1, LORN_EL1, and LORC_EL1 registers in the System register space. These registers describe only memory addresses in the Non-secure memory map. These registers are UNDEFINED if accessed when SCR_EL3.NS == 0.

If a LoadLOAcquire or a StoreLORelease does not match with any LORegion, then:

- The LoadLOAcquire will behave as a Load-Acquire, and will be ordered in the same way with respect to all accesses, independent of their LORegions.
- The StoreLORelease will behave as a Store-Release, and will be ordered in the same way with respect to all accesses, independent of their LORegions.

Note

If no LORegions are implemented, then the LoadLOAcquire and StoreLORelease will therefore behave as a Load-Acquire and Store-Release.
A new access type `AccType_LIMITEDORDERED` has been added for these limited ordering instructions to be identified.
B2.4 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. The Arm architecture defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Application level access to functionality related to caches on page B2-185
- Implication of caches for the application programmer on page B2-186.
- Preloading caches on page B2-188.

B2.4.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one Location is likely to be followed by accesses to adjacent Locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. The Arm architecture permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.4.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 on page B2-185 shows an example of such a system in an Armv8-A system that supports virtual addressing.
The AArch64 Application Level Memory Model

B2.4 Caches and memory hierarchy

Figure B2-1  Multiple levels of cache in a memory hierarchy

--- Note ---

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in Figure B2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU), Point of Coherency (PoC), Point of Persistence (PoP), and Point of Deep Persistence (PoDP).

For more information, including the definitions of PoU, PoC, PoP, and PoDP, see About cache maintenance in AArch64 state on page D7-5050.

If FEAT_MTE2 is implemented, the behavior of cache maintenance instructions is modified. For more information, see Allocation Tags on page D9-5221.

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

**Cacheability**

This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

**Shareability**

This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see Memory types and attributes on page B2-196.

B2.4.3   Application level access to functionality related to caches

As indicated in About the Application level programmers' model on page B1-136, the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

**When the value of SCTLR_EL1.UCI is 1**

Software executing at EL0 can access:

- The data cache maintenance instructions, DC CVAU, DC CVAC, DC CVAP, DC CVADP, and DC CIVAC. See The data cache maintenance instruction (DC) on page D7-5056.
• The instruction cache maintenance instruction IC IVAU. See The instruction cache maintenance instruction (IC) on page D7-5056.

Attempted execution of these instructions might generate a Permission fault as described in Permission fault on page D8-5183.

When the value of SCTLR_EL1.UCT is 1

Software executing at EL0 can access the cache type register. See CTR_EL0.

When the value of SCTLR_EL1.DZE is 1

Software executing at EL0 can access the data cache zero instruction DC ZVA. See Data cache zero instruction on page D7-5068.

The SCTLR_EL1.{UCI, UCT, DZE} control fields are accessible only by software executing at EL1 or higher. When HCR_EL2.{E2H, TGE} == {1,1}, the controls {UCI, UCT and DZE} are found in SCTLR_EL2.

This functionality is UNDEFINED at EL0 when the value of the corresponding SCTLR_EL1 control field is 0.

B2.4.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

• When memory locations are updated by other agents in the system that do not use hardware management of coherency.
• When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

• In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
• In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

• By not using the caches in situations where coherency issues can arise. This can be achieved by:
  — Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  — Not enabling caches in the system.

• By using cache maintenance instructions to manage the coherency issues in software. See Application level access to functionality related to caches on page B2-185.

• By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory on page B2-198 and Shareable, Inner Shareable, and Outer Shareable Normal memory on page B2-197.

——— Note ————

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.
Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

### Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization event on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a Context synchronization event, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The Arm architecture requires the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory. A write has been made coherent with an instruction fetch of a shareability domain when:

- **CTR_EL0.{DIC, IDC} == {0, 0}**
  - The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

- **CTR_EL0.{DIC, IDC} == {1, 0}**
  - The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

- **CTR_EL0.{DIC, IDC} == {0, 1}**
  - The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

- **CTR_EL0.{DIC, IDC} == {1, 1}**
  - The write is complete for the shareability domain.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context synchronization events and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

```assembly
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <wt> containing a new 32-bit instruction, to be held in Cacheable space at a location pointed to by Xn.

STR Wt, [Xn]  ; Coherency example for data and instruction accesses within the same Inner Shareable domain.
DC CVAU, Xn    ; Clean data cache by VA to point of unification (PoU)
DSB ISH        ; Ensure visibility of the data cleaned from cache
IC IVAU, Xn    ; Invalidate instruction cache by VA to PoU
DSB ISH        ; Ensure completion of the invalidations
ISB             ; Synchronize the fetched instruction stream

Note

- If this sequence is not executed between writing data to a location and executing the instruction at that location, the lack of coherency between instruction caches and memory means that the instructions that are executed might be the old instruction or the updated instruction, and which is used can arbitrarily vary during execution. It must not be assumed by software, before the synchronization sequence is executed, that when the updated instruction has been seen, the old instruction will not be seen again.
• For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the Armv8-A AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See Non-cacheable accesses and instruction caches on page D7-5049.

• This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Arm architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions on page B2-156.

• The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.

### B2.4.5 Preloading caches

The Arm architecture provides memory system hints PRFM, LDNP, and STNP that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError interrupt exception. For more information, see ISS encoding for an exception from a Data Abort on page D17-5685.

`PrefetchHint()` defines the prefetch hint types.

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PRFM and load/store instructions that provide hints to the memory system, see Prefetch memory on page C3-267 and Load/store SIMD and floating-point non-temporal pair on page C3-265. For more information on SVE PRF* instructions that provide hints to the memory system, see Predicated non-contiguous element accesses on page C3-293.
B2.5 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment.
- Alignment of data accesses.

B2.5.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See PC alignment checking on page D1-4668.

B2.5.2 Alignment of data accesses

An unaligned access to any type of Device memory causes an Alignment fault.

Unaligned accesses to Normal memory

The behavior of unaligned accesses to Normal memory is dependent on all of the following:

- The instruction causing the memory access.
- The memory attributes of the accessed memory.
- The value of SCTLR_ELx.{A, nAA}.
- Whether or not FEAT_LSE2 is implemented.

Load or Store of Single or Multiple registers

For all instructions that load or store single or multiple registers, but not Load-Exclusive, Store-Exclusive, Load-Acquire/Store-Release, Atomic, and SETG* Memory Copy and Memory Set instructions, if the address that is accessed is not aligned to the size of the data element being accessed, then:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

- An unaligned access is performed.
- If FEAT_LSE2 is not implemented, the access is not guaranteed to be single-copy atomic except at the byte access level.
- If FEAT_LSE2 is implemented:
  - If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, the memory access is single-copy atomic. For LDNP, LDP, or STP instructions, the entire memory access will be single-copy atomic.
  - If all the bytes of the memory accessed do not lie within a 16-byte quantity aligned to 16 bytes, or the access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory, the access is not guaranteed to be single-copy atomic except at the byte access level.

For these instructions, the definition of an unaligned access is based on the size of the accessed elements, not the overall size of the memory access. This affects SIMD and SVE element and structure loads and stores, and also load/store pair instructions.

For predicated SVE vector element and structure load or store instructions, alignment checks are based on the memory element access size, not on the vector element size.

For predicated SVE vector element and structure load or store instructions, Inactive elements cannot cause an Alignment fault.

For unpredicated SVE vector register load or store instructions, the base address is checked for 16-byte alignment.

For unpredicated SVE predicate register load or store instructions, the base address is checked for 2-byte alignment.
Load-Exclusive/Store-Exclusive and Atomic instructions

For Load-Exclusive/Store-Exclusive, and Atomic instructions including those with acquire or acquire-release semantics:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

If FEAT_LSE2 is not implemented, these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If FEAT_LSE2 is implemented, then:

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, an unaligned access is performed.
- If all the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes, or the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  - An unaligned access is performed meeting all of the semantics of the instruction.
  - An Alignment fault is generated.

Where memory access is performed, then it is single-copy atomic.

For these instructions, the definition of an unaligned access is based on the overall access size.

If FEAT_LS64 is implemented, when a single-copy atomic 64-byte instruction accesses a memory location that is not aligned to 64 bytes, an Alignment fault always occurs, regardless of the value of SCTLR_ELx.A.

Non-atomic Load-Acquire/Store-Release instructions

For Load-Acquire/Store-Release instructions that do not have exclusive or atomic behaviors:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

If FEAT_LSE2 is not implemented, then these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If FEAT_LSE2 is implemented, then:

- If the memory access is not to Normal Inner Write-Back or Outer Write-Back Cacheable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  - An unaligned access is performed meeting all of the semantics of the instruction.
  - An Alignment fault is generated.
- If all of the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes then the following applies:
  - If SCTLR_ELx.nAA applicable to the current Exception level is 0, an Alignment fault is generated.
  - If SCTLR_ELx.nAA applicable to the current Exception level is 1, then an unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.

In this case, the architecture does no define the order of the different transactions of the access defined by the single instructions relative to each other.

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, an unaligned access meeting all the semantics of the instruction is performed.

Note

- Unaligned accesses typically take additional cycles to complete compared to a naturally-aligned access.
- An operation that is not single-copy atomic above the byte level can abort on any memory access that it makes and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the page boundary.
Memory Copy and Memory Set instructions

For SETG* instructions:
• There is an alignment check regardless of the value of SCTLR_ELx.A.
• If Xn is not a multiple of 16, an Alignment fault is generated.
• If Xd is not aligned to a multiple of 16, an Alignment fault is generated.

For more information, see the individual SETG* instruction descriptions.
B2.6 Endian support

General description of endianness in the Arm architecture describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:
• Instruction endianness on page B2-193.
• Data endianness on page B2-193.
• Endianness of memory-mapped peripherals on page B2-195.

B2.6.1 General description of endianness in the Arm architecture

This section describes only memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:
• The quadword at address A.
• The doubleword at address A and A+8.
• The words at addresses A, A+4, A+8, and A+12.
• The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
• The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B2-2 have the following definitions:
B_A Byte at address A.
HW_A Halfword at address A.
MSByte Most significant byte.
LSByte Least significant byte.

Figure B2-2 Endianness relationships
The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address 0x1000 always results in an access to the bytes at memory locations 0x1000, 0x1001, 0x1002, and 0x1003. The endianness mapping scheme determines the significance of these 4 bytes.

B2.6.2 Instruction endianness

A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.6.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores.

For more information, see Endianness in SIMD operations on page B2-194.

Note

This means the Armv8 architecture introduces a requirement for 128-bit endian conversions.

Instructions to reverse bytes in a general-purpose register, a SIMD and floating-point register, or an SVE register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B2-2 on page B2-193 shows the instructions that provide this functionality:

<table>
<thead>
<tr>
<th>Function</th>
<th>Instructions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reverse bytes in 32-bit word or words&lt;sup&gt;a&lt;/sup&gt;</td>
<td>REV32</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse bytes in whole register</td>
<td>REV</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse bytes in 16-bit halfwords</td>
<td>REV16</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse elements in doublewords, vector</td>
<td>REV64</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
<tr>
<td>Reverse elements in words, vector</td>
<td>REV32</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
<tr>
<td>Reverse elements in halfwords, vector</td>
<td>REV16</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
<tr>
<td>Reverse bytes/halfwords/words within elements, predicated</td>
<td>REVB, REVH, REVW</td>
<td>For use with SVE registers</td>
</tr>
</tbody>
</table>

<sup>a</sup> Can operate on multiple words.
Endianness in SIMD operations

SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

Memory system with little-endian addressing (LE)

Memory system with big-endian addressing (BE)
```

Figure B2-3 SIMD byte order example

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in Chapter J1 Armv8 Pseudocode.

Endianness in SVE operations

Rules on byte and element order of SIMD load and store instructions apply to SVE load and store instructions.

Additional rules apply to the data endianness of memory accesses performed by SVE load and store instructions.

For predicated SVE vector element and structure load and store instructions, an endianness conversion is performed using the memory element access size. The size of the vector element is not used in endianness conversion.

For unpredicated SVE vector register load and store instructions, the vector byte elements are transferred in increasing element number order without any endianness conversion.

For unpredicated SVE predicate register load and store instructions, each 8 bits from the predicate are transferred as a byte in increasing element number order without any endianness conversion.

When an SVE load instruction is executed, endianness conversion occurs before any sign-extension or zero-extension into a vector element.

When an SVE store instruction is executed, endianness conversion occurs after any truncation from the vector element to the memory element access size.
B2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a Cross Trigger Interface, see Chapter H8 About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 Recommended External Interface to the Performance Monitors.
- A memory-mapped register interface to the Activity Monitors, see Chapter I4 Recommended External Interface to the Activity Monitors.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.
- The memory-mapped register interface to an Arm trace component. See, for example, the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.
B2.7 Memory types and attributes

The ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page B2-200.
- Memory access restrictions on page B2-207.

B2.7.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time.
- Writes to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See Multi-register loads and stores that access Normal memory on page B2-200.

**Note**

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.

- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
  - Memory accesses return UNKNOWN values.
  - UNPREDICTABLE effects on memory-mapped peripherals.

- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page B2-154 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page B2-197.
• Non-shareable Normal memory on page B2-198.
• Cacheability attributes for Normal memory on page B2-198.

See also:
• Multi-register loads and stores that access Normal memory on page B2-200.
• Atomicity in the Arm architecture on page B2-154.
• Memory barriers on page B2-174.
• Concurrent modification and execution of instructions on page B2-156.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

• Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
• Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
• Non-shareable.

The shareability attributes define the data coherency requirements of the location, which hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses on page B2-187.

Note

• System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
• This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

• Each observer is a member of only a single Inner Shareability domain.
• Each observer is a member of only a single Outer Shareability domain.
• All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

• Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
• The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example B2-1 on page B2-198 shows how they might be used.
Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

**Non-shareable Normal memory**

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

**Cacheability attributes for Normal memory**

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information, see *Cacheability, cache allocation hints, and cache transient hints on page D7-5046.*

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.
- For other cases, see *Mismatched memory attributes on page B2-208.*
The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

• A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.

• A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

• For accesses to Normal memory that is Non-cacheable, a DM B instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations on page B2-163.

Note
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

• Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.

• No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.

• An implementation might not have any outer cache.

Example B2-2, Example B2-3 on page B2-200, and Example B2-4 on page B2-200 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

Note

• L1 cache is the level closest to the PE, see Memory hierarchy on page B2-184.

• When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

• The Inner cacheability attribute applied to L1 and L2 cache.

• The Outer cacheability attribute applied to L3 cache.
Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:
- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SVE or SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.7.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering      Identified as G or nG, see Gathering on page B2-203.
Reordering     Identified as R or nR, see Reordering on page B2-204.
Early Write Acknowledgement 
Identified as E or nE, see Early Write Acknowledgement on page B2-205.

The Armv8 Device memory types are:

Device-nGnRnE  Device non-Gathering, non-Reordering, No Early Write Acknowledgement. Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
Device-nGnRE   Device non-Gathering, non-Reordering, Early Write Acknowledgement. Equivalent to the Device memory type in earlier versions of the architecture.
Device-nGRE    Device non-Gathering, Reordering, Early Write Acknowledgement. Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.
Device-GRE     Device Gathering, Reordering, Early Write Acknowledgement. Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that Speculative accesses to Device-GRE memory is forbidden.
Collectively these are referred to as any Device memory type. Going down the list, the memory types are described as getting weaker; conversely the going up the list the memory types are described as getting stronger.

--- Note ---

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

The following exceptions to this apply:

- Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
- For reads, including hardware speculation, that are performed by an SVE unpredicate load instruction, all of the following are true:
  - For any 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by the instruction, any byte in the window can be accessed by the instruction.
  - All bytes accessed by the instruction will be in a 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by the instruction.
- For reads, including hardware speculation, that are performed by an SVE predicated load instruction that is not a non-temporal load, all of the following are true:
  - For any 64-byte window aligned to 64 bytes containing at least 1 byte that is explicitly accessed by an Active element of the instruction, any byte in the window can be accessed by the instruction.
  - All bytes accessed by the instruction will be in a 64-byte window aligned to 64 bytes that contains at least 1 byte that is explicitly accessed by an Active element of the instruction.
- For reads, including hardware speculation, that are performed by an SVE predicated load instruction from memory locations with the Gathering attributes, all of the following are true:
  - For any 128-byte window aligned to 128 bytes containing at least 1 byte that is explicitly accessed by an Active element of the instruction, any byte in the window can be accessed by the instruction.
  - All bytes accessed by the instruction are in a 128-byte window aligned to 128 bytes that contains at least 1 byte that is explicitly accessed by an Active element of the instruction.
- The architecture permits a Memory Copy and Memory Set CPY* instruction to perform speculative reads of any memory location, even those marked as Device, within a 64-byte quantity, aligned to 64 bytes, of a location that is within the range [Xs] to [Xs+Xn-1].
- For Device memory with the Gathering attribute, reads generated by the LDNP instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.
- Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See Properties of single-copy atomic accesses on page B2-156.
Note — An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page B2-154 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program defines only a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

— Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory type completes in finite time.
- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit memory write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two writes of Device memory type to the same location might be merged before they reach the endpoint, unless both writes have the non-Gathering attribute or there is an ordered-before relationship between the two writes.
- For accesses to any Device memory type, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of implementation defined size. For more information, see Ordering relations on page B2-163.
- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.

Note — This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

Note — In the EL1&0 translation regime in systems where HCR_EL2.TGE==1 and HCR_EL2.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS[24] to be 0.

See also Memory access restrictions on page B2-207.

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation
table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR_EL2.PTW bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

--- Note ---
In general, making a translation table walk to any Device memory type is the result of a programming error.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

--- Note ---
This also applies to writebacks from the cache, whether caused by a Natural eviction or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their single-copy atomic sizes, except that there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by multi-register load/store instructions that generate more than one single-copy atomic access. See Multi-register loads and stores that access Device memory on page B2-206.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

Gathering between memory accesses generated by Memory Copy and Memory Set instructions is always permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

--- Note ---
- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
— The accesses are not generated by a Store-Release instruction.

• The Arm architecture defines only programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R          Indicates that the location has the Reordering attribute. Accesses to the location can be reordered within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable memory, see Ordering relations on page B2-163.

nR         Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

Note

Some interconnect fabrics, such as PCIe, perform very limited reordering, which is not important for the software usage. It is outside the scope of the Arm architecture to prohibit the use of a non-Reordering memory type with these interconnects.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

• The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.

• The Arm architecture defines only programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

• The non-Reordering property is only required by the architecture to apply the order of arrival of accesses to a single memory-mapped peripheral of an IMPLEMENTATION DEFINED size, and is not required to have an impact on the order of observation of memory accesses to SDRAM. For this reason, there is no effect of the non-Reordering attribute on the ordering relations between accesses to different locations described in Ordering relations on page B2-163 as part of the formal definition of the memory model.

• If the same memory location is mapped with different aliases, and different attribute values, these are a type of mismatched attribute. The different attributes could be:
  — A different Reordering attribute value.
  — A different Device memory attribute value.
  — When FEAT_XS is implemented, a different XS attribute value.

For information about the effects of accessing memory with mismatched attributes, see Mismatched memory attributes on page B2-208.
An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

The non-Reordering attribute has no effect on the memory accesses caused by Memory Copy and Memory Set instructions.

**Early Write Acknowledgement**

In the Device memory attribute:

| E  | Indicates that the location has the Early Write Acknowledgement attribute. |
| nE | Indicates that the location has the No Early Write Acknowledgement attribute. |

If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgement of a write comes from the endpoint, it is guaranteed that:
  - Only the endpoint of the write access returns a write acknowledgement of the access.
  - No earlier point in the memory system returns a write acknowledgement.

- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgement of a write comes from the endpoint, the acknowledgement of a write is not required to come from the endpoint.

**Note**

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

This means that a DSB barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system if that is required by the system architecture.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the endpoint.

**Note**

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
• The areas of the physical memory map for which write acknowledgement from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgement from the endpoint.

• Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgement from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgement from the endpoint.

• For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a DSB instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

---

**Multi-register loads and stores that access Device memory**

For all instructions that load or store more than one general-purpose register and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register, the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more SIMD&FP or SVE registers, and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions, even for access to any type of Device memory.

The architecture permits that the non-speculative execution of an instruction that loads or stores more than one general-purpose or SIMD and floating-point register might result in repeated accesses to the same address.

**SVE loads and stores that access Device memory**

All rules applying to Device memory accesses by Advanced SIMD and floating-point load and store instructions apply to Device memory access by SVE load and store instructions.

Additional rules apply to Device memory access by SVE load and store instructions.

When an SVE vector prefetch instruction is executed, any resulting memory read is guaranteed not to access Device memory.

When an SVE Non-fault vector load is executed, or when any element from a First-fault load except the **First active element** attempts to access Device memory, the resulting memory reads will not access Device memory.

When an SVE Non-fault vector load instruction is executed, an attempt by any **Active element** to access Device memory is suppressed and reported in the FFR.

When an SVE First-fault vector load instruction is executed, any memory read performed for the **First active element** can access Device memory.

When an SVE First-fault vector load instruction is executed, an attempt by any **Active element** other than the **First active element** to access Device memory is suppressed and is reported in the FFR.

Any access to Device memory performed by an SVE load or store instruction is relaxed such that it might behave as if:

• The Gathering attribute is set, regardless of the configured value of the nG attribute.
• The Reordering attribute is set, regardless of the configured value of the nR attribute.
• The Early Acknowledgement attribute is set, regardless of the configured value of the nE attribute.

Whether or not attributes are classified as mismatched is determined strictly by the memory attributes derived from the page-table entry.
B2.7.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For two explicit memory read effects to any two adjacent bytes in memory, \( p \) and \( p+1 \), generated by the same instruction, and for two explicit memory write effects to any two adjacent bytes in memory, \( p \) and \( p+1 \), that are generated by the same instruction:
  - The bytes \( p \) and \( p+1 \) must have the same memory type and Shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LD1, ST1, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes \( p \) and \( p+1 \).

For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or Shareability attributes on page K1-11589.

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and Crossing a peripheral boundary with a Device access on page K1-11590 describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

Note

- The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.
- This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.
- Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
B2.8 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see Chapter D8 The AArch64 Virtual Memory System Architecture.

Physical memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.
- When FEAT_XS is implemented, XS attribute.

Collectively these are referred to as memory attributes.

If FEAT_MTE2 is implemented, accesses to a location which use a common definition of the memory attributes but the Tagged attribute of that location differs do not cause a mismatched access to occur.

--- Note ---

In this document, the terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

---

When a memory Location is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of Speculative read accesses.
- Prohibition on Gathering.
- Prohibition on reordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:

   - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - Either:
     - In the EL1&0 translation regime, HCR_EL2.MIOCNCE has a value of 0.
     - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
• Either:
  — All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
  — All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
• Any Device memory type.
• Inner Non-cacheable, Outer Non-cacheable Normal memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
• Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
• Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
• Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
• After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
• Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
• Executing a DMB barrier instruction, with scope that applies to the common shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

In all cases:
• Location refers to any byte within the current coherency granule.
• A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
• In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering and completion of data and instruction cache instructions on page D7-5063.

--- Note ---

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.
2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:

- Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
- A DMB barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

--- Note ---

The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

--- Note ---

As described in Non-cacheable accesses and instruction caches on page D7-5049, a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache. Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.
B2.9  Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

Note

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table B2-3 on page B2-211 shows the synchronization primitives and the associated CLREX instruction.

<sup>a</sup> Instruction in the A64 instruction set.
<sup>b</sup> A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register. A pair instruction operates on two doublewords if accessing X registers, or on two words if accessing W registers.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page B2-217. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- Exclusive access instructions and Non-shareable memory locations on page B2-212.
- Exclusive access instructions and Shareable memory locations on page B2-213.
- Marking and the size of the marked memory block on page B2-217.
- Context switch support on page B2-217.
Use of WFE and SEV instructions by spin-locks on page B2-221.

B2.9 Synchronization and semaphores

B2.9.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a local Exclusives monitor, or local monitor, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:
- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place, the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is set.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is clear.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:
- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B2-4 on page B2-213 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.
The AArch64 Application Level Memory Model
B2.9 Synchronization and semaphores

Figure B2-4  Local monitor state machine diagram

For more information about marking, see Marking and the size of the marked memory block on page B2-217.

Note

For the local monitor state machine, as shown in Figure B2-4:

• The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

• A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

• The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.

• It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExc1 is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4.

An implementation must ensure that:

• The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4.

• Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 must not indefinitely delay forward progress of execution.

B2.9.2  Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.
For shareable memory locations, exclusive access instructions rely on:
• A local monitor for each PE in the system, which marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations on page B2-212, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  — Updating memory.
  — Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.
• A global monitor that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  — Can hold at least one marked block.
  — Maintains a state machine for each marked block it can hold.

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-218.

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:
• Any type of memory in the system implementation that does not support hardware cache coherency.
• Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:
• Whether the global monitor is implemented.
• If the global monitor is implemented, which address ranges or memory types it monitors.

If FEAT_MTE2 is implemented, it is IMPLEMENTATION DEFINED whether a global monitor monitors access to the Tag PA space. For more information, see Chapter D9 The Memory Tagging Extension.

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all Arm PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:
• Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
• Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The architecture only requires that Conventional memory mapped in this way supports this functionality.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

• The instruction generates an External abort.
• The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of ESR_ELx.DFSC = 110101.

If the IMPLEMENTATION DEFINED MMU fault is generated for the EL1&0 translation regime then:

— If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
— Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.
• The instruction is treated as a NOP.
• The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
• The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
• The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by Arm PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

• Some address ranges.
• Some memory types.

**Operation of the global Exclusives monitor**

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

---

**Note**

The global monitor supports only a single outstanding exclusive access to shareable memory per PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

• The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  — A status value of 0 is returned to a register to acknowledge the successful store.
  — The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  — If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.

• If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  — A status value of 1 is returned to a register to indicate that the store failed.
  — The global monitor is not affected and remains in Open Access state for the requesting PE.
• If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  — If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  — If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:
• Accesses generated by PE(n).
• Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:
• In the Exclusive Access state is set.
• In the Open Access state is clear.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see Mechanisms for entering a low-power state on page D1-4676.

Figure B2-5 shows the state machine for PE(n) in a global monitor.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see Marking and the size of the marked memory block on page B2-217.
Note

For the global monitor state machine, as shown in Figure B2-5 on page B2-216:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.

- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 on page B2-216 shows only how the operations by (!n) cause state transitions of the state machine for PE(n).

- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.

- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.9.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size $2^a$ bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the Exclusives reservation granule. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where $a$ is 4.
- 512 words in an implementation where $a$ is 11.

For example, in an implementation where $a$ is 4, a successful LDXB of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.9.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.
B2.9.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDXP/STXP pair or a LDXR/STXR pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a LoadExcl/StoreExcl instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-3 on page B2-211. In this context, a LoadExcl/StoreExcl pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target VA of a StoreExcl is different from the VA of the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, the status value returned by the StoreExcl is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

Note

This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched addresses, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched addresses.

- The data at the address accessed by the LoadExcl, and at the address accessed by the StoreExcl, is UNKNOWN.

This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExcl instruction is the same as the transaction size of the preceding LoadExcl instruction executed in that thread. If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

Note

This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes.

- The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if they access the same number of registers. For more information, see CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers on page B2-220.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the StoreExcl instruction accesses the same number of registers as the preceding LoadExcl instruction executed in that thread. If the StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they access the same number of registers. For more information, see CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers on page B2-220.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the Tag Checked property of a memory access due to a StoreExcl instruction is the same as the Tag Checked property of a memory access by the preceding LoadExcl instruction executed in that thread. If the Tag Checked property of memory accesses due to a LoadExcl/StoreExcl pair in the same thread of execution differ, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

Note

This means the StoreExcl might pass for some instances of such a LoadExcl/StoreExcl pair, and fail for other instances of such a LoadExcl/StoreExcl pair.

- The data at the address accessed by the LoadExcl/StoreExcl pair is UNKNOWN.
This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the memory is accessed with the same Tag Checked property.

- **LoadExcl/StoreExcl** loops are guaranteed to make forward progress only if, for any LoadExcl/StoreExcl loop within a single thread of execution, the software meets all of the following conditions:
  1. Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory effects, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, ISB barriers, or indirect branches.
  2. Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:
     - There are no stores or PRFM instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
     - There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
     - There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
     - All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the LoadExcl/StoreExcl loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

- Performing stores to a PA covered by the Exclusives monitor.
- Prefetching with intent to write to a PA covered by the Exclusives monitor.
- Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.
- Executing instruction cache invalidate all instructions.
- Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.
- Executing TLB maintenance to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the **LoadExcl** and **StoreExcl** operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the **LoadExcl** instruction and the **StoreExcl** instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between **LoadExcl** and **StoreExcl** instructions in a single thread of execution.

- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.

- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.

- For the memory location accessed by a **LoadExcl/StoreExcl** pair, if the memory attributes for a **StoreExcl** instruction are different from the memory attributes for the preceding **LoadExcl** instruction in the same thread of execution, behavior is **CONSTRAINED UNPREDICTABLE**. Where this occurs because the translation of the accessed address changes between the **LoadExcl** instruction and the **StoreExcl** instruction, the **CONSTRAINED UNPREDICTABLE** behavior is as follows:

  - The **StoreExcl** either passes or fails, and the status value returned by the **StoreExcl** is UNKNOWN.

  ____________

  **Note**

  This means the **StoreExcl** might pass for some instances of a **LoadExcl/StoreExcl** pair with changed memory attributes, and fail for other instances of a **LoadExcl/StoreExcl** pair with changed memory attributes.

  ____________

  - The data at the address accessed by the **StoreExcl** is UNKNOWN.

  ____________

  **Note**

  Another bullet point in this list covers the case where the memory attributes of a **LoadExcl/StoreExcl** pair differ as a result of using different VAs with different attributes that point to the same PA.
• The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global
Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction
might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance
instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing
the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

—— Note ———
Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a
PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

—— Note ———
If the mapping of the VA to PA is changed between the LoadExcl instruction and the STREX instruction, and
the change is performed using a break-before-make sequence as described in Using break-before-make when
updating translation table entries on page D8-5198, if the StoreExcl is performed after another write to the
same PA as the StoreExcl, and that other write was performed after the old translation was properly
invalidated and that invalidation was properly synchronized, then the StoreExcl will not pass its monitor
check.

—— Note ———
— The TLB invalidation will clear either the local or global monitor.
— The PA will be checked between the LoadExcl and StoreExcl.

• The Exclusive Access state for an address accessed by a PE can be lost as a result of a PFRM PST* instruction
to the same PA executed by another PE. This means that a very high rate of repeated PFRM PST* accesses to a
memory location might impede the forward progress of another PE.
• If FEAT_MTE2 is implemented, and if a Tag Unchecked store exclusive instruction would not perform the
store and return a status value of 1, it is CONSTRAINED UNPREDICTABLE whether:
— The instruction is a Tag Checked access,
— The instruction is a Tag Unchecked access.
For more information, see Chapter D9 The Memory Tagging Extension.

—— Note ———
In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an
implementation must ensure that forward progress is made by at least one PE.

CONSTRANGED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive
access a different number of registers
As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive
pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED
UNPREDICTABLE if, in a single thread of execution, either:
• An LDXP instruction of two 32-bit quantities is followed by an STXR instruction of one 64-bit quantity at the
same address.
• An LDXR instruction of one 64-bit quantity is followed by an STXP instruction of two 32-bit quantities at the
same address.
In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:
• The STXP or STXR instruction generates an external Data Abort.
• The STXP or STXR instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data
Abort Fault status code of ESR_ELx.DFSC = 0b110101.
• The STXP or STXR instruction always fails, returning a status of 1.
• The STXP or STXR instruction always passes, returning a status of 0.
• This STXP or STXR instruction has the same pass or fail behavior that it would have had if the instruction had
used the same size and number of registers as the preceding LDXR or LDXP instruction.
B2.9.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, and SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait for Event* on page D1-4676. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

--- Note

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
The AArch64 Application Level Memory Model

B2.9 Synchronization and semaphores
Part C
The AArch64 Instruction Set
Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- *About the A64 instruction set* on page C1-226.
- *Structure of the A64 assembler language* on page C1-228.
- *Address generation* on page C1-234.
- *Instruction aliases* on page C1-237.
C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

- A miscellaneous group of branch instructions, exception generating instructions, and System instructions.
- Data-processing instructions associated with general-purpose registers. These instructions are supported by two functional groups, depending on whether the operands:
  - Are all held in registers.
  - Include an operand with a constant immediate value.
- Load and store instructions associated with the general-purpose register file, the SIMD and floating-point register file, and the SVE register file.
- SIMD and scalar floating-point data-processing instructions that operate on the SIMD and floating-point registers.
- SVE data-processing instructions that operate on the SVE registers.

The encoding hierarchy within a functional group breaks down as follows:

- A functional group consists of a set of related instruction classes. A64 instruction set encoding on page C4-388 provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
- An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of three alphabetic lists:
  - The load, store, and data-processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See Chapter C6 A64 Base Instruction Descriptions.
  - The load, store, and data-processing instructions associated with the SIMD and floating-point support. See Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.
  - The load, store, and data-processing instructions associated with SVE support. See Chapter C8 SVE Instruction Descriptions.
- An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an instruction variant. Instruction variants can occur because of differences in:
  - The size or format of the operands.
  - The register file used for the operands.
  - The addressing mode used for load/load/store memory operands.
Instruction variants might also arise as the result of other factors. Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See The stack pointer registers on page D1-4636.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.
For SIMD and floating-point register access and SVE register access, the value used selects one of 32 registers.
- Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bitfields. Some computed values in instruction variants use one or more immediate bitfields together with the secondary encoding bitfields.
All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.
C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- General requirements.
- Common syntax terms.
- Instruction Mnemonics on page C1-229.
- Condition code on page C1-229.
- Register names on page C1-230.

C1.2.1 General requirements

The letter W denotes a general-purpose register holding a 32-bit word, and X denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character.

In Example C1-1 on page C1-229, the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

- UPPER: Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name Xn indicates that the X is required, followed by a variable register number, for example X29.
- < >: Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.
- {}: Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.
- []: Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.
- a|b: Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, U(ADD|SUB)W represents UADDW or USUBW.
- ±: This indicates an optional + or - sign. If neither is used then + is assumed.
- uimm: An n-bit unsigned, positive, immediate value.
- simm: An n-bit two’s complement, signed immediate value, where n includes the sign bit.
- SP: See Register names on page C1-230.
- Wn: See Register names on page C1-230.
- WSP: See Register names on page C1-230.
- WZR: See Register names on page C1-230.
- Xn: See Register names on page C1-230.
- XZR: See Register names on page C1-230.
C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following ADD instructions all have different opcodes. However, the programmer must remember only one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1  ADD instructions with different opcodes

```
ADD W0, W1, W2  // add 32-bit register
ADD X0, X1, X2  // add 64-bit register
ADD X0, X1, W2, SXTW // add 64-bit extended register
ADD X0, X1, #42  // add 64-bit immediate
```

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see Condition flags and related instructions on page C6-1167.

Table C1-1 on page C1-229 shows the available Condition codes.

Table C1-1 Condition codes

<td>Any</td>
</tr>
</tbody>
</table>

a. Unordered means at least one NaN operand.
b. The Condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.
C1.2.5 SVE Condition code aliases

The SVE assembler syntax defines an alternative set of SVE condition code aliases for use with AArch64 conditional instructions, as follows:

Table C1-2 on page C1-230 shows the available SVE Condition code aliases.

<table>
<thead>

</tbody>
</table>

C1.2.6 Register names

This section describes the AArch64 registers. It contains the following subsections:

- General-purpose register file and zero register and stack pointer.
- SIMD and floating-point register file on page C1-231.
- SIMD and floating-point scalar register names on page C1-232.
- SIMD vector register names on page C1-232.
- SIMD vector element names on page C1-232.

General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.
Table C1-3 shows the qualified names for registers, where \( n \) is a register number 0-30.

### Table C1-3 Naming of general-purpose registers, the zero register, and the stack pointer

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wn</td>
<td>32 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>Xn</td>
<td>64 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>WZR</td>
<td>32 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>XZR</td>
<td>64 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>WSP</td>
<td>32 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
<tr>
<td>SP</td>
<td>64 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
</tbody>
</table>

This list gives more information about the instruction arguments shown in Table C1-3:

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see Procedure Call Standard for the Arm 64-bit Architecture.

### SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See General-purpose register file and zero register and stack pointer on page C1-230.

--- Note ---

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.
SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-4 shows the qualified names for accessing scalar SIMD and floating-point registers. The letter $n$ denotes a register number between 0 and 31.

Table C1-4 SIMD and floating-point scalar register names

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>$8n$</td>
</tr>
<tr>
<td>16 bits</td>
<td>$16n$</td>
</tr>
<tr>
<td>32 bits</td>
<td>$32n$</td>
</tr>
<tr>
<td>64 bits</td>
<td>$64n$</td>
</tr>
<tr>
<td>128 bits</td>
<td>$128n$</td>
</tr>
</tbody>
</table>

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-5 shows the SIMD vector register names. The letter $n$ denotes a register number between 0 and 31.

Table C1-5 SIMD vector register names

<table>
<thead>
<tr>
<th>Shape</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits × 8 lanes</td>
<td>$Vn.8B$</td>
</tr>
<tr>
<td>8 bits × 16 lanes</td>
<td>$Vn.16B$</td>
</tr>
<tr>
<td>16 bits × 4 lanes</td>
<td>$Vn.4H$</td>
</tr>
<tr>
<td>16 bits × 8 lanes</td>
<td>$Vn.8H$</td>
</tr>
<tr>
<td>32 bits × 2 lanes</td>
<td>$Vn.2S$</td>
</tr>
<tr>
<td>32 bits × 4 lanes</td>
<td>$Vn.4S$</td>
</tr>
<tr>
<td>64 bits × 1 lane</td>
<td>$Vn.1D$</td>
</tr>
<tr>
<td>64 bits × 2 lanes</td>
<td>$Vn.2D$</td>
</tr>
</tbody>
</table>

SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.
Table C1-6 shows the vector register names and the element index. The letter $i$ denotes the element index.

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>Vn.8[i]</td>
</tr>
<tr>
<td>16 bits</td>
<td>Vn.16[i]</td>
</tr>
<tr>
<td>32 bits</td>
<td>Vn.32[i]</td>
</tr>
<tr>
<td>64 bits</td>
<td>Vn.64[i]</td>
</tr>
</tbody>
</table>

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See **SIMD vector register names** on page C1-232. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

- V9.2S[1] //optional number of lanes
- V9.4S[1] //optional number of lanes

**Note**

The SIMD and floating-point register element name Vn.5[0] is not equivalent to the scalar SIMD and floating-point register name Sn. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

**SIMD vector register list**

Where an instruction operates on multiple SIMD and floating-point registers, for example vector load/store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers V4 to V7, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S } //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

**SIMD vector element list**

Registers in a list can also have a vector element form. For example, the LD4 instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.4S, V5.4S, V6.4S, V7.4S }[3] //alternative with optional number of lanes
```
C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- Memory Management Unit (MMU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see Address tagging on page D8-5162.
- If FEAT_PAuth is implemented, a Pointer authentication code (PAC), see Pointer authentication on page D8-5164.

For more information on memory management and address translation, see Chapter D8 The AArch64 Virtual Memory System Architecture.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative load/store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/store addressing modes

Load/store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, SP, with an optional immediate or register offset. Table C1-7 on page C1-234 shows the assembler syntax for the complete set of load/store addressing modes.

<table>
<thead>
<tr>
<th>Addressing Mode</th>
<th>Immediate</th>
<th>Register</th>
<th>Extended Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base register only (no offset)</td>
<td>[base{, #0}]</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Base plus offset</td>
<td>[base{, #imm}]</td>
<td>[base, Xm{, LSL #imm}]</td>
<td>[base, Wm, (S</td>
</tr>
<tr>
<td>Pre-indexed</td>
<td>[base, #imm]!</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Post-indexed</td>
<td>[base], #imm</td>
<td>[base], Xm</td>
<td>-</td>
</tr>
<tr>
<td>Literal (PC-relative)</td>
<td>label</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

a. The post-indexed by register offset mode can be used with the SIMD load/store structure instructions described in Load/store Advanced SIMD on page C3-265. Otherwise the post-indexed by register offset mode is not available.
Some types of load/store instruction support only a subset of the load/store addressing modes listed in Table C1-7 on page C1-234. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can be used only for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of load/store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of load/store instruction and the transfer size.

Table C1-8 shows the offset and the type of load/store instruction.

<table>
<thead>
<tr>
<th>Offset bits</th>
<th>Sign</th>
<th>Scaling</th>
<th>Write-Back</th>
<th>Load/store type</th>
</tr>
</thead>
<tbody>
<tr>

<td>Unscaled</td>
<td>Optional</td>
<td>Single register</td>
</tr>
<tr>
<td>12</td>
<td>Unsigned</td>
<td>Scaled</td>
<td>No</td>
<td>Single register</td>
</tr>
</tbody>
</table>

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if LSL #imm is present and where imm must be equal to log2(transfer_size). The SXTX extend/shift option is functionally equivalent to LSL, but the LSL option is preferred in source code.
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by #imm, where imm must be equal to log2(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific load/store instruction requires this. SP cannot be used as a register offset.
Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Table C1-9 on page C1-236 shows the arithmetic instructions that can compute addressing modes.

### Table C1-9 Arithmetic instructions to compute addressing modes

<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

#### Note

- For the 64-bit base plus register offset form, the UTX mnemonic is an alias for the LSL shift option, but LSL is preferred for disassembly. Similarly the SXTX extend/shift option is functionally equivalent to the LSL option, but the LSL option is preferred in source code.

- To calculate a base plus immediate offset the ADD instructions defined in Arithmetic (immediate) on page C3-298 accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single ADD instruction cannot support the full range of byte offsets available to a single register load/store with a scaled 12-bit immediate offset. For example, a quadword LDR effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two ADD instructions. The following example shows this:

```c
ADD Xd, base, #((imm & 0xFFF)
ADD Xd, Xd, #((imm>>12), LSL #12
```

- To calculate a base plus extended register offset, the ADD instructions defined in Arithmetic (extended register) on page C3-304 provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

```c
ADD Xd, base, Wm, SXTW #3 // Xd = base + (SignExtend(Wm) LSL 3)
ADD Xd, base, Wm, UXTH #4 // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
```

- If the same extended register offset is used by more than one load/store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then reuse it as a simple register offset. The extend and scale calculation can be performed using the SBFIZ and UBFIZ bitfield instructions defined in Bitfield move on page C3-300, for example:

```c
SBFIZ Xd, Xm, #3, #32 //Xd = "Wm, SXTW #3"
UBFIZ Xd, Xm, #4, #16 //Xd = "Wm, UXTH #4"
```
C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.
Chapter C2
About the A64 Instruction Descriptions

This chapter describes the instruction descriptions contained in Chapter C6 A64 Base Instruction Descriptions, Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions, and Chapter C8 SVE Instruction Descriptions.

It contains the following sections:

• Understanding the A64 instruction descriptions on page C2-240.
• General information about the A64 instruction descriptions on page C2-243.
C2.1 Understanding the A64 instruction descriptions

Each instruction description in Chapter C6 and Chapter C7 has the following content:
1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction. If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in Chapter C6 there are the following titles for different forms of the `ADD` instruction:
- `ADD (extended register)` on page C6-1174.
- `ADD (immediate)` on page C6-1177.
- `ADD (shifted register)` on page C6-1179.

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:
- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address $A$ shows, from left to right, the bytes at addresses $A+3$, $A+2$, $A+1$, and $A$.

There might be variants of an encoding, if the assembler syntax prototype differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in Chapter C6 there are the following subheadings for variants of the `ADC` instruction encoding:
- 32-bit variant ($sf = 0$).
- 64-bit variant ($sf = 1$).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.
Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates on page C2-242.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The Assembler symbols subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

- < > Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

- { } Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

- # This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.

- +/- This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

- <Xn> The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

- <Wn> The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

- <Xn|SP> The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

- <Wn|WSP> The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

- <Bn>, <Hn>, <Sn>, <Dn>, <Qn> The 8, 16, 32, 64, or 128-bit name of a SIMD and floating-point register in a scalar context, as described in Register names on page C1-230.

- <Vn> The name of a SIMD and floating-point register in a vector context, as described in Register names on page C1-230.

- <Zn> The name of an SVE vector register, as described in SVE vector registers on page B1-140.

- <Pn> The name of an SVE predicate register, as described in SVE predicate registers on page B1-141.
If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.

--- Note ---

*Register names on page C1-230* provides the A64 register names.

### C2.1.6 Pseudocode describing how the instruction operates

The *Operation* subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

--- Note ---

For a description of Arm pseudocode, see *Appendix K16 Arm Pseudocode Definition*. This appendix also describes the execution model for an instruction.

### C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.
C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in Fixed values in AArch64 instruction and System register descriptions apply to the AArch64 descriptions throughout this manual. The following subsections provide this information:

- Execution of instructions in debug state.
- Fixed values in AArch64 instruction and System register descriptions.
- Modified immediate constants in A64 instructions on page C2-244.

C2.2.1 Execution of instructions in debug state

In general, except for the instructions described in Debug state on page C3-250, the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state on page H2-10243.

Note

For many instructions, execution is unchanged in Debug state. Executing instructions in Debug state on page H2-10243 identifies these instructions.

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

- **RAZ** Read-As-Zero. See Read-As-Zero (RAZ).
  - In diagrams, a RAZ bit can be shown as 0.

- **(0), RES0** Reserved, Should-Be-Zero (SBZ) or RES0.
  - In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:
    - The instruction is UNDEFINED.
    - The instruction is treated as a NOP.
    - The instruction executes as if the value of the bit was 0.
    - Any destination registers of the instruction become UNKNOWN.
  - This notation can be expanded for fields, so a three-bit field can be shown as either (0)(0)(0) or as (000).
  - In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES0 fields, the (0) and RES0 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

- **RAO** Read-As-One. See Read-As-One (RAO).
  - In diagrams, a RAO bit can be shown as 1.

- **(1), RES1** Reserved, Should-Be-One (SBO) or RES1.
In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates an SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of RES1 for more information.

**Note**

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES1 fields, and RES1 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

### C2.2.3 Modified immediate constants in A64 instructions

It contains the following subsections:

- Modified immediate constants in A64 floating-point instructions.

#### Modified immediate constants in A64 floating-point instructions

Table C2-1 on page C2-244 shows the immediate constants available in FMOV (scalar, immediate) and FMOV (vector, immediate) floating-point instructions.

<table>
<thead>
<tr>
<th>Data type</th>
<th>immediate</th>
<th>Constant a</th>
</tr>
</thead>
<tbody>
<tr>
<td>F16</td>
<td>abcdefgh</td>
<td>aBbcdefgh0000000</td>
</tr>
<tr>

<td>abcdefgh</td>
<td>aBbbbbbc defgh0000000000000000</td>
</tr>
<tr>
<td>F64</td>
<td>abcdefgh</td>
<td>aBbbbbbb bcdefgh00000000000000000000000000</td>
</tr>
</tbody>
</table>

a. In this column, B = NOT(b). The bit pattern represents the floating-point number \((-1)^s \times 2^{exp} \times \text{mantissa}\), where

\[ S = \text{UInt}(a), \quad \text{exp} = \text{UInt}(\text{NOT}(b)\text{::c:d}) - 1 \quad \text{and} \quad \text{mantissa} = (16+\text{UInt}(e:f:g:h))/16. \]

The immediate value shown in the table is either:

- The value of the imm8 field for an FMOV (scalar, immediate) instruction, see FMOV (scalar, immediate) on page C7-2340.
- The value obtained by concatenating the a:b:c:d:e:f:g:h fields for an FMOV (vector, immediate) instruction, see FMOV (vector, immediate) on page C7-2332.
Table C2-2 shows the floating-point constant values encoded in the $b:c:d:e:f:g:h$ fields of the FMOV (vector, immediate) instruction.

Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

• Branches, Exception generating, and System instructions on page C3-248.
• Loads and stores on page C3-256.
• Loads and stores - SVE on page C3-287.
• Data processing - immediate on page C3-298.
• Data processing - register on page C3-303.
• Data processing - SIMD and floating-point on page C3-311.
• Data processing - SVE on page C3-339.
• Data processing - SVE2 on page C3-368.

For a structured breakdown of instruction groups by encoding, see Chapter C4 A64 Instruction Set Encoding.
C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and System instructions. It contains the following subsections:

- Conditional branch.
- Unconditional branch (immediate) on page C3-249.
- Unconditional branch (register) on page C3-249.
- Exception generation and return on page C3-249.
- System register instructions on page C3-250.
- System instructions on page C3-250.
- Hint instructions on page C3-251.
- Barriers and CLREX instructions on page C3-251.
- Pointer authentication instructions on page C3-252.

For information about the encoding structure of the instructions in this instruction group, see Branches, Exception Generating and System instructions on page C4-534.

——— Note ————

Software must:

- Use only BLR or BL to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the BLR or BL instruction incremented by four.
- Use only RET to perform a subroutine return, when that subroutine is expected to have been entered by a BL or BLR instruction.
- Use only B, BR, or the instructions listed in Table C3-1 on page C3-248 to perform a control transfer that is not a subroutine call or subroutine return described in this Note.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the Condition flags or the value in a general-purpose register. See Table C1-1 on page C1-229 for a list of the Condition codes that can be used for cond.

Table C3-1 on page C3-248 shows the Conditional branch instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>Branch offset range from the PC</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>B, cond</td>
<td>Branch conditionally</td>
<td>±1MB</td>
<td>B.cond on page C6-1215</td>
</tr>
<tr>
<td>BC, cond</td>
<td>Branch Consistent conditionally</td>
<td>±1MB</td>
<td>BC.cond on page C6-1216</td>
</tr>
<tr>
<td>CBNZ</td>
<td>Compare and branch if nonzero</td>
<td>±1MB</td>
<td>CBNZ on page C6-1250</td>
</tr>
<tr>
<td>CBZ</td>
<td>Compare and branch if zero</td>
<td>±1MB</td>
<td>CBZ on page C6-1251</td>
</tr>
<tr>
<td>TBNZ</td>
<td>Test bit and branch if nonzero</td>
<td>±32KB</td>
<td>TBNZ on page C6-1996</td>
</tr>
<tr>
<td>TBZ</td>
<td>Test bit and branch if zero</td>
<td>±32KB</td>
<td>TBZ on page C6-1997</td>
</tr>
</tbody>
</table>
C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 on page C3-249 shows the Unconditional branch instructions with an immediate branch offset.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>Immediate branch offset range from the PC</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Branch unconditionally</td>
<td>±128MB</td>
<td>B on page C6-1214</td>
</tr>
<tr>
<td>BL</td>
<td>Branch with link</td>
<td>±128MB</td>
<td>BL on page C6-1229</td>
</tr>
</tbody>
</table>

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 on page C3-249 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLR</td>
<td>Branch with link to register</td>
<td>BLR on page C6-1230</td>
</tr>
<tr>
<td>BR</td>
<td>Branch to register</td>
<td>BR on page C6-1233</td>
</tr>
<tr>
<td>RET</td>
<td>Return from subroutine</td>
<td>RET on page C6-1754</td>
</tr>
</tbody>
</table>

C3.1.4 Exception generation and return

This section describes the following exceptions:

- Exception generating.
- Exception return on page C3-250.
- Debug state on page C3-250.

Exception generating

Table C3-4 on page C3-249 shows the Exception generating instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>BRK</td>
<td>Breakpoint Instruction</td>
<td>BRK on page C6-1237</td>

</tbody>
</table>

For more information about:
- CSDB, PSSBB, SB, SSBB, TSB CSYNC, see Memory barriers on page B2-174.
- ESB, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.
- PSB CSYNC, see Chapter D13 The Statistical Profiling Extension.

C3.1.10 Pointer authentication instructions

FEAT_PAuth adds support for pointer authentication, see Pointer authentication on page D8-5164. This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:
- Basic pointer authentication instructions.
- Combined instructions that include pointer authentication on page C3-254.

Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-13 on page C3-252 shows the instructions that add a Pointer Authentication Code (PAC) to the address in a register:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>

</tbody>
</table>
C3.2 Loads and stores

This section describes the load/store instructions. It contains the following subsections:

- Load/store register.
- Load/store register (unscaled offset) on page C3-257.
- Load/store pair on page C3-258.
- Load/store non-temporal pair on page C3-259.
- Load/store unprivileged on page C3-260.
- Load-Exclusive/Store-Exclusive on page C3-260.
- LoadLOAcquire/StoreLORelease on page C3-263.
- Load/store scalar SIMD and floating-point on page C3-263.
- Load/store Advanced SIMD on page C3-265.
- Prefetch memory on page C3-267.
- Atomic instructions on page C3-268.
- Memory Tagging instructions on page C3-273.
- Memory Copy and Memory Set instructions on page C3-274.

The requirements for the alignment of data memory accesses are strict. For more information, see Alignment of data accesses on page B2-189.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See SP alignment checking on page D1-4668. Using a misaligned stack pointer generates an SP alignment fault exception.

For information about the encoding structure of the instructions in this instruction group, see Loads and Stores on page C4-547.

--- Note ---

In some cases, load/store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-11584.

C3.2.1 Load/store register

The load/store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also Load/store addressing modes on page C1-234.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.
If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is **CONSTRAINED UNPREDICTABLE** and one of the following behaviors must occur:

- The instruction is treated as **UNDEFINED**.
- The instruction is treated as a **NOP**.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is **UNKNOWN**.

Table C3-17 shows the load/store register instructions.

**Table C3-17 Load/store register instructions**

### C3.2.2 Load/store register (unscaled offset)

The load/store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/store addressing modes* on page C1-234.
The load/store register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:
- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a load/store instruction, for example LDR, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-18. Arm recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a load/store single register mnemonic, for example, LDR.

Table C3-18 shows the load/store register instructions with an unscaled offset.

C3.2.3 Load/store pair

The load/store pair instructions support the following addressing modes:
- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes on page C1-234.

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:
- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:
- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-19 shows the load/store pair instructions.

</tr>
</tbody>
</table>

### C3.2.4 Load/store non-temporal pair

The load/store non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See Load/store addressing modes on page C1-234.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-20 on page C3-259 shows the load/store non-temporal pair instructions.

</tbody>
</table>
C3.2.5  **Load/store unprivileged**

The load/store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/store addressing modes* on page C1-234.

The access permissions that apply to accesses made at EL0 apply to the memory accesses made by a load/store unprivileged instruction that is executed either:

- At EL1 when the *Effective value* of PSTATE.UAO is 0.
- At EL2 when both the *Effective value* of HCR_EL2.{E2H, TGE} is \{1, 1\} and the *Effective value* of PSTATE.UAO is 0.

Otherwise, memory accesses made by a load/store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding load/store register instruction, see *Load/store register* on page C3-256.

--- Note ---

This means that when the value of PSTATE.UAO is 1 the access permissions for a load/store unprivileged instruction are always the same as those for the corresponding load/store register instruction.

---

Table C3-21 on page C3-260 shows the load/store unprivileged instructions.

</tr>
</tbody>
</table>

C3.2.6  **Load-Exclusive/Store-Exclusive**

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See *Load/store addressing modes* on page C1-234.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See *Synchronization and semaphores* on page B2-211.
If FEAT_LSE2 is not implemented then:

- The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

For more information on alignment requirements and behaviors, see *Load-Exclusive/ Store-Exclusive and Atomic instructions* on page B2-190.

When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location being stored to.

Table C3-22 shows the Load-Exclusive/Store-Exclusive instructions.

#### C3.2.7 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC, and Store-Release instructions support only one addressing mode:

- Base register with no offset.

See *Load/store addressing modes* on page C1-234.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction has the Release semantics only if the store is successful.

Armv8.1 adds more instructions with load-acquire and store-release mechanisms, see *LoadLOAcquire/StoreLORelease* on page C3-263.

FEAT_LRCPC2 introduces changes to the alignment requirements of Load-Acquire/Store-Release instructions.
Table C3-23 on page C3-262 shows the Non-exclusive Load-Acquire/Store-Release instructions.

C3.2.8 LoadLOAcquire/StoreLORelease

The LoadLOAcquire/StoreLORelease instructions support only one addressing mode:

- Base register with no offset.

See *Load/store addressing modes* on page C1-234.

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of LoadLOAcquire/StoreLORelease, see *LoadLOAcquire, StoreLORelease* on page B2-181.

The LoadLOAcquire/StoreLORelease instructions require natural alignment, and an unaligned address generates an Alignment fault.

Table C3-25 on page C3-263 shows the LoadLOAcquire/StoreLORelease instructions.

C3.2.9 Load/store scalar SIMD and floating-point

The load/store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in *SIMD and floating-point scalar register names* on page C1-232. The memory addressing modes available, described in *Load/store addressing modes* on page C1-234, are identical to the general-purpose register load/store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the load/store instructions that transfer general-purpose registers, load/store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

**Load/store scalar SIMD and floating-point register**

The load/store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see Load/store addressing modes on page C1-234.

**Note**

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see Load/store scalar SIMD and floating-point register (unscaled offset).

Table C3-26 on page C3-264 shows the load/store instructions for a single SIMD and floating-point register.

### Table C3-26 Load/store single SIMD and floating-point register instructions

</tr>
</tbody>
</table>

### Load/store scalar SIMD and floating-point register (unscaled offset)

The load/store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also Load/store addressing modes on page C1-234.

The load/store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the load/store register (unscaled offset) instructions, that disambiguate this instruction class from the load/store register instruction, see Load/store register (unscaled offset) on page C3-257.

Table C3-27 on page C3-264 shows the load/store SIMD and floating-point register instructions with an unscaled offset.

<td>Store scalar SIMD&amp;FP register (unscaled offset)</td>
<td>STUR (SIMD&amp;FP) on page C7-2817</td>
</tr>
</tbody>
</table>

### Load/store SIMD and floating-point register pair

The load/store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes on page C1-234.
If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-28 shows the load/store SIMD and floating-point register pair instructions.

### Table C3-28 Load/store SIMD and floating-point register pair instructions

<table>
<thead>

<td>Store pair of scalar SIMD&amp;FP registers</td>
<td>STP (SIMD&amp;FP) on page C7-2807</td>
</tr>
</tbody>
</table>

**Load/store SIMD and floating-point non-temporal pair**

The load/store SIMD and floating-point non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also *Load/store addressing modes* on page C1-234.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a load non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-29 shows the load/store SIMD and floating-point Non-temporal pair instructions.

**C3.2.10 Load/store Advanced SIMD**

The Advanced SIMD load/store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
• Post-indexed by an immediate, equal to the number of bytes transferred.

Load/store vector instructions, like other load/store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the load/store instructions that transfer general-purpose registers, the load/store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

**Load/store structures**

Table C3-30 on page C3-266 shows the load/store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

C3.2.11 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as preloading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.

A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.
The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

- PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM
- PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM
- PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM

<prfop> is defined as <type><target><policy>.

Here:
- <type> is one of:
  - PLD: Prefetch for load.
  - PST: Prefetch for store.
  - PLI: Preload instructions.
- <target> is one of:
  - L1: Level 1 cache.
  - L2: Level 2 cache.
  - L3: Level 3 cache.
- <policy> is one of:
  - KEEP: Retained or temporal prefetch, allocated in the cache normally.
  - STRM: Streaming or non-temporal prefetch, for data that is used only once.

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in Load/store register (unscaled offset) on page C3-257.

Table C3-32 shows the Prefetch memory instructions.

### C3.2.12 Atomic instructions

The atomic instructions perform atomic read and write operations on a memory location such that the architecture guarantees that no modification of that memory location by another observer can occur between the read and the write defined by that instruction.

This section describes the following operations:

- Atomic memory operations,
- Single-copy atomic 64-byte load/store on page C3-271.
- Swap on page C3-272.
- Compare and Swap on page C3-272.

#### Atomic memory operations

The atomic memory operation instructions support only one addressing mode:

- Base register only.

See also Load/store addressing modes on page C1-234.
For the purpose of permission checking, and for watchpoints, all of the Atomic memory operation instructions are treated as performing both a load and a store.

If FEAT_LSE2 is not implemented then the LD<OP> and ST<OP> instructions require natural alignment, and an unaligned address generates an Alignment fault. For more information on alignment requirements and behaviors, see Load-Exclusive/Store-Exclusive and Atomic instructions on page B2-190.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

For the LD<OP> instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The ST<OP> instructions, and LD<OP> instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a DMB LD barrier.

</table>
Single-copy atomic 64-byte load/store

If FEAT_LS64 is implemented, the following instructions are implemented:

- LD64B.
- ST64B.

If FEAT_LS64_V is implemented, the following instructions are implemented:

- LD64B.
- ST64B.
- ST64BV.

If FEAT_LS64_ACCDATA is implemented, the following instructions are implemented:

- LD64B.
- ST64B.
- ST64BV.
- ST64BV0.

The single-copy atomic 64-byte load/store instructions support one addressing mode:
- Base register only.

See also Load/store addressing modes on page C1-234.

The memory location accessed by the instructions is required to be aligned on a 64-byte boundary, otherwise an Alignment fault occurs.

When the instructions access a memory type that is not one of the following, a data abort for unsupported Exclusive or atomic access is generated for the stage of translation that provided the memory type:

- Normal Inner Non-cacheable, Outer Non-cacheable.
- Device-GRE.
- Device-nGRE.
- Device-nGnRE.
- Device-nGnRnE.

Regardless of the memory type:
- The memory access generated by an ST64BV or ST64BV0 instruction is not merged with any accesses.
- The memory access generated by an ST64B instruction is not merged with any accesses generated by store instructions appearing in program order after the instruction.

Table C3-34 shows the single-copy atomic 64-byte load/store instructions.

</tr>
</tbody>
</table>

**Swap**

The swap instructions support only one addressing mode:
- Base register only.

See also *Load/store addressing modes on page C1-234.*

For the purpose of permission checking, and for watchpoints, all of the Swap instructions are treated as performing both a load and a store.

If FEAT_LSE2 is not implemented, then the SWP instructions require natural alignment, and an unaligned address generates an Alignment fault. For more information on alignment requirements and behaviors, see *Load-Exclusive/Store-Exclusive and Atomic instructions on page B2-190.*

The instructions are provided with ordering options, which map to the acquire and release definitions used in the architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the SWP instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

<table>

</tr>
</tbody>
</table>

**Compare and Swap**

The Compare and Swap instructions support only one addressing mode:
- Base register only.

See also *Load/store addressing modes on page C1-234.*

For the purpose of permission checking, and for watchpoints, all of the Compare and Swap instructions are treated as performing both a load and a store.

If FEAT_LSE2 is not implemented then:
- The CAS instructions require natural alignment.
- The CASP instructions require alignment to the total size of the memory being accessed.
For more information on alignment requirements and behaviors, see *Load-Exclusive/ Store-Exclusive and Atomic instructions* on page B2-190.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the architecture. If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the CAS and CASP instructions, the architecture permits that a data read clears any Exclusives monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

C3.2.14 Memory Copy and Memory Set instructions

If FEAT_MOPS is implemented, the CPY*, SETE*, SETM*, and SETP* instructions described in this section are implemented. If FEAT_MOPS and FEAT_MTE are implemented, the SETG* instructions described in this section are also implemented. Collectively, the instructions described in this section are referred to as Memory Copy and Memory Set instructions.

To perform a memory copy or memory set, three instructions - a prologue, then a main, and then an epilogue - are expected to be run in succession, with no instruction appearing in the code between them:
- To perform a memory copy, forward-only: CPYFP*, then CPYFM*, and then CPYFE*.
- To perform a memory copy, forward or backward: CPYP*, then CPYMP*, and then CPYEP*.
- To perform a memory set with tag setting: SETGP*, then SETGM*, and then SETGE*.
- To perform a memory set without tag setting: SETP*, then SETM*, and then SETE*.

The variant of each instruction is also expected to be the same throughout one of these sequences. For example, CPYFPWTWN, CPYFPWTWN, CPYFEWTWN.

Fetching of a Memory Copy and Memory Set instruction multiple times during its execution is permissible.

The handling of synchronous exceptions generated by Memory Copy and Memory Set instructions is described in ESR_ELx, FAR_ELx, Definition of a precise exception and imprecise exception on page D1-4638, and Synchronous exception entry on page D1-4642.
The handling of asynchronous exceptions generated by Memory Copy and Memory Set instructions is described in *Definition of a precise exception and imprecise exception* on page D1-4638 and *Asynchronous exception entry* on page D1-4644.

Memory Copy and Memory Set exceptions can be generated by execution of Memory Copy and Memory Set instructions restarting on a physical hardware PE implementation that is different from the physical hardware PE implementation that an exception was taken from. For more information, see *Memory Copy and Memory Set exceptions* on page D1-4654.

If an exception is taken during the execution of a Memory Copy and Memory Set instruction, that instruction has not been executed for the purposes of instruction counting, instruction tracing, statistical profiling, or single stepping.

For the purposes of single stepping and performance monitoring, each Memory Copy and Memory Set instruction is regarded as a single instruction that performs a store and, in the case of $\text{CPY}^*$ instructions, also performs a load.

For Memory Copy and Memory Set instructions, the following are not architecturally defined:

- The size of the memory transactions they create.
- The order between accesses to different addresses.

The $\text{CPY}^*$ instructions are guaranteed to make forward progress if none of the following four leaf level translation table entries fault:

- The source leaf level translation table entry held in $X_s$.
- The next leaf level translation table entry, as determined by the copy direction, adjacent to the source leaf level translation table entry held in $X_s$.
- The destination leaf level translation table entry held in $X_d$.
- The next leaf level translation table entry, as determined by the copy direction, adjacent to the destination leaf level translation table entry held in $X_d$.

The $\text{SET}^*$ instructions are guaranteed to make forward progress if neither of the following two leaf level translation table entries fault:

- The destination leaf level translation table entry held in $X_d$.
- The next leaf level translation table entry adjacent to the destination leaf level translation table entry held in $X_d$.

--- **Note** ---

The forward progress described in this section can be achieved by ensuring that, when a memory management fault is encountered, all bytes leading up to the fault have been operated on.

Table C3-44 on page C3-275 shows the memory copy, forward-only instructions.

C3.3 Loads and stores - SVE

SVE vector load and store instructions transfer data in memory to or from elements of one or more vector or predicate transfer registers. SVE also includes vector prefetch instructions that provide read and write hints to the memory system. For SVE predicated load, store, and prefetch instructions, the memory element access size and type that is associated with each vector element is specified by a suffix to the instruction mnemonic, independently of the element size of the transfer registers. For example, LD1SH. The following table shows the supported instruction suffixes for SVE load, store, and prefetch instructions:

<table>
<thead>
<tr>
<th>Instruction suffix</th>
<th>Memory element access size and type</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Unsigned byte</td>
</tr>
<tr>
<td>H</td>
<td>Unsigned halfword or half-precision floating-point</td>
</tr>
<tr>
<td>W</td>
<td>Unsigned word or single-precision floating-point</td>
</tr>
<tr>
<td>D</td>
<td>Unsigned doubleword or double-precision floating-point</td>
</tr>
<tr>
<td>SB</td>
<td>Signed byte</td>
</tr>
<tr>
<td>SH</td>
<td>Signed halfword</td>
</tr>
<tr>
<td>SW</td>
<td>Signed word</td>
</tr>
</tbody>
</table>

The element size of the transfer registers is always greater than or equal to the memory element access size. When the element size of the transfer registers is strictly greater than the memory element access size, then these are referred to as unpacked data accesses. In the case of unpacked data accesses:

- For load instructions, each element access is sign-extended or zero-extended to fill the vector element, according to its memory element access size and type.
- For store instructions, each vector element is truncated to the memory element access size.

Where the vector element size and the memory element access size are the same, then these are referred to as packed data accesses. Signed access types are not supported for packed data accesses. Packed and unpacked access sizes and types relate to the vector element size of the transfer registers, as defined in the following table:

<table>
<thead>
<tr>
<th>Vector element</th>
<th>Packed access suffix</th>
<th>Unpacked access suffixes</th>
</tr>
</thead>
<tbody>
<tr>
<td>.B</td>
<td>B</td>
<td>-</td>
</tr>
<tr>
<td>.H</td>
<td>H</td>
<td>B, SB</td>
</tr>
<tr>
<td>.S</td>
<td>W</td>
<td>H, SH, B, SB</td>
</tr>
<tr>
<td>.D</td>
<td>D</td>
<td>W, SW, H, SH, B, SB</td>
</tr>
</tbody>
</table>

For gather-load and scatter-store instructions, the vector element size can only be .S or .D. This means that any non-contiguous memory element access of less than a word is unpacked. Non-contiguous memory element accesses of a word can be either packed or unpacked, depending on the vector element size.

Load, store, and prefetch instructions consist of the following:

- Predicated single vector contiguous element accesses on page C3-288.
- Predicated multiple vector contiguous structure load/store on page C3-291.
- Predicated non-contiguous element accesses on page C3-293.
- Predicated replicating element loads on page C3-295.
- Unpredicated vector register load/store on page C3-296.
- Unpredicated predicate register load/store on page C3-296.
All predicated load instructions zero the *Inactive elements* of the destination vector, except for Non-fault loads and First-fault loads when the corresponding FFR element is FALSE.

Prefetch instructions provide hints to hardware and do not change architectural state. Therefore, a *Governing predicate* for a prefetch instruction provides an additional hint which indicates the memory locations to be prefetched. Prefetch instructions require a prefetch operation specifier. SVE prefetch instructions support all of the prefetch operations except for the PLI prefetch operand types.

Load, store, and prefetch instructions that multiply a scalar index register or an index vector element by the memory element access size specify a shift type, followed by a shift amount in bits. The shift type can be one of *LSL*, *SXTW*, or *UXTW*. The shift amount is always Log2 of the memory element access size, in bytes. The shift amount defaults to zero when the memory element access size is a byte, and the shift size can be omitted. The shift type of *LSL* must be omitted if the shift amount is omitted.

When included as part of the assembler syntax for an instruction, $\text{MUL } VL$ indicates that the specified immediate index value is multiplied by the size of the addressed vector or predicate in memory, measured in bytes, irrespective of predication. For a detailed description of the meaning of this assembler syntax for each instruction, see the appropriate subsection below. When used in pseudocode, the symbol $\text{vl}$ represents the vector length, measured in bits.

SVE load, store, and prefetch instructions do not support pre-indexed or post-indexed addressing.

### C3.3.1 Predicated single vector contiguous element accesses

Predicated contiguous load and store instructions access memory locations starting from an address that is defined by a scalar base register plus either:

- A scalar index register.
- An immediate index value that is in the range -8 to 7, inclusive. This defaults to zero if omitted.

The predicated contiguous load and store instructions have two supporting addressing modes:

- Scalar base plus immediate index.
- Scalar base plus scalar index.

Predicated contiguous prefetch instructions address memory locations in a similar manner, with the index being either:

- A scalar index register.
- An immediate index value that is in the range of -32 to 31, inclusive. This defaults to zero if omitted.

For predicated contiguous load and store SVE instructions:

- The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the number of vector elements, irrespective of predication, and then multiplied by the memory element access size in bytes. The resulting offset is incremented following each element access by the memory element access size.
- The scalar index register value is multiplied by the memory element access size in bytes. The index value is incremented by one after each element access, but the scalar index register is not updated by the instruction.
When alignment checking is enabled for loads and stores, the value of the base address register must be aligned to the memory element access size.

C3.3 Loads and stores - SVE

C3.3.2 Predicated multiple vector contiguous structure load/store

Predicated multiple vector contiguous structure load/store instructions are defined by a scalar base register plus either:

• A scalar index register.
• An immediate index that is a multiple of N, in the range -8N to 7N, inclusive. This defaults to zero if omitted.

The predicated contiguous structure load and store instructions have two supporting addressing modes:

• Scalar base plus immediate.
• Scalar base plus scalar index.

For the predicated multiple vector contiguous structure load/store SVE instructions:

• The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the number of vector elements, irrespective of predication, and then multiplied by the memory element access size in bytes. The resulting offset is incremented following each element access by the memory element access size.

• The scalar index register value is multiplied by the memory element access size in bytes. Following each element access, the index value is incremented by one but the instruction does not update the scalar index register.

• Each predicate element applies to a single structure in memory, or equivalently to the same element number within each of the two, three, or four transferred vector registers.

• These instructions support packed data accesses only.
When alignment checking is enabled for loads and stores, the base address must be aligned to the element access size.

### C3.3 Loads and stores - SVE

#### C3.3.3 Predicated non-contiguous element accesses

Predicated non-contiguous element accesses address non-contiguous memory locations that are specified by either:

- A scalar base register plus a vector of indices or offsets.
- A vector of base addresses plus an immediate byte offset. The immediate byte offset is a multiple of the memory element access size, in the range 0 to 31 times the memory element access size, inclusive, and defaults to zero if omitted.

The predicated non-contiguous element accesses have two supporting addressing modes:

- Scalar base plus 64-bit vector index.
- Scalar base plus 32-bit vector index.
- Vector base plus immediate offset.

For this group of SVE instructions:

- Vector registers used as part of the address must specify a vector element size of 32 bits or 64 bits, .S or .D. For load and store instructions, the transfer register must specify the same vector element size.
- If the index vector register contains 32-bit index values then the lowest 32 bits of each index vector element can either be zero-extended or sign-extended to 64 bits.
- For load and store instructions, the index vector elements are then optionally multiplied by the memory element access size, in bytes, if a shift amount is specified. For prefetch instructions, the index vector elements are always multiplied by the memory element access size, in bytes.

C3.3.5 Unpredicated vector register load/store

The unpredicated vector register load, LDR, and store, STR, instructions transfer a single vector register from or to memory locations that are specified by a scalar base register plus an immediate index value that is in the range -256 to 255, inclusive. The immediate index value defaults to zero if omitted.

The unpredicated vector register load/store instructions have one supporting addressing mode:

- Scalar base plus immediate index.

For the unpredicated vector register load/store SVE instructions:

- The immediate index value is a vector index, not an element index. The immediate index value is multiplied by the current vector register length in bytes.
- The data transfer is performed as a contiguous stream of byte accesses in ascending element order, without endianness conversion.
- When alignment checking is enabled for loads and stores, the base address must be 16-byte aligned.

C3.3.6 Unpredicated predicate register load/store

The unpredicated predicate register load, LDR, and store, STR, instructions transfer a single predicate register from or to memory locations that are specified by a scalar base register plus an immediate index value that is in the range -256 to 255, inclusive. The immediate index value defaults to zero if omitted.

The unpredicated predicate register load/store instructions have one supporting addressing mode:

- Scalar base plus immediate index.

For unpredicated predicate register load/store SVE instructions:

- The immediate index value is a predicate index, not an element index. The immediate index value is multiplied by the current predicate register length, in bytes.
- The data transfer is performed as a contiguous stream of byte accesses, each byte containing 8 consecutive predicate bits, in ascending bit and element order, without endianness conversion.
- When alignment checking is enabled for loads and stores, the base address must be 2-byte aligned.

C3.4 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- Arithmetic (immediate).
- Logical (immediate).
- Move (wide immediate) on page C3-299.
- Move (immediate) on page C3-299.
- PC-relative address calculation on page C3-300.
- Bitfield move on page C3-300.
- Bitfield insert and extract on page C3-301
- Extract register on page C3-301.
- Shift (immediate) on page C3-301.
- Sign-extend and Zero-extend on page C3-302.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Immediate on page C4-530.

C3.4.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits. The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-54 on page C3-298 shows the Arithmetic instructions with an immediate offset.

<table>
<thead>

<td>CMP (immediate) on page C6-1278</td>
</tr>
<tr>
<td>CMN</td>
<td>Compare negative</td>
<td>CMN (immediate) on page C6-1272</td>
</tr>
</tbody>
</table>

C3.4.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size \( e = 2, 4, 8, 16, 32 \) or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to \( (e - 1) \) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to \( (e - 1) \) bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

Note: Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.
#### Note

Apart from `ANDS` and its `TST` alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a `CBZ`, `CBNZ`, `TBZ`, or `TBNZ` conditional branch.

Table C3-55 shows the Logical immediate instructions.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### C3.4.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-56 on page C3-299 shows the Move (wide immediate) instructions.

<table>
<thead>
<tr>

<td><code>MOVN</code> on page C6-1703</td>
</tr>
<tr>
<td>MOVK</td>
<td>Move wide with keep</td>
<td><code>MOVK</code> on page C6-1701</td>
</tr>
</tbody>
</table>

### C3.4.4 Move (immediate)

The Move (immediate) instructions are aliases for a single `MOVZ`, `MOVN`, or `ORR` (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the `MOVZ`, `MOVN`, and `ORR` instruction to encode the immediate, then an assembler must prefer `MOVZ` to `MOVN`, and `MOVZ` or `MOVN` to `ORR`, to ensure reversability. A disassembler must output `ORR` (immediate with zero register) `MOVZ`, and `MOVN`, as a `MOV` mnemonic except that the underlying instruction must be used when:

- `ORR` has an immediate that can be generated by a `MOVZ` or `MOVN` instruction.
- A `MOVN` instruction has an immediate that can be encoded by `MOVZ`.
- `MOVZ` #0 or `MOVN` #0 have a shift amount other than `LSL` #0.
Table C3-57 shows the Move (immediate) instructions.

</tr>
</tbody>
</table>

**C3.4.5 PC-relative address calculation**

The `ADR` instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The `ADRP` instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an `A00` (immediate) instruction, or a load/store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

---

**Note**

The term *page* used in the `ADRP` description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-58 on page C3-300 shows the instructions used for PC-relative address calculations are as follows:

<table>
<thead>
<tr>
<th>Mnemonic</th>

</tr>
</tbody>
</table>

**C3.4.6 Bitfield move**

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For `BFM`, the remaining bits are unchanged.
- For `UBFM`, the lower bits, if any, and upper bits, if any, are set to zero.
- For `SBFM`, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.
Table C3-59 shows the Bitfield move instructions.

#### C3.4.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-61 on page C3-301 shows the Extract (immediate) instructions.

C3.5 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- Arithmetic (shifted register).
- Arithmetic (extended register) on page C3-304.
- Arithmetic with carry on page C3-305.
- Flag manipulation instructions on page C3-305.
- Logical (shifted register) on page C3-305.
- Move (register) on page C3-306.
- Shift (register) on page C3-306.
- Multiply and divide on page C3-307.
- CRC32 on page C3-308.
- Bit operation on page C3-309.
- Conditional select on page C3-309.
- Conditional comparison on page C3-310.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Register on page C4-590.

C3.5.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, and LSR accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See Arithmetic (extended register) on page C3-304 for arithmetic instructions that can operate on the current stack pointer.

Table C3-64 on page C3-303 shows the Arithmetic (shifted register) instructions.

<table>
<thead>
<tr>

<td>NEG (shifted register) on page C6-1718</td>
</tr>
<tr>
<td>NEGS</td>
<td>Negate and set flags</td>
<td>NEGS on page C6-1720</td>
</tr>
</tbody>
</table>
C3.5.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator SXTB, SXTW, UXTB, UXTH, or UXTW. This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators UXTX and SXTX use all 64 bits of the second source register with an optional shift. In that case, Arm recommends UXTX as the operator. If and only if at least one register is SP, Arm recommends use of the LSL operator name, rather than UXTX, and when the shift amount is also zero then both the operator and the shift amount can be omitted. UXTW and SXTW both use all 32 bits of the second source register with an optional shift. In that case Arm recommends UXTW as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than UXTW, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators UXTW and SXTW both use all 32 bits of the second source register with an optional shift. In that case, Arm recommends UXTW as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than UXTW, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as \( m \) for all except the UXTX/LSL and SXTX extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1 // SUB SP, SP, X1, UXTX #0
```

Table C3-65 on page C3-304 shows the Arithmetic (extended register) instructions.

</tbody>
</table>
C3.5.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-66 on page C3-305 shows the Arithmetic with carry instructions

<table>
<thead>
<tr>

</tr>
<tr>
<td>NGCS</td>
<td>Negate with carry and set flags</td>
<td>NGCS on page C6-1724</td>
</tr>
</tbody>
</table>

C3.5.4 Flag manipulation instructions

The Flag manipulation instructions set the value of the NZCV condition flags directly.

The instructions SETF8 and SETF16 accept one source register and set the NZV condition flags based on the value of the input register. The instruction RMIF accepts one source register and two immediate values, rotating the first source register using the first immediate value and setting the NZCV condition flags masked by the second immediate value.

The instructions XAFLAG and AXFLAG convert PSTATE condition flags between the FCMP instruction format and an alternative format. See Table C6-1 on page C6-1168 for more information.

Table C3-67 on page C3-305 shows the Flag manipulation instructions.

</tr>
<tr>
<td>XAFLAG</td>
<td>Convert from alternative format to FCMP comparison format</td>
<td>XAFLAG on page C6-2034</td>
</tr>
</tbody>
</table>

C3.5.5 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR, and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.
Note
Apart from ANDS, TST, and BICS, the logical instructions do not set the Condition flags, but the final result of a bit operation can usually directly control a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-68 shows the Logical (shifted register) instructions.

### C3.5.6 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

### Table C3-69 MOV register instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>

</tr>
<tr>
<td></td>
<td>Move register to SP or move SP to register</td>
<td>MOV (to/from SP) on page C6-1692</td>
</tr>
</tbody>
</table>

### C3.5.7 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].
C3.5 Data processing - register

</table>

C3.5.8 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- *Multiply*.
- *Divide* on page C3-308.

### Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using SMULH or UMULH to generate the upper 64 bits. Table C3-72 on page C3-307 shows the Multiply instructions.

</tbody>
</table>
Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division (INT_MIN / -1) is performed where INT_MIN is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is INT_MIN.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-73 shows the Divide instructions.

C3.5.9  CRC32

The CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32, and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to 0b0001, the CRC instructions are implemented.

These instructions are optional in an Armv8.0 implementation.

All implementations of Armv8.1 architecture and later are required to implement the CRC32 instructions.
Table C3-74 on page C3-309 shows the CRC instructions.

### C3.5.11  Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.
Table C3-76 shows the Conditional select instructions.

**C3.5.12  Conditional comparison**

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-77 on page C3-310 shows the Conditional comparison instructions.

C3.6 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

Common features of SIMD instructions gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:
- Floating-point move (register) on page C3-312.
- Floating-point move (immediate) on page C3-312.
- Floating-point conversion on page C3-313.
- Floating-point round to integral value on page C3-314.
- Floating-point multiply-add on page C3-316.
- Floating-point arithmetic (one source) on page C3-316.
- Floating-point arithmetic (two sources) on page C3-316.
- Floating-point minimum and maximum on page C3-317.
- Floating-point comparison on page C3-317.
- Floating-point conditional select on page C3-318.

The following subsections describe the SIMD data processing instructions:
- SIMD move on page C3-318
- SIMD arithmetic on page C3-318.
- SIMD compare on page C3-322.
- SIMD widening and narrowing arithmetic on page C3-322.
- SIMD table lookup on page C3-331.
- SIMD by element arithmetic on page C3-325.
- SIMD permute on page C3-327.
- SIMD immediate on page C3-327.
- SIMD shift (immediate) on page C3-327.
- SIMD floating-point and integer conversion on page C3-328.
- SIMD reduce (across vector lanes) on page C3-329.
- SIMD pairwise arithmetic on page C3-330.
- SIMD integer dot product on page C3-331.
- SIMD table lookup on page C3-331.
- SIMD complex number arithmetic on page C3-332.
- SIMD BFloat16 floating-point multiply-add on page C3-332.
- SIMD BFloat16 on page C3-332.
- SIMD integer matrix multiply-accumulate on page C3-334.
- The Cryptographic Extension on page C3-334.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Scalar Floating-Point and Advanced SIMD on page C4-601.

For information about the floating-point exceptions, see Floating-point exceptions and exception traps on page A1-64.

C3.6.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

**Wide**
Indicated by the suffix W. The element width of the destination register and the first source operand is double that of the second source operand.

**Long**
Indicated by the suffix L. The element width of the destination register is double that of both source operands.

**Narrow**
Indicated by the suffix N. The element width of the destination register is half that of both source operands.
In addition, each vector form of the instruction is part of a pair, with a second and upper half suffix of 2, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

Note

This is referred to as a lane set specifier.

### C3.6.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions DUP, INS, and UMOV. However, Arm recommends using the FMOV instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-78 on page C3-312 shows the Floating-point move (register) instructions.

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>Floating-point move to or from general-purpose register without conversion</td>
<td>FMOV (general) on page C7-2336</td>
</tr>
</tbody>
</table>

### C3.6.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with 0x followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. Arm recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

Note

When FEAT_FP16 is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as \((\pm n/16 \times 2^r)\), where \(n\) is an integer in the range \(16 \leq n \leq 31\) and \(r\) is an integer in the range of \(-3 \leq r \leq 4\), that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Table C3-79 on page C3-312 shows the Floating-point move (immediate) instruction:

<table>
<thead>
<tr>

<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FMOV</td>
<td>Floating-point immediate</td>
<td>FMOV (scalar, immediate) on page C7-2340</td>
</tr>
</tbody>
</table>
C3.6.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- Convert floating-point precision.
- Convert between floating-point and integer or fixed-point.

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-80 on page C3-313 shows the Floating-point precision conversion instruction.

<table>
<thead>

<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCVT</td>
<td>Floating-point convert precision (scalar)</td>
<td>FCVT on page C7-2196</td>
</tr>
</tbody>
</table>

Convert floating-point single-precision to BFloat16

The BFCVT instruction is provided by FEAT_BF16. This instruction converts a single-precision floating-point input to BFloat16 format, honoring the FPCR rounding mode controls to give a more accurate conversion than simply removing the bottom 16 bits of the input.

Table C3-81 on page C3-313 shows this instruction.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>BFCVT</td>
<td>BFloat16 floating-point convert from single-precision to BFloat16 format (scalar)</td>
<td>BFCVT on page C7-2061</td>
</tr>
</tbody>
</table>

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point value in a general-purpose register. For a fixed-point value, the final immediate operand indicates that the general-purpose register holds a fixed-point number and fbits indicates the number of bits after the binary point. fbits is in the range 1-32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs if the floating-point input is a NaN, infinity, or a numerical value that cannot be represented in the destination register. An out of range integer or fixed-point result is saturated to the size of the destination register.

Inexact

Occurs if the numeric result that differs from the input value.

Input Denormal

Can occur when zero replaces a double-precision or single-precision denormal input, see Flushing denormalized numbers to zero on page A1-58 and Input Denormal exceptions on page A1-65.
Table C3-82 on page C3-314 shows the Floating-point and fixed-point conversion instructions.

### C3.6.5 Floating-point round to integral value

The following subsections describe instructions which round a floating-point number to an integral valued floating-point number in the same format:

- *Floating-point round to an integer of the same size as the register* on page C3-315
- *Floating-point round to 32-bit or 64-bit integer* on page C3-315
Floating-point round to an integer of the same size as the register

The following instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:
- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

These instructions can cause the following floating-point exceptions:

**Invalid Operation**
- Occurs in response to a floating-point input of a signaling NaN.

**Inexact, FRINTX instruction only**
- Occurs if the result is numeric and does not have the same numerical value as the input.

**Input Denormal**
- Can occur when zero replaces a double-precision or single-precision denormal input, see *Flushing denormalized numbers to zero* on page A1-58 and *Input Denormal exceptions* on page A1-65.

Table C3-83 on page C3-315 shows the Floating-point round to integer instructions.

</table>

Floating-point round to 32-bit or 64-bit integer

The following instructions are present if FEAT_FRINTTS is implemented. The instructions round to a value that fits in a 32-bit integer or a 64-bit integer size, and use either round towards zero or the ambient rounding model.

**Invalid Operation**
- Forced to be the most negative integer representable in the target size, and occurs in response to a floating-point input of a signaling NaN, an infinite input, or an out of range input.

**Inexact**
- Occurs if the result is numeric and does not have the same numerical value as the input.

**Input Denormal**
- Can occur when zero replaces a double-precision or single-precision denormal input, see *Flushing denormalized numbers to zero* on page A1-58 and *Input Denormal exceptions* on page A1-65.
Table C3-84 on page C3-316 shows the Floating-point round to 32-bit or 64-bit integer instructions.

</tr>
</tbody>
</table>
C3.6.9 Floating-point minimum and maximum

The $\min(x,y)$ and $\max(x,y)$ operations return a quiet NaN when either $x$ or $y$ is NaN.

As described in Flushing denormalized numbers to zero on page A1-58, if flushing denormalized inputs to zero is enabled, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both $x$ and $y$ are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by $\max()$ and -0.0 by $\min()$.

The $\minNum(x,y)$ and $\maxNum(x,y)$ operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN, the result is then identical to $\min(x,y)$ and $\max(x,y)$.

Table C3-88 on page C3-317 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

C3.6.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are unordered, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

--- Note ---

The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the Condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

--- Note ---

If FEAT_FlagM2 is implemented, instructions AXFLAG and XAFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See FEAT_FlagM on page A2-101 for more information.
Table C3-89 shows the Floating-point comparison instructions.

C3.6.14  SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

--- Note ---

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-93 on page C3-322 shows that SIMD compare instructions.

### C3.6.21 SIMD floating-point and integer conversion

The SIMD floating-point and integer conversion instructions generate the Invalid Operation floating-point exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out of range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact floating-point exception.
Table C3-100 on page C3-329 shows the SIMD floating-point and integer conversion instructions.

**C3.6.22 SIMD reduce (across vector lanes)**

The SIMD reduce (across vector lanes) instructions perform arithmetic operations horizontally, that is across all lanes of the input vector. They deliver a single scalar result.
Table C3-101 shows the SIMD reduce (across vector lanes) instructions.

C3.6.24 SIMD integer dot product

FEAT_DotProd provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second vector.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

Note That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

Table C3-103 on page C3-331 shows the SIMD integer dot product instructions.

C3.6.25 SIMD table lookup

Table C3-104 on page C3-331 shows the SIMD table lookup instructions.
C3.6.26   SIMD complex number arithmetic

FEAT_FCMA provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If FEAT_FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Table C3-105 on page C3-332 shows the FEAT_FCMA SIMD instructions.

Table C3-105 SIMD complex number arithmetic instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>

</tr>
</tbody>
</table>

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in Complex multiplication on page K12-11746.

C3.6.27   SIMD BFloat16

If FEAT_BF16 is implemented, the instructions in this section are available.

SIMD BFloat16 floating-point multiply-add

The BFloat16 floating-point multiply-add instructions perform an implicit conversion of the bottom (even-numbered) or top (odd-numbered) BFloat16 source elements to IEEE 754 single-precision floating-point format before performing a fused multiply-add without intermediate rounding to the overlapping single-precision destination element. These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

Table C3-106 SIMD BFloat16 floating-point multiply-add instructions

</tr>
</tbody>
</table>

SIMD BFloat16 floating-point dot product

The BFloat16 floating-point dot product instruction, BFDP, performs an implicit conversion of vectors of BFloat16 input values to IEEE 754 single-precision floating-point format.

The BFloat16 dot product instructions delimit their source vectors into pairs of BFloat16 elements.
If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, a $\texttt{BFDOT}$ instruction:

- Performs an unfused, widening sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the corresponding or indexed pair in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the FPSR cumulative exception bits.
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits are all zero.
- Flashes denormalized inputs and results to zero, as if FPCR.FIZ and FPCR.FIZ are 0.
- Generates only the default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, a $\texttt{BFDOT}$ instruction:

- Performs a fused, widening sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the corresponding or indexed pair in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Generates only the default NaN, as if FPCR.DN is 1.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the Effective value of the FPCR in the current execution mode, and captured in the FPSR cumulative exception bits.

</tr>
</tbody>
</table>

### SIMD BFloat16 floating-point matrix multiply

The BFloat16 floating-point matrix multiply instruction, $\texttt{BFMMLA}$, treats each source and destination vector as a single matrix:

- The first source vector 2x4 BF16 matrix is organized in row-by-row order.
- The second source vector 4x2 BF16 matrix is organized in a column-by-column order.
- The destination vector 2x2 single-precision matrix is organized in row-by-row order.

One matrix multiplication is performed per source vector and accumulated into the corresponding destination vector. This corresponds to accumulating two 2-way BFloat16 widening dot products into each single-precision destination element, following the numeric behaviors described for $\texttt{BFDOT}$ instruction in SIMD BFloat16 floating-point dot product on page C3-332.

SIMD BFloat16 floating-point convert

The BFloat16 floating-point convert instructions perform accurately rounded down-conversion of IEEE 754 single-precision source vector elements to BFloat16 format.

The `BFCVTN` instruction places its half-width BFloat16 results in the bottom or even-numbered 16-bit elements of the destination vector, and sets the top or odd-numbered elements to zero.

The `BFCVTN2` instruction places its half-width BFloat16 results in the top or odd-numbered 16-bit elements of the destination vector, leaving the bottom or even-numbered elements unchanged.

These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

#### C3.6.28 SIMD integer matrix multiply-accumulate

The integer matrix multiply-accumulate instructions are provided by `FEAT_I8MM`.

The integer matrix multiply-accumulate instructions treat each source and destination vector as a single matrix:

- The first source vector 2x8 matrix is organized in row-by-row order.
- The second source vector 8x2 matrix is organized in column-by-column order.
- The destination vector 2x2 matrix is organized in row-by-row order.

One matrix multiplication is performed per segment.

Table C3-110 on page C3-334 shows these instructions.

#### C3.6.29 The Cryptographic Extension

The instructions provided by the OPTIONAL Armv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide, see:

- Announcing the Advanced Encryption Standard.
- *The Galois/Counter Mode of Operation*.
- Announcing the Secure Hash Standard.
Table C3-111 shows the Armv8.0 Cryptographic Extension instructions.

^a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

See *The Armv8 Cryptographic Extension* on page A2-80 for information about the permitted implementation options for the Cryptographic Extension.

**Armv8.2 extensions to the Cryptographic Extension**

Armv8.2 supports the following **OPTIONAL** extensions to the Cryptographic Extension:

- \(FEAT\_SHA512, SHA2-512\) functionality.
- \(FEAT\_SHA3, SHA3\) functionality on page C3-336.
- \(FEAT\_SM3, SM3\) functionality on page C3-337.
- \(FEAT\_SM4, SM4\) functionality on page C3-337.

**\(FEAT\_SHA512, SHA2-512\) functionality**

\(FEAT\_SHA512\) provides instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512\|224 and SHA-512\|256. These are all based on the SHA-512 computation, and therefore this set of instructions is described as the \(SHA512\) instructions.

Implementation of \(FEAT\_SHA512\) requires the implementation of the SHA1 and SHA2-256 instructions from the Armv8.0 Cryptographic Extension.

--- **Note** ---

Implementation of \(FEAT\_SHA512\) does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the PMULL instructions, from the Armv8.0 Cryptographic Extension.
When `FEAT_SHA512` is implemented, the value of `ID_AA64ISAR0_EL1.SHA2` is 0b00010, indicating support for the SHA512 instructions.

Table C3-112 shows the `FEAT_SHA512` instructions:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHA512H</td>
<td>SHA512 Hash update part 1</td>
<td>SHA512H on page C7-2597</td>
</tr>

</tr>
<tr>
<td>SHA512SU1</td>
<td>SHA512 Schedule Update 1</td>
<td>SHA512SU1 on page C7-2602</td>
</tr>
</tbody>
</table>

*Use of the SHA512 instructions* on page K12-11748 shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

**FEAT_SHA3, SHA3 functionality**

`FEAT_SHA3` provides instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the SHA3 instructions.

--- Note ---

Implementation of `FEAT_SHA3` does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the `PMULL` instructions, from the Armv8.0 Cryptographic Extension.

When `FEAT_SHA3` is implemented, the value of `ID_AA64ISAR0_EL1.SHA3` is 0b00001, indicating support for the SHA3 instructions.

Table C3-113 shows the `FEAT_SHA3` instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The Arm acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can compute two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

*Use of the SHA3 instructions* on page K12-11749 shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.
**FEAT_SM3, SM3 functionality**

FEAT_SM3 provides instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the SM3 instructions.

FEAT_SM3 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA512.

--- Note ---

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM3 functionality.

When FEAT_SM3 is implemented, the value of ID_AA64ISAR0_EL1.SM3 is 0b0001, indicating support for the SM3 instructions.

Table C3-114 shows the FEAT_SM3 instructions. The SM3 algorithm computes a digest of 256 bits, which can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

--- Note ---

The SM3 instruction names refer to intermediate variables defined as part of the SM3 Cryptographic Hash Algorithm specification.

</tbody>
</table>

Use of the SM3 instructions on page K12-11750 shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

**FEAT_SM4, SM4 functionality**

FEAT_SM4 provides instruction to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the SM4 instructions.

FEAT_SM4 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA3.

--- Note ---

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM4 functionality.

When FEAT_SM4 is implemented, the value of ID_AA64ISAR0_EL1.SM4 is 0b00001, indicating support for the SM4 instructions.
Table C3-115 shows the FEAT_SM4 instructions. The SM4 algorithm is 128-bit wide block cipher. The SM4E instruction accelerates a single round of encryption or decryption, and the SM4EKEY instruction accelerates a single round of key generation:

**Integer operations**

The following instructions operate on signed or unsigned integer data within a vector.

**SVE Integer arithmetic**

For binary operations, the Integer arithmetic instructions perform arithmetic operations on a source vector containing integer element values, and a second source vector of either integer element values or an immediate value.

For ternary operations, these instructions perform arithmetic operations on a source vector containing integer element values, a second source vector of either integer element values or an immediate value, and a third source vector containing integer element values.

SVE Integer dot product

The Integer dot product instructions delimit the source vectors into groups of four 8-bit or 16-bit integer elements. Within each group of four elements, the elements in the first source vector are multiplied by the corresponding elements in the second source vector. The resulting widened products are summed and added to the 32-bit or 64-bit element of the accumulator and destination vector that aligns with the group of four elements in the first source vector.

The indexed forms of these instructions specify a single, numbered, group of four elements within each 128-bit segment of the second source vector as the multiplier for all the groups of four elements within the corresponding 128-bit segment of the first source vector.

SVE Integer matrix multiply operations

The Integer matrix multiply instructions facilitate matrix multiplication and include integer matrix multiply-accumulate instructions.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. Within each segment:

- The first source vector 2x8 8-bit matrix is organized in row-by-row order.
- The second source vector 8x2 8-bit matrix is organized in a column-by-column order.
- The destination vector 2x2 32-bit matrix is organized in row-by-row order.

One matrix multiplication is performed per vector segment of 128 bits and accumulated into the destination vector segment.
SVE Integer comparison

The Integer comparison instructions compare Active elements in the first source vector with the corresponding elements in a second vector or with an immediate value. The Boolean result of each comparison is placed in the corresponding element of the destination predicate. Inactive elements in the destination predicate register are set to FALSE. All integer comparisons set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero.

The wide element variants of the compare instructions allow a packed vector of narrower elements to be compared with wider 64-bit elements. These instructions treat the second source vector as having a fixed 64-bit doubleword element size and compare each narrow element of the first source vector with the corresponding vertically-aligned wide element of the second source vector. For example, if the first source vector contained 8-bit byte elements, then 8-bit element[0] to element[7] of the first source vector are compared with 64-bit element[0] of the second source vector, 8-bit element[8] to element[15] with 64-bit element[1], and so on. All 64 bits of the wide elements are significant for the comparison, with the narrow elements being sign-extended or zero-extended to 64 bits as appropriate for the type of comparison.

SVE Vector address calculation

The Vector address calculation instructions compute vectors of addresses and addresses of vectors. This includes instructions to add a multiple of the current vector length or predicate register length, in bytes, to a general-purpose register.

The **ADR** instruction is an integer arithmetic operation that is used to calculate a vector of 64-bit or 32-bit addresses.

The **ADR** destination vector elements are computed by the addition of the corresponding elements in the source vectors, with an optional sign or zero extension and optional bitwise left shift of 1-3 bits applied to the final operands. This can be considered as the addition of a vector base and a scaled vector index.

The **ADR** instruction computes a vector of 32-bit addresses by the addition of a 32-bit base and a scaled 32-bit unsigned index. The **ADR** instruction computes a vector of 64-bit addresses by one of:

- Addition of a 64-bit base and a scaled 64-bit unsigned index.
- Addition of a 64-bit base and a scaled, zero-extended 32-bit index.
• Addition of a 64-bit base and a scaled, sign-extended 32-bit index.

### SVE Bitwise shift, reverse, and count

Bitwise shifts, reversals, and counts within vector elements.

Shift counts saturate at the number of bits per element, rather than being used modulo the element size. If modulo behavior is required, then the modulus must be computed separately.
The wide element variants of the bitwise shift instructions allow a packed vector of narrower elements to be shifted by wider 64-bit shift amounts. These instructions treat the second source vector as having a fixed 64-bit doubleword element size and shift each narrow element of the first source vector by the corresponding vertically-aligned wide element of the second source vector. For example, if the first source vector contained 8-bit byte elements, then 8-bit element[0] to element[7] of the first vector are shifted by 64-bit element[0] of the second source vector, 8-bit element [8] to element[15] by 64-bit element[1], and so on. All 64 bits of the wide shift amount are significant.

SVE Floating-point multiply accumulate

The Floating-point multiply accumulate instructions perform floating-point fused multiply-add or multiply-subtract operations and their negated forms. There are two groups of these instructions, as follows:

- Instructions where the result of the operation is written to the addend register.
  - Supported instructions are: FMLA, FMLS, FNMLA, FNMLS.
- Instructions where the result of the operation is written to the multiplicand register.
  - Supported instructions are: FMAD, FMSB, FN MAD, FNMSB.

SVE Floating-point complex arithmetic

The Floating-point complex arithmetic instructions perform arithmetic on vectors containing floating-point complex numbers as interleaved pairs of elements, where the even-numbered elements contain the real components and the odd-numbered elements contain the imaginary components.

The FCADD instructions rotate the complex numbers in the second source vector by 90 degrees or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, before adding active pairs of elements to the corresponding elements of the first source vector in a destructive manner.
The FCMLA instructions perform a transformation of the operands to allow the creation of multiply-add or multiply-subtract operations on complex numbers by combining two of the instructions. The transformations performed are as follows:

- The complex numbers in the second source vector, considered in polar form, are rotated by 0 degrees or 180 degrees before multiplying by the duplicated real components of the first source vector.
- The complex numbers in the second source vector, considered in polar form, are rotated by 90 degrees or 270 degrees before multiplying by the duplicated imaginary components of the first source vector.

The resulting products are then added to the corresponding components of the destination and addend vector, without intermediate rounding.

Two FCMLA instructions can be used as follows:

```
FCMLA Zda.S, Pg/M, Zn.S, Zm.S, #A
...
FCMLA Zda.S, Pg/M, Zn.S, Zm.S, #B
```

For example, some meaningful combinations of A and B are:

- A=0, B=90. In this case, the two vectors of complex numbers in Zn and Zm are multiplied and the products are added to the complex numbers in Zda.
- A=0, B=270. In this case, the conjugates of the complex numbers in Zn are multiplied by the complex numbers in Zm and the products are added to the complex numbers in Zda.
- A=180, B=270. In this case, the two vectors of complex numbers in Zn and Zm are multiplied and the products are subtracted from the complex numbers in Zda.
- A=180, B=90. In this case, the conjugates of the complex numbers in Zn are multiplied by the complex numbers in Zm and the products are subtracted from the complex numbers in Zda.

Note

The lack of intermediate rounding can give unexpected results in certain cases relative to a traditional sequence of independent multiply, add, and subtract instructions.

In addition, when using these instructions, the behavior of calculations such as \((\infty+i)\) multiplied by \((0+i)\) is \((\text{NaN}+\text{NaN}i)\), rather than the result expected by ISO C, which is complex. The expectation is that these instructions are only used in situations where the effect of differences in the rounding and handling of infinities are not material to the calculation.

SVE Floating-point comparisons

The Floating-point comparison instructions compare active floating-point element values in the first source vector with corresponding elements in the second vector or with the immediate value +0.0. The Boolean result of each comparison is placed in the corresponding element of the destination predicate. Inactive elements in the destination predicate register are set to FALSE. Floating-point vector comparisons do not set the condition flags.

SVE Floating-point matrix multiply operations

The Floating-point matrix multiply instructions facilitate matrix multiplication and include floating-point matrix multiply-accumulate instructions, and companion instructions that support data rearrangements in vector registers as required by the double-precision matrix multiply-accumulate instructions.

The matrix multiply-accumulate instructions delimit source and destination vectors into segments. Within each segment:

- The first source vector 2x2 matrix is organized in row-by-row order.
- The second source vector 2x2 matrix is organized in a column-by-column order.
- The destination vector 2x2 matrix is organized in row-by-row order.

One matrix multiplication is performed per vector segment and accumulated into the destination vector segment. For the double-precision matrix multiply-accumulate instructions, the vector segment length and minimum vector length is 256 bits. Double-precision matrix multiply-accumulate instructions are not supported when the vector length is 128 bits. For the single-precision matrix multiply-accumulate instruction, the vector segment length is 128 bits.

The floating-point matrix multiply-accumulate instructions strictly define the order of accumulations, and the multiplications and additions are not fused, so intermediate rounding is performed after every multiplication and every addition.

The following table shows the floating-point matrix multiplication instructions and companion instructions that are supported if ID_AA64ZFR0_EL1.F64MM is 1:

The following table shows the floating-point matrix multiplication instructions and companion instructions that are supported if ID_AA64ZFR0_EL1.F32MM is 1:

### SVE BF16 floating-point multiply-add

The BF16 floating-point multiply-add instructions perform an implicit conversion of the bottom (even-numbered) or top (odd-numbered) BF16 source elements to IEEE 754 single-precision floating-point format before performing a fused multiply-add without intermediate rounding to the overlapping single-precision destination element. These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

### SVE BF16 floating-point dot product

The BF16 floating-point dot product instruction, BFDOT, performs an implicit conversion of vectors of BF16 input values to IEEE 754 single-precision floating-point format.

The BF16 dot product instructions delimit their source vectors into pairs of BF16 elements.
If FEAT_EBF16 is not implemented or FPCR.EBF is 0, irrespective of the other control bits in the FPCR, a $\text{BFDO}T$ instruction:

- Performs an unfused, widening sum-of-products of each pair of adjacent BF\text{loat16} elements in the first source vector with the corresponding or indexed pair in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BF\text{loat16} elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the FPSR cumulative exception bits.
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits are all zero.
- Flushes denormalized inputs and results to zero, as if FPCR.FIZ and FPCR.FIZ are 0.
- Generates only the default NaN, as if FPCR.DN is 1.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, a $\text{BFDO}T$ instruction:

- Performs a fused, widening sum-of-products of each pair of adjacent BF\text{loat16} elements in the first source vector with the corresponding or indexed pair in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BF\text{loat16} elements in the first source vector.
- Generates only the default NaN, as if FPCR.DN is 1.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as controlled by the Effective value of the FPCR in the current execution mode, and captured in the FPSR cumulative exception bits.

</table>

### SVE BF\text{loat16} floating-point matrix multiply

The BF\text{loat16} floating-point matrix multiply instruction, BF\text{MMLA}, delimits source and destination vectors into 128-bit segments. Within each segment:

- The first source vector 2x4 BF\text{16} matrix is organized in row-by-row order.
- The second source vector 4x2 BF\text{16} matrix is organized in a column-by-column order.
- The destination vector 2x2 single-precision matrix is organized in row-by-row order.

One matrix multiplication is performed per source vector segment and accumulated into the corresponding destination vector segment. This corresponds to accumulating two 2-way BF\text{loat16} widening dot products into each single-precision destination element, following the numeric behaviors described for $\text{BFDO}T$ instruction in SVE BF\text{loat16} floating-point dot product on page C3-353.

SVE BFloat16 floating-point convert

The BFloat16 floating-point convert instructions perform accurately rounded down-conversion of IEEE 754 single-precision source vector elements to BFloat16 format.

The BFCVT instruction places its BFloat16 results in the bottom or even-numbered 16-bit elements of the destination vector, and sets the top or odd-numbered elements to zero.

The BFCVTNT instruction places its BFloat16 results in the top or odd-numbered 16-bit elements of the destination vector, leaving the bottom or even-numbered elements unchanged.

These instructions follow the normal floating-point behaviors that apply to single-precision arithmetic, controlled by the Effective value of the FPCR, and captured in the FPSR cumulative exception bits.

</tbody>
</table>

Predicate operations

The Predicate instructions perform operations that manipulate the predicate registers.

Some of these instructions are insensitive to the predicate element size and specify an explicit byte element size qualifier, .B, but an assembler must accept any qualifier, or none.

SVE Predicate initialization

The Predicate initialization instructions initialize predicate elements. Predicate elements can be initialized to be FALSE, or to be TRUE when their element number is less than:

- A fixed number of elements from the following range: VL1-VL8, VL16, VL32, VL64, VL128 or VL256.
- The largest power of two elements, POW2.
- The largest multiple of three or four elements, MUL3 or MUL4.
- The number of accessible elements, ALL, which is implicitly a multiple of two.

Unspecified or out of range constraint encodings generate a predicate with values that are all FALSE and do not cause an Undefined Instruction exception.

### SVE Predicate move operations

The Predicate move instructions operate on all bits of the predicate registers, implying a fixed, 1-bit predicate element size. The flag-setting variants set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero. Because these instructions operate with a fixed, 1-bit element size, the *Governing predicate* for the flag-setting variants should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

</tbody>
</table>

### SVE Predicate logical operations

The Predicate logical operation instructions perform bitwise logical operations on predicate registers that operate on all bits of the register, implying a fixed, 1-bit predicate element size. The flag-setting variants set the N, Z, and C condition flags based on the predicate result, and set the V flag to zero. Inactive elements in the destination Predicate register are set to zero, except for PTEST which does not specify a destination register. Because these instructions operate with a fixed, 1-bit element size, the *Governing predicate* for the flag-setting variants should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

**FFR predicate handling**

The FFR predicate handling instructions work with SVE First-fault and Non-fault loads using the FFR to determine which elements have been successfully loaded and which remain to be loaded on a subsequent iteration.

The RDFFRS instruction sets the N, Z, and C condition flags based on the predicate result, and sets the V flag to zero. Because these instructions operate with a fixed, 1-bit element size, the Governing predicate for the RDFFRS instruction should be in the canonical form for a predicate element size in order to generate a meaningful set of condition flags for that element size.

**Predicate counts**

The Predicate count instructions count either the number of Active predicate elements that are set to TRUE, or the number of elements implied by a named predicate constraint. The count can be placed in a general-purpose register, or used to increment or decrement a vector or general-purpose register.

Signed or unsigned saturating variants handle cases where, for example, an increment might cause a vectorized scalar loop index to overflow and therefore never satisfy a loop termination condition that compares it with a limit that is close to the maximum integer value.

The named predicate constraint limits the number of elements to:

- A fixed number of elements from the following range: VL1-VL8, VL16, VL32, VL64, VL128 or VL256.
- The largest power of two elements, POW2.
- The largest multiple of three or four elements, MUL3 or MUL4.
- The number of accessible elements, ALL, implicitly a multiple of two.

Loop control

These instructions control counted vector loops and vector loops with data-dependent termination conditions. These instructions create a loop partition predicate with Active elements set to TRUE up to the point where the loop should terminate, and FALSE thereafter. Two loop concepts are supported, simple loops and data-dependent loops.

Simple loops

An up-counting WHILE instruction that increments the value of the first scalar operand and compares the value with a second, fixed scalar operand. The instruction generates a destination predicate with all of the following characteristics:

- The predicate elements starting from the lowest numbered element are true while the comparison is true.
- The predicate elements thereafter, up to the highest numbered element, are false when the comparison becomes false.

All 32 bits or 64 bits of the scalar operands are significant for the purposes of comparison. The full 32-bit or 64-bit value of the first operand is incremented by 1 for each destination predicate element, irrespective of the element size. The first general-purpose register operand is not updated.

If all of the following occur, a comparison can never fail, resulting in an all-true predicate:

- The comparison includes an equality test.
- The second scalar operand is equal to the maximum integer value of the selected size and type of comparison.

The N, Z, C, and V condition flags are unconditionally set to control a subsequent conditional branch.

Data-independent loops

For data-dependent termination conditions, it is necessary to convert the result of a vector comparison into a loop partition predicate. The new partition truncates the current vector partition immediately before or after the first active TRUE comparison. The N, Z, C, and V condition flags are optionally set to control a subsequent conditional branch.

The BRK instructions set active destination predicate elements to TRUE up to and including the first active TRUE element in their source predicate register, setting subsequent elements to FALSE.

The BRKP instructions set active destination predicate elements to TRUE up to but excluding the first active TRUE element in their source predicate register, setting subsequent elements to FALSE.

The BRKPA and BRKPB instructions propagate the result of a previous BRKB or BRKPB instruction, by setting their destination predicate register to all FALSE if the Last active element of their first source predicate register is not TRUE, but otherwise generate the destination predicate from their second source predicate as described for the BRK and BRKB instructions.

C3-360 Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved. ARM DDI 0487I.a Non-Confidential
The BRKN instructions propagate the result of a previous BRK8 or BRKPB instruction by setting the destination predicate register to all FALSE if the Last active element of their first source predicate register is not TRUE, but otherwise leave the destination predicate unchanged. The destination and second source predicate must have been created by another instruction, such as RDFFR or WHILE.

### C3.7.2 Move operations

#### Element permute and shuffle

The Element permute and shuffle instructions move data between different vector elements, or between vector elements and scalar registers.

These instructions perform the following operations:

- Conditionally extract the Last active element of a vector or the following element.
  - The supported instructions are CLASTA and CLASTB.
- Unconditionally extract the Last active element of a vector or the following element.
  - The supported instructions are LASTA and LASTB.
• Variable permute instructions where the permutation is determined by the values in a predicate register or a table of element index values.
  — The supported instructions are COMPACT, SPLICE, and TBL.
• Fixed permute instructions where the form of the permutation is encoded in the instruction.
  — The supported instructions are: DUP, EXT, INSR, REV, REVb, REVh, REW, SUNPKHI, SUNPKLO, TRN1, TRN2, UUNPKHT, UUNPKLO, UZP1, UZP2, ZIP1, and ZIP2.

</tbody>
</table>

The Predicate instructions are used to move and permute predicate elements. These instructions generally mirror the fixed vector permutes to allow predicates to follow their data. The permutes move all of the bits in a predicate element, not just the canonical bits.

**Index vector generation**

The **INDEX** instruction initializes a vector horizontally by setting its first element to an integer value, and then repeatedly incrementing it by a second integer value to generate the subsequent elements. Each integer value can be specified as a signed immediate or a general-purpose register.

<table>
<thead>
<tr>

<td><strong>INDEX</strong> <em>(immediate, scalar)</em> on page C8-3389</td>
</tr>
</tbody>
</table>

**Move prefix**

The **MOVPRFX** (predicated) instruction is a predicated vector move that can be combined with a predicated destructive instruction that immediately follows it, in program order, to create a single constructive operation, or to convert an instruction with merging predication to use zeroing predication.

The **MOVPRFX** (unpredicated) instruction is an unpredicated vector move that can be combined with a predicated or unpredicated destructive instruction that immediately follows it, in program order, to create a single constructive operation.

The *Operational information* section of an SVE instruction description indicates whether or not an instruction can be predictably prefixed by a **MOVPRFX** instruction. If the *Operational information* of an SVE instruction description does not mention **MOVPRFX** or if the section does not exist, then the instruction cannot be predictably prefixed by a **MOVPRFX** instruction.

The prefixed instruction that immediately follows a **MOVPRFX** instruction in program order must be an implemented SVE instruction that can be predictably prefixed by a **MOVPRFX** instruction, or an A64 **HLT** instruction, or an A64 **BRK** instruction. For an SVE instruction that can be predictably prefixed by a **MOVPRFX** instruction, all of the following apply:

- The destination register field implicitly specifies one of the source operands, which means that it is a destructive binary or ternary vector operation or unary operation with merging predication, excluding **MOVPRFX**.
- The destination register is the same as the **MOVPRFX** destination register.
- The prefixed instruction does not use the **MOVPRFX** destination register in any of its other source register fields, even if it has a different name but refers to the same architectural register state. For example, Z1, V1, and D1 all refer to the same architectural register.
- If the **MOVPRFX** instruction is predicated, then the prefixed instruction is predicated using the same *Governing predicate* register, and the maximum encoded element size is the same as the **MOVPRFX** element size, excluding the fixed-size 64-bit elements of the wide elements form of bitwise shift and integer compare operations.
- If the **MOVPRFX** instruction is unpredicated, then the prefixed instruction can use any *Governing predicate* register and element size, or it can be unpredicated. A predicated **MOVPRFX** cannot be used with an unpredicated instruction.

If the instruction that follows a **MOVPRFX** instruction is not an implemented SVE instruction that can be predictably prefixed by a **MOVPRFX** instruction, the two instructions behave in one of the following **CONSTRAINED UNPREDICTABLE** ways:

- Either or both instructions can execute with their individually described effects.
Either instruction can generate an Undefined Instruction exception.
Either or both instructions can execute as a NOP.
The second instruction can execute with an UNKNOWN value for any of its source registers.
Any register that is written by either or both instructions can be set to an unknown value.
A control flow instruction that writes the PC can set the PC to an unknown value.

Table C3-148 Move prefix instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOVPRFX</td>
<td>Move prefix (predicated)</td>

</tr>
<tr>
<td></td>
<td>Move prefix (unpredicated)</td>
<td>MOVPRFX (unpredicated) on page C8-3745</td>
</tr>
</tbody>
</table>

Unless the combination of a constructive operation with merging predication is specifically required, it is strongly recommended that, for performance reasons, software should prefer to use the zeroing form of predicated MOVPRFX or the unpredicated MOVPRFX instruction.

When a MOVPRFX instruction is executed, except for PMU events SVE_MVPREFX_SPEC, SVE_MVPREFX_Z_SPEC, SVE_MVPREFX_M_SPEC, and SVE_MVPREFX_U_SPEC, 0x807C-0x807F, it is IMPLEMENTATION DEFINED for each execution of the instruction whether or not any Performance Monitor counts the instruction. This can vary dynamically for each execution of the same instruction.

When a microarchitectural operation is executed because of a MOVPRFX instruction, except for PMU events SVE_MVPREFX_SPEC, SVE_MVPREFX_Z_SPEC, SVE_MVPREFX_M_SPEC, and SVE_MVPREFX_U_SPEC, 0x807C-0x807F, it is implementation defined for each execution of the operation whether or not the Performance Monitor counts the operation. This can vary dynamically for each execution of the same instruction.

MOVPRFX instruction behavior in self-hosted debug

A MOVPRFX instruction can legally prefix a BRK or HLT instruction.

If a hardware breakpoint is programmed with the address of a legal MOVPRFX instruction, when any of the following events occur, the hardware breakpoint generates a Breakpoint exception:

- The MOVPRFX instruction is committed for execution.
- The combined MOVPRFX and Prefixed instruction is committed for execution.

If a hardware breakpoint is programmed with the address of an illegal MOVPRFX instruction or a Prefixed instruction, when any of the MOVPRFX instruction and Prefixed instruction are committed for execution, it is CONSTRAINED UNPREDICTABLE whether or not the hardware breakpoint generates a Breakpoint exception.

If a single-step is performed for a MOVPRFX instruction, it is CONSTRAINED UNPREDICTABLE whether the PE steps over the pair of instructions or steps over only the MOVPRFX instruction.

C3.7.3 Reduction operations

Horizontal reductions

The Horizontal reduction instructions perform arithmetic horizontally across Active elements of a single source vector and deliver a scalar result.

The floating-point horizontal accumulating sum instruction, FADDA, operates strictly in order of increasing element number across a vector, using the scalar destination register as a source for the initial value of the accumulator. This preserves the original program evaluation order where non-associativity is required.

The other floating-point reductions calculate their result using a recursive pair-wise algorithm that does not preserve the original program order, but permits increased parallelism for code that does not require strict order of evaluation.

Integer reductions are fully associative, and the order of evaluation is not specified by the architecture.

- Extended table lookup permute on page C3-383.
- Non-temporal gather/scatter on page C3-383.
- Cryptography support on page C3-384.

C3.8.1 Down-counting loops

A down-counting WHILE instruction decrements the value of the first scalar operand and compares the value with a second, fixed scalar operand. The instruction generates a destination predicate with all of the following characteristics:

- The predicate elements starting from the highest-numbered element are true while the comparison remains true.
- The predicate elements thereafter, down to the lowest-numbered element, are false when the comparison becomes false.

All 32 bits or 64 bits of the scalar operands are significant for the purposes of comparison. The full 32-bit or 64-bit value of the first operand is decremented by 1 for each destination predicate element, irrespective of the element size. The first general-purpose register operand is not updated.

If all of the following occur, a comparison can never fail, resulting in an all-true predicate:

- The comparison includes an equality test.
- The second scalar operand is equal to the minimum integer value of the selected size and type of comparison.

</tbody>
</table>

C3.8.3 Uniform DSP operations

The uniform DSP instructions are based on AArch64 Advanced SIMD instructions with the same mnemonic. The instructions operate on integer operands and produce results with a uniform element size. The operation of an instruction might include one or more of rounding, halving, saturation, and accumulation.

### C3.8.4 Widening DSP operations

The widening DSP instructions are based on AArch64 Advanced SIMD instructions with similar mnemonics. The instructions operate on integer values and produce results that are twice the width of some or all of the inputs. The instructions read the narrow inputs from either the even-numbered (bottom) or odd-numbered (top) source elements and place each result in the double-width destination elements that overlap the narrow source elements.

C3.8.5 Narrowing DSP operation

The narrowing DSP instructions are based on AArch64 Advanced SIMD instructions with similar mnemonics. The instructions operate on integer values and produce results that are half the width of the inputs. The instructions read wide source elements and place each result in one of the following:

- The overlapped even-numbered (bottom) half-width destination elements. The odd-numbered destination elements are set to zero.
- The overlapped odd-numbered (top) half-width destination elements. The even-numbered destination elements are unchanged, which means that the instructions are implicitly merging operations.

C3.8.6 Unary narrowing operations

The unary narrowing instructions are unpredicated and do not write to the source register. The instructions read elements from the source vector and saturate each value to the half-width destination element size. The instructions place the narrow results in one of the following:

- The overlapped even-numbered (bottom) half-width elements. The odd-numbered elements are set to zero.
- The overlapped odd-numbered (top) half-width elements. The even-numbered elements are unchanged.

Non-saturating (truncating) conversions can be performed using existing SVE instructions such as shifts, masks, and permutes.

### C3.8.7 Non-widening pairwise arithmetic

The non-widening pairwise arithmetic instructions operate on pairs of adjacent elements in each source vector and produce a result element that is the same size as a single input element. The results from the first and second source vectors are interleaved, so that the source and result elements overlap. The result is destructively placed in the first source vector. The AArch64 Advanced SIMD instructions do not interleave the results from the first and second source vectors. Predication applies to the destination vector. The even-numbered predicate elements enable an operation on a pair of elements in the first source vector. The odd-numbered predicate elements enable an operation on a pair of elements in the second source vector. Inactive elements in the destination vector register are not modified.

C3.8.9 Bitwise ternary logical instructions

The bitwise ternary logical instructions enable complex bit processing codes to be accelerated using multiple bitwise logical operations in a shorter instruction sequence. All of the following operations are supported by the bitwise ternary logical instructions:

- The BCAX instruction combines a ternary bitwise clear with an exclusive OR.
- The EOR3 instruction provides a ternary exclusive OR.
- The XAR instruction combines an exclusive OR with rotation by a constant amount.
- The bitwise select instructions, BSL, BSL1N, BSL2N, and NBSL, can be used with other bitwise logical instructions to generate all 256 possible bitwise combinations of three input bits using at most three instructions.

The bitwise ternary logical instructions are unpredicated.

C3.8.10 Large integer arithmetic

The large integer arithmetic instructions aid the processing of large integers in vector registers by maintaining multiple carry chains that are interleaved in accumulator vectors. A large integer arithmetic instruction takes as input all of the following:

- Either the even-numbered (bottom) or odd-numbered (top) elements of the first source vector.
- A 1-bit carry input from the least-significant bit of the odd-numbered elements of the second source vector.

The inputs to the instruction are added to or subtracted from the even-numbered elements of the destination and accumulator vector. The 1-bit carry output is placed in the corresponding odd-numbered element of the destination vector.

C3.8.11 Multiplication by indexed elements

The multiplication by indexed elements instructions take all integer elements in each 128-bit vector segment of the first source vector and multiplies them by the indexed element in the corresponding segment of the second source vector.
The products might be destructively added to or subtracted from the corresponding elements of an addend vector.

The second source vector elements are specified using an immediate index that selects the same element position in each 128-bit vector segment. The index range is 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the element size.

### C3.8.12 Complex integer arithmetic

Complex integer arithmetic instructions operate on signed integer complex numbers in vectors containing the following interleaved element pairs:

- The even-numbered elements contain the real parts of the complex numbers.
- The odd-numbered elements contain the imaginary parts of the complex numbers.
Uniform complex integer arithmetic

The uniform complex integer arithmetic instructions operate on vectors containing integral complex numbers. The instructions operate on complex numbers that are in polar form.

The **CADD** instructions rotate the complex numbers in the second source vector before adding element pairs to the corresponding elements of the first source vector, in a destructive manner. The rotation direction is 90 degrees or 270 degrees from the positive real axis towards the positive imaginary axis.

The **CMLA** instructions transform the operands to enable multiply-add or multiply-subtract operations on complex numbers by combining two of the instructions. The following transformations are done:

- The complex numbers in the second source vector are rotated by 0 degrees or 180 degrees before multiplying by the duplicated real components of the first source vector.
- The complex numbers in the second source vector are rotated by 90 degrees or 270 degrees before multiplying by the duplicated imaginary components of the first source vector.

The resulting products are added to the corresponding components of the destination and addend vector.

Two **CMLA** instructions can be used, as follows:

- \( CMLA \) \( Zda.S, Zn.S, Zm.S, #A \)
- \( CMLA \) \( Zda.S, Zn.S, Zm.S, #B \)

Some meaningful combinations of \( A \) and \( B \) are:

- \( A=0, B=90 \). The complex number vectors, \( Zn \) and \( Zm \), are multiplied and the products are added to the complex numbers in \( Zda \).
- \( A=0, B=270 \). The complex number conjugates in \( Zn \) are multiplied by the complex numbers in \( Zm \) and the products are added to the complex numbers in \( Zda \).
- \( A=180, B=270 \). The two complex number vectors, \( Zn \) and \( Zm \), are multiplied and the products are subtracted from the complex numbers in \( Zda \).
- \( A=180, B=90 \). The complex number conjugates in \( Zn \) are multiplied by the complex numbers in \( Zm \) and the products are subtracted from the complex numbers in \( Zda \).

The **CMLA** indexed form uses a single complex number in each 128-bit segment of the second source vector as the multiplier for all complex numbers in the corresponding first source vector segment. The complex numbers in the second source vector are specified using an immediate index that selects the same complex number position in each 128-bit vector segment. The index range is 0 to one less than the number of complex numbers per 128-bit segment, encoded in 1 to 2 bits depending on the complex number size.

Widening complex integer arithmetic

The widening complex integer instructions deinterleave the real and imaginary components of integral complex numbers, and generate complex result components that have a higher numeric precision than the input values. The instructions differ from other complex instructions that process the real and imaginary components of complex numbers and write the complex result components to the destination.

The following instructions are useful when generating the widened components of the result of a complex multiply-add:

- \texttt{SQDMLALBT} - the imaginary results.
- \texttt{SQDMLS LT} - the real results.
- \texttt{SQDMLALB} - the conjugate real results.
- \texttt{SQDMLSLT} - the conjugate imaginary results.

The following instructions are useful when generating the widened components of the result of a complex addition \((X + jY)\) or \((X - jY)\), given complex numbers \(X\) and \(Y\):

- \texttt{SADDLT} - the imaginary results when computing \((X + jY)\) or real values when computing \((X - jY)\).
- \texttt{SSUBLT} - the real results when computing \((X + jY)\) or imaginary values when computing \((X - jY)\).

Complex integer dot product

The complex integer dot product instructions delimit the source vectors into pairs of 8-bit or 16-bit signed integer complex numbers. The complex numbers in the first source vector are multiplied by the corresponding complex numbers in the second source vector. The wide real or wide imaginary part of the product is accumulated into a 32-bit or 64-bit destination vector element that overlaps all four of the elements that form a pair of complex number values in the first source vector.

Each instruction implicitly deinterleaves the real and imaginary components of their complex number inputs, so that the destination vector accumulates four wide real sums or four wide imaginary sums.

The complex numbers in the second source vector are rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, considered in polar form, by applying the following transformations before the dot product operations:

- If the rotation is \#0, the imaginary parts of the complex numbers in the second source vector are negated. The destination vector accumulates the real parts of a complex dot product.
- If the rotation is \#90, the real and imaginary parts of the complex numbers the second source vector are swapped. The destination vector accumulates the imaginary parts of a complex dot product.
- If the rotation is \#180, there is no transformation. The destination vector accumulates the real parts of a complex conjugate dot product.
- If the rotation is \#270, the real parts of the complex numbers in the second source vector are negated and then swapped with the imaginary parts. The destination vector accumulates the imaginary parts of a complex conjugate dot product.
The indexed form of the instruction selects a single complex number pair within each 128-bit segment of the second source vector to multiply with all complex number pairs within the corresponding 128-bit segment of the first source vector. The complex number pairs within the second source vector are specified using an immediate index which selects the same complex number pair position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex number pairs per 128-bit segment, encoded in 1 or 2 bits depending on the size of the complex number pair.

Each complex number is represented in a vector register as an even and odd pair of elements. The real part is the even-numbered element and the imaginary part is the odd-numbered element.

C3.8.13 Floating-point extra conversions

The floating-point extra conversion instructions convert to and from fully packed vectors of narrower floating-point elements.

The FCVTLT instruction converts the top or odd-numbered narrow floating-point vector elements to wider elements of the next higher precision. The conversion is similar to what is done by the widening integer instructions.

The FCVTNT and FCVXNT instructions convert wider floating-point vector elements to the top or odd-numbered narrower elements of the next lower precision. The conversion is similar to what is done by the narrowing integer instructions.

The FCVTXNT and FCVTX instructions convert from double-precision to fully packed half-precision in two narrowing steps, double-precision to single-precision and then single-precision to half-precision. The two-step conversion is done without an intermediate rounding error by using von Neumann rounding, which rounds an inexact mantissa to an odd value.

The existing SVE FCVT instructions implement the corresponding widening and narrowing conversions on the bottom or even-numbered half-width elements.

C3.8.14 Floating-point widening multiply-accumulate

The floating-point widening multiply-accumulate instructions multiply the even-numbered or odd-numbered half-precision elements of the two source vectors and then destructively add or subtract the single-precision intermediate products. Intermediate rounding is not done. The result is placed into the overlapping single-precision elements of the addend vector.

The instructions implicitly convert the half-precision inputs to single-precision and can be used to mitigate the impact of round-off errors when accumulating half-precision floating-point values over many iterations.
The instructions are unpredicated and preserve the multiplier and multiplicand source vectors.

**C3.8.15 Floating-point integer binary logarithm**

The floating-point integer binary logarithm instruction returns the signed integer base 2 logarithm of each floating-point input element |x| after normalization.

The instruction produces the unbiased exponent of x used in the representation of the floating-point value. For positive x, \( x = \text{significand} \times 2^{\text{exponent}} \).

The integer results are placed in elements of the destination vector, which have the same width as the floating-point input elements:

- If x is normal, the result is the base 2 logarithm of x.
- If x is subnormal, the result corresponds to the normalized representation.
- If x is infinite, the result is \( 2^{(\text{esize}-1) - 1} \).
- If x is ±0.0 or NaN, the result is \( -2^{(\text{esize}-1)} \).

Inactive elements in the destination vector register are not modified.

**C3.8.16 Cross-lane match detect**

This section includes instructions that detect or count matching elements within another vector, or within a 128-bit vector segment.
Vector Histogram Count

The vector histogram count instructions create vector histograms.

- **HISTSEG** compares each 8-bit byte element in the first source vector with all of the elements in the corresponding 128-bit segment of the second source vector. The instruction counts the matching elements and places the result in the corresponding destination vector element. The instruction is unpredicated.

- **HISTCNT** compares each active 32-bit or 64-bit element in the first source vector with all elements in the second source vector that have an element number less than or equal to the *Active element* in the first source vector. The number of matching elements is counted and the result is placed in the corresponding destination vector element. *Inactive elements* in the destination vector are set to zero. *Inactive elements* in the second source vector do not cause a match.

<table>

</tr>
</tbody>
</table>

Character match

The character match instructions can be used to scan each 128-bit segment of the second source vector for an 8-bit or 16-bit character string from the first source vector.

The **MATCH** and **NMATCH** instructions compare each active 8-bit or 16-bit character in the first source vector with all of the characters in the corresponding 128-bit segment of the second source vector. When the first source character matches any (MATCH) or does not match any (NMATCH) character in the second segment, a true value is placed in the corresponding destination predicate element, otherwise a false value is placed in the destination predicate element. *Inactive elements* in the destination predicate register are set to zero.

The instruction sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

</tr>
</tbody>
</table>

Contiguous conflict detection

The contiguous conflict detection instructions check two addresses for a conflict or overlap between address ranges that could result in a loop-carried dependency through memory. The address range has the form [addr, addr+VL+8], where VL is the accessible vector length in bits. A conflict can occur when contiguous load and store instructions use these addresses within the same loop iteration.
The instructions generate a predicate with elements that are true when the addresses cannot conflict within the same iteration, and false thereafter. The instructions set the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag is set to zero.

The bit permutation instructions are optional. The bit permutation instructions are configured by the ID_AA64ZFR0_EL1.BitPerm bit. The instructions can be used to scatter, gather, or separate a set of bits within each first source vector element under the control of a bit mask or sieve in the corresponding second source vector elements. The instructions are unpredicated.

The BDEP instruction scatters the lowest-numbered contiguous bits within each first source vector element to the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The order of the bits is preserved. The bits corresponding to a zero mask bit are set to zero.

The BEXT instruction gathers bits in each first source vector element from the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The bits are gathered to the lowest-numbered contiguous bits of the corresponding destination element, preserving their order. The remaining higher-numbered bits are set to zero.

The BGRP instruction selects bits from each first source vector element and groups them into the corresponding destination element, using a corresponding mask element in the second source vector, as follows:

- The nonzero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the lowest-numbered contiguous bits of the destination element.
- The zero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the highest-numbered contiguous bits of the destination element.

The bit order within each group is preserved.

The polynomial arithmetic instructions support polynomial arithmetic over [0, 1], where exclusive-OR takes the place of addition. The instructions can be used in applications such as CRC calculations, AES-GCM, elliptic curve cryptography, Diffie-Hellman key exchange, and others.

The PMUL and widening PMULL instructions perform a polynomial multiplication over [0, 1]. The PMULL instructions read the source operands from either the even-numbered (bottom) or odd-numbered (top) narrow elements. Each double-width result is placed in the destination elements that overlap the narrow source elements.

### C3.8.17 Bit permutation

The bit permutation instructions are optional. The bit permutation instructions are configured by the ID_AA64ZFR0_EL1.BitPerm bit. The instructions can be used to scatter, gather, or separate a set of bits within each first source vector element under the control of a bit mask or sieve in the corresponding second source vector elements. The instructions are unpredicated.

The BDEP instruction scatters the lowest-numbered contiguous bits within each first source vector element to the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The order of the bits is preserved. The bits corresponding to a zero mask bit are set to zero.

The BEXT instruction gathers bits in each first source vector element from the bit positions that are indicated by nonzero bits in the corresponding mask element of the second source vector. The bits are gathered to the lowest-numbered contiguous bits of the corresponding destination element, preserving their order. The remaining higher-numbered bits are set to zero.

The BGRP instruction selects bits from each first source vector element and groups them into the corresponding destination element, using a corresponding mask element in the second source vector, as follows:

- The nonzero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the lowest-numbered contiguous bits of the destination element.
- The zero bits in the mask element select the bit positions from the corresponding first source vector element. The selected bits are gathered into the highest-numbered contiguous bits of the destination element.

The bit order within each group is preserved.

### C3.8.18 Polynomial arithmetic

The polynomial arithmetic instructions support polynomial arithmetic over [0, 1], where exclusive-OR takes the place of addition. The instructions can be used in applications such as CRC calculations, AES-GCM, elliptic curve cryptography, Diffie-Hellman key exchange, and others.

The PMUL and widening PMULL instructions perform a polynomial multiplication over [0, 1]. The PMULL instructions read the source operands from either the even-numbered (bottom) or odd-numbered (top) narrow elements. Each double-width result is placed in the destination elements that overlap the narrow source elements.
The interleaving bitwise exclusive-OR instructions operate on the even-numbered (bottom) elements of the first source vector register and the odd-numbered (top) elements of the second source vector register. The result is either placed in the even-numbered elements of the destination vector, leaving the odd-numbered elements unchanged, or placed in the odd-numbered elements of the destination vector, leaving the even-numbered elements unchanged.

These instructions are unpredicated.

### C3.8.19 Vector concatenation

The vector concatenation instructions have new constructive versions that are introduced in SVE2 that preserve both of the source operands. In the constructive versions of the instruction, only the first source vector register number is encoded, which requires the source vectors to be in consecutively numbered registers (modulo 32).

### C3.8.21 Non-temporal gather/scatter

The non-temporal gather load and scatter store instructions provide a hint to the memory system that the data structure being accessed has a low reuse frequency. The memory system can use the hint to avoid retaining the data or evicting more frequently-used data from the caches.
These instructions support a single addressing mode consisting of 64-bit or 32-bit vector base addresses plus an unscaled 64-bit scalar offset that defaults to the zero register, XZR. Other addressing modes can be constructed using extra instructions.

### C3.8.22 Cryptography support

Implementation of cryptography acceleration instructions is optional and controlled by the ID_AA64ZFR0_EL1.{SM4, SHA3, AES} bit fields. Implementation of the instructions requires consistency is maintained with the existing Armv8 cryptographic functionality support, as follows:

- If none of the SVE2 cryptographic instructions are implemented, then the Armv8 AES, SHA1, and SHA256 instructions and the Armv8.4 SHA12, SHA3, SM3, and SM4 instructions can be implemented.
- If the SVE2 SHA3 instructions are implemented, then implementation of the Armv8.4 SHA3 instructions is required.
- If the SVE2 SM4 instructions are implemented, then implementation of the Armv8.4 SM4 instructions is required, but implementing any of the following instructions is optional:
  - The Armv8 AES, SHA1, and SHA256 instructions.
  - The Armv8.4 SHA12 and SHA3 instructions.
- If the SVE2 AES instructions are implemented, then implementation of the Armv8 AES instructions is required, but implementing any of the Armv8 SHA256, SHA12, SHA3, SM3, and SM4 instructions is optional.
- If all of the SVE2 cryptographic instructions are implemented, then implementation of the equivalent Armv8 and Armv8.4 instructions is required.

### AES-128 instructions

AES-128 is a 128-bit block cipher that is computed using a combination of linear XOR operations, the use of rotations by fixed values, and a set of 8-bit non-linear substitutions.
The following instructions accelerate a single encryption round:

- The `AES E` instruction reads a 16-byte state array from each 128-bit segment of the first source vector and a round key from the corresponding 128-bit segment of the second source vector. A single round of the `AddRoundKey()`, `SubBytes()`, and `ShiftRows()` transformations, in accordance with the AES standard, is applied to each state array.

- The `AES IMC` instruction reads a 16-byte state array from each 128-bit segment of the source register and performs a single round of the `MixColumns()` transformation on each state array in accordance with the AES standard.

The following instructions accelerate a single decryption round:

- The `AES D` instruction reads a 16-byte state array from each 128-bit segment of the first source vector and a round key from the corresponding 128-bit segment of the second source vector. A single round of the `AddRoundKey()`, `InvSubBytes()`, and `InvShiftRows()` transformations in accordance with the AES standard, is applied to each state array.

- The `AES IMC` instruction reads a 16-byte state array from each 128-bit segment of the source register and performs a single round of the `InvMixColumns()` transformation on each state array in accordance with the AES standard.

Each updated state array is destructively placed in the corresponding segment of the first source vector. The AES instructions are unpredicated.

### SHA-3 instructions

The SHA-3 instructions accelerate the SHA-3 hash algorithm.

The SHA-3 hash is based on a running digest of 1600 bits, arranged as a five by five array of 64-bit values. The instructions map the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is done on these registers during a round of the SHA-3 hash calculation.

Two or more parallel SHA-3 hash calculations are combined as a SIMD operation, where one calculation operates on the 0th 64-bit element of each vector, and the other calculation operates on the first 64-bit element of each vector. The SIMD operation is useful for the fast parallel hash algorithm recently introduced into the SHA-3 standard that allows a single input stream to be computed using multiple SHA-3 hashes in parallel.

The SHA3 instructions are unpredicated.

See also *Bitwise ternary logical instructions*. 
SM4 instructions

SM4 is the standard Chinese symmetric encryption algorithm which can be accelerated using a similar approach to that used for AES.

SM4 is a 128-bit wide block cipher that is computed using a combination of linear XOR operations, the use of fixed-value rotations, and a set of 8-bit non-linear substitutions.

- The SM4E instruction reads 16 bytes of input data from each 128-bit segment of the first source vector, and four iterations of 32-bit round keys from the corresponding 128-bit segments of the second source vector. Each input data block is encrypted by four rounds in accordance with the SM4 standard, and destructively placed in the corresponding segments of the first source vector.

- The SM4EKEY instruction reads four rounds of 32-bit input key values from each 128-bit segment of the first source vector, and four rounds of 32-bit constants from the corresponding 128-bit segment of the second source vector. The four rounds of output key values are derived in accordance with the SM4 standard, and placed in the corresponding segments of the destination vector.

The SM4 instructions are unpredicated.

Chapter C4
A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

•  *A64 instruction set encoding on page C4-388.*

In this chapter:

•  In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
•  In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
C4.1 A64 instruction set encoding

The A64 instruction encoding is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>25 24</th>
<th>23 22 21 20</th>
<th>19 18 17 16</th>
<th>15 14 13 12</th>
<th>11 10 09 08</th>
<th>07 06 05 04</th>
<th>03 02 01 00</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>op1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>op0</td>
</tr>
</tbody>
</table>

Table C4-1 Main encoding table for the A64 instruction set

C4.11 SVE encodings

This section describes the encoding of the SVE encodings group. The encodings in this section are decoded from A64 instruction set encoding on page C4-388.

SVE integer multiply vectors (predicated)

This section describes the encoding of the SVE integer multiply vectors (predicated) instruction class. The encodings in this section are decoded from *SVE Integer Binary Arithmetic - Predicated* on page C4-413.
This section describes the encoding of the SVE integer divide vectors (predicated) instruction class. The encodings in this section are decoded from *SVE Integer Binary Arithmetic - Predicated* on page C4-413.

![Binary representation of a SVE instruction](image)

### SVE Integer Divide Vectors (Predicated)

The binary representation of the SVE integer divide vectors (predicated) instruction is shown above. The instruction's fields are decoded as follows:

- **H** (High): Determines the function (MUL, SMULH, or UMULH).
- **U** (Upper): Determines the predication.

### SVE Bitwise Logical Operations (Predicated)

This section describes the encoding of the SVE bitwise logical operations (predicated) instruction class. The encodings in this section are decoded from *SVE Integer Binary Arithmetic - Predicated* on page C4-413.

The binary representation of the SVE bitwise logical operations (predicated) instruction is shown above. The instruction's fields are decoded as follows:

- **R** (Register): Determines the function (SDIV, UDIV, SDIVR, or UDIVR).
- **U** (Upper): Determines the predication.
C4.1.14 SVE Integer Reduction

This section describes the encoding of the SVE Integer Reduction group. The encodings in this section are decoded from SVE encodings on page C4-399.

### C4.1.30 SVE Permute Vector - Segments

This section describes the encoding of the SVE Permute Vector - Segments group. The encodings in this section are decoded from SVE encodings on page C4-399.
This section describes the encoding of the SVE permute vector segments instruction class. The encodings in this section are decoded from "SVE Permute Vector - Segments on page C4-442."

This section describes the encoding of the SVE Integer Compare - Vectors group. The encodings in this section are decoded from "SVE encodings on page C4-399."
This section describes the encoding of the SVE integer compare vectors instruction class. The encodings in this section are decoded from *SVE Integer Compare - Vectors* on page C4-443.

### SVE integer compare vectors

This section describes the encoding of the SVE integer compare vectors instruction class. The encodings in this section are decoded from *SVE Integer Compare - Vectors* on page C4-443.

### SVE integer compare with wide elements

This section describes the encoding of the SVE integer compare with wide elements instruction class. The encodings in this section are decoded from *SVE Integer Compare - Vectors* on page C4-443.
C4.1.32 SVE Propagate Break

This section describes the encoding of the SVE Propagate Break group. The encodings in this section are decoded from *SVE encodings* on page C4-399.

![Table C4-33 Encoding table for the SVE Propagate Break group](image)

**SVE propagate break from previous partition**

This section describes the encoding of the SVE propagate break from previous partition instruction class. The encodings in this section are decoded from *SVE Propagate Break*. 
C4.1.33 SVE Partition Break

This section describes the encoding of the SVE Partition Break group. The encodings in this section are decoded from SVE encodings on page C4-399.

C4.1 A64 instruction set encoding

This section describes the encoding of the SVE2 saturating multiply-add long instruction class. The encodings in this section are decoded from *SVE Integer Multiply-Add - Unpredicated* on page C4-461.

### SVE2 saturating multiply-add long

This section describes the encoding of the SVE2 saturating multiply-add long instruction class. The encodings in this section are decoded from *SVE Integer Multiply-Add - Unpredicated* on page C4-461.

### SVE2 saturating multiply-add high

This section describes the encoding of the SVE2 saturating multiply-add high instruction class. The encodings in this section are decoded from *SVE Integer Multiply-Add - Unpredicated* on page C4-461.
SVE mixed sign dot product

This section describes the encoding of the SVE mixed sign dot product instruction class. The encodings in this section are decoded from *SVE Integer Multiply-Add - Unpredicated* on page C4-461.

C4.1.41 SVE2 Integer - Predicated

This section describes the encoding of the SVE2 Integer - Predicated group. The encodings in this section are decoded from *SVE encodings* on page C4-399.

### Table C4-42 Encoding table for the SVE2 Integer - Predicated group

<table>
<thead>
<tr>
<th>Decode fields</th>

Load register (literal)

This section describes the encoding of the Load register (literal) instruction class. The encodings in this section are decoded from *Loads and Stores* on page C4-547.
Memory Copy and Memory Set

This section describes the encoding of the Memory Copy and Memory Set instruction class. The encodings in this section are decoded from Loads and Stores on page C4-547.

A64 Instruction Set Encoding
C4.1 A64 instruction set encoding
Chapter C5
The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- The System instruction class encoding space on page C5-654.
- Special-purpose registers on page C5-671.
- A64 System instructions for cache maintenance on page C5-776.
- A64 System instructions for address translation on page C5-841.
- A64 System instructions for TLB maintenance on page C5-866.
- A64 System instructions for prediction restriction on page C5-1146.
- A64 System instructions for the Branch Record Buffer Extension on page C5-1159.

See General information about the A64 instruction descriptions on page C2-243 for information about entries used in the instruction encoding descriptions.
C5.1 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

• Access to System registers, including the debug registers, that provide system control, and system status information.
• Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
• The cache and TLB maintenance instructions and address translation instructions.
• Barriers and the CLREX instruction.
• Architectural hint instructions.

This section describes the general model for accessing this functionality.

--- Note ---

• See Fixed values in AArch64 instruction and System register descriptions on page C2-243 for information about abbreviations used in the System instruction descriptions.

• In AArch32 state much of this functionality is provided through the System register interface described in The AArch32 System register interface on page G1-8993. In AArch64 state, the parameters used to characterize the System register encoding space are \{op0, op1, Crn, Crn, op2\}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface on page G1-8994. There is no particular significance to the naming of these parameters, and no functional distinction between the opn parameters and the CRx parameters.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview on page C5-655 then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

• \(op0==0b00\), architectural hints, barriers and CLREX, and PSTATE access on page C5-656.
• \(op0==0b01\), cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.
• \(op0==0b11\), Moves to and from Special-purpose registers on page C5-668.

For the description of the next level of encoding hierarchy of System registers, see:

• \(op0==0b10\), Moves to and from debug and trace System registers on page D16-5519.
• \(op0==0b11\), Moves to and from non-debug System registers, Special-purpose registers on page D16-5523.
• Reserved encodings for IMPLEMENTATION DEFINED registers on page D16-5542.

C5.1.1 Principles of the System instruction class encoding

An encoding in the System instruction space is identified by a set of arguments, \{op0, op1, Crn, Crn, op2\}. These form an encoding hierarchy, where:

\(op0\) Defines the top-level division of the encoding space, see System instruction class encoding overview on page C5-655.

\(op1\) Identifies the lowest Exception level at which the encoding is accessible, as follows:

Accessible at EL0 \( op1 \) has the value 3.
Accessible at EL1 \( op1 \) has the value 0, 1, or 2. The value is the same as the \( op1 \) value used to access the equivalent AArch32 register.

Accessible at Secure EL1 \( op1 \) has the value 7.

Accessible at EL2 \( op1 \) has the value 4 or 5. The value 5 is used for the EL12 encodings that access EL1 System registers used when FEAT_VHE is implemented and HCR_EL2.E2H is 1.
Accessible at EL3  op1 has the value 6.

Arm strongly recommends that implementers adopt this use of op1 when using the IMPLEMENTATION DEFINED regions of the encoding space described in Reserved encodings for IMPLEMENTATION DEFINED registers on page D16-5542.

C5.1.2  System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:
- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 16 15</th>
<th>12 11 8 7</th>
<th>5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 0 1 0</td>
<td>L</td>
<td>op0</td>
<td>op1</td>
<td>CRn</td>
<td>CRm</td>
<td>op2</td>
</tr>
</tbody>
</table>
```

The value of L indicates the transfer direction:
- 0  Transfer to System register.
- 1  Transfer from System register.

The op0 field is the top level encoding of the System instruction type. Its possible values are:

- **0b00** These encodings provide:
  - Instructions with an immediate field for accessing PSTATE, the current PE state.
  - The architectural hint instructions.
  - Barriers and the CLREX instruction.

  For more information about these encodings, see op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-656.

- **0b01** These encodings provide:
  - Cache maintenance instructions.
  - TLB maintenance instructions.
  - Address translation instructions.
  - Prediction restriction instructions.
  - BRBE instructions.

  **Note** These are equivalent to operations in the AArch32 (coproc==0b1111) encoding space.

  For more information, see op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions on page C5-659.

- **0b10** These encodings provide moves to and from:
  - Legacy AArch32 System registers for execution environments, to provide access to these registers from higher Exception levels that are using AArch64.
  - Debug and trace registers.

  **Note** These are equivalent to the registers in the AArch32 (coproc==0b1110) encoding space.

  For more information, see op0==0b10, Moves to and from debug and trace System registers on page D16-5519.
The A64 System Instruction Class
C5.1 The System instruction class encoding space

0b11

These encodings provide:
• Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

Note
The accessed registers are equivalent to the registers in the AArch32 (coproc==0b1111) encoding space.

• Access to Special-purpose registers.

For more information, see Instructions for accessing Special-purpose registers on page C5-668 and Instructions for accessing non-debug System registers on page D16-5523.

UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

• All unallocated encodings are treated as UNDEFINED.
• All encodings with \( L = 1 \) and \( op0 = 0b0x \) are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see Reserved encoding space for IMPLEMENTATION DEFINED instructions on page C5-667.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

• Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L = 0 \) is UNDEFINED.
• Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L = 1 \) is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in Principles of the System instruction class encoding on page C5-654.

C5.1.3 \( op0 == 0b00 \), architectural hints, barriers and CLREX, and PSTATE access

The different groups of System register instructions with \( op0 == 0b00 \):

• Are identified by the value of \( CRn \).
• Are always encoded with a value of 0b11111 in the \( Rt \) field.

The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|------------------------|----------|----------|----------|----------|----------|
| 1 1 0 1 0 1 0 1 0 0 L 0 0 op1 CRn CRm op2 1 1 1 1 1 |

The encoding of the \( CRn \) field is as follows:

0b0010  See Architectural hint instructions.
0b0011  See Barriers and CLREX on page C5-657.
0b0100  See Instructions for accessing the PSTATE fields on page C5-658.

Architectural hint instructions

Within the \( op0 == 0b00 \) encodings, the architectural hint instructions are identified by \( CRn \) having the value 0b0010. The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 5 4 0 |
|------------------------|----------|----------|----------|----------|----------|
| 1 1 0 1 0 1 0 1 0 0 L 0 0 CRn CRm op2 1 1 1 1 1 |
The value of op<6:0>, formed by concatenating the CRm and op2 fields, determines the hint instruction as follows:

0b000000  NOP instruction.
0b000001  YIELD instruction.
0b000010  WFE instruction.
0b000011  WFI instruction.
0b000010  SEV instruction.
0b000101  SEVL instruction.
0b000110  DGH instruction.
0b000111  XPACD, XPACI, XPACLRI instruction.
0b001000  PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIA1716 variant.
0b001010  PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIB1716 variant.
0b001100  AUTIA, AUTIA1716, AUTIASP, AUTIAZ instruction, AUTIA1716 variant.
0b001110  AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIB1716 variant.
0b010000  ESB instruction.
0b010001  PSB CSYNC instruction.
0b010010  TSB CSYNC instruction.
0b010100  CSDB instruction.
0b011000  PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIAZ variant.
0b011001  PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIASP variant.
0b011010  PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIBZ variant.
0b011011  PACIB, PACIB176, PACIBSP, PACIBZ, PACIZB instruction, PACIBSP variant.
0b011100  AUTIA, AUTIA1716, AUTIASP, AUTIAZ instruction, AUTIAZ variant.
0b011101  AUTIA, AUTIA1716, AUTIASP, AUTIAZ instruction, AUTIASP variant.
0b011110  AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBZ variant.
0b011111  AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBSP variant.
0b100xx0  BTI instruction.

These instructions are described in Chapter C6 A64 Base Instruction Descriptions.

--- Note ---
- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

For more information about:
- The WFE, WFI, SEV, and SEVL instructions, see Mechanisms for entering a low-power state on page D1-4676.
- The YIELD instruction, see Software control features and EL0 on page B1-146.

**Barriers and CLREX**

Within the op0==0b0 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b1011. The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|------------------------|------------------|------------------|------------------|------------------|
| 1 1 0 1 0 1 0 1 0 0 0 0 0 1 1 0 1 1 1 0 1 1 1 1 0 |
| op0      op1      CRn      op2      1 1 1 1 1 1 |

The value of op2 determines the instruction, as follows:

0b001  DSB instruction, Memory nXS barrier variant.
0b010  CLREX instruction.
0b100  DSB instruction, Memory barrier variant.
0b101  DMB instruction.
The A64 System Instruction Class
C5.1 The System instruction class encoding space

0b110 ISB instruction.
0b000, 0b011, 0b111 UNDEFINED.

These instructions are described in Chapter C6 A64 Base Instruction Descriptions.

Note
- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:
- The barrier instructions, see Memory barriers on page B2-174.
- The CLREX instruction, see Synchronization and semaphores on page B2-211.

Instructions for accessing the PSTATE fields

Within the op0=0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is shown in Figure C5-1 and Figure C5-2:

Figure C5-1 Instructions using #Imm4

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | op1 | 0 | 1 | 0 | Imm4 | op2 | 1 | 1 | 1 | 1 |
| op0 | CRn | CRm | Rt |

Figure C5-2 Instructions using #Imm1

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Imm1 | op2 | 1 | 1 | 1 | 1 |
| op0 | CRn | CRm | Rt |

These instructions are:
- CFINV ; Inverts the value of PSTATE.C
- MSR DAIFSet, #Imm4 ; Used to set any or all of DAIF to 1
- MSR DAIFClr, #Imm4 ; Used to clear any or all of DAIF to 0
- MSR SPSel, #Imm4 ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
- MSR UA0, #Imm4 ; Used to set the value of PSTATE.UA0
- MSR PAN, #Imm4 ; Used to set the value of PSTATE.PAN
- MSR DIT, #Imm4 ; Used to set the value of PSTATE.DIT
- MSR SSBS, #Imm4 ; Used to set the value of PSTATE.SSBS
- MSR TCO, #Imm4 ; Used to set the value of PSTATE.TCO
- MSR ALLINT, #Imm1 ; Used to set the value of PSTATE.ALLINT

The value of op2 selects the instruction form, which defines the constraints on the values of the op1 and Imm4 or Imm1 arguments, as follows:

op2==0b000 Selects the CFINV instruction.
op2==0b011 Selects the MSR UA0 instruction.
op2==0b100 Selects the MSR PAN instruction.
op2==0b101 Selects the MSR SPSel instruction.
op2==0b001 Selects the MSR SSBS instruction.
op2==0b010 Selects the MSR DIT instruction.
op2==0b100 Selects the MSR TCO instruction.
C5.1 The System instruction class encoding space

op2==0b110 Selects the MSR DAIFSet instruction, that sets the specified PSTATE.\{D, A, I, F\} bits to 1.

op2==0b111 Selects the MSR DAIFClr instruction, that clears the specified PSTATE.\{D, A, I, F\} bits to 0.

op2==0b000 Selects the MSR ALLINT instruction.

All other combinations of op1 and op2 are reserved, and the corresponding instructions are UNDEFINED.

--- Note ---

For PSTATE updates, instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Writes to PSTATE occur in program order without the need for additional synchronization. Changing PSTATE.SPSel to use SP_EL0 synchronizes any updates to SP_EL0 that have been written by an MSR to SP_EL0, without the need for additional synchronization.

C5.1.4 op0==0b01, cache maintenance, TLB maintenance, address translation, prediction restriction, and BRBE instructions

The System instructions are encoded with op0==0b01. The different groups of System instructions are identified by the values of CRn and Crm, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|-------------------------|-----------------|-----------------|-----------------|
| 1 1 0 1 0 1 0 0 0 1 0 1  | CRn CRm op2 Xt  |
| op0                     |

The grouping of these instructions depending on the CRn and Crm fields is as follows:

CRn==7 The instruction group is determined by the value of CRn, as follows:

CRn=={1, 5} Instruction cache maintenance instructions.
See Cache maintenance instructions, and data cache zero operation.

CRn==2 Branch Record Buffer instructions.
See Branch Record Buffer instructions on page C5-667.

CRn==3 Prediction restriction instructions.
See Prediction restriction instructions on page C5-661.

CRn==4 Data cache zero operation.
See Cache maintenance instructions, and data cache zero operation.

CRn=={6, 10, 11, 12, 14} Data cache maintenance instructions.
See Cache maintenance instructions, and data cache zero operation.

CRn==8 See Address translation instructions on page C5-661.

CRn=={8, 9} See TLB maintenance instructions on page C5-662.

CRn=={11, 15} See Reserved encoding space for IMPLEMENTATION DEFINED instructions on page C5-667.

Cache maintenance instructions, and data cache zero operation

Table C5-1 on page C5-660 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

• The instruction is UNDEFINED.

ARM DDI 0487I.a Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved. C5-659
ID081822 Non-Confidential
The instruction behaves as if the Xt field is set to 0b11111.

**TLB maintenance instructions**

Table C5-4 lists the TLB maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to 0b11111.

For more information, see *Chapter D15 The Branch Record Buffer Extension.*

Reserved encoding space for IMPLEMENTATION DEFINED instructions

The A64 instruction set reserves the following encoding space for IMPLEMENTATION DEFINED instructions:

The value of \( L \) defines the use of \( Rt \) as follows:

- **0**: \( Rt \) is an argument supplied to the instruction.
- **1**: \( Rt \) is a result returned by the instruction.

IMPLEMENTATION DEFINED instructions in this encoding space are accessed using the SYS and SYSL instructions, see *SYS* on page C6-1993 and *SYSL* on page C6-1995.
C5.1.5  **op0==0b11, Moves to and from Special-purpose registers**

The instructions that move data to and from non-debug System registers are encoded with \( \text{op0} == 0b11 \), except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

\[
\begin{array}{c|cccccccccc|c|c|c|c|c|c|c|c|c|c|c|c}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & |L| & 1 & 1 & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} & \text{Rt} \\
\end{array}
\]

### Instructions for accessing Special-purpose registers

The value of \( \text{CRn} \) provides the next level of decode of these instructions. For Special-purpose registers, the value of \( \text{CRn} \) is 4.

The A64 instructions for accessing Special-purpose registers are:

- **MSR** `<Special-purpose register>`, \( \text{Xt} \); Write to Special-purpose register
- **MRS** \( \text{Xt}, <\text{Special-purpose register}> \); Read from Special-purpose register

For these accesses, \( \text{CRn} \) has the value 4. The encoding for Special-purpose register accesses is:

\[
\begin{array}{c|cccccccccc|c|c|c|c|c|c|c|c|c|c|c|c}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & |L| & 1 & 1 & \text{op1} & 0 & 0 & \text{Rm} & \text{op2} & \text{Rt} \\
\end{array}
\]

The full list of Special-purpose registers is in Table C5-6 on page C5-668. The characteristic of a Special-purpose register is that all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Table C5-6 on page C5-668 lists the encodings for \( \text{op1} \), \( \text{CRn} \), and \( \text{op2} \) fields for accesses to the Special-purpose registers in AArch64.

C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- **ALLINT**, that holds the PSTATE.ALLINT bit.
- **CurrentEL**, that holds PSTATE.EL, and that software can read to determine the current Exception level.
- **DAIF**, that holds the current PSTATE.{D, A, I, F} interrupt mask bits.
- **DIT**, that holds the PSTATE.DIT bit.
- **ELR_EL1**, that holds the address to return to for an exception return from EL1.
- **ELR_EL2**, that holds the address to return to for an exception return from EL2.
- **ELR_EL3**, that holds the address to return to for an exception return from EL3.
- **FPCR**, that provides control of floating-point operation.
- **FPSR**, that provides floating-point status information.
- **NZCV**, that holds the PSTATE.{N, Z, C, V} condition flags.
- **PAN**, that holds the PSTATE.PAN state bit.
- **SP_EL0**, that holds the stack pointer for EL0.
- **SP_EL1**, that holds the stack pointer for EL1.
- **SP_EL2**, that holds the stack pointer for EL2.
- **SP_EL3**, that holds the stack pointer for EL3.
- **SPSel**, that holds PSTATE.SP, that at EL1 or higher selects the current SP.
- **SPSR_abt**, that holds process state on taking an exception to AArch32 Abort mode.
- **SPSR_EL1**, that holds process state on taking an exception to AArch64 EL1.
- **SPSR_EL2**, that holds process state on taking an exception to AArch64 EL2.
- **SPSR_EL3**, that holds process state on taking an exception to AArch64 EL3.
- **SPSR_fiq**, that holds process state on taking an exception to AArch32 FIQ mode.
- **SPSR_irq**, that holds process state on taking an exception to AArch32 IRQ mode.
- **SPSR_und**, that holds process state on taking an exception to AArch32 Undefined mode.
- **SSBS**, that holds the PSTATE.SSBS bit.
- **SVCR**, controls Streaming SVE mode and SME behavior.
- **TCO**, that holds the PSTATE.TCO bit.
- **UAO**, that holds the PSTATE.UAO bit.

The following registers are also Special-purpose registers:

- **DLR_EL0**, that holds the address to return to for a return from Debug state.
- **DSPSR_EL0**, that holds process state on entry to Debug state.
C5.2.1 ALLINT, All Interrupt Mask Bit

The ALLINT characteristics are:

Purpose

Allows access to the all interrupt mask bit.

Configurations

This register is present only when FEAT_NMI is implemented. Otherwise, direct accesses to ALLINT are UNDEFINED.

Attributes

ALLINT is a 64-bit register.

Field descriptions

![Field diagram]

Bits [63:14]

Reserved, RES0.

ALLINT, bit [13]

All interrupt mask. An interrupt is controlled by PSTATE.ALLINT when all of the following apply:

- SCTLR_ELx.NMI is 1.
- The interrupt is targeted at ELx.
- Execution is at ELx.

0b0 This control does not cause any interrupts to be masked.

0b1 If SCTLR_ELx.NMI is 1 and execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx, with or without Superpriority, is masked.

The value of this bit is set to the inverse value in the SCTLR_ELx.SPINTMASK field on taking an exception to ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:0]

Reserved, RES0.

Accessing ALLINT

Accesses to this register use the following encodings in the System register encoding space:
### MRS \(<Xt>, ALLINT\)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b00</td>
<td>0b0100</td>
<td>0b0011</td>
<td>0b00</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
UNDEFINED;
elsesif PSTATE.EL == EL1 then
X\([t, 64]\) = Zeros(50):PSTATE.ALLINT:Zeros(13);
elsesif PSTATE.EL == EL2 then
X\([t, 64]\) = Zeros(50):PSTATE.ALLINT:Zeros(13);
elsesif PSTATE.EL == EL3 then
X\([t, 64]\) = Zeros(50):PSTATE.ALLINT:Zeros(13);

### MSR ALLINT, \(<Xt>\)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b00</td>
<td>0b0100</td>
<td>0b0011</td>
<td>0b00</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
UNDEFINED;
elsesif PSTATE.EL == EL1 then
  if EL2Enabled() && IsHCRXEL2Enabled() && HCRX_EL2.TALLINT == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    PSTATE.ALLINT = X\([t, 64]\)<13>;
elsesif PSTATE.EL == EL2 then
  PSTATE.ALLINT = X\([t, 64]\)<13>;
elsesif PSTATE.EL == EL3 then
  PSTATE.ALLINT = X\([t, 64]\)<13>;

### MSR ALLINT, \(#<imm>\)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>0b001</td>
<td>0b0100</td>

<td>0b00</td>
</tr>
</tbody>
</table>

C5.2.2 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

**Purpose**

Holds the current Exception level.

**Configurations**

There are no configuration notes.

**Attributes**

CurrentEL is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-4</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31-2</td>
<td>Current Exception level.</td>
</tr>
<tr>
<td>1-0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**EL, bits [3:2]**

Current Exception level.

- 0b00: EL0.
- 0b01: EL1.
- 0b10: EL2.
- 0b11: EL3.

When the HCR_EL2.NV bit is 1, EL1 read accesses to the CurrentEL register return the value of 0b10 in this field.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to 1.
  - When the highest implemented Exception level is EL2, this field resets to 2.
  - Otherwise, this field resets to 3.

**Accessing CurrentEL**

Accesses to this register use the following encodings in the System register encoding space:
MRS \(X_t\), CurrentEL

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b000</td>
<td>0b0100</td>
<td>0b0010</td>
<td>0b010</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        \(X[t, 64]\) = Zeros(60):'10':Zeros(2);
    else
        \(X[t, 64]\) = Zeros(60):PSTATE.EL:Zeros(2);
elsif PSTATE.EL == EL2 then
    \(X[t, 64]\) = Zeros(60):PSTATE.EL:Zeros(2);
elsif PSTATE.EL == EL3 then
    \(X[t, 64]\) = Zeros(60):PSTATE.EL:Zeros(2);
C5.2.3 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

**Purpose**
Allows access to the interrupt mask bits.

**Configurations**
There are no configuration notes.

**Attributes**
DAIF is a 64-bit register.

**Field descriptions**

### Bits [63:10]
Reserved, RES0.

### D, bit [9]
Process state D mask.
- **0b0** Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
- **0b1** Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.

### A, bit [8]
SError interrupt mask bit.
- **0b0** Exception not masked.
- **0b1** Exception masked.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.

### I, bit [7]
IRQ mask bit.
- **0b0** Exception not masked.
- **0b1** Exception masked.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.
F, bit [6]
FIQ mask bit.
0b0 Exception not masked.
0b1 Exception masked.
The reset behavior of this field is:
• On a Warm reset, this field resets to 1.

Bits [5:0]
Reserved, RES0.

Accessing DAIF
Accesses to this register use the following encodings in the System register encoding space:

*MRS <Xt>, DAIF*

<table>
<thead>
<tr>
<th>op0</th>

C5.2.4 DIT, Data Independent Timing

The DIT characteristics are:

**Purpose**

Allows access to the Data Independent Timing bit.

**Configurations**

This register is present only when FEAT_DIT is implemented. Otherwise, direct accesses to DIT are **UNDEFINED**.

**Attributes**

DIT is a 64-bit register.

**Field descriptions**

![DIT Field Description Diagram]

**Bits [63:25]**

Reserved, RES0.

**DIT, bit [24]**

Data Independent Timing.

0b0 The architecture makes no statement about the timing properties of any instructions.

0b1 The architecture requires that:

- The timing of every load and store instruction is insensitive to the value of the data being loaded or stored.

- For certain data processing instructions, the instruction takes a time which is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- For certain data processing instructions, the response of the instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

The data processing instructions affected by this bit are:

- All cryptographic instructions. These instructions are:
  - AESD, AESE, AESIMC, AESMC, SHA1C, SHA1H, SHA1M, SHA1P, SHA1SU0, SHA1SU1, SHA256H, SHA256H2, SHA256SU0, SHA256SU1, SHA512H, SHA512H2, SHA512SU0, SHA512SU1, EOR3, RAX1, XAR, BCAX, SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, SM3PARTW2, SME, and SM4EKEY.

- A subset of those instructions which use the general-purpose register file. These instructions are:
  - ADC, ADCS, ADD, ADDS, AND, ANDS, ASR, ASRV, BFC, BFI, BPM, BFXIL, BIC, BICS, COMN, CMP, CFINV, CINC, CINV, CLS, CLZ, CM, CNP, CMP, CNEG, CSEL, CSET, CSETM, CSINC, CSINV, CSNEG, EON, EOR, EXTR, LSL, LSLV, LSR, LSRV, MADD, MNEG, MOV, MOVK, MOVN, MOVZ, MSUB, MUL, MN, NEG, NEGS, NG, NGCS,
C5.2 Special-purpose registers

The A64 System Instruction Class

### Notes

The architecture makes no statement about the timing properties when the PSTATE.DIT bit is not set. However, it is likely that many of these instructions have timing that is invariant of the data in many situations.

In particular, Arm strongly recommends that the Armv8.3 pointer authentication instructions do not have their timing dependent on the key value used in the pointer authentication in all cases, regardless of the PSTATE.DIT bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**Bits [23:0]**

Reserved, RES0.

**Accessing DIT**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, DIT**

<table>
<thead>
<tr>

C5.2.5 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

**Purpose**
When taking an exception to EL1, holds the address to return to.

**Configurations**
There are no configuration notes.

**Attributes**
ELR_EL1 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return address</td>
</tr>
<tr>
<td></td>
<td>An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.</td>

C5.2.6 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

**Purpose**

When taking an exception to EL2, holds the address to return to.

**Configurations**

AArch64 System register ELR_EL2 bits [31:0] are architecturally mapped to AArch32 System register ELR_hyp[31:0].

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

ELR_EL2 is a 64-bit register.

**Field descriptions**

Bits [63:0]  
Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing ELR_EL2**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic ELR_EL2 or ELR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

C5.2.7 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

**Purpose**

When taking an exception to EL3, holds the address to return to.

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to ELR_EL3 are UNDEFINED.

**Attributes**

ELR_EL3 is a 64-bit register.

**Field descriptions**

```
Return address

Bits [63:0]
```

Return address.

An exception return from EL3 using AArch64 makes ELR_EL3 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing ELR_EL3**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, ELR_EL3**

<table>

  ELR_EL3 = X[t, 64];
C5.2.8 FPCR, Floating-point Control Register

The FPCR characteristics are:

**Purpose**

Controls floating-point behavior.

**Configurations**

AArch64 System register FPCR bits [26:15] are architecturally mapped to AArch32 System register FPSCR[26:15].

AArch64 System register FPCR bits [12:8] are architecturally mapped to AArch32 System register FPSCR[12:8].

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

**Attributes**

FPCR is a 64-bit register.

**Field descriptions**

![Field description diagram]

**Bits [63:27]**

Reserved, RES0.

**AHP, bit [26]**

Alternative half-precision control bit.

- 0b0 IEEE half-precision format selected.
- 0b1 Alternative half-precision format selected.

This bit is used only for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the FEAT_FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DN, bit [25]**

Default NaN use for NaN propagation.

- 0b0 NaN operands propagate through to the output of a floating-point operation.
- 0b1 Any operation involving one or more NaNs returns the Default NaN.

This bit has no effect on the output of FABS, FMAX*, FMIN*, and FNEG instructions, and a default NaN is never returned as a result of these instructions.
The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**FZ, bit [24]**

Flushing denormalized numbers to zero control bit.

- **0b0**  If FPCR.AH is 0, the flushing to zero of single-precision and double-precision
denormalized inputs to, and outputs of, floating-point instructions not enabled by this
control, but other factors might cause the input denormalized numbers to be flushed to
zero.
  - If FPCR.AH is 1, the flushing to zero of single-precision and double-precision
denormalized outputs of floating-point instructions not enabled by this control, but
other factors might cause the input denormalized numbers to be flushed to zero.

- **0b1**  If FPCR.AH is 0, denormalized single-precision and double-precision inputs to, and
outputs from, floating-point instructions are flushed to zero.
  - If FPCR.AH is 1, denormalized single-precision and double-precision outputs from
floating-point instructions are flushed to zero.

For more information, see Flushing denormalized numbers to zero on page A1-58 and the
pseudocode of the floating-point instructions.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**RMode, bits [23:22]**

Rounding Mode control field.

- **0b00**  Round to Nearest (RN) mode.
- **0b01**  Round towards Plus Infinity (RP) mode.
- **0b10**  Round towards Minus Infinity (RM) mode.
- **0b11**  Round towards Zero (RZ) mode.

The specified rounding mode is used by both scalar and Advanced SIMD floating-point
instructions.

If FPCR.AH is 1, then the following instructions use Round to Nearest mode regardless of the value
of this bit:
- The FRECPE, FRECPS, FRECPIX, FRSQRT, and FRSQRTS instructions.
- The BFCT, BFCTN, BFCTN2, BFCTTN, BFCTTL, and BFCTALT instructions.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Stride, bits [21:20]**

This field has no function in AArch64 state, and non-zero values are ignored during execution in
AArch64 state.

This field is included only for context saving and restoration of the AArch32 FPSCR.Stride field.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**FZ16, bit [19]**

When FEAT_FP16 is implemented:

Flushing denormalized numbers to zero control bit on half-precision data-processing instructions.

- **0b0**  For some instructions, this bit disables flushing to zero of inputs and outputs that are
half-precision denormalized numbers.
- **0b1**  Flushing denormalized numbers to zero enabled.
For some instructions that do not convert a half-precision input to a higher precision output, this bit enables flushing to zero of inputs and outputs that are half-precision denormalized numbers.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations.

For more information, see Flushing denormalized numbers to zero on page A1-58 and the pseudocode of the floating-point instructions.

The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
  Reserved, RES0.

Len, bits [18:16]

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state.

This field is included only for context saving and restoration of the AArch32 FPSCR.Len field.

The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDE, bit [15]

Input Denormal floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IDC bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.IDE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The value of this bit controls both scalar and vector floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [14]

Reserved, RES0.

EBF, bit [13]

When **FEAT_EBF16 is implemented:**

The value of this bit controls the numeric behaviors of BFloat16 dot product calculations performed by the BFDOT, BFMMMLA, BFMOPA, and BFMOPS instructions.

When ID_AA64ISAR1_EL1.BF16 and ID_AA64ZFR0_EL1.BF16 are 0b0010, the PE supports the FPCR.EBF field. Otherwise, FPCR.EBF is RES0.

0b0 These instructions use the standard BFloat16 behaviors:
        • Ignoring the FPCR.RMode control and using the rounding mode defined for BFloat16. For more information, see Rounding on page E1-7146.
        • Flushing denormalized inputs and outputs to zero, as if the FPCR.FZ and FPCR.FIZ controls had the value '1'.
        • Performing unfused multiplies and additions with intermediate rounding of all products and sums.
These instructions use the extended BFloat16 behaviors:

- Supporting all four IEEE 754 rounding modes selected by the FPCR.RMode control.
- Optionally, flushing denormalized inputs and outputs to zero, as governed by the FPCR.FZ and FPCR.FIZ controls.
- Performing a fused two-way sum-of-products for each pair of adjacent BFloat16 elements, without intermediate rounding of the products, but rounding the single-precision sum before addition to the accumulator.
- Generating the default NaN as intermediate sum-of-products when any multiplier input is a NaN, or any product is infinity × 0.0, or there are infinite products with differing signs.
- Generating an intermediate sum-of-products of the same infinity when there are infinite products all with the same sign.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**IXE, bit [12]**

Inexact floating-point exception trap enable.

- 0b0 Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IXC bit is set to 1.
- 0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.IXE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The value of this bit controls both scalar and vector floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**UFE, bit [11]**

Underflow floating-point exception trap enable.

- 0b0 Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.UFC bit is set to 1.
- 0b1 Trapped exception handling selected. If the floating-point exception occurs and Flush-to-zero is not enabled, the PE does not update the FPSR.UFC bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.UFE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The value of this bit controls both scalar and vector floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**OFE, bit [10]**

Overflow floating-point exception trap enable.

- 0b0 Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.OFC bit is set to 1.
DZE, bit [9]
Divide by Zero floating-point exception trap enable.

0b0  Untrapped exception handling selected. If the floating-point exception occurs, the FPCR.DZE bit is set to 1.

0b1  Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPCR.DZE bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.DZE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The value of this bit controls both scalar and vector floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOE, bit [8]
Invalid Operation floating-point exception trap enable.

0b0  Untrapped exception handling selected. If the floating-point exception occurs, the FPCR.IOE bit is set to 1.

0b1  Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPCR.IOE bit.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.IOE is treated as 0 for all purposes other than a direct read or write of the FPCR.

The value of this bit controls both scalar and vector floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [7:3]
Reserved, RES0.

NEP, bit [2]

When FEAT_AFP is implemented:

Controls how the output elements other than the lowest element of the vector are determined for Advanced SIMD scalar instructions.

0b0  Does not affect how the output elements other than the lowest are determined for Advanced SIMD scalar instructions.

0b1  The output elements other than the lowest are taken from the following registers:

• For 3-input scalar versions of the FMLA (by element) and FMLS (by element) instructions, the <Hd>, <Sd>, or <Dd> register.
• For 3-input versions of the FMADD, FMSUB, FNADD, and FNNSUB instructions, the \(<Ha>\), \(<Sa>\), or \(<Da>\) register.

• For 2-input scalar versions of the FACGE, FACGT, FCMEQ (register), FCMGE (register), and FCMGT (register) instructions, the \(<Hm>\), \(<Sm>\), or \(<Dm>\) register.

• For 2-input scalar versions of the FABD, FADD (scalar), FDIV (scalar), FMAX (scalar), FMAXNM (scalar), FMIN (scalar), FMINNM (scalar), FMUL (by element), FMULX (scalar), FMULX (by element), FNMUL (scalar), FRECPS, FRSQRTS, and FSUB (scalar) instructions, the \(<Hn>\), \(<Sn>\), or \(<Dn>\) register.

• For 1-input scalar versions of the following instructions, the \(<Hd>\), \(<Sd>\), or \(<Dd>\) register:
  — The (vector) versions of the FCVTAS, FCVTASU, FCVTMS, FCVTMSU, FCVTNS, FCVTNU, FCVTPS, and FCVTTPU instructions.
  — The (vector, fixed-point) and (vector, integer) versions of the FCVTZS, FCVTZSU, SCVT, and UCVTF instructions.
  — The (scalar) versions of the FABS, FNEG, FRINT32X, FRINT32Z, FRINT64X, FRINT64Z, FRINTA, FRINTI, FRINTM, FRINTN, FRINTP, FRINTX, FRINTZ, and FSQRT instructions.
  — The (scalar, fixed-point) and (scalar, integer) versions of the SCVT, and UCVTF instructions.
  — The BFCTV, FCVT, FCVTXN, FRECPE, FRECPIX, and FRSQRTE instructions.

When the PE is in Streaming SVE mode, and FEAT_SME_FA64 is not implemented or not enabled at the current Exception level, the value of FPCR.NEP is treated as 0 for all purposes other than a direct read or write of the FPCR.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**AH, bit [1]**

**When FEAT_AFP is implemented:**

Alternate Handling. Controls alternate handling of floating-point numbers.

The Arm architecture supports two models for handling some of the corner cases of the floating-point behaviors, such as the nature of flushing of denormalized numbers, the detection of tininess and other exceptions and a range of other behaviors. The value of the FPCR.AH bit selects between these models.

For more information on the FPCR.AH bit, see *Flushing denormalized numbers to zero* on page A1-58, *Floating-point exceptions and exception traps* on page A1-64 and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
**FIZ, bit [0]**

*When FEAT_AFP is implemented:*

Flush Inputs to Zero. Controls whether single-precision, double-precision and BFloat16 input operands that are denormalized numbers are flushed to zero.

- **0b0** The flushing to zero of single-precision and double-precision denormalized inputs to floating-point instructions not enabled by this control, but other factors might cause the input denormalized numbers to be flushed to zero.

- **0b1** Denormalized single-precision and double-precision inputs to most floating-point instructions flushed to zero.

For more information, see *Flushing denormalized numbers to zero* on page A1-58 and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES0.

### Accessing FPCR

Accesses to this register use the following encodings in the System register encoding space:

#### MRS <Xt>, FPCR

C5.2.9 FPSR, Floating-point Status Register

The FPSR characteristics are:

**Purpose**

Provides floating-point system status information.

**Configurations**

AArch64 System register FPSR bits [31:27] are architecturally mapped to AArch32 System register FPSCR[31:27].

AArch64 System register FPSR bit [7] is architecturally mapped to AArch32 System register FPSCR[7].

AArch64 System register FPSR bits [4:0] are architecturally mapped to AArch32 System register FPSCR[4:0].

**Attributes**

FPSR is a 64-bit register.

**Field descriptions**

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

*When AArch32 is supported and AArch32 floating-point is implemented:*

Negative condition flag for AArch32 floating-point comparison operations.

--- **Note** ---

AArch64 floating-point comparisons set the PSTATE.N flag instead.

---

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Z, bit [30]**

*When AArch32 is supported and AArch32 floating-point is implemented:*

Zero condition flag for AArch32 floating-point comparison operations.

--- **Note** ---

AArch64 floating-point comparisons set the PSTATE.Z flag instead.

---

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]

When AArch32 is supported and AArch32 floating-point is implemented:

Carry condition flag for AArch32 floating-point comparison operations.

--- Note ---

AArch64 floating-point comparisons set the PSTATE.C flag instead.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

V, bit [28]

When AArch32 is supported and AArch32 floating-point is implemented:

Overflow condition flag for AArch32 floating-point comparison operations.

--- Note ---

AArch64 floating-point comparisons set the PSTATE.V flag instead.

---

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IDE is 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IXE is 0.
The criteria for the Inexact floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see Floating-point exceptions and exception traps on page A1-64.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**UFC, bit [3]**

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.UFE is 0 or if flushing denormalized numbers to zero is enabled.

The criteria for the Underflow floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see Floating-point exceptions and exception traps on page A1-64.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**OFC, bit [2]**

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.OFE is 0.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DZC, bit [1]**

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.DZE is 0.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IOC, bit [0]**

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IOE is 0.

The criteria for the Invalid Operation floating-point exception to occur are affected by the value of the FPCR.AH bit. For more information, see Floating-point exceptions and exception traps on page A1-64.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing FPSR**

Accesses to this register use the following encodings in the System register encoding space:
MRS <Xt>, FPSR

```
if PSTATE.EL == EL0 then
    if Halted() && HaveEL(EL3) && EDSCR.SDD == '1' && boolean IMPLEMENTATION_DEFINED "EL3 trap priority when SDD == '1'" && CPTR_EL3.TFP == '1' then
        UNDEFINED;

C5.2.10 NZCV, Condition Flags

The NZCV characteristics are:

**Purpose**

Allows access to the condition flags.

**Configurations**

There are no configuration notes.

**Attributes**

NZCV is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| [31] | N, bit
Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative. |
| [30] | Z, bit
Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison. |
| [29] | C, bit
Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition. |
| [28] | V, bit
Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition. |
| [27:0] | Reserved, RES0. |

**Accessing NZCV**

Accesses to this register use the following encodings in the System register encoding space:

C5.2.11 PAN, Privileged Access Never

The PAN characteristics are:

**Purpose**

Allows access to the Privileged Access Never bit.

**Configurations**

This register is present only when FEAT_PAN is implemented. Otherwise, direct accesses to PAN are UNDEFINED.

**Attributes**

PAN is a 64-bit register.

**Field descriptions**

![Field descriptions diagram]

**Bits [63:23]**

Reserved, RES0.

**PAN, bit [22]**

Privileged Access Never.

- **0b0** Privileged reads and write are not disabled by this mechanism.
- **0b1** Disables privileged read and write accesses to addresses accessible at EL0 for an enabled stage 1 translation regime that defines the EL0 permissions.

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the SCTLR_EL1.SPAN bit is 0, this bit is set to 1.
- When the target of the exception is EL2, HCR_EL2.{E2H, TGE} is \{1, 1\}, and the value of the SCTLR_EL2.SPAN bit is 0, this bit is set to 1.

**Bits [21:0]**

Reserved, RES0.

**Accessing PAN**

Accesses to this register use the following encodings in the System register encoding space:

C5.2.13 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

**Purpose**

Holds the stack pointer associated with EL1. When executing at EL1, the value of SPSel.SP determines the current stack pointer:

<table>
<thead>
<tr>
<th>SPSel.SP</th>
<th>Current stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL1</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

SP_EL1 is a 64-bit register.

**Field descriptions**

Bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SP_EL1**

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL1 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:
MRS \langle Xt \rangle, SP_EL1

\[
\begin{array}{cccccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b11 & 0b100 & 0b0100 & 0b0001 & 0b000
\end{array}
\]

if PSTATE_EL == EL0 then
    UNDEFINED;
elsif PSTATE_EL == EL1 then
    if EL2Enabled() \&\& HCR_EL2.<NV2,NV> == '11' then

C5.2.14   SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

**Purpose**

Holds the stack pointer associated with EL2. When executing at EL2, the value of SPSel.SP determines the current stack pointer:

<table>
<thead>
<tr>
<th>SPSel.SP</th>
<th>Current stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL2</td>
</tr>
</tbody>
</table>

**Configurations**

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

SP_EL2 is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td></td>
</tr>
<tr>
<td>32</td>
<td></td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SP_EL2**

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL2 as the current stack pointer.

**Note**

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:
**MRS \(<X_t>, SP_{EL2}\)**

```
MRS <X_t>, SP_EL2

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>

C5.2.15 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

**Purpose**

Holds the stack pointer associated with EL3. When executing at EL3, the value of SPSel.SP determines the current stack pointer:

<table>
<thead>
<tr>
<th>SPSel.SP</th>
<th>Current stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL3</td>
</tr>
</tbody>
</table>

**Configurations**

This register is present only when EL3 is implemented. Otherwise, direct accesses to SP_EL3 are UNDEFINED.

**Attributes**

SP_EL3 is a 64-bit register.

**Field descriptions**

Bits [63:0]  
Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
C5.2.16 SPSel, Stack Pointer Select

The SPSel characteristics are:

**Purpose**
Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

**Configurations**
There are no configuration notes.

**Attributes**
SPSel is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:1]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>0</td>
<td>Stack pointer to use. Possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>Use SP_EL0 at all Exception levels.</td>
</tr>
<tr>
<td>1</td>
<td>Use SP_ELx for Exception level ELx.</td>
</tr>
</tbody>
</table>

When FEAT_NMI is implemented and SCTLR_ELx.SPINTMASK is 1, if execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx is masked regardless of any denotation of Superpriority.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.

**Accessing SPSel**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSel**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b000</td>
<td>0b0100</td>
<td>0b0010</td>
<td>0b000</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = Zeros(63):PSTATE.SP;
elsif PSTATE.EL == EL2 then
    X[t, 64] = Zeros(63):PSTATE.SP;
elsif PSTATE.EL == EL3 then
    X[t, 64] = Zeros(63):PSTATE.SP;
**MSR SPSel, <Xt>**

C5.2.17  SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Abort mode.

**Configurations**

AArch64 System register SPSR_abt bits [31:0] are architecturally mapped to AArch32 System register SPSR_abt[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

**Attributes**

SPSR_abt is a 64-bit register.

**Field descriptions**

*When EL1 can only use AArch64:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

*Otherwise:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>
| 31:0 | N, Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an illegal exception return operation in Abort mode. The reset behavior of this field is:
|      | • On a Warm reset, this field resets to an architecturally UNKNOWN value. |
| 30   | Z, Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an illegal exception return operation in Abort mode. The reset behavior of this field is:
|      | • On a Warm reset, this field resets to an architecturally UNKNOWN value. |
C, bit [29]
Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and
copied to PSTATE.C on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]
Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and
copied to PSTATE.V on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode,
and copied to PSTATE.Q on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]
If-Then. Set to the value of PSTATE.IT on taking an exception to Abort mode, and copied to
PSTATE.IT on executing an illegal exception return operation in Abort mode.

SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
• IT[1:0] is SPSR_abt[26:25].
• IT[7:2] is SPSR_abt[15:10].

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]
RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.
Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction
set state.

SSBS, bit [23]
When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Abort mode, and
copied to PSTATE.SSBS on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]
When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode, and
copied to PSTATE.PAN on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:

Reserved, RES0.

DIT, bit [21]

**When FEAT_DIT is implemented:**

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode, and copied to PSTATE.DIT on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and copied to PSTATE.IL on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode, and copied to PSTATE.GE on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to PSTATE.E on executing an illegal exception return operation in Abort mode.

If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an illegal exception return operation in Abort mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and copied to PSTATE.A on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied to PSTATE.I on executing an illegal exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied to PSTATE.F on executing an illegal exception return operation in Abort mode.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and copied to PSTATE.T on executing an illegal exception return operation in Abort mode.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to PSTATE.M[4:0] on executing an illegal exception return operation in Abort mode.
0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an illegal exception return operation in Abort mode is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-8952.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_abt

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSR_abt**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

<td>0b001</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
    endif
elsif PSTATE.EL == EL2 then
    SPSR_abt = X[t, 64];
elsif PSTATE.EL == EL3 then
    SPSR_abt = X[t, 64];
C5.2.18 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to EL1.

**Configurations**

AArch64 System register SPSR_EL1 bits [31:0] are architecturally mapped to AArch32 System register SPSR_svc[31:0].

**Attributes**

SPSR_EL1 is a 64-bit register.

**Field descriptions**

*When AArch32 is supported and exception taken from AArch32 state:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1. The reset behavior of this field is:</td>
</tr>
<tr>
<td>Z</td>
<td>Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1. The reset behavior of this field is:</td>
</tr>
<tr>
<td>V</td>
<td>Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1. The reset behavior of this field is:</td>
</tr>
<tr>
<td>C</td>
<td>Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1. The reset behavior of this field is:</td>
</tr>
</tbody>
</table>

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL1, and copied to PSTATE.Q on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]
If-Then. Set to the value of PSTATE.IT on taking an exception to EL1, and copied to PSTATE.IT on executing an exception return operation in EL1.

SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
• IT[1:0] is SPSR_EL1[26:25].
• IT[7:2] is SPSR_EL1[15:10].

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]
When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSBS, bit [23]
When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]
When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to
PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL1, and
copied to PSTATE.GE on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to EL1, and copied to PSTATE.E
on executing an exception return operation in EL1.

If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the
implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an
exception return operation in EL1, if the implementation does not support big-endian operation at
the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not
support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to
PSTATE.A on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to
PSTATE.I on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to
PSTATE.F on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL1, and copied to
PSTATE.T on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL1 from AArch32
state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

0b1 AArch32 execution state.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]
AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL1, and copied to PSTATE.M[3:0] on executing an exception return operation in EL1.

0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0111 Abort.
0b1011 Undefined.
0b1111 System.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in Illegal exception returns from AArch64 state on page D1-4645.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

When exception taken from AArch64 state:

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]
Reserved, RES0.

N, bit [31]
Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]
Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]
Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

Reserved, RES0.

**TCO, bit [25]**

When **FEAT_MTE is implemented**:
Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL1, and copied to PSTATE.TCO on executing an exception return operation in EL1.
When **FEAT_MTE is not implemented**, it is **CONSTRAINED UNPREDICTABLE** whether this field is RES0 or behaves as if **FEAT_MTE is implemented**.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**DIT, bit [24]**

When **FEAT_DIT is implemented**:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**UAO, bit [23]**

When **FEAT_UAO is implemented**:
User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL1, and copied to PSTATE.UAO on executing an exception return operation in EL1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**PAN, bit [22]**

When **FEAT_PAN is implemented**:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.
SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:14]
Reserved, RES0.

ALLINT, bit [13]
When FEAT_NMI is implemented:
All IRQ or FIQ interrupts mask. Set to the value of PSTATE.ALLINT on taking an exception to EL1, and copied to PSTATE.ALLINT on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSBS, bit [12]
When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

BTYPE, bits [11:10]
When FEAT_BTI is implemented:
Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL1, and copied to PSTATE.BTYPE on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

D, bit [9]
Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL1, and copied to PSTATE.D on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [5]**

Reserved, RES0.

**M[4], bit [4]**

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL1 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

0b0  AArch64 execution state.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**M[3:0], bits [3:0]**

AArch64 Exception level and selected Stack Pointer.

0b0000  EL0t.
0b0100  EL1t.
0b0101  EL1h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in **Illegal exception returns from AArch64 state on page D1-4645**.

The bits in this field are interpreted as follows:
• M[3:2]: On an exception to EL1:
  — If the Effective value of HCR_EL2.{NV, NV1} != {1,0} or the exception is not taken from EL1, then M[3:2] is set to the value of PSTATE.EL on taking an exception to EL1.
  — If the Effective value of HCR_EL2.{NV, NV1} == {1,0} and the exception is not taken from EL1, then M[3:2] is set to 0b10.
  — M[3:2] is copied to PSTATE.EL on executing a legal exception return operation in EL1.
• M[1] is unused and is 0 for all non-reserved values.
• M[0] is set to the value of PSTATE.SP on taking an exception to EL1 and copied to PSTATE.SP on executing an exception return operation in EL1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing SPSR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic SPSR_EL1 or SPSR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSR_EL1**

```
C5.2.19 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to EL2.

**Configurations**

AArch64 System register SPSR_EL2 bits [31:0] are architecturally mapped to AArch32 System register SPSR_hyp[31:0].

This register has no effect if EL2 is not enabled in the current Security state.

**Attributes**

SPSR_EL2 is a 64-bit register.

**Field descriptions**

*When AArch32 is supported and exception taken from AArch32 state:*

An exception return from EL2 using AArch64 makes SPSR_EL2 become **UNKNOWN**.

**Bits [63:32]**

Reserved, **RES0**.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL2, and copied to PSTATE.Q on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]
If-Then. Set to the value of PSTATE.IT on taking an exception to EL2, and copied to PSTATE.IT on executing an exception return operation in EL2.
SPSR_EL2.IT must contain a value that is valid for the instruction being returned to.
The IT field is split as follows:
• IT[1:0] is SPSR_EL2[26:25].
• IT[7:2] is SPSR_EL2[15:10].
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]
When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSBS, bit [23]
When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]
When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL2, and copied to PSTATE.GE on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on taking an exception to EL2, and copied to PSTATE.E on executing an exception return operation in EL2.

If the implementation does not support big-endian operation, SPSR_EL2.E is **RES0**. If the implementation does not support little-endian operation, SPSR_EL2.E is **RES1**. On executing an exception return operation in EL2, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL2.E is **RES0**, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL2.E is **RES1**.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL2, and copied to PSTATE.T on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL2 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

0b1 AArch32 execution state.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL2, and copied to PSTATE.M[3:0] on executing an exception return operation in EL2.

0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0111 Abort.
0b1010 Hyp.
0b1011 Undefined.
0b1111 System.

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in Illegal exception returns from AArch64 state on page D1-4645.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

When exception taken from AArch64 state:

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When FEAT_MTE is implemented:

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL2, and copied to PSTATE.TCO on executing an exception return operation in EL2.

When FEAT_MTE is not implemented, it is CONstrained UNpredictable whether this field is RES0 or behaves as if FEAT_MTE is implemented.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL2, and copied to PSTATE.UAO on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:14]
Reserved, RES0.

ALLINT, bit [13]
When FEAT_NMI is implemented:
All IRQ or FIQ interrupts mask. Set to the value of PSTATE.ALLINT on taking an exception to EL2, and copied to PSTATE.ALLINT on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SSBS, bit [12]
When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

BTYPE, bits [11:10]
When FEAT_BTI is implemented:
Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL2, and copied to PSTATE.BTYPE on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

D, bit [9]
Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL2, and copied to PSTATE.D on executing an exception return operation in EL2.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
A, bit [8]

S_Error interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL2 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

0b0  AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000  EL0t.
0b0100  EL1t.
0b0101  EL1h.
0b1000  EL2t.
0b1001  EL2h.

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in Illegal exception returns from AArch64 state on page D1-4645.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL2 and copied to PSTATE.EL on executing an exception return operation in EL2.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL2 and copied to PSTATE.SP on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SPSR_EL2 or SPSR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.
Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSR_EL2**

<table>

C5.2.20  SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL3.

Configurations

This register is present only when EL3 is implemented. Otherwise, direct accesses to SPSR_EL3 are UNDEFINED.

Attributes

SPSR_EL3 is a 64-bit register.

Field descriptions

*When AArch32 is supported and exception taken from AArch32 state:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL3, and copied to PSTATE.Q on executing an exception return operation in EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]
If-Then. Set to the value of PSTATE.IT on taking an exception to EL3, and copied to PSTATE.IT on executing an exception return operation in EL3.

SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR_EL3[26:25].
- IT[7:2] is SPSR_EL3[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and copied to PSTATE.DIT on executing an exception return operation in EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and copied to PSTATE.SSBS on executing an exception return operation in EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL3, and conditionally copied to PSTATE.SS on executing an exception return operation in EL3.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL3, and copied to PSTATE.IL on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL3, and copied to PSTATE.GE on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to EL3, and copied to PSTATE.E on executing an exception return operation in EL3.

If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an exception return operation in EL3, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL3, and copied to PSTATE.T on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4], bit [4]
Execution state. Set to \(0b1\), the value of PSTATE.nRW, on taking an exception to EL3 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.

\(0b1\) AArch32 execution state.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**M[3:0], bits [3:0]**

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL3, and copied to PSTATE.M[3:0] on executing an exception return operation in EL3.

<table>
<thead>
<tr>
<th>Value</th>

</tbody>
</table>

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in *Illegal exception returns from AArch64 state* on page D1-4645.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### When exception taken from AArch64 state:

An exception return from EL3 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]
Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]
Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:26]
Reserved, RES0.

TCO, bit [25]
When FEAT_MTE is implemented:
Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL3, and copied to PSTATE.TCO on executing an exception return operation in EL3.

When FEAT_MTE is not implemented, it is CONSTRAINED UNPREDICTABLE whether this field is RES0 or behaves as if FEAT_MTE is implemented.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

DIT, bit [24]
When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and copied to PSTATE.DIT on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

UAO, bit [23]
When FEAT_UAO is implemented:
User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL3, and copied to PSTATE.UAO on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]
When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**SSBS**, bit [12]

When **FEAT_SBS** is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and copied to PSTATE.SSBS on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Otherwise:

Reserved, RES0.

**BTYPE**, bits [11:10]

When **FEAT_BT** is implemented:

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL3, and copied to PSTATE.BTYPE on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Otherwise:

Reserved, RES0.

**D**, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL3, and copied to PSTATE.D on executing an exception return operation in EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
A, bit [8]
SEError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]
Reserved, RES0.

M[4], bit [4]
Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL3 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.
0b0 AArch64 execution state.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]
AArch64 Exception level and selected Stack Pointer.
0b0000 EL0t.
0b0100 EL1t.
0b0101 EL1h.
0b1000 EL2t.
0b1001 EL2h.
0b1100 EL3t.
0b1101 EL3h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in Illegal exception returns from AArch64 state on page D1-4645.

The bits in this field are interpreted as follows:
• M[3:2] is set to the value of PSTATE.EL on taking an exception to EL3 and copied to PSTATE.EL on executing an exception return operation in EL3.
• M[1] is unused and is 0 for all non-reserved values.
• M[0] is set to the value of PSTATE.SP on taking an exception to EL3 and copied to PSTATE.SP on executing an exception return operation in EL3.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing SPSR_EL3

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSR_EL3**

<table>
<thead>
<tr>

elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  SPSR_EL3 = X[t, 64];
C5.2.21 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved process state when an exception is taken to FIQ mode.

Configurations

AArch64 System register SPSR_fiq bits [31:0] are architecturally mapped to AArch32 System register SPSR_fiq[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

Attributes

SPSR_fiq is a 64-bit register.

Field descriptions

When EL1 can only use AArch64:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:0]

Reserved, RES0.

Otherwise:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

| 31 | 28 | 27 | 26 | 25 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q | J | IL | GE | IT[7:2] | E | A | I | F | T | M[4:0] |
| IT[1:0] | SSBS | DIT | PAN |

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to FIQ mode, and copied to PSTATE.N on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to FIQ mode, and copied to PSTATE.Z on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to FIQ mode, and copied to PSTATE.C on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to FIQ mode, and copied to PSTATE.V on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to FIQ mode, and copied to PSTATE.Q on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to FIQ mode, and copied to PSTATE.IT on executing an illegal exception return operation in FIQ mode.

SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
• IT[1:0] is SPSR_fiq[26:25].
• IT[7:2] is SPSR_fiq[15:10].

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to FIQ mode, and copied to PSTATE.SSBS on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to FIQ mode, and copied to PSTATE.PAN on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to FIQ mode, and copied to PSTATE.DIT on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to FIQ mode, and copied to PSTATE.IL on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to FIQ mode, and copied to PSTATE.GE on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to FIQ mode, and copied to PSTATE.E on executing an illegal exception return operation in FIQ mode.

If the implementation does not support big-endian operation, SPSR_fiq.E is RES0. If the implementation does not support little-endian operation, SPSR_fiq.E is RES1. On executing an illegal exception return operation in FIQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_fiq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_fiq.E is RES1.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to FIQ mode, and copied to PSTATE.A on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to FIQ mode, and copied to PSTATE.I on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to FIQ mode, and copied to PSTATE.F on executing an illegal exception return operation in FIQ mode.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to FIQ mode, and copied to PSTATE.T on executing an illegal exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to FIQ mode, and copied to PSTATE.M[4:0] on executing an illegal exception return operation in FIQ mode.

- 0b10000: User
- 0b10001: FIQ
- 0b10010: IRQ
- 0b10011: Supervisor
- 0b10111: Abort
- 0b11011: Undefined
- 0b11111: System

Other values are reserved. If SPSR_fiq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an illegal exception return operation in FIQ mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-8952.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

C5.2.22  **SPSR_irq, Saved Program Status Register (IRQ mode)**

The SPSR_irq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to IRQ mode.

**Configurations**

AArch64 System register SPSR_irq bits [31:0] are architecturally mapped to AArch32 System register SPSR_irq[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

**Attributes**

SPSR_irq is a 64-bit register.

**Field descriptions**

*When EL1 can only use AArch64:*

![Diagram of SPSR_irq bits]

**Bits [63:0]**

Reserved, RES0.

**Otherwise:**

![Diagram of SPSR_irq bits]

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to IRQ mode, and copied to PSTATE.N on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to IRQ mode, and copied to PSTATE.Z on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to IRQ mode, and copied to PSTATE.C on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to IRQ mode, and copied to PSTATE.V on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to IRQ mode, and copied to PSTATE.Q on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to IRQ mode, and copied to PSTATE.IT on executing an illegal exception return operation in IRQ mode.

SPSR_irq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
• IT[1:0] is SPSR_irq[26:25].
• IT[7:2] is SPSR_irq[15:10].

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to IRQ mode, and copied to PSTATE.SSBS on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to IRQ mode, and copied to PSTATE.PAN on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
    Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:
    Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to IRQ mode, and copied to PSTATE.DIT on executing an illegal exception return operation in IRQ mode.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
    Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to IRQ mode, and copied to PSTATE.IL on executing an illegal exception return operation in IRQ mode.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to IRQ mode, and copied to PSTATE.GE on executing an illegal exception return operation in IRQ mode.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to IRQ mode, and copied to PSTATE.E on executing an illegal exception return operation in IRQ mode.

If the implementation does not support big-endian operation, SPSR_irq.E is RES0. If the implementation does not support little-endian operation, SPSR_irq.E is RES1. On executing an illegal exception return operation in IRQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_irq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_irq.E is RES1.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to IRQ mode, and copied to PSTATE.A on executing an illegal exception return operation in IRQ mode.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to IRQ mode, and copied to PSTATE.I on executing an illegal exception return operation in IRQ mode.
    The reset behavior of this field is:
    • On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to IRQ mode, and copied to PSTATE.F on executing an illegal exception return operation in IRQ mode.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to IRQ mode, and copied to PSTATE.T on executing an illegal exception return operation in IRQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to IRQ mode, and copied to PSTATE.M[4:0] on executing an illegal exception return operation in IRQ mode.

- 0b10000 User.
- 0b10001 FIQ.
- 0b10010 IRQ.
- 0b10011 Supervisor.
- 0b10111 Abort.
- 0b11011 Undefined.
- 0b11111 System.

Other values are reserved. If SPSR_irq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an illegal exception return operation in IRQ mode is an illegal return event, as described in _Illegal return events from AArch32 state_ on page G1-8952.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SPSR_irq**

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, SPSR_irq**

<table>

C5.2.23 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Undefined mode.

**Configurations**

AArch64 System register SPSR_und bits [31:0] are architecturally mapped to AArch32 System register SPSR_und[31:0].

If EL1 only supports execution in AArch64 state, this register is RES0 from EL2 and EL3.

**Attributes**

SPSR_und is a 64-bit register.

**Field descriptions**

*When EL1 can only use AArch64:*

```
<table>

```

Bits [63:32]
Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Undefined mode, and copied to PSTATE.N on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Undefined mode, and copied to PSTATE.Z on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Undefined mode, and copied to PSTATE.C on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Undefined mode, and copied to PSTATE.V on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Undefined mode, and copied to PSTATE.Q on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Undefined mode, and copied to PSTATE.IT on executing an illegal exception return operation in Undefined mode.

SPSR_und.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
* IT[1:0] is SPSR_und[26:25].
* IT[7:2] is SPSR_und[15:10].

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

*When FEAT_SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Undefined mode, and copied to PSTATE.SSBS on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

PAN, bit [22]

*When FEAT_PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Undefined mode, and copied to PSTATE.PAN on executing an illegal exception return operation in Undefined mode.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**DIT, bit [21]**

*When FEAT_DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Undefined mode, and copied to PSTATE.DIT on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Undefined mode, and copied to PSTATE.IL on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Undefined mode, and copied to PSTATE.GE on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on taking an exception to Undefined mode, and copied to PSTATE.E on executing an illegal exception return operation in Undefined mode.

If the implementation does not support big-endian operation, SPSR_und.E is RES0. If the implementation does not support little-endian operation, SPSR_und.E is RES1. On executing an illegal exception return operation in Undefined mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_und.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_und.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Undefined mode, and copied to PSTATE.A on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Undefined mode, and copied to PSTATE.I on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Undefined mode, and copied to PSTATE.F on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Undefined mode, and copied to PSTATE.T on executing an illegal exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Undefined mode, and copied to PSTATE.M[4:0] on executing an illegal exception return operation in Undefined mode.

<table>
<thead>
<tr>
<th>Value</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b10000</td>
<td>User.</td>
</tr>
<tr>
<td>0b10001</td>
<td>FIQ.</td>
</tr>
<tr>
<td>0b10010</td>
<td>IRQ.</td>
</tr>
<tr>
<td>0b10011</td>
<td>Supervisor.</td>
</tr>
<tr>
<td>0b10111</td>
<td>Abort.</td>
</tr>
<tr>
<td>0b11011</td>
<td>Undefined.</td>
</tr>
<tr>
<td>0b11111</td>
<td>System.</td>
</tr>
</tbody>
</table>

Other values are reserved. If SPSR_und.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an illegal exception return operation in Undefined mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-8952.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_und
Accesses to this register use the following encodings in the System register encoding space:

C5.2.24 SSBS, Speculative Store Bypass Safe

The SSBS characteristics are:

**Purpose**

Allows access to the Speculative Store Bypass Safe bit.

**Configurations**

This register is present only when FEAT_SSBS is implemented. Otherwise, direct accesses to SSBS are UNDEFINED.

**Attributes**

SSBS is a 64-bit register.

**Field descriptions**

![Register Layout]

**Bits [63:13]**

Reserved, RES0.

**SSBS, bit [12]**

Speculative Store Bypass Safe.

Prohibits speculative loads or stores which might practically allow a cache timing side channel.

A cache timing side channel might be exploited where a load or store uses an address that is derived from a register that is being loaded from memory using a load instruction speculatively read from a memory location. If PSTATE.SSBS is enabled, the address derived from the load instruction might be from earlier in the coherence order than the latest store to that memory location with the same virtual address.

- **0b0** Hardware is not permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.

- **0b1** Hardware is permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.

The value of this bit is set to the value in the SCTLR_ELx.DSSBS field on taking an exception to ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

**Bits [11:0]**

Reserved, RES0.

C5.2.25 SVCR, Streaming Vector Control Register

The SVCR characteristics are:

**Purpose**

Controls Streaming SVE mode and SME behavior.

**Configurations**

This register is present only when FEAT_SME is implemented. Otherwise, direct accesses to SVCR are UNDEFINED.

**Attributes**

SVCR is a 64-bit register.

**Field descriptions**

```
<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>RES0</td>
<td>ZA</td>
<td>SM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:2]**

Reserved, RES0.

**ZA, bit [1]**

Enables SME ZA storage.

When this storage is disabled, execution of an instruction which can access it is trapped. The exception is reported using an ESR_ELx.{EC, SMTC} value of \{0x1D, 0x3\}.

The possible values of this bit are:

- \(0b0\) SME ZA storage is invalid and not accessible.
  - This control causes execution at any Exception level of instructions that can access this storage to be trapped.

- \(0b1\) SME ZA storage is valid and accessible.
  - This control does not cause execution of any instructions to be trapped.

When a write to SVCR.ZA changes the value of PSTATE.ZA, the following applies:

- When changed from 0 to 1, all implemented bits of the storage are set to zero.
- When changed from 1 to 0, there is no observable change to the storage.

Changes to this field do not have an affect on the SVE vector and predicate registers and FPSR.

A direct or indirect read of ZA appears to occur in program order relative to a direct write of SVCR, and to MSR SVCRZA and MSR SVCRSMZA instructions, without the need for explicit synchronization.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

**SM, bit [0]**

Enables Streaming SVE mode.

When the PE is in Streaming SVE mode, the Streaming SVE vector length (SVL) applies to SVE instructions, and execution at any Exception level of an instruction which is illegal in that mode is trapped. The exception is reported using an ESR_ELx.{EC, SMTC} value of \{0x1D, 0x1\}. 

---

The A64 System Instruction Class
C5.2 Special-purpose registers
When the PE is not in Streaming SVE mode, the SVE vector length (VL) applies to SVE instructions, and execution at any Exception level of an instruction which is only legal in that mode is trapped. The exception is reported using an ESR_ELx.\{EC, SMTC\} value of \{0x1D, 0x2\}.

The possible values of this bit are:

0b0  The PE is not in Streaming SVE mode.
0b1  The PE is in Streaming SVE mode.

When a write to SVCR.SM changes the value of PSTATE.SM, the following applies:

- When changed from 0 to 1, an entry to Streaming SVE mode is performed.
- When changed from 1 to 0, an exit from Streaming SVE mode is performed.
- All implemented bits of the SVE registers Z0-Z31, P0-P15, and FFR in the new mode are set to zero.
- FPSR in the new mode is set to 0x0000_0000_0800_009f, in which all cumulative status bits are set to 1.

Changes to this field do not have an affect on SME ZA storage.

A direct or indirect read of SM appears to occur in program order relative to a direct write of SVCR, and to MSR SVCSM and MSR SVCSMZA instructions, without the need for explicit synchronization.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

### Accessing SVCR

SVCR is read/write and can be accessed from any Exception level.

Accesses to this register use the following encodings in the System register encoding space:

\[
\begin{array}{cccccc}
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b011</td>
<td>0b0100</td>
<td>0b0010</td>
<td>0b010</td>
</tr>
</tbody>
</table>
\end{array}
\]

if PSTATE_EL == EL0 then

C5.2.26   TCO, Tag Check Override

The TCO characteristics are:

**Purpose**

When `FEAT_MTE` is implemented, this register allows tag checks to be disabled globally.

When `FEAT_MTE` is not implemented, it is **CONSTRAINED UNPREDICTABLE** whether this register is `RES0` or behaves as if `FEAT_MTE` is implemented.

**Configurations**

This register is present only when `FEAT_MTE` is implemented. Otherwise, direct accesses to TCO are **UNDEFINED**.

**Attributes**

TCO is a 64-bit register.

**Field descriptions**

- **Bits [63:26]**
  - Reserved, `RES0`.

- **TCO, bit [25]**
  - Allows memory tag checks to be globally disabled.
  - 0b0: Loads and Stores are not affected by this control.
  - 0b1: Loads and Stores are unchecked.

- **Bits [24:0]**
  - Reserved, `RES0`.

**Accessing TCO**

For information about the operation of the MSR (immediate) accessor, see **MSR (immediate)**.

Accesses to this register use the following encodings in the System register encoding space:

**MRS <Xt>, TCO**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>

C5.2.27 UAO, User Access Override

The UAO characteristics are:

Purpose

Allows access to the User Access Override bit.

Configurations

This register is present only when FEAT_UAO is implemented. Otherwise, direct accesses to UAO are UNDEFINED.

Attributes

UAO is a 64-bit register.

Field descriptions

Bits [63:24] Reserved, RES0.

UAO, bit [23]

User Access Override.

0b0 The behavior of LDTR* and STTR* instructions is as defined in the base Armv8 architecture.

0b1 When executed at the following Exception levels, LDTR* and STTR* instructions behave as the equivalent LDRs and STRs instructions:

- EL1.
- EL2 with HCR_EL2.{E2H, TGE} == {1, 1}.

When executed at EL3, or at EL2 with HCR_EL2.E2H == 0 or HCR_EL2.TGE == 0, the LDTR* and STTR* instructions behave as the equivalent LDRs and STRs instructions, regardless of the setting of the PSTATE.UAO bit.

Bits [22:0] Reserved, RES0.

Accessing UAO

For more information about the operation of the MSR (immediate) accessor, see MSR (immediate).

Accesses to this register use the following encodings in the System register encoding space:
**MRS <Xt>, UAO**

\[
\begin{array}{cccccc}

\]
C5.3 A64 System instructions for cache maintenance

This section lists the A64 System instructions for cache maintenance.
C5.3.1   DC CGDSW, Clean of Data and Allocation Tags by Set/Way

The DC CGDSW characteristics are:

Purpose

Clean data and Allocation Tags in data cache by set/way.

Configurations

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC CGDSW are UNDEFINED.

Attributes

DC CGDSW is a 64-bit System instruction.

Field descriptions

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CGDSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.
Accesses to this instruction use the following encodings in the System instruction encoding space:

\[ \text{DC CGDSW, }<\text{Xt}> \]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>

C5.3.2 DC CGDVAC, Clean of Data and Allocation Tags by VA to PoC

The DC CGDVAC characteristics are:

**Purpose**

Clean data and Allocation Tags in data cache by address to Point of Coherency.

**Configurations**

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CGDVAC are UNDEFINED.

**Attributes**

DC CGDVAC is a 64-bit System instruction.

**Field descriptions**

**Bits [63:0]**

Virtual address to use. No alignment restrictions apply to this VA.

**Executing DC CGDVAC instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC)* on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**DC CGDVAC, <Xt>**

<table>

C5.3.3 DC CGDVADP, Clean of Data and Allocation Tags by VA to PoDP

The DC CGDVADP characteristics are:

Purpose

Clean Allocation Tags and data in data cache by address to Point of Deep Persistence.

If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a DC CGDVAP.

Configurations

This instruction is present only when FEAT_DPB2 is implemented and FEAT_MTE is implemented. Otherwise, direct accesses to DC CGDVADP are UNDEFINED.

Attributes

DC CGDVADP is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CGDVADP instruction

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, see Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.5  DC CGSW, Clean of Allocation Tags by Set/Way

The DC CGSW characteristics are:

**Purpose**

Clean Allocation Tags in data cache by set/way.

**Configurations**

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC CGSW are UNDEFINED.

**Attributes**

DC CGSW is a 64-bit System instruction.

**Field descriptions**

- **Bits [63:32]**
  - Reserved, RES0.

- **SetWay, bits [31:4]**
  - Contains two fields:
    - Way, bits[31:32-A], the number of the way to operate on.
    - Set, bits[B-1:L], the number of the set to operate on.
  - Bits[L-1:4] are RES0.
  - \( A = \log_2(\text{ASSOCIATIVITY}) \), \( L = \log_2(\text{LINELEN}) \), \( B = (L + S) \), \( S = \log_2(\text{NSETS}) \).
  - ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

- **Level, bits [3:1]**
  - Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

- **Bit [0]**
  - Reserved, RES0.

**Executing DC CGSW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.
Accesses to this instruction use the following encodings in the System instruction encoding space:

\[ \text{DC CGSW, \langle Xt \rangle} \]

C5.3.6 DC CGVAC, Clean of Allocation Tags by VA to PoC

The DC CGVAC characteristics are:

**Purpose**
Clean Allocation Tags in data cache by address to Point of Coherency.

**Configurations**
This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CGVAC are UNDEFINED.

**Attributes**
DC CGVAC is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

**Bits [63:0]**
Virtual address to use. No alignment restrictions apply to this VA.

**Executing DC CGVAC instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC)* on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**DC CGVAC, <Xt>**

<table>

C5.3.7 DC CGVADP, Clean of Allocation Tags by VA to PoDP

The DC CGVADP characteristics are:

**Purpose**

Clean Allocation tags by address to Point of Deep Persistence.

If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a DC CGVAP.

**Configurations**

This instruction is present only when FEAT_DPBP2 is implemented and FEAT_MTE is implemented. Otherwise, direct accesses to DC CGVADP are UNDEFINED.

**Attributes**

DC CGVADP is a 64-bit System instruction.

**Field descriptions**

Virtual address to use

No alignment restrictions apply to this VA.

**Executing DC CGVADP instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, see Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC)* on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.12 DC CIGSW, Clean and Invalidate of Allocation Tags by Set/Way

The DC CIGSW characteristics are:

**Purpose**

Clean and Invalidate Allocation Tags in data cache by set/way.

**Configurations**

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC CIGSW are UNDEFINED.

**Attributes**

DC CIGSW is a 64-bit System instruction.

**Field descriptions**

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

**Executing DC CIGSW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.
Accesses to this instruction use the following encodings in the System instruction encoding space:

**DC CIGSW, <Xt>**

<table>

C5.3.13  DC CIGVAC, Clean and Invalidate of Allocation Tags by VA to PoC

The DC CIGVAC characteristics are:

Purpose

Clean and Invalidate Allocation Tags in data cache by address to Point of Coherency.

Configurations

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC CIGVAC are UNDEFINED.

Attributes

DC CIGVAC is a 64-bit System instruction.

Field descriptions

Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CIGVAC instruction

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D7-5056.

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault.

For more information, see Permission fault.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\begin{array}{cccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
0b01 & 0b011 & 0b1111 & 0b1110 & 0b011 \\
\end{array}
\]

C5.3.14 DC CIPAPA, Data or unified Cache line Clean and Invalidate by PA to PoPA

The DC CIPAPA characteristics are:

**Purpose**

Clean and Invalidate data cache by physical address to the Point of Physical Aliasing.

**Configurations**

This instruction is present only when FEAT_RME is implemented. Otherwise, direct accesses to DC CIPAPA are UNDEFINED.

**Attributes**

DC CIPAPA is a 64-bit System instruction.

**Field descriptions**

NS, bit [63]

Together with the NSE field, this field specifies the target physical address space.

<table>
<thead>
<tr>
<th>NSE</th>
<th>NS</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b0</td>

<tr>
<td>0b1</td>
<td>0b1</td>
<td>Realm.</td>
</tr>
</tbody>
</table>

NSE, bit [62]

Together with the NS field, this field specifies the target physical address space.

For a description of the values derived by evaluating NS and NSE together, see DC CIPAPA.NS.

Bits [61:52]

Reserved, RES0.

Bits [51:0]

Physical address to use. No alignment restrictions apply to this PA.

**Executing DC CIPAPA instruction**

- This instruction is not subject to any translation, permission checks, or granule protection checks.
- This instruction affects all caches in the Outer Shareable shareability domain.
- This instruction has the same ordering, observability, and completion behavior as VA-based cache maintenance instructions issued to the Outer Shareable shareability domain.

Accesses to this instruction use the following encodings in the System instruction encoding space:
**DC CIPAPA, <Xt>**

```

C5.3.21 DC CVAU, Data or unified Cache line Clean by VA to PoU

The DC CVAU characteristics are:

**Purpose**

Clean data cache by address to Point of Unification.

**Configurations**

AArch64 System register DC CVAU performs the same function as AArch32 System register DCCMVAU.

**Attributes**

DC CVAU is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

** Bits [63:0] **

Virtual address to use. No alignment restrictions apply to this VA.

** Executing DC CVAU instruction **

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.22  DC GVA, Data Cache set Allocation Tag by VA

The DC GVA characteristics are:

**Purpose**
Write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0. The Allocation Tag used is determined by the input address.

**Configurations**
This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC GVA are **UNDEFINED**.

**Attributes**
DC GVA is a 64-bit System instruction.

**Field descriptions**

Boosts [63:0]
Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

**Executing DC GVA instruction**
When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being modified is any type of Device memory, this instruction can give an alignment fault that is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of stores to each Allocation Tag within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**DC GVA, <Xt>**

  AArch64.MemZero(X[t, 64], CacheType_Tag);
C5.3.23 DC GZVA, Data Cache set Allocation Tags and Zero by VA

The DC GZVA characteristics are:

**Purpose**

Zero data and write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0. The Allocation Tag used is determined by the input address.

**Configurations**

This instruction is present only when FEAT_MTE is implemented. Otherwise, direct accesses to DC GZVA are UNDEFINED.

**Attributes**

DC GZVA is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 32</td>
<td></td>
</tr>
<tr>
<td>31 0</td>
<td></td>
</tr>
</tbody>
</table>

**Executing DC GZVA instruction**

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte and Allocation tag within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.24 DC IGDSW, Invalidate of Data and Allocation Tags by Set/Way

The DC IGDSW characteristics are:

**Purpose**

Invalidate data and Allocation Tags in data cache by set/way.

**Configurations**

This instruction is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to DC IGDSW are UNDEFINED.

**Attributes**

DC IGDSW is a 64-bit System instruction.

**Field descriptions**

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

**Executing DC IGDSW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.
Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.28 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

**Purpose**

Invalidate data cache by set/way.

When `FEAT_MTE2` is implemented, this instruction might invalidate Allocation Tags from caches. When it invalidates Allocation Tags from caches, it also cleans them.

**Configurations**

AArch64 System register DC ISW performs the same function as AArch32 System register `DCISW`.

**Attributes**

DC ISW is a 64-bit System instruction.

**Field descriptions**

Bits [63:32]

Reserved, RES0.

**SetWay, bits [31:4]**

Contains two fields:

- **Way**, bits [31:32-A], the number of the way to operate on.
- **Set**, bits [B-1:L], the number of the set to operate on.

Bits [L-1:4] are RES0.

\[ A = \log_2(\text{ASSOCIATIVITY}), \quad L = \log_2(\text{LINELEN}), \quad B = (L + S), \quad S = \log_2(\text{NSETS}). \]

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Executing DC ISW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is **CONSTRAINED UNPREDICTABLE** and one of the following occurs:

- The instruction is **UNDEFINED**.
- The instruction performs cache maintenance on one of:
  - No cache lines.
— A single arbitrary cache line.
— Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.29 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

**Purpose**

Invalidate data cache by address to Point of Coherency.

When FEAT_MTE2 is implemented, this instruction might invalidate Allocation Tags from caches. When it invalidates Allocation Tags from caches, it also cleans them.

**Configurations**

AArch64 System register DC IVAC performs the same function as AArch32 System register DCIMVAC.

**Attributes**

DC IVAC is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing DC IVAC instruction**

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

This instruction requires write access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in Permission fault.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D7-5056.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**DC IVAC, <xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

    AArch64.DC(X[t, 64], CacheType_Data, CacheOp_Invalidate, CacheOpScope_PoC);
C5.3.30 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose
Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

Configurations
There are no configuration notes.

Attributes
DC ZVA is a 64-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 32</td>
<td>Virtual address to use</td>
</tr>
<tr>
<td>31 0</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

Bits [63:0]
Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing DC ZVA instruction

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 0.

If the memory region being zeroed is any type of Device memory, this instruction can give an Alignment fault which is prioritized in the same way as other Alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

• Generates a Permission fault if the translation system does not permit writes to the locations.
• Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\text{DC ZVA, } <\text{Xt}> \\
\begin{array}{cccc}
\text{op0} & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} \\
\hline
0b01 & 0b011 & 0b0111 & 0b0100 & 0b001 \\
\end{array}
\]

C5.3.31 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

**Purpose**
Invalidate all instruction caches of the PE executing the instruction to the Point of Unification.

**Configurations**
AArch64 System register IC IALLU performs the same function as AArch32 System register ICIALLU.

**Attributes**
IC IALLU is a 64-bit System instruction.

**Field descriptions**
This instruction has no applicable fields.
The value in the register specified by <Xt> is ignored.

**Executing IC IALLU instruction**
The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.32 IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The IC IALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches in the Inner Shareable domain of the PE executing the instruction to the Point of Unification.

**Configurations**

AArch64 System register IC IALLUIS performs the same function as AArch32 System register ICIALLUIS.

**Attributes**

IC IALLUIS is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

**Executing IC IALLUIS instruction**

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

C5.3.33 IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

**Purpose**
Invalidate instruction cache by address to Point of Unification.

**Configurations**
AArch64 System register IC IVAU performs the same function as AArch32 System register ICIMVAU.

**Attributes**
IC IVAU is a 64-bit System instruction.

**Field descriptions**

Abbreviation: IC IVAU

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-32</td>
<td>Virtual address to use. No alignment restrictions apply to this VA.</td>
</tr>
<tr>
<td>31-0</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

**Bits [63:0]**
Virtual address to use. No alignment restrictions apply to this VA.

**Executing IC IVAU instruction**

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The instruction cache maintenance instruction (IC) on page D7-5056.

If EL0 access is enabled, when executed at EL0, if this instruction does not have read access permission to the VA, it is IMPLEMENTATION DEFINED whether it generates a Permission fault.

For more information, see Permission fault.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**IC IVAU(, <Xt>)**

<table>

C5.4 A64 System instructions for address translation

This section lists the A64 System instructions for address translation.
C5.4.1  AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

**Purpose**

Performs stage 1 and 2 address translations from EL0, with permissions as if reading from the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.\{E2H, TGE\} is not \{1, 1\}, the EL1&0 translation regime.
  - If HCR_EL2.\{E2H, TGE\} is \{1, 1\}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

AT S12E0R is a 64-bit System instruction.

**Field descriptions**

![Input address for translation](image)

**Bits [63:0]**

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

**Executing AT S12E0R instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.4.5   AT S1E0R, Address Translate Stage 1 EL0 Read

The AT S1E0R characteristics are:

**Purpose**

Performs stage 1 address translation from EL0, with permissions as if reading from the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

AT S1E0R is a 64-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:32]</td>
<td></td>
</tr>
<tr>
<td>[31:0]</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

**Executing AT S1E0R instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.4.8  AT S1E1RP, Address Translate Stage 1 EL1 Read PAN

The AT S1E1RP characteristics are:

**Purpose**

Performs a stage 1 address translation, where the value of PSTATE.PAN determines if a read from a location will generate a Permission fault for a privileged access, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.
- Otherwise, the EL1&0 translation regime, accessed from EL1.

**Configurations**

This instruction is present only when FEAT_PAN2 is implemented. Otherwise, direct accesses to AT S1E1RP are UNDEFINED.

**Attributes**

AT S1E1RP is a 64-bit System instruction.

**Field descriptions**

C5.5 A64 System instructions for TLB maintenance

This section lists the A64 System instructions for TLB maintenance.

For more information about these instructions see TLB maintenance instructions on page D8-5201. In particular, for the full description of the scope of each instruction see TLB maintenance instruction scope on page D8-5206.
C5.5.1 TLBI ALLE1, TLBI ALLE1NXS, TLB Invalidate All, EL1

The TLBI ALLE1 and TLBI ALLE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate an address using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate an address using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation only applies to the PE that executes this System instruction.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE1, TLBI ALLE1NXS is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

**Executing TLBI ALLE1, TLBI ALLE1NXS instruction**

The Rt field should be set to 0b11111. If the Rt field is not set to 0b11111, it is CONstrained UNpredictable whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to 0b11111.
Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.2 TLBI ALLE1IS, TLBI ALLE1ISNXS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS and TLBI ALLE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - \( \text{SCR}_{\text{EL3}} \cdot \{\text{NSE, NS}\} \) is \( \{0, 0\} \) and the entry would be required to translate an address using the Secure EL1&0 translation regime.
  - \( \text{SCR}_{\text{EL3}} \cdot \{\text{NSE, NS}\} \) is \( \{0, 1\} \) and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - \( \text{SCR}_{\text{EL3}} \cdot \{\text{NSE, NS}\} \) is \( \{1, 1\} \) and the entry would be required to translate an address using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - \( \text{SCR}_{\text{EL3}} \).NS is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
  - \( \text{SCR}_{\text{EL3}} \).NS is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

---

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE1IS, TLBI ALLE1ISNXS is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by \(<Xt>\) is ignored.

**Executing TLBI ALLE1IS, TLBI ALLE1ISNXS instruction**

The Rt field should be set to \(0b11111\). If the Rt field is not set to \(0b11111\), it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
The instruction behaves as if the Rt field is set to 0b11111.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.7 TLBI ALLE3, TLBI ALLE3NXS, TLB Invalidate All, EL3

The TLBI ALLE3 and TLBI ALLE3NXS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE3, TLBI ALLE3NXS is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by \(<Xt>\) is ignored.

**Executing TLBI ALLE3, TLBI ALLE3NXS instruction**

The Rt field should be set to \(0b11111\). If the Rt field is not set to \(0b11111\), it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to \(0b11111\).

C5.5.11 TLBI ASIDE1IS, TLBI ASIDE1ISNXS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS and TLBI ASIDE1ISNXS characteristics are:

Purpose
Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the current Security state:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate an address using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of SCR_EL3.NS if FEAT_RME is not implemented, or SCR_EL3.{NSE, NS} if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations
There are no configuration notes.

Attributes
TLBI ASIDE1IS, TLBI ASIDE1ISNXS is a 64-bit System instruction.

C5.5.12 TLBI ASIDE1OS, TLBI ASIDE1OSNXS, TLB Invalidate by ASID, EL1, Outer Shareable

The TLBI ASIDE1OS and TLBI ASIDE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the current Security state:
  - If \( \text{HCR\_EL2}.\{\text{E2H, TGE}\} \) is not \( \{1, 1\} \), the entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.
  - If \( \text{HCR\_EL2}.\{\text{E2H, TGE}\} \) is \( \{1, 1\} \), the entry would be required to translate an address using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( \text{SCR\_EL3.NS} \) if \( \text{FEAT\_RME} \) is not implemented, or \( \text{SCR\_EL3.\{NSE, NS\}} \) if \( \text{FEAT\_RME} \) is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

If \( \text{FEAT\_XS} \) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when \( \text{FEAT\_TLBIOS} \) is implemented. Otherwise, direct accesses to TLBI ASIDE1OS, TLBI ASIDE1OSNXS are UNDEFINED.

**Attributes**

TLBI ASIDE1OS, TLBI ASIDE1OSNXS is a 64-bit System instruction.

**Field descriptions**

</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

C5.5.13   TLBI IPAS2E1, TLBI IPAS2E1NXS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 and TLBI IPAS2E1NXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2E1, TLBI IPAS2E1NXS is a 64-bit System instruction.

IPA[51:48]: 
IPA[47:12]: 
IPA[47:12]: 
IPA[47:12]:
NS, bit [63]

When FEAT_RME is implemented:

- When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
  - 0b0: IPA is in the Secure IPA space.
  - 0b1: IPA is in the Non-secure IPA space.

- When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

- When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

- Not Secure. Specifies the IPA space.
  - 0b0: IPA is in the Secure IPA space.
  - 0b1: IPA is in the Non-secure IPA space.

- When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

- When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

- Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

- 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.

- 0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.
Otherwise:
  Reserved, RES0.

Bits [43:40]
  Reserved, RES0.

IPA[51:48], bits [39:36]

When FEAT_LPA is implemented:
  Extension to IPA[47:12]. For more information, see IPA[47:12].

Otherwise:
  Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48
bits, the upper bits of this field are RES0.

When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use,
IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing TLBI IPAS2E1, TLBI IPAS2E1NXS instruction

        AArch64.TLBI_IPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH, TLBILevel_Any, TLBI_ExcludeXS, X[p, 64]);
The TLBI IPAS2E1IS and TLBI IPAS2E1ISNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2E1IS, TLBI IPAS2E1ISNXS is a 64-bit System instruction.

**Field descriptions**
NS, bit [63]

When **FEAT_RME** is implemented:

When the instruction is executed and \( \text{SCR}_\text{EL3}.\{\text{NSE, NS}\} = \{0, 0\} \), NS selects the IPA space.
- 0b0  IPA is in the Secure IPA space.

C5.5.15 TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI IPAS2E1OS and TLBI IPAS2E1OSNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS are undefined.

**Attributes**

TLBI IPAS2E1OS, TLBI IPAS2E1OSNXS is a 64-bit System instruction.

NS, bit [63]

When FEAT_RME is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

Not Secure. Specifies the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.
Otherwise:
  Reserved, RES0.

Bits [43:40]
  Reserved, RES0.

IPA[51:48], bits [39:36]
  Extension to IPA[47:12]. For more information, see IPA[47:12].

IPA[47:12], bits [35:0]
  Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.
  When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

C5.5.16 TLBI IPAS2LE1, TLBI IPAS2LE1NXS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 and TLBI IPAS2LE1NXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2LE1, TLBI IPAS2LE1NXS is a 64-bit System instruction.

**Field descriptions**

![Field descriptions diagram]
NS, bit [63]

When *FEAT_RME* is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
- 0b0 IPA is in the Secure IPA space.
- 0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When *FEAT_SEL2* is implemented and *FEAT_RME* is not implemented:

Not Secure. Specifies the IPA space.
- 0b0 IPA is in the Secure IPA space.
- 0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When *FEAT_SEL2* is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When *FEAT_TTL* is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

- 0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: If *FEAT_LPA2* is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- 0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: If *FEAT_LPA2* is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.
- 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.
Otherwje:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

When FEAT_LPA is implemented:

Extension to IPA[47:12]. For more information, see IPA[47:12].

Otherwise:

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

C5.5.17 TLBI IPAS2LE1IS, TLBI IPAS2LE1ISNXS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI IPAS2LE1IS and TLBI IPAS2LE1ISNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see Invalidating TLB entries from stage 2 translations on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2LE1IS, TLBI IPAS2LE1ISNXS is a 64-bit System instruction.

```
NS, bit [63]

When `FEAT_RME` is implemented:
- When the instruction is executed and `SCR_EL3.{NSE, NS} == {0, 0}`, NS selects the IPA space.
  - 0b0 IPA is in the Secure IPA space.
  - 0b1 IPA is in the Non-secure IPA space.
- When the instruction is executed and `SCR_EL3.{NSE, NS} == {1, 1}`, this field is RES0, and the instruction applies only to the Realm IPA space.
- When the instruction is executed and `SCR_EL3.{NSE, NS} == {0, 1}`, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When `FEAT_SEL2` is implemented and `FEAT_RME` is not implemented:
- Not Secure. Specifies the IPA space.
  - 0b0 IPA is in the Secure IPA space.
  - 0b1 IPA is in the Non-secure IPA space.
- When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.
- When `FEAT_SEL2` is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:
- Reserved, RES0.

Bits [62:48]
Reserved, RES0.

TTL, bits [47:44]

When `FEAT_TTL` is implemented:
Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.
- 0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : If `FEAT_LPA2` is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- 0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : If `FEAT_LPA2` is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- 0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.
Otherwise:
Reserved, RES0.

Bits [43:40]
Reserved, RES0.

IPA[51:48], bits [39:36]

When FEAT_LPA is implemented:
Extension to IPA[47:12]. For more information, see IPA[47:12].

Otherwise:
Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use,IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

C5.5.18 TLBI IPAS2LE1OS, TLBI IPAS2LE1OSNXS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable

The TLBI IPAS2LE1OS and TLBI IPAS2LE1OSNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate the specified IPA using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI IPAS2LE1OS, TLBI IPAS2LE1OSNXS are UNDEFINED.

**Attributes**

TLBI IPAS2LE1OS, TLBI IPAS2LE1OSNXS is a 64-bit System instruction.

**Field descriptions**
NS, bit [63]

When FEAT_RME is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

Not Secure. Specifies the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:
Reserved, RES0.

Bits [62:48]
Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : If FEAT_LPA2 is implemented, level 0. Otherwise, treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : If FEAT_LPA2 is implemented, level 1. Otherwise, treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.
Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]
Extension to IPA[47:12]. For more information, see IPA[47:12].

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When FEAT_LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

C5.5.19 TLBI PAALL, TLB Invalidate GPT Information by PA, All Entries, Local

The TLBI PAALL characteristics are:

**Purpose**

Invalidates cached copies of GPT entries from TLBs. Details:

- The invalidation applies to TLB entries containing GPT information that relates to a physical address.
- The invalidation applies to all TLB entries containing GPT information.
- The invalidation affects only the TLBs for the PE executing the operation.

The full set of TLB maintenance instructions that invalidate cached GPT entries is: TLBI PAALL, TLBI PAALLOS, TLBI RPALOS, and TLBI RPAOS.

These instructions have the same ordering, observability, and completion behavior as all other TLBI instructions.

**Configurations**

This instruction is present only when FEAT_RME is implemented. Otherwise, direct accesses to TLBI PAALL are UNDEFINED.

**Attributes**

TLBI PAALL is a 64-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

**Executing TLBI PAALL instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.21 TLBI RIPAS2E1, TLBI RIPAS2E1NXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI RIPAS2E1 and TLBI RIPAS2E1NXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula \([BaseADDR <= VA < BaseADDR + ((NUM +1) \times 2^{5 \times SCALE +1}) \times Translation_Granule_Size]\).

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2E1, TLBI RIPAS2E1NXS are UNDEFINED.
Attributes

TLBI RIPAS2E1, TLBI RIPAS2E1NXS is a 64-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| NS, bit [63] | When FEAT_RME is implemented:  
When the instruction is executed and SCR_EL3.{NSE, NS} == \{0, 0\}, NS selects the IPA space.  
0b0 IPA is in the Secure IPA space.  
0b1 IPA is in the Non-secure IPA space.  
When the instruction is executed and SCR_EL3.{NSE, NS} == \{1, 1\}, this field is RES0, and the instruction applies only to the Realm IPA space.  
When the instruction is executed and SCR_EL3.{NSE, NS} == \{0, 1\}, this field is RES0, and the instruction applies only to the Non-secure IPA space.  
When FEAT_SEL2 is implemented and FEAT_RME is not implemented:  
Not Secure. Specifies the IPA space.  
0b0 IPA is in the Secure IPA space.  
0b1 IPA is in the Non-secure IPA space.  
When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.  
When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.  
Otherwise:  
Reserved, RES0. |
| Bits [62:48] | Reserved, RES0. |
0b00 Reserved.  
0b01 4K translation granule.  
0b10 16K translation granule.  
0b11 64K translation granule.  
The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries. |
| SCALE, bits [45:44] | The exponent element of the calculation that is used to produce the upper range. |
NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries.
  - If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
- When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
- When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.
- When using a 4KB translation granule, this field is BaseADDR[48:12].
- When using a 16KB translation granule, this field is BaseADDR[50:14].
- When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.22  TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI RIPAS2E1IS and TLBI RIPAS2E1ISNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{5 \times \text{SCALE} + 1} \times \text{Translation_Granule_Size})]$. The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
- The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **unpredictable** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined. Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS are **undefined**.
Attributes

TLBI RIPAS2E1IS, TLBI RIPAS2E1ISNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_RME is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.

0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries.
  If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
- When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
- When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.
Otherwise:
The starting address for the range of the maintenance instruction.
- When using a 4KB translation granule, this field is BaseADDR[48:12].
- When using a 16KB translation granule, this field is BaseADDR[50:14].
- When using a 64KB translation granule, this field is BaseADDR[52:16].

```

C5.5.23 TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI RIPAS2E1OS and TLBI RIPAS2E1OSNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq VA < \text{BaseADDR} + ((\text{NUM} +1)*2^{5\text{SCALE} +1} * \text{Translation_Granule_Size})\].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 00000000000000000000000000.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS are **UNDEFINED**.
Attributes

TLBI RIPAS2E1OS, TLBI RIPAS2E1OSNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_RME is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.

0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.
NUM, bits [43:39]
   The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
   TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the
   level described by the TTL hint.
   
   0b00   The entries in the range can be using any level for the translation table entries.
   0b01   All entries to invalidate are Level 1 translation table entries.
   \color{red}{\textit{If FEAT\_LPA2 is not implemented, when using a 16KB translation granule, this value}}
   \color{red}{\textit{is reserved and hardware should treat this field as 0b00.}}
   0b10   All entries to invalidate are Level 2 translation table entries.
   0b11   All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
   \textit{When FEAT\_LPA2 is implemented and TCR\_EL1.DS == 1:}
   
   The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16]
   for all translation granules.
   
   When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
   When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

   \textit{Otherwise:}
   
   The starting address for the range of the maintenance instruction.
   
   When using a 4KB translation granule, this field is BaseADDR[48:12].
   When using a 16KB translation granule, this field is BaseADDR[50:14].
   When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.24 TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI RIPAS2LE1 and TLBI RIPAS2LE1NXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq VA < \text{BaseADDR} + ((\text{NUM} +1) \cdot 2^{5\times\text{SCALE} +1}) \cdot \text{Translation_Granule_Size}\].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see *Invalidating TLB entries from stage 2 translations* on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS are UNDEFINED.
Attributes

TLBI RIPAS2LE1, TLBI RIPAS2LE1NXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]

When FEAT_RME is implemented:

When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the instruction applies only to the Realm IPA space.
When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:

Not Secure. Specifies the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.
When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field is RES0.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.
0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

    if !EL2Enabled() then
        return;
    else
        AArch64.TLBI_RIPAS2(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Shareability_NSH, TLBILevel_Last, TLBIAllAttr, X[t, 64]);
```

```
TLB I RIPAS2LE1NXS{, <Xt>}
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

C5.5.25 TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI RIPAS2LE1IS and TLBI RIPAS2LE1ISNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is {0, 0} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {0, 1} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is {1, 1} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM+1)*2(5*SCALE+1) * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000000.

For more information about the architectural requirements for this System instruction, see **Invalidating TLB entries from stage 2 translations** on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS are UNDEFINED.
Attributes

TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS is a 64-bit System instruction.

Field descriptions

NS, bit [63]
When FEAT_RME is implemented:
When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.
When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the
instruction applies only to the Realm IPA space.
When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the
instruction applies only to the Non-secure IPA space.
When FEAT_SEL2 is implemented and FEAT_RME is not implemented:
Not Secure. Specifies the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.
When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies
only to the Non-secure IPA space.
When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field
is RES0.
Otherwise:
Reserved, RES0.

Bits [62:48]
Reserved, RES0.

TG, bits [47:46]
Translation granule size.
0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.
The instruction takes a translation granule size for the translations that are being invalidated. If the
translations used a different translation granule size than the one being specified, then the
architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.
NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

<table>
<thead>
<tr>

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granularity, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granularity, BaseADDR[15:14] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.

When using a 4KB translation granularity, this field is BaseADDR[48:12].
When using a 16KB translation granularity, this field is BaseADDR[50:14].
When using a 64KB translation granularity, this field is BaseADDR[52:16].

Executing TLBI RIPAS2LE1IS, TLBI RIPAS2LE1ISNXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

else
  UNDEFINED;
endif;}
The TLBI RIPAS2LE1OS and TLBI RIPAS2LE1OSNXS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- If FEAT_RME is implemented, one of the following applies:
  - SCR_EL3.{NSE, NS} is \{0, 0\} and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{0, 1\} and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
  - SCR_EL3.{NSE, NS} is \{1, 1\} and the entry would be required to translate any IPA in the specified address range using the Realm EL1&0 translation regime.
- If FEAT_RME is not implemented, one of the following applies:
  - SCR_EL3.NS is 0 and the entry would be required to translate any IPA in the specified address range using the Secure EL1&0 translation regime.
  - SCR_EL3.NS is 1 and the entry would be required to translate any IPA in the specified address range using the Non-secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^{5*SCALE +1} * Translation_Granule_Size)].

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see
Invalidating TLB entries from stage 2 translations on page D8-5211.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.
Both variants perform the same invalidation, but the TLBI System instruction without the nXS
qualifier waits for all memory accesses using in-scope old translation information to complete
before it is considered complete.
The TLBI System instruction with the nXS qualifier is considered complete when the subset of these
memory accesses with XS attribute set to 0 are complete.

Configurations
This instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is
implemented. Otherwise, direct accesses to TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS are
UNDEFINED.

Attributes
TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS is a 64-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>NS</th>
<th>RES0</th>
<th>TG</th>
<th>NUM</th>
<th>TTL</th>
<th>BaseADDR</th>
</tr>
</thead>
</table>

NS, bit [63]

When FEAT_RME is implemented:
When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 0}, NS selects the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.
When the instruction is executed and SCR_EL3.{NSE, NS} == {1, 1}, this field is RES0, and the
instruction applies only to the Realm IPA space.
When the instruction is executed and SCR_EL3.{NSE, NS} == {0, 1}, this field is RES0, and the
instruction applies only to the Non-secure IPA space.

When FEAT_SEL2 is implemented and FEAT_RME is not implemented:
Not Secure. Specifies the IPA space.
0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.
When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies
only to the Non-secure IPA space.
When FEAT_SEL2 is not implemented, or if EL2 is disabled in the current Security state, this field
is RES0.

Otherwise:
Reserved, RES0.

Bits [62:48]
Reserved, RES0.
TG, bits [47:46]
Translation granule size.
0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.
The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
0b00  The entries in the range can be using any level for the translation table entries.
0b01  All entries to invalidate are Level 1 translation table entries.
      If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10  All entries to invalidate are Level 2 translation table entries.
0b11  All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.
Otherwise:
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RIPAS2LE1OS, TLBI RIPAS2LE1OSNXS instruction
Accesses to this instruction use the following encodings in the System instruction encoding space:

    TLBILevel_Last, TLBI_ExcludeXS, X[t, 64]);
The TLBI RPALOS characteristics are:

**Purpose**

Invalidates cached copies of GPT entries from TLBs. Details:

- The invalidation applies to TLB entries containing GPT information that relates to a physical address.
- The invalidation affects all TLBs in the Outer Shareable domain.
- Invalidates TLB entries containing GPT information from the final level of the GPT walk that relates to the supplied physical address.
- Invalidations are range-based, invalidating TLB entries starting from the address in BaseADDR, within the range as specified by SIZE.

The full set of TLB maintenance instructions that invalidate cached GPT entries is: TLBI PAALL, TLBI PAALLOS, TLBI RPALOS, and TLBI RPAOS.

These instructions have the same ordering, observability, and completion behavior as all other TLBI instructions.

**Configurations**

This instruction is present only when FEAT_RME is implemented. Otherwise, direct accesses to TLBI RPALOS are UNDEFINED.

**Attributes**

TLBI RPALOS is a 64-bit System instruction.

**Field descriptions**

```
<table>
<thead>
<tr>
<th></th>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>40</th>
<th>39</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SIZE</td>
<td>RES0</td>
<td>Address</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:48]**

Reserved, RES0.

**SIZE, bits [47:44]**

Size of the range for invalidation.

If SIZE is a reserved value, no TLB entries are required to be invalidated.

- 0b0000: 4KB.
- 0b0001: 16KB.
- 0b0010: 64KB.
- 0b0011: 2MB.
- 0b0100: 32MB.
- 0b0101: 512MB.
- 0b0110: 1GB.
- 0b0111: 16GB.
- 0b1000: 64GB.
- 0b1001: 512GB.

All other values are reserved.
If SIZE gives a range smaller than the configured physical granule size in GPCCR_EL3.PGS, then the effective value of SIZE is taken to be the size configured by GPCCR_EL3.PGS.

If GPCCR_EL3.PGS is configured to a reserved value, no TLB entries are required to be invalidated.

**Bits [43:40]**

Reserved, RES0.

**Address, bits [39:0]**

The starting address for the range of the maintenance instruction.

This field is decoded with reference to the value of GPCCR_EL3.PGS to give BaseADDR as follows:

```
<table>
<thead>
<tr>
<th>GPCCR_EL3.PGS</th>
<th>BaseADDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00 (4KB)</td>
<td>BaseADDR [51:12] = Xt[39:0]</td>
</tr>
<tr>
<td>0b10 (16KB)</td>
<td>BaseADDR [51:14] = Xt[39:2]</td>
</tr>
<tr>
<td>0b01 (64KB)</td>
<td>BaseADDR [51:16] = Xt[39:4]</td>
</tr>
</tbody>
</table>
```

Other bits of BaseADDR are treated as zero, to give the effective value of BaseADDR.

If the effective value of BaseADDR is not aligned to the size of the effective value of SIZE, no TLB entries are required to be invalidated.

If GPCCR_EL3.PGS is configured to a reserved value, no TLB entries are required to be invalidated.

**Executing TLBI RPALOS instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI RPALOS{, <Xt>}  
```

```
C5.5.29   TLBI RVAAE1, TLBI RVAAE1NXS, TLB Range Invalidate by VA, All ASID, EL1

The TLBI RVAAE1 and TLBI RVAAE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)*2^{(5*\text{SCALE} +1)} * \text{Translation_Granule_Size})\].
- When EL2 is implemented and enabled in the current Security state:
  - If \(\text{HCR\_EL2\_[E2H, TGE]}\) is not \(\{1, 1\}\), the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(\text{HCR\_EL2\_[E2H, TGE]}\) is \(\{1, 1\}\), the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \(\text{SCR\_EL3\_NS}\) if \(\text{FEAT\_RME}\) is not implemented, or \(\text{SCR\_EL3\_[NSE, NS]}\) if \(\text{FEAT\_RME}\) is implemented.

The invalidation applies to the PE that executes this System instruction.

--- **Note** ---

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \(\text{TTL} = 01\) and \(\text{BaseADDR}[29:12]\) is not equal to \(00000000000000000000000000\).
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[20:12]\) is not equal to \(00000000000\).
- For the 16K translation granule:
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[24:14]\) is not equal to \(000000000000\).
- For the 64K translation granule:
  - If \(\text{TTL} = 01\) and \(\text{BaseADDR}[41:16]\) is not equal to \(0000000000000000000000000000000000\).
  - If \(\text{TTL} = 10\) and \(\text{BaseADDR}[28:16]\) is not equal to \(0000000000000000000000000000000000\).

If \(\text{FEAT\_XS}\) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when \(\text{FEAT\_TLBIRANGE}\) is implemented. Otherwise, direct accesses to TLBI RVAAE1, TLBI RVAAE1NXS are UNDEFINED.

**Attributes**

TLBI RVAAE1, TLBI RVAAE1NXS is a 64-bit System instruction.
Field descriptions

Bits [63:48]
Reserved, RES0.

TG, bits [47:46]
Translation granule size.
0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.
The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
0b00 The entries in the range can be using any level for the translation table entries.
0b01 All entries to invalidate are Level 1 translation table entries.
If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10 All entries to invalidate are Level 2 translation table entries.
0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:
The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.
When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

    TLBI_ExcludeXS, X[t, 64]);
The TLBI RVAAE1IS and TLBI RVAAE1ISNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + (\text{NUM} +1) \times 2^{(5\times \text{SCALE} +1) \times \text{Translation_Granule_Size}}]$.
- When EL2 is implemented and enabled in the current Security state:
  - If $HCR\_EL2\{E2H, TGE\}$ is not $\{1, 1\}$, the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If $HCR\_EL2\{E2H, TGE\}$ is $\{1, 1\}$, the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
- The Security state is indicated by the value of $SCR\_EL3\{\text{NS, NS}\}$ if FEAT_RME is not implemented, or $SCR\_EL3\{\text{NSE, NS}\}$ if FEAT_RME is implemented.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if $SCR\_EL3\{\text{EEL2}\}==1$, then:

- A PE with $SCR\_EL3\{\text{EEL2}\}==1$ is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with $SCR\_EL3\{\text{EEL2}\}==0$.
- A PE with $SCR\_EL3\{\text{EEL2}\}==0$ is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with $SCR\_EL3\{\text{EEL2}\}==1$.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If $TTL==01$ and $\text{BaseADDR}[29:12]$ is not equal to $000000000000000000$.
  - If $TTL==10$ and $\text{BaseADDR}[20:12]$ is not equal to $0000000000$.
- For the 16K translation granule:
  - If $TTL==10$ and $\text{BaseADDR}[24:14]$ is not equal to $000000000000$.
- For the 64K translation granule:
  - If $TTL==01$ and $\text{BaseADDR}[41:16]$ is not equal to $00000000000000000000000000$. 
If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

Configurations

This instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAAE1IS, TLBI RVAAE1ISNXS are UNDEFINED.

Attributes

TLBI RVAAE1IS, TLBI RVAAE1ISNXS is a 64-bit System instruction.

Field descriptions

**Bits [63:48]**

Reserved, RES0.

**TG, bits [47:46]**

Translation granule size.

0b00  Reserved.

0b01  4K translation granule.

0b10  16K translation granule.

0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

**SCALE, bits [45:44]**

The exponent element of the calculation that is used to produce the upper range.

**NUM, bits [43:39]**

The base element of the calculation that is used to produce the upper range.

**TTL, bits [38:37]**

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00  The entries in the range can be using any level for the translation table entries.

0b01  All entries to invalidate are Level 1 translation table entries.

If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10  All entries to invalidate are Level 2 translation table entries.

0b11  All entries to invalidate are Level 3 translation table entries.
BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

When using a 4KB translation granule, BaseADDR[15:12] is treated as 0b0000.
When using a 16KB translation granule, BaseADDR[15:14] is treated as 0b00.

Otherwise:
The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.31 TLBI RVAAE1OS, TLBI RVAAE1OSNXS, TLB Range Invalidate by VA, All ASID, EL1, Outer Shareable

The TLBI RVAAE1OS and TLBI RVAAE1OSNXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} +1)} \times \text{Translation_Granule_Size})]\).
- When EL2 is implemented and enabled in the current Security state:
  - If \(\text{HCR\_EL2.\{E2H, TGE}\}}\) is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \(\text{HCR\_EL2.\{E2H, TGE\}}\) is \{1, 1\}, the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \(\text{SCR\_EL3.NS}\) if \(\text{FEAT\_RME}\) is not implemented, or \(\text{SCR\_EL3.\{NSE, NS\}}\) if \(\text{FEAT\_RME}\) is implemented.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

—— Note ———

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if \(\text{SCR\_EL3.EEL2} == 1\), then:

- A PE with \(\text{SCR\_EL3.EEL2} == 1\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR\_EL3.EEL2} == 0\).
- A PE with \(\text{SCR\_EL3.EEL2} == 0\) is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with \(\text{SCR\_EL3.EEL2} == 1\).
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

—— Note ———

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If \(\text{TTL} == 01\) and \(\text{BaseADDR[29:12]}\) is not equal to \(000000000000000000000000\).
  - If \(\text{TTL} == 10\) and \(\text{BaseADDR[20:12]}\) is not equal to \(00000000\).
- For the 16K translation granule:
  - If \(\text{TTL} == 10\) and \(\text{BaseADDR[24:14]}\) is not equal to \(00000000000\).
- For the 64K translation granule:
  - If \(\text{TTL} == 01\) and \(\text{BaseADDR[41:16]}\) is not equal to \(00000000000000000000000000\).
If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

If FEAT_XS is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

end
C5.5.32 TLBI RVAALE1, TLBI RVAALE1NXS, TLB Range Invalidate by VA, All ASID, Last level, EL1

The TLBI RVAALE1 and TLBI RVAALE1NXS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry is within the address range determined by the formula \[ \text{BaseADDR} \leq VA < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{5\times \text{SCALE} + 1} \times \text{Translation Granule Size}) \].
- When EL2 is implemented and enabled in the current Security state:
  - If \( \text{HCR\_EL2.} \{\text{E2H, TGE}\} \) is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.
  - If \( \text{HCR\_EL2.} \{\text{E2H, TGE}\} \) is \{1, 1\}, the entry would be required to translate any of the VAs in the specified address range using the EL2&0 translation regime for the Security state.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The Security state is indicated by the value of \( \text{SCR\_EL3.} \{\text{NSE, NS}\} \) if \( \text{FEAT\_RME} \) is not implemented, or \( \text{SCR\_EL3.} \{\text{NSE, NS}\} \) if \( \text{FEAT\_RME} \) is implemented.

The invalidation applies to the PE that executes this System instruction.

--- **Note** ---

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \( \text{TTL==01} \) and \( \text{BaseADDR[29:12]} \) is not equal to 0000000000000000.
  - If \( \text{TTL==10} \) and \( \text{BaseADDR[20:12]} \) is not equal to 00000000.
- For the 16K translation granule:
  - If \( \text{TTL==10} \) and \( \text{BaseADDR[24:14]} \) is not equal to 000000000000.
- For the 64K translation granule:
  - If \( \text{TTL==01} \) and \( \text{BaseADDR[41:16]} \) is not equal to 00000000000000000000.
  - If \( \text{TTL==10} \) and \( \text{BaseADDR[28:16]} \) is not equal to 000000000000.

If \( \text{FEAT\_XS} \) is implemented, the nXS variant of this System instruction is defined.

Both variants perform the same invalidation, but the TLBI System instruction without the nXS qualifier waits for all memory accesses using in-scope old translation information to complete before it is considered complete.

The TLBI System instruction with the nXS qualifier is considered complete when the subset of these memory accesses with XS attribute set to 0 are complete.

**Configurations**

This instruction is present only when \( \text{FEAT\_TLBIRANGE} \) is implemented. Otherwise, direct accesses to TLBI RVAALE1, TLBI RVAALE1NXS are UNDEFINED.

**Attributes**

TLBI RVAALE1, TLBI RVAALE1NXS is a 64-bit System instruction.

</tr>
</tbody>
</table>

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00: Reserved.
- 0b01: 4K translation granule.
- 0b10: 16K translation granule.
- 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: All entries to invalidate are Level 1 translation table entries. If FEAT_LPA2 is not implemented, when using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

When FEAT_LPA2 is implemented and TCR_EL1.DS == 1:

The starting address for the range of the maintenance instructions. This field is BaseADDR[52:16] for all translation granules.

- When using a 4KB translation granule, BaseADDR[52:16] is treated as 0b0000.
- When using a 16KB translation granule, BaseADDR[52:16] is treated as 0b00.

Otherwise:

The starting address for the range of the maintenance instruction.

- When using a 4KB translation granule, this field is BaseADDR[48:12].
- When using a 16KB translation granule, this field is BaseADDR[50:14].
- When using a 64KB translation granule, this field is BaseADDR[52:16].
Executing TLBI RVAALE1, TLBI RVAALE1NXS instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:
