C8.2.306  **LDFF1SH** (scalar plus vector)

Gather load with first-faulting behavior of signed halfwords to active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign or zero-extended from 32 to 64 bits and then optionally multiplied by 2. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.314   LDNF1B

Contiguous load with non-faulting behavior of unsigned bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

8-bit element

Contiguous load with non-faulting behavior of unsigned bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

16-bit element

Contiguous load with non-faulting behavior of unsigned bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Z[t, VL] = result;
```
C8.2.319   LDNF1SW

Contiguous load with non-faulting behavior of signed words to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

```
LDNF1SW { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decoding for this encoding

```
if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer g = UInt(Pg);
constant integer esize = 64;
constant integer msize = 32;
boolean unsigned = FALSE;
integer offset = SInt(imm4);
```

Assembler symbols

- `<Zt>`: Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
- `<Pg>`: Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<imm>`: Is the optional signed immediate vector offset, in the range -8 to 7, defaulting to 0, encoded in the "imm4" field.

Operation

```
CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;

### C8.2.323 LDNT1B (vector plus scalar)

Gather load non-temporal of unsigned bytes to active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

c
    Z[t, VL] = result;
C8.2.336 LDR (predicate)

Load a predicate register from a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 which is multiplied by the current predicate register size in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, each containing 8 consecutive predicate bits in ascending element order, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then a general-purpose base register must be aligned to 2 bytes.

Encoding

LDR <Pt>, [<Xn|SP>{, #<imm>, MUL VL}]

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Pt);
integer n = UInt(Rn);
integer imm = SInt(imm9h:imm9l);

Assembler symbols

<Pt> Is the name of the destination scalable predicate register, encoded in the "Pt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm> Is the optional signed immediate vector offset, in the range -256 to 255, defaulting to 0, encoded in the "imm9h:imm9l" fields.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = PL DIV 8;
bits(64) base;
integer offset = imm * elements;
bits(PL) result;

if n == 31 then
    CheckSPAlignment();
    if HaveMTEExt() then SetTagCheckedInstruction(FALSE);
    base = SP[];
else
    if HaveMTEExt() then SetTagCheckedInstruction(TRUE);
    base = X[n, 64];

boolean aligned = AArch64.CheckAlignment(base + offset, 2, AccType_SVE, FALSE);
for e = 0 to elements-1
    Elem[result, e, 8] = AArch64.MemSingle[base + offset, 1, AccType_SVE, aligned];
    offset = offset + 1;
P[t, PL] = result;
C8.2.337  LDR (vector)

Load a vector register from a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 which is multiplied by the current vector register size in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

Encoding

LDR <Zt>, [<Xn|SP>{, #<imm>, MUL VL}]

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer imm = SInt(imm9h:imm9l);

Assembler symbols

<Zt>  Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>  Is the optional signed immediate vector offset, in the range -256 to 255, defaulting to 0, encoded in the "imm9h:imm9l" fields.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV 8;
bits(64) base;
integer offset = imm * elements;
bits(VL) result;
if n == 31 then
    CheckSPAlignment();
    if HaveMTEExt() then SetTagCheckedInstruction(FALSE);
    base = SP[];
else
    if HaveMTEExt() then SetTagCheckedInstruction(TRUE);
    base = X[n, 64];
boolean aligned = AArch64.CheckAlignment(base + offset, 16, AccType_SVE, FALSE);
for e = 0 to elements-1
    Elem[result, e, 8] = AArch64.MemSingle[base + offset, 1, AccType_SVE, aligned];
    offset = offset + 1;
Z[t, VL] = result;
C8.2.338  LSL (immediate, predicated)

Shift left by immediate each active element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate shift amount is an unsigned value in the range 0 to number of bits per element minus 1. Inactive elements in the destination vector register remain unmodified.

Encoding

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.351 MATCH
This instruction compares each active 8-bit or 16-bit character in the first source vector with all of the characters in
the corresponding 128-bit segment of the second source vector. Where the first source element detects any matching
characters in the second segment it places true in the corresponding element of the destination predicate, otherwise
false. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C)
condition flags based on the predicate result, and the V flag to zero.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and
enabled at the current Exception level.

PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d, PL] = result;
C8.2.352 MLA (indexed)

Multiply all integer elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively added to the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

C8.2.354   MLS (indexed)

Multiply all integer elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively subtracted from the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

16-bit

```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.356   MOV

Unconditionally broadcast the logical bitmask immediate into each element of the destination vector. This instruction is unpredicated. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits.

This instruction is an alias of the DUPM instruction. This means that:

- The encodings in this description are named to match the encodings of DUPM.
- The description of DUPM gives the operational pseudocode for this instruction.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 |  |  | 5 4 | 0 |
| 0 0 0 0 0 | 1 0 1 1 0 0 0 0 | imm13 | Zd |
```

**Encoding**

MOV <Zd>.<T>, #<const>

is equivalent to

DUPM <Zd>.<T>, #<const>

and is the preferred disassembly when SVEMoveMaskPreferred(imm13).

**Assembler symbols**

- `<Zd>` is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<T>` is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:
  - `S` when imm13<12> = 0, imm13<5:0> = 0xxxxx
  - `H` when imm13<12> = 0, imm13<5:0> = 10xxxx
  - `B` when imm13<12> = 0, imm13<5:0> = 110xxx
  - `B` when imm13<12> = 0, imm13<5:0> = 1110xx
  - `B` when imm13<12> = 0, imm13<5:0> = 11110x
  - `D` when imm13<12> = 1, imm13<5:0> = xxxxxx

The following encodings are reserved:

- imm13<12> = 0, imm13<5:0> = 111110.
- imm13<12> = 0, imm13<5:0> = 111111.

- `<const>` is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

**Operation**

The description of DUPM gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C8.2.357 MOV

Read all elements from the source predicate and place in the destination predicate. This instruction is unpredicated. Does not set the condition flags.

This instruction is an alias of the ORR (predicates) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (predicates).
- The description of ORR (predicates) gives the operational pseudocode for this instruction.

</tr>
</tbody>
</table>

**Encoding**

MOV <Pd>.B, <Pn>.B

is equivalent to

and is the preferred disassembly when $S == '0' \&\& Pn == Pm \&\& Pm == Pg.

**Assembler symbols**

<Pd> Is the name of the destination scalable predicate register, encoded in the "Pd" field.

<Pn> Is the name of the first source scalable predicate register, encoded in the "Pn" field.

**Operation**

The description of ORR (predicates) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.358 **MOV (immediate, predicated, merging)**

Move a signed integer immediate to each active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

This instruction is an alias of the CPY (immediate, merging) instruction. This means that:

- The encodings in this description are named to match the encodings of CPY (immediate, merging).
- The description of CPY (immediate, merging) gives the operational pseudocode for this instruction.

| 31 30 29 28|27 26 25 24|23 22 21 20|19 16 15 14 13 12| 5 4 0 |
|---|---|---|---|---|---|
| 0 0 0 0 1 0 1 | size 0 1 | Pg 0 1 | sh | imm8 | Zd |

**Encoding**

MOV <Zd>.<T>, <Pg>/M, #<imm>{, <shift>}

is equivalent to

CPY <Zd>.<T>, <Pg>/M, #<imm>{, <shift>}

and is always the preferred disassembly.

**Assembler symbols**

- **<Zd>**
  - Is the name of the destination scalable vector register, encoded in the "Zd" field.
- **<T>**
  - Is the size specifier, encoded in the "size" field. It can have the following values:
    - B when size = 00
    - H when size = 01
    - S when size = 10
    - D when size = 11
- **<Pg>**
  - Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- **<imm>**
  - Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.
- **<shift>**
  - Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
    - LSL #0 when sh = 0
    - LSL #8 when sh = 1

**Operation**

The description of CPY (immediate, merging) gives the operational pseudocode for this instruction.
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.359\ MOV (immediate, predicated, zeroing)

Move a signed integer immediate to each active element in the destination vector. Inactive elements in the destination vector register are set to zero.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

This instruction is an alias of the CPY (immediate, zeroing) instruction. This means that:

- The encodings in this description are named to match the encodings of CPY (immediate, zeroing).
- The description of CPY (immediate, zeroing) gives the operational pseudocode for this instruction.

Encoding

\[
\text{MOV } <Zd>.<T>, <Pg>/Z, #<imm>{, <shift>}
\]

is equivalent to

\[
\text{CPY } <Zd>.<T>, <Pg>/Z, #<imm>{, <shift>}
\]

and is always the preferred disassembly.

Assembler symbols

\(<Zd>\) Is the name of the destination scalable vector register, encoded in the "Zd" field.

\(<T>\) Is the size specifier, encoded in the "size" field. It can have the following values:

- B when \(\text{size} = 00\)
- H when \(\text{size} = 01\)
- S when \(\text{size} = 10\)
- D when \(\text{size} = 11\)

\(<Pg>\) Is the name of the governing scalable predicate register, encoded in the "Pg" field.

\(<imm>\) Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.

\(<\text{shift}>\) Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

- LSL #0 when \(\text{sh} = 0\)
- LSL #8 when \(\text{sh} = 1\)

Operation

The description of CPY (immediate, zeroing) gives the operational pseudocode for this instruction.
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.360  MOV (immediate, unpredicated)

Unconditionally broadcast the signed integer immediate into each element of the destination vector. This instruction is unpredicated.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

This instruction is an alias of the DUP (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (immediate).
- The description of DUP (immediate) gives the operational pseudocode for this instruction.

Encoding

MOV <Zd>.<T>, #<imm>{, <shift>}

is equivalent to

DUP     <Zd>.<T>, #<imm>{, <shift>}

and is always the preferred disassembly.

Assemble symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00
H when size = 01
S when size = 10
D when size = 11

<imm> Is a signed immediate in the range -128 to 127, encoded in the "imm8" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

LSL #0 when sh = 0
LSL #8 when sh = 1

Operation

The description of DUP (immediate) gives the operational pseudocode for this instruction.
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C8.2.361   MOV (predicate, predicated, merging)

Read active elements from the source predicate and place in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register remain unmodified. Does not set the condition flags.

This instruction is an alias of the SEL (predicates) instruction. This means that:

• The encodings in this description are named to match the encodings of SEL (predicates).
• The description of SEL (predicates) gives the operational pseudocode for this instruction.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 14 13 | 10 9 8 | 5 4 3 0 ]
S

  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.
C8.2.362   MOV (predicate, predicated, zeroing)

Read active elements from the source predicate and place in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

This instruction is an alias of the AND (predicates) instruction. This means that:

- The encodings in this description are named to match the encodings of AND (predicates).
- The description of AND (predicates) gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>Encoding</th>
<th>MOV &lt;Pd&gt;.B, &lt;Pg&gt;/Z, &lt;Pn&gt;.B</th>
</tr>
</thead>
</table>

is equivalent to and is the preferred disassembly when \( S == '0' \) && \( Pn == Pm \).

**Assembler symbols**

- \(<Pd>\) Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- \(<Pg>\) Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- \(<Pn>\) Is the name of the first source scalable predicate register, encoded in the "Pn" field.

**Operation**

The description of AND (predicates) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.363 MOV (scalar, predicated)

Move the general-purpose scalar source register to each active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

This instruction is an alias of the CPY (scalar) instruction. This means that:

- The encodings in this description are named to match the encodings of CPY (scalar).
- The description of CPY (scalar) gives the operational pseudocode for this instruction.

**Assembler symbols**

- `<Zd>`: Is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<T>`: Is the size specifier, encoded in the "size" field. It can have the following values:
  - `B` when size = 00
  - `H` when size = 01
  - `S` when size = 10
  - `D` when size = 11
- `<Pg>`: Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<R>`: Is a width specifier, encoded in the "size" field. It can have the following values:
  - `W` when size = 01
  - `w` when size = x0
  - `X` when size = 11
- `<n|SP>`: Is the number [0-30] of the general-purpose source register or the name SP (31), encoded in the "Rn" field.

**Operation**

The description of CPY (scalar) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
— The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.364 MOV (scalar, unpredicated)

Unconditionally broadcast the general-purpose scalar source register into each element of the destination vector. This instruction is unpredicated.

This instruction is an alias of the DUP (scalar) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (scalar).
- The description of DUP (scalar) gives the operational pseudocode for this instruction.

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] | 5 4 | 0 |

### Assembler symbols

- `<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<V>` Is a width specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<n>` Is the number [0-31] of the source SIMD&FP register, encoded in the "Vn" field.

### Operation

The description of CPY (SIMD&FP scalar) gives the operational pseudocode for this instruction.

### Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.366  **MOV (SIMD&FP scalar, unpredicated)**

Unconditionally broadcast the SIMD&FP scalar into each element of the destination vector. This instruction is unpredicated.

This instruction is an alias of the DUP (indexed) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (indexed).
- The description of DUP (indexed) gives the operational pseudocode for this instruction.

### Encoding

\[
\text{MOV } <Zd>.<T>, <Zn>.<T>[<imm>]
\]

is equivalent to

\[
\text{DUP } <Zd>.<T>, <Zn>.<T>[<imm>]
\]

and is the preferred disassembly when \(\text{BitCount}(\text{imm2:tsz}) > 1\).

### Encoding

\[
\text{MOV } <Zd>.<T>, <V><n>
\]

is equivalent to

\[
\text{DUP } <Zd>.<T>, <Zn>.<T>[0]
\]

and is the preferred disassembly when \(\text{BitCount}(\text{imm2:tsz}) == 1\).

### Assembler symbols

- **<Zd>** Is the name of the destination scalable vector register, encoded in the "Zd" field.
- **<T>** Is the size specifier, encoded in the "tsz" field. It can have the following values:
  - B when tsz = xxxx1
  - H when tsz = xxx10
  - S when tsz = xx100
  - D when tsz = x1000
  - Q when tsz = 10000
  - The encoding tsz = 00000 is reserved.
- **<Zn>** Is the name of the source scalable vector register, encoded in the "Zn" field.
- **<imm>** Is the immediate index, in the range 0 to one less than the number of elements in 512 bits, encoded in "imm2:tsz".
- **<V>** Is a width specifier, encoded in the "tsz" field. It can have the following values:
  - B when tsz = xxxx1
  - H when tsz = xxx10
  - S when tsz = xx100
  - D when tsz = x1000
Q  when tsz = 10000
The encoding tsz = 00000 is reserved.

<n> Is the number [0-31] of the source SIMD&FP register, encoded in the "Zn" field.

Operation

The description of DUP (indexed) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C8.2.367   MOV (vector, predicated)

Move elements from the source vector to the corresponding elements of the destination vector. Inactive elements in
the destination vector register remain unmodified.

This instruction is an alias of the SEL (vectors) instruction. This means that:

- The encodings in this description are named to match the encodings of SEL (vectors).
- The description of SEL (vectors) gives the operational pseudocode for this instruction.

```
<table>
<thead>
<tr>

<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 0 0 0 1 0 1 size 1</td>
<td>Zm</td>
<td>1 1</td>
<td>Pv</td>
</tr>
</tbody>
</table>
```

**Encoding**

MOV <Zd>.<T>, <Pv>/M, <Zn>.<T>

is equivalent to

SEL <Zd>.<T>, <Pv>, <Zn>.<T>, <Zd>.<T>

and is the preferred disassembly when Zd == Zm.

**Assembler symbols**

- `<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Pv>` Is the name of the vector select predicate register, encoded in the "Pv" field.
- `<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.

**Operation**

The description of SEL (vectors) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.368 MOV (vector, unpredicated)

Move vector register. This instruction is unpredicated.

This instruction is an alias of the ORR (vectors, unpredicated) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (vectors, unpredicated).
- The description of ORR (vectors, unpredicated) gives the operational pseudocode for this instruction.

```
[31 30 29 28|27 26 25 24|23 22 21 20] | 16|15 14 13 12|11 10 9 | | 5 4 | | 0 |
0 0 0 0 0 1 0 0 0 1 1 | Zm 0 0 1 1 0 0 | Zn | Zd
```

**Encoding**

MOV <Zd>.D, <Zn>.D

is equivalent to

ORR <Zd>.D, <Zn>.D, <Zn>.D

and is the preferred disassembly when Zn == Zm.

**Assembler symbols**

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

**Operation**

The description of ORR (vectors, unpredicated) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.369   MOVPRFX (predicated)

The predicated MOVPRFX instruction is a hint to hardware that the instruction may be combined with the destructive instruction which follows it in program order to create a single constructive operation. Since it is a hint it is also permitted to be implemented as a discrete vector copy, and the result of executing the pair of instructions with or without combining is identical. The choice of combined versus discrete operation may vary dynamically.

Unless the combination of a constructive operation with merging predication is specifically required, it is strongly recommended that for performance reasons software should prefer to use the zeroing form of predicated MOVPRFX or the unpredicated MOVPRFX instruction.

Although the operation of the instruction is defined as a simple predicated vector copy, it is required that the prefixed instruction at PC+4 must be an SVE destructive binary or ternary instruction encoding, or a unary operation with merging predication, but excluding other MOVPRFX instructions. The prefixed instruction must specify the same predicate register, and have the same maximum element size (ignoring a fixed 64-bit "wide vector" operand), and the same destination vector as the MOVPRFX instruction. The prefixed instruction must not use the destination register in any other operand position, even if they have different names but refer to the same architectural register state. Any other use is UNPREDICTABLE.

Encoding

MOVPRFX <Zd>.<T>, <Pg>/<ZM>, <Zn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);
boolean merging = (M == '1');

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:
    B when size = 00
    H when size = 01
    S when size = 10
    D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<ZM> Is the predication qualifier, encoded in the "M" field. It can have the following values:
    Z when M = 0
    M when M = 1

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.
Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand1 = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(VL) dest = Z[d, VL];
bits(VL) result;

for e = 0 to elements-1
  if Elem[mask, e, esize] == '1' then
    bits(esize) element = Elem[operand1, e, esize];
    Elem[result, e, esize] = element;
  elsif merging then
    Elem[result, e, esize] = Elem[dest, e, esize];
  else
    Elem[result, e, esize] = Zeros(esize);

Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.370 MOVPRFX (unpredicated)

The unpredicated MOVPRFX instruction is a hint to hardware that the instruction may be combined with the destructive instruction which follows it in program order to create a single constructive operation. Since it is a hint it is also permitted to be implemented as a discrete vector copy, and the result of executing the pair of instructions with or without combining is identical. The choice of combined versus discrete operation may vary dynamically.

Although the operation of the instruction is defined as a simple unpredicated vector copy, it is required that the prefixed instruction at PC+4 must be an SVE destructive binary or ternary instruction encoding, or a unary operation with merging predication, but excluding other MOVPRFX instructions. The prefixed instruction must specify the same destination vector as the MOVPRFX instruction. The prefixed instruction must not use the destination register in any other operand position, even if they have different names but refer to the same architectural register state. Any other use is UNPREDICTABLE.

Encoding

MOVPRFX <Zd>, <Zn>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer n = UInt(Zn);
integer d = UInt(Zd);

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(VL) result = Z[n, VL];
Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.371 MOVS (predicated)

Read active elements from the source predicate and place in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is an alias of the ANDS instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS.
- The description of ANDS gives the operational pseudocode for this instruction.

**Encoding**

MOVS <Pd>.B, <Pg>/Z, <Pn>.B

is equivalent to

and is the preferred disassembly when $S == '1'$ && $Pn == Pm$.

**Assembler symbols**

- `<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- `<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- `<Pn>` Is the name of the first source scalable predicate register, encoded in the "Pn" field.

**Operation**

The description of ANDS gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C8.2.372   **MOVS (unpredicated)**

Read all elements from the source predicate and place in the destination predicate. This instruction is unpredicated. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is an alias of the **ORRS** instruction. This means that:

- The encodings in this description are named to match the encodings of **ORRS**.
- The description of **ORRS** gives the operational pseudocode for this instruction.

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
**C8.2.374 MUL (immediate)**

Multiply by an immediate each element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a signed 8-bit value in the range -128 to +127, inclusive. This instruction is unpredicated.

```
[31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12] | 5 4 | 0 |
0 0 1 0 0 1 0 1 1 1 0 0 0 0 1 1 0 1 0 | imm8 | Zdn |
```

**Encoding**

MUL <Zdn>,<T>, <Zdn>,<T>, #<imm>

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = SInt(imm8);
```

**Assembler symbols**

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<imm>` Is the signed immediate operand, in the range -128 to 127, encoded in the "imm8" field.

**Operation**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
    integer element1 = SInt(Elem[operand1, e, esize]);
    Elem[result, e, esize] = (element1 * imm)<esize-1:0>;
Z[dn, VL] = result;
```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.375 MUL (indexed)

Multiply all integer elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The results are placed in the corresponding elements of the destination vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element. This instruction is unpredicated.

16-bit

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 16|15 14 13 12|11 10 9 | 5 4 | 0 |

for e = 0 to elements-1
    if Elem[mask, e, esize] == '1'
        integer element = SInt(Elem[operand, e, esize]);
        element = -element;
        Elem[result, e, esize] = element<esize-1:0>;
Z[d, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
This instruction compares each active 8-bit or 16-bit character in the first source vector with all of the characters in the corresponding 128-bit segment of the second source vector. Where the first source element detects no matching characters in the second segment it places true in the corresponding element of the destination predicate, otherwise false. Inactive elements in the destination predicate register are set to zero. Sets the \texttt{FIRST (N)}, \texttt{NONE (Z)}, \texttt{!LAST (C)} condition flags based on the predicate result, and the V flag to zero.

This instruction is illegal when executed in Streaming SVE mode, unless \texttt{FEAT\_SME\_FA64} is implemented and enabled at the current Exception level.

        ElemP[result, e, esize] = NOT(element1 OR element2);
    else
        ElemP[result, e, esize] = '0';
if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d, PL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.
C8.2.384  NORS

Bitwise NOR active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

Encoding

Decode for this encoding
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = TRUE;

Assembler symbols
<Pd> Is the name of the destination scalable predicate register, encoded in the "Pd" field.
<Pg> Is the name of the governing scalable predicate register, encoded in the "Pg" field.
<Pn> Is the name of the first source scalable predicate register, encoded in the "Pn" field.
<Pm> Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(PL) operand1 = P[n, PL];

Encoding

NOT <Zd>.<T>, <Pg>/M, <Zn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 <<< UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);

Assembler symbols

<Zd>    Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T>    Is the size specifier, encoded in the "size" field. It can have the following values:
    B    when size = 00
    H    when size = 01
    S    when size = 10
    D    when size = 11
<Pg>    Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn>    Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(VL) result = Z[d, VL];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = NOT element;

Z[d, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.387 NOTS

Bitwise invert each active element of the source predicate, and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is an alias of the EORS instruction. This means that:

- The encodings in this description are named to match the encodings of EORS.
- The description of EORS gives the operational pseudocode for this instruction.

**Encoding**

NOTS \(<Pd>.B, <Pg>/Z, <Pn>.B\)

is equivalent to

EORS \(<Pd>.B, <Pg>/Z, <Pn>.B, <Pg>.B\)

and is the preferred disassembly when \(Pm == Pg\).

**Assembler symbols**

- \(<Pd>\) Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- \(<Pg>\) Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- \(<Pn>\) Is the name of the first source scalable predicate register, encoded in the "Pn" field.

**Operation**

The description of EORS gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C8.2.388 ORN (immediate)

Bitwise inclusive OR an inverted immediate with each 64-bit element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This instruction is a pseudo-instruction of the ORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

<td>0 0 0 0 0</td>
<td>imm13</td>
<td>Zdn</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Encoding**

ORN `<Zdn>.<T>, <Zdn>.<T>, #<const>`

is equivalent to

ORR `<Zdn>.<T>, <Zdn>.<T>, #(-<const> - 1)`

and is never the preferred disassembly.

**Assembler symbols**

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "imm13<12>:imm13<5:0>" field. It can have the following values:
  - S when `imm13<12> = 0, imm13<5:0> = 0xxxxx`
  - H when `imm13<12> = 0, imm13<5:0> = 10xxxx`
  - B when `imm13<12> = 0, imm13<5:0> = 110xxx`
  - B when `imm13<12> = 0, imm13<5:0> = 1110xx`
  - B when `imm13<12> = 0, imm13<5:0> = 11110x`
  - D when `imm13<12> = 1, imm13<5:0> = xxxxxx`

The following encodings are reserved:

- `imm13<12> = 0, imm13<5:0> = 111110`
- `imm13<12> = 0, imm13<5:0> = 111111`

- `<const>` Is a 64, 32, 16 or 8-bit bitmask consisting of replicated 2, 4, 8, 16, 32 or 64 bit fields, each field containing a rotated run of non-zero bits, encoded in the "imm13" field.

**Operation**

The description of ORR (immediate) gives the operational pseudocode for this instruction.
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.389  ORN (predicates)

Bitwise inclusive OR inverted active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Does not set the condition flags.

if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
    P[d, PL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.
C8.2.393 ORR (vectors, predicated)

Bitwise inclusive OR active elements of the second source vector with corresponding elements of the first source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12| 10  9 |  5  4 |  0 ]
0 0 0 0 0 1 0 0 size 0 1 1 0 0 0 0 0 Pg Zm Zdn
```

Encoding

ORR <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand1 = Z[dn, VL];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m, VL] else Zeros(VL);
bits(VL) result;
for e = 0 to elements-1
  bits(esize) element1 = Elem[operand1, e, esize];
  bits(esize) element2 = Elem[operand2, e, esize];
  if Elem[mask, e, esize] == '1' then
    Elem[result, e, esize] = element1 OR element2;
  else
    Elem[result, e, esize] = Elem[operand1, e, esize];
Z[dn, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.394  ORR (vectors, unpredicated)

Bitwise inclusive OR all elements of the second source vector with corresponding elements of the first source vector and place the first in the corresponding elements of the destination vector. This instruction is unpredicated.

This instruction is used by the alias MOV (vector, unpredicated). See Alias conditions for details of when each alias is preferred.

</thead>
<tbody>
<tr>
<td>MOV (vector, unpredicated) Zn == Zm</td>
</tr>
</tbody>
</table>

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
Z[d, VL] = operand1 OR operand2;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C8.2.395  ORRS

Bitwise inclusive OR active elements of the second source predicate with corresponding elements of the first source predicate and place the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is used by the alias MOVS (unpredicated). See *Alias conditions* for details of when each alias is preferred.

```
Encoding

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
boolean setflags = TRUE;
```

  ElemP(result, e, esize) = element1 OR element2;
else
  ElemP(result, e, esize) = '0';

if setflags then
  PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[d, PL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C8.2.396   ORV

Bitwise inclusive OR horizontally across all lanes of a vector, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as zero.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12| 10 9 |  5 4 |  0 |
| 0  0  0  0 | 0  1  1  0 | 0  0  0  1 | Pg   | Zn   | Vd   |
```

**Encoding**

ORV <V><d>, <Pg>, <Zn><T>

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
```

**Assembler symbols**

<V> Is a width specifier, encoded in the "size" field. It can have the following values:
- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<d> Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:
- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

**Operation**

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(esize) result = Zeros(esize);

for e = 0 to elements-1
   if Elem[mask, e, esize] == '1'
      result = result OR Elem[operand, e, esize];
V[d, esize] = result;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.397 PFALSE

Set all elements in the destination predicate to false.

Encoding

PFALSE <Pd>.B

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer d = UInt(Pd);

Assembler symbols

<Pd> Is the name of the destination scalable predicate register, encoded in the "Pd" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
P[d, PL] = Zeros(PL);

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.398 PFIRST

Sets the first active element in the destination predicate to true, otherwise elements from the source predicate are passed through unchanged. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 8 | 5 4 3 0 ]
0 0 1 0 0 1 0 1 0 1 0 1 0 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 Pd Pg Pdn
```

**Encoding**

PFIRST <Pd>.B, <Pg>, <Pd>.B

**Decode for this encoding**

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer dn = UInt(Pdn);

**Assembler symbols**

<Pd> Is the name of the source and destination scalable predicate register, encoded in the "Pd" field.
<Pg> Is the name of the governing scalable predicate register, encoded in the "Pg" field.

**Operation**

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(PL) result = P[dn, PL];
integer first = -1;

for e = 0 to elements-1
  if ElemP[mask, e, esize] == '1' && first == -1 then
    first = e;
  if first >= 0 then
    ElemP[result, first, esize] = '1';
PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[dn, PL] = result;

**Operational information**

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C8.2.399  PMUL

Polynomial multiply over \([0, 1]\) all elements of the second source vector to corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. This instruction is unpredicated.

```
<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20</th>
<th>16 15 14 13 12 11 10 9 8 7 6 5 4</th>

### Operational information

If `FEAT_SVE2` is implemented or `FEAT_SME` is implemented, then when `PSTATE.DIT` is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.402   PNEXT

An instruction used to construct a loop which iterates over all true elements in the vector select predicate register. If all elements in the first source predicate register are false it determines the first true element in the vector select predicate register, otherwise it determines the next true element in the vector select predicate register that follows the last true element in the first source predicate register. All elements of the destination predicate register are set to false, except the element corresponding to the determined vector select element, if any, which is set to true. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

Encoding

PNEXT <Pdn>.<T>, <Pv>, <Pdn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer v = UInt(Pv);
integer dn = UInt(Pdn);

Assembler symbols

<Pdn> Is the name of the first source and destination scalable predicate register, encoded in the "Pdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |
| D | when size = 11 |

<Pv> Is the name of the vector select predicate register, encoded in the "Pv" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[v, PL];
bits(PL) operand = P[dn, PL];
bits(PL) result;
integer next = LastActiveElement(operand, esize) + 1;
while next < elements && (ElemP[mask, next, esize] == '0') do
next = next + 1;
result = Zeros(PL);
if next < elements then
ElemP[result, next, esize] = '1';
PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
P[dn, PL] = result;

**Operational information**

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.
C8.2.403 PRFB (scalar plus immediate)

Contiguous prefetch of byte elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The predicate may be used to suppress prefetches from unwanted addresses.

Encoding

PRFB <prfop>, <Pg>, [<Xn|SP>{, #<imm>, MUL VL}]

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Rn);
integer level = UInt(prfop<2:1>);
boolean stream = (prfop<0> == '1');
pref_hint = if prfop<3> == '0' then Prefetch_READ else Prefetch_WRITE;
integer scale = 0;
integer offset = SInt(imm6);

Assembler symbols

<prfop> Is the prefetch operation specifier, encoded in the "prfop" field. It can have the following values:

PLDL1KEEP when prfop = 0000
PLDL1STRM when prfop = 0001
PLDL2KEEP when prfop = 0010
PLDL2STRM when prfop = 0011
PLDL3KEEP when prfop = 0100

#uimm4 when prfop = x11x
PSTL1KEEP when prfop = 1000
PSTL1STRM when prfop = 1001
PSTL2KEEP when prfop = 1010
PSTL2STRM when prfop = 1011
PSTL3KEEP when prfop = 1100
PSTL3STRM when prfop = 1101

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the optional signed immediate vector offset, in the range -32 to 31, defaulting to 0, encoded in the "imm6" field.
Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bounds(PL) mask = P[g, PL];
bounds(64) base;

if AnyActiveElement(mask, esize) then
    base = if n == 31 then SP[] else X[n, 64];

for e = 0 to elements-1
    if ElemP[mask, e, esize] == '1' then
        integer eoff = (offset * elements) + e;
        bounds(64) addr = base + (eoff << scale);
        Hint_Prefetch(addr, pref_hint, level, stream);
C8.2.404   PRFB (scalar plus scalar)

Contiguous prefetch of byte elements from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element prefetch the index value is incremented, but the index register is not updated.

The predicate may be used to suppress prefetches from unwanted addresses.

<Pg>  Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xm>  Is the 64-bit name of the general-purpose offset register, encoded in the "Rm" field.
Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(64) base;
bits(64) offset;

if AnyActiveElement(mask, esize) then
    base = if n == 31 then SP[] else X[n, 64];
    offset = X[m, 64];

for e = 0 to elements-1
    if Elem[mask, e, esize] == '1' then
        integer eoff = UInt(offset) + e;
        bits(64) addr = base + (eoff << scale);
        Hint_Prefetch(addr, pref_hint, level, stream);
C8.2.405  **PRFB (scalar plus vector)**

Gather prefetch of bytes from the active memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally sign or zero-extended from 32 to 64 bits. Inactive addresses are not prefetched from memory.

The `<prfop>` symbol specifies the prefetch hint as a combination of three options: access type PLD for load or PST for store; target cache level L1, L2 or L3; temporality (KEEP for temporal or STRM for non-temporal).

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

**32-bit scaled offset**

```
[31 30 29 28 27 26 25 24 23 22 21 20] 16 15 14 13 12 10 9 | 5 4 3 0

Assembler symbols

<prfop>  Is the prefetch operation specifier, encoded in the "prfop" field. It can have the following values:

- PLDL1KEEP when prfop = 0000
- PLDL1STRM when prfop = 0001
- PLDL2KEEP when prfop = 0010
- PLDL2STRM when prfop = 0011
- PLDL3KEEP when prfop = 0100
- PLDL3STRM when prfop = 0101
- #uimm4 when prfop = x11x
- PSTL1KEEP when prfop = 1000
- PSTL1STRM when prfop = 1001
- PSTL2KEEP when prfop = 1010
- PSTL2STRM when prfop = 1011
- PSTL3KEEP when prfop = 1100
- PSTL3STRM when prfop = 1101

<Pg>  Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn>  Is the name of the base scalable vector register, encoded in the "Zn" field.

<imm>  Is the optional unsigned immediate byte offset, a multiple of 8 in the range 0 to 248, defaulting to 0, encoded in the "imm5" field.

Operation for all encodings

CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) base;
if AnyActiveElement(mask, esize) then
    base = Z[n, VL];
for e = 0 to elements-1
    if Elem[mask, e, esize] == '1' then
        bits(64) addr = ZeroExtend(Elem[base, e, esize], 64) + (offset << scale);
        Hint_Prefetch(addr, pref_hint, level, stream);
C8.2.411 PRFH (scalar plus immediate)

Contiguous prefetch of halfword elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The predicate may be used to suppress prefetches from unwanted addresses.

Encoding

PSTL1STRM when prfop = 1001
PSTL2KEEP when prfop = 1010
PSTL2STRM when prfop = 1011
PSTL3KEEP when prfop = 1100
PSTL3STRM when prfop = 1101

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Zm> Is the name of the offset scalable vector register, encoded in the "Zm" field.
<mod> Is the index extend and shift specifier, encoded in the "xs" field. It can have the following values:

- **UXTW** when \( xs = 0 \)
- **SXTW** when \( xs = 1 \)

### Operation for all encodings

```c
CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(64) base;
bits(VL) offset;

if AnyActiveElement(mask, esize) then
    base = if n == 31 then SP[] else X[n, 64];
    offset = Z[m, VL];

for e = 0 to elements-1
    if Elem[mask, e, esize] == '1' then
        integer off = Int(Elem[offset, e, esize]<offs_size-1:0>, offs_unsigned);
        bits(64) addr = base + (off << scale);
        Hint_Prefetch(addr, pref_hint, level, stream);
```
C8.2.418   PRFW (vector plus immediate)

Gather prefetch of words from the active memory addresses generated by a vector base plus immediate index. The index is a multiple of 4 in the range 0 to 124. Inactive addresses are not prefetched from memory.

The <prfop> symbol specifies the prefetch hint as a combination of three options: access type PLD for load or PST for store; target cache level L1, L2 or L3; temporality (KEEP for temporal or STRM for non-temporal).

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

if ElemP[operand2, element, esize] == '1' then
   result = operand1;
ext
   result = Zeros(PL);
P[d, PL] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.420  PTEST

Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate source register, and the V flag to zero.

\[
\begin{array}{cccccccccccccccc}
0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & \text{Pg} & 0 & \text{Pn} & 0 & 0 & 0 & 0 & 0 & 0 & S
\end{array}
\]

**Encoding**

PTEST <Pg>, <Pn>.B

**Decode for this encoding**

```plaintext
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
```

**Assembler symbols**

- `<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- `<Pn>` Is the name of the source scalable predicate register, encoded in the "Pn" field.

**Operation**

```plaintext
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(PL) mask = P[g, PL];
bits(PL) result = P[n, PL];
PSTATE.<N,Z,C,V> = PredTest(mask, result, esize);
```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the predicate register written by this instruction might be significantly delayed.
C8.2.421  PTRUE

Set elements of the destination predicate to true if the element number satisfies the named predicate constraint, or
to false otherwise. If the constraint specifies more elements than are available at the current vector length then all
elements of the destination predicate are set to false.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than
Undefined Instruction exception. Does not set the condition flags.

Encoding

PTRUE <Pd>.<T>{, <pattern>}

Decode for this encoding

D when size = 11

The encoding size = 00 is reserved.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

**Operation**

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result = Z[d, VL];
constant integer halfesize = esize DIV 2;
constant integer round_const = 1 << (halfesize - 1);
for e = 0 to elements-1
```
integer element1 = UInt(Elem[operand1, e, esize]);
integer element2 = UInt(Elem[operand2, e, esize]);
integer res = ((element1 + element2) + round_const) >> halfesize;
Elem[result, 2*e + 1, halfesize] = res<halfesize-1:0>;

Z[d, VL] = result;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.426  RAX1

Rotate each 64-bit element of the second source vector left by 1 and exclusive OR with the corresponding elements of the first source vector. The results are placed in the corresponding elements of the destination vector. This instruction is unpredicated.

ID_AA64ZFR0_EL1.SHA3 indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE2

(FEAT_SVE_SHA3)

Encoding

RAX1 <Zd>.D, <Zn>.D, <Zm>.D

Decode for this encoding

if !HaveSVE2SHA3() then UNDEFINED;
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);

Assembler symbols

<Zd>  Is the name of the destination scalable vector register, encoded in the "Zd" field.
<Zn>  Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm>  Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV 64;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
## C8.2.430 RDFFRS

Read the first-fault register (FFR) and place active elements in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

### Encoding

RDFFRS <Pd>.B, <Pg>/Z

### Decode for this encoding

```plaintext
if !HaveSVE() then UNDEFINED;
integer g = UInt(Pg);
integer d = UInt(Pd);
boolean setflags = TRUE;
```

### Assembler symbols

- `<Pd>` is the name of the destination scalable predicate register, encoded in the "Pd" field.
- `<Pg>` is the name of the governing scalable predicate register, encoded in the "Pg" field.

### Operation

```plaintext
CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(PL) mask = P[g, PL];
bits(PL) ffr = FFR[PL];
bits(PL) result = ffr AND mask;
if setflags then
    PSTATE.<N,Z,C,V> = PredTest(mask, result, 8);
P[d, PL] = result;
```

### Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.431   RDVL

Multiply the current vector register size in bytes by an immediate in the range -32 to 31 and place the result in the 64-bit destination general-purpose register.

<table>
<thead>
<tr>
<th>31 30 29 28</th>

RDVL <Xd>, #<imm>

**Decode for this encoding**
if !HaveSVE() && !HaveSME() then UNDEFINED;
integer d = UInt(Rd);
integer imm = SInt(imm6);

**Assembler symbols**

<Xd> Is the 64-bit name of the destination general-purpose register, encoded in the "Rd" field.

<imm> Is the signed immediate operand, in the range -32 to 31, encoded in the "imm6" field.

**Operation**
CheckSVEEnabled();
constant integer VL = CurrentVL;
integer len = imm * (VL DIV 8);
X[d, 64] = len<63:0>;

**Operational information**
If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.432   REV (predicate)

Reverse the order of all elements in the source predicate and place in the destination predicate. This instruction is unpredicated.

Encoding

REV <Pd>.<T>, <Pn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Pn);
integer d = UInt(Pd);

Assembler symbols

<Pd> Is the name of the destination scalable predicate register, encoded in the "Pd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:
  B when size = 00
  H when size = 01
  S when size = 10
  D when size = 11

<Pn> Is the name of the source scalable predicate register, encoded in the "Pn" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(PL) operand = P[n, PL];
bits(PL) result = Reverse(operand, esize DIV 8);
P[d, PL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.433  REV (vector)

Reverse the order of all elements in the source vector and place in the destination vector. This instruction is unpredicated.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9  | 5 4  | 0 |
| 0 0 0 0 0 0 1 0 1 | 1 1 1 0 0 0 0 0 1 1 1 0 | Zn | Zd |
```

**Encoding**

REV `<Zd>..<T>`, `<Zn>..<T>`

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer d = UInt(Zd);
```

**Assembler symbols**

`<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.

`<T>` Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

`<Zn>` Is the name of the source scalable vector register, encoded in the "Zn" field.

**Operation**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(VL) operand = Z[n, VL];
bits(VL) result = Reverse(operand, esize);
Z[d, VL] = result;
```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.434  REVB, REVH, REVW

Reverse the order of 8-bit bytes, 16-bit halfwords or 32-bit words within each active element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

**Byte**

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12] | 10 9  | 5 4 | 0 |
0 0 0 0 0 1 0 1 | size | 1 0 0 1 0 0 1 0 0 | Pg | Zn | Zd
```

**Encoding**

REVB <Zd>.<T>, <Pg>/M, <Zn>.<T>

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;

C8.2.437   RSHRNT

Shift each unsigned integer value in the source vector elements right by an immediate value, and place the rounded
results in the odd-numbered half-width destination elements, leaving the even-numbered elements unchanged. The
immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is
unpredicated.

Encoding

RSHRNT <Zd>.<T>, <Zn>.<Tb>, #<const>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
bz(t3) tsize = tszh:tszl;
integer esize;
case tsize of
  when '000' UNDEFINED;
  when '001' esize = 8;
  when '01x' esize = 16;
  when '1xx' esize = 32;
integer n = UInt(Zn);
integer d = UInt(Zd);
integer shift = (2 * esize) - UInt(tsize:imm3);

Assembler symbols

<Zd>   Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T>   Is the size specifier, encoded in the "tszh:tszl" field. It can have the following values:
  B   when tzh = 0, tszl = 01
  H   when tzh = 0, tszl = 1x
  S   when tzh = 1, tszl = xx
The encoding tzh = 0, tszl = 00 is reserved.

<Zn>   Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Tb>   Is the size specifier, encoded in the "tszh:tszl" field. It can have the following values:
  H   when tzh = 0, tszl = 01
  S   when tzh = 0, tszl = 1x
  D   when tzh = 1, tszl = xx
The encoding tzh = 0, tszl = 00 is reserved.

<const>   Is the immediate shift amount, in the range 1 to number of bits per element, encoded in "tsz:imm3".

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV (2 * esize);
bits(VL) operand = Z[n, VL];
bits(VL) result = Z[d, VL];
integer round_const = 1 << (shift-1);

for e = 0 to elements-1

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.447 SADDLB

Add the corresponding even-numbered signed elements of the first and second source vectors, and place the results in the overlapping double-width elements of the destination vector. This instruction is unpredicated.

```
[31 30 29 28|27 26 25 24|23 22 21 20]  16|15 14 13 12|11 10 9 | 5 4 | 0 |
  0 1 0 0 0 1 0 1 | size 0 | Zm 0 0 0 0 | 0 0 | Zn | Zd |
      S    U    T
```

**Encoding**

SADDLB <Zd>.<T>, <Zn>.<Tb>, <Zm>.<Tb>

**Decode for this encoding**

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
integer sel1 = 0;
integer sel2 = 0;
boolean unsigned = FALSE;
```

**Assembler symbols**

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10
- D when size = 11

The encoding size = 00 is reserved.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Tb> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 01
- H when size = 10
- S when size = 11

The encoding size = 00 is reserved.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

**Operation**

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, 2*e + sel1, esize DIV 2], unsigned);
```
integer element2 = Int(Elem[operand2, 2*e + sel2, esize DIV 2], unsigned);
integer res = element1 + element2;
Elem[result, e, esize] = res<esize-1:0>;

Z[d, VL] = result;

**Operational information**

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.450 SADDV

Signed add horizontally across all lanes of a vector, and place the result in the SIMD&FP scalar destination register. Narrow elements are first sign-extended to 64 bits. Inactive elements in the source vector are treated as zero.

Encoding

SADDV <Dd>, <Pg>, <Zn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '11' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);

Assembler symbols

<Dd> Is the 64-bit name of the destination SIMD&FP register, encoded in the "Vd" field.
<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00
H when size = 01
S when size = 10

The encoding size = 11 is reserved.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand = Z[n, VL];
integer sum = 0;

for e = 0 to elements-1
  if Elem[mask, e, esize] == '1' then
    integer element = SInt(Elem[operand, e, esize]);
    sum = sum + element;

V[d, 64] = sum<63:0>;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.
C8.2.451 SADDWB

Add the even-numbered signed elements of the second source vector to the overlapping double-width elements of the first source vector and place the results in the corresponding double-width elements of the destination vector. This instruction is unpredicated.

Encoding
SADDWB <Zd>,<T>, <Zn>,<T>, <Zm>,<Tb>

Decode for this encoding
if !HaveSVE2() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);

end;
```
The instruction might be immediately preceded in program order by a MOVPREFIX instruction. The MOVPREFIX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPREFIX and this instruction is UNPREDICTABLE:

- The MOVPREFIX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPREFIX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.459  SDOT (indexed)

The signed integer indexed dot product instruction computes the dot product of a group of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the first source vector multiplied by a group of four signed 8-bit or 16-bit integer values in an indexed 32-bit or 64-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit or 64-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. This instruction is unpredicated.

32-bit

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 16 15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 1 0 0 0 1 0 0 1 0 1 1 2 | Zm 0 0 0 0 0 0 | Zn | Zda |
```

Encoding

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 32;
integer index = UInt(i2);
integer n = UInt(Zn);
integer m = UInt(Zm);

```

64-bit

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 16 15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 1 0 0 0 1 0 0 1 0 1 1 1 1 | Zm 0 0 0 0 0 0 | Zn | Zda |
```

Encoding

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 64;
integer index = UInt(i1);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
```

Assembler symbols

<Zda> Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.
<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> For the 32-bit variant: is the name of the second source scalable vector register Z0-Z7, encoded in the "Zm" field.
For the 64-bit variant: is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.

<imm> For the 32-bit variant: is the immediate index of a 32-bit group of four 8-bit values within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field.
For the 64-bit variant: is the immediate index of a 64-bit group of four 16-bit values within each 128-bit vector segment, in the range 0 to 1, encoded in the "i1" field.

### Operation for all encodings

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant integer eltspersegment = 128 DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) operand3 = Z[da, VL];
bits(VL) result;

for e = 0 to elements-1

    integer element2 = SInt(Elem[operand2, 4 * s + i, esize DIV 4]);
    res = res + element1 * element2;
  Elem[result, e, esize] = res;

Z[da, VL] = result;

### Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.460 SDOT (vectors)

The signed integer dot product instruction computes the dot product of a group of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the first source vector multiplied by a group of four signed 8-bit or 16-bit integer values in the corresponding 32-bit or 64-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit or 64-bit element of the destination vector.

This instruction is unpredicated.

```
[31 30 29 28 27 26 25 24 23 22 21 20] 16 15 14 13 12 11 10 9  5  4  0
0 1 0 0 0 1 0 0  size 0  Zm  0 0 0 0 0 0  Zn  Zda
U
```

Encoding

```
SDOT <Zda>.<T>, <Zn>.<Tb>, <Zm>.<Tb>
```

Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size IN {'0x'} then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
```

Assembler symbols

<Zda> Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

<T> Is the size specifier, encoded in the "size<0>" field. It can have the following values:

S when size<0> = 0
D when size<0> = 1

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Tb> Is the size specifier, encoded in the "size<0>" field. It can have the following values:

B when size<0> = 0
H when size<0> = 1

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) operand3 = Z[da, VL];
bits(VL) result;
for e = 0 to elements-1
    bits(esize) res = Elem[operand3, e, esize];
    for i = 0 to 3
        integer element1 = SInt(Elem[operand1, 4 * e + i, esize DIV 4]);
        integer element2 = SInt(Elem[operand2, 4 * e + i, esize DIV 4]);
```
res = res + element1 * element2;
Elem[result, e, esize] = res;

Z[da, VL] = result;

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.461 SEL (predicates)

Read active elements from the first source predicate and inactive elements from the second source predicate and place in the corresponding elements of the destination predicate. Does not set the condition flags.

This instruction is used by the alias MOV (predicate, predicated, merging). See *Alias conditions* for details of when each alias is preferred.

Encoding

SEL <Pd>.B, <Pg>, <Pn>.B, <Pm>.B

Decode for this encoding

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8;
integer g = UInt(Pg);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
```

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (predicate, predicated, merging)</td>
<td>Pd == Pm</td>
</tr>
</tbody>
</table>

Assembler symbols

- `<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- `<Pg>` Is the name of the governing scalable predicate register, encoded in the "Pg" field.
- `<Pn>` Is the name of the first source scalable predicate register, encoded in the "Pn" field.
- `<Pm>` Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(PL) operand1 = P[n, PL];
bits(PL) operand2 = P[m, PL];
bits(PL) result;
for e = 0 to elements-1
    bit element1 = ElemP(operand1, e, esize);
    bit element2 = ElemP(operand2, e, esize);
    if ElemP[mask, e, esize] == '1' then
        ElemP[result, e, esize] = element1;
    else
```

```
```
\texttt{ElemP[result, e, esize] = element2;}

\texttt{P[d, PL] = result;}

\textbf{Operational information}

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.462 SEL (vectors)

Select elements from the first source vector where the corresponding vector select predicate element is true, and from the second source vector where the predicate element is false, placing them in the corresponding elements of the destination vector.

This instruction is used by the alias MOV (vector, predicated). See Alias conditions for details of when each alias is preferred.

Encoding

SEL <Zd>.<T>, <Pv>, <Zn>.<T>, <Zm>.<T>

Decode for this encoding

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer v = UInt(Pv);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
```

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (vector, predicated)</td>
<td>Zd == Zm</td>
</tr>
</tbody>
</table>

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Character</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>size = 00</td>
</tr>
<tr>
<td>H</td>
<td>size = 01</td>
</tr>
<tr>
<td>S</td>
<td>size = 10</td>
</tr>
<tr>
<td>D</td>
<td>size = 11</td>
</tr>
</tbody>
</table>

<Pv> Is the name of the vector select predicate register, encoded in the "Pv" field.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```c
CheckSVEEnabled();
classic integer VL = CurrentVL;
classic integer PL = VL DIV 8;
classic integer elements = VL DIV esize;
bits(PL) mask = P[v, PL];
```
bits(VL) operand1 = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(VL) operand2 = if AnyActiveElement(NOT(mask), esize) then Z[m, VL] else Zeros(VL);
bits(VL) result;

for e = 0 to elements-1
  if ElemP[mask, e, esize] == '1' then
    Elem[result, e, esize] = Elem[operand1, e, esize];
  else
    Elem[result, e, esize] = Elem[operand2, e, esize];

Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.463  SETFFR

Initialise the first-fault register (FFR) to all true prior to a sequence of first-fault or non-fault loads. This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

```
[31 30 29 28][27 26 25 24][23 22 21 20][19 18 17 16][15 14 13 12][11 10 9 8][7 6 5 4][3 2 1 0]

  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.465 SHRNB

Shift each unsigned integer value in the source vector elements right by an immediate value, and place the truncated results in the even-numbered half-width destination elements, while setting the odd-numbered elements to zero. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

Encoding

SHRNB <Zd>.<T>, <Zn>.<Tb>, #<const>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
bits(3) tsize = tszh:tszl;
integer esize;
case tsize of
  when '000' UNDEFINED;
  when '001' esize = 8;

  — The values of the NZCV flags.
C8.2.470  SM4E

The SM4E instruction reads 16 bytes of input data from each 128-bit segment of the first source vector, together with four iterations of 32-bit round keys from the corresponding 128-bit segments of the second source vector. Each block of data is encrypted by four rounds in accordance with the SM4 standard, and destructively placed in the corresponding segments of the first source vector. This instruction is unpredicated.

ID_AA64ZFR0_EL1.SM4 indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE2

(FEAT_SVE_SM4)

Encoding

| SM4E | <Zdn>.S, <Zdn>.S, <Zm>.S |

- The MOVPRFX instruction must be unpredicated.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.488   SMMLA

The signed integer matrix multiply-accumulate instruction multiplies the 2×8 matrix of signed 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of signed 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.490   SMULH (unpredicated)

Widening multiply signed integer values of all elements of the first source vector by corresponding elements of the second source vector and place the high half of the result in the corresponding elements of the destination vector. This instruction is unpredicated.

Encoding

SMULH <Zd>.<T>, <Zn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
boolean unsigned = FALSE;

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00
H when size = 01
S when size = 10
D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;
for e = 0 to elements-1
    integer element1 = Int(Elem[operand1, e, esize], unsigned);
    integer element2 = Int(Elem[operand2, e, esize], unsigned);
    integer product = (element1 * element2) >> esize;
    Elem[result, e, esize] = product<esize-1:0>;
Z[d, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.491 SMULLB (indexed)

Multiply the even-numbered signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment, and place the results in the overlapping double-width elements of the destination vector register.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 2 or 3 bits depending on the size of the element.

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.497 SQADD (immediate)

Signed saturating add of an unsigned immediate to each element of the source vector, and destructively place the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's signed integer range \(-2^{(N-1)}\) to \((2^{(N-1)})-1\). This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

Encoding

SQADD <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}

Decode for this encoding

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
boolean unsigned = FALSE;
```

Assembler symbols

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size == 00
  - H when size == 01
  - S when size == 10
  - D when size == 11
- `<imm>` Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when sh == 0
  - LSL #8 when sh == 1

Operation

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
```
for e = 0 to elements-1

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is **UNPREDICTABLE**:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.499  SQADD (vectors, unpredicated)

Signed saturating add all elements of the second source vector to corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. Each result element is saturated to the N-bit element's signed integer range $-2^{{(N-1)}}$ to $(2^{{(N-1)}})-1$. This instruction is unpredicated.

Encoding

SQADD <Zd>.<T>, <Zn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = $8 <<$UInt(size);
integer n = $UInt(Zn);
integer m = $UInt(Zm);
integer d = $UInt(Zd);
boolean unsigned = FALSE;

Assembler symbols

<Zd>  Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T>  Is the size specifier, encoded in the "size" field. It can have the following values:
  B  when size = 00
  H  when size = 01
  S  when size = 10
  D  when size = 11

<Zn>  Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm>  Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, e, esize], unsigned);
  integer element2 = Int(Elem[operand2, e, esize], unsigned);
  (Elem[result, e, esize], -) = SatQ(element1 + element2, esize, unsigned);

Z[d, VL] = result;
C8.2.500 SQCADD

Add the real and imaginary components of the integral complex numbers from the first source vector to the complex numbers from the second source vector which have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±i beforehand. Destructively place the results in the corresponding elements of the first source vector. Each result element is saturated to the N-bit element’s signed integer range -2(N-1) to (2(N-1))-1. This instruction is unpredicated.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.501  SQDECB

Determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

boolean unsigned = FALSE;
integer ssize = 64;

Assembler symbols

<Xdn> Is the 64-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.
<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:

B when size = 00
H when size = 01
S when size = 10
D when size = 11
Is the 32-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.

**Operation for all encodings**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(ssize) operand1 = X[dn, ssize];
bits(PL) operand2 = P[m, PL];
bits(ssize) result;
integer count = 0;

for e = 0 to elements-1
  if ElemP[operand2, e, esize] == '1' then
    count = count + 1;

integer element = Int(operand1, unsigned);
(result, -) = SatQ(element - count, ssize, unsigned);
X[dn, 64] = Extend(result, 64, unsigned);
```

**Operational information**

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.
C8.2.507   SQDECP (vector)

Counts the number of true elements in the source predicate and then uses the result to decrement all destination
vector elements. The results are saturated to the element signed integer range.

The predicate size specifier may be omitted in assembler source code, but this is deprecated and will be prohibited
in a future release of the architecture.

Encoding

SQDECP <Zdn>.<T>, <Pm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = $ << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Zdn);
boolean unsigned = FALSE;

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10
D when size = 11

The encoding size = 00 is reserved.

<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.

Operation

CheckSVEEnabled();
const integer VL = CurrentVL;
const integer PL = VL DIV 8;
const integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(PL) operand2 = P[m, PL];
bits(VL) result;
integer count = 0;
for e = 0 to elements-1
  if Elem[operand2, e, esize] == '1' then
    count = count + 1;

  integer element = Int(Elem[operand1, e, esize], unsigned);
  (Elem[result, e, esize], -) = SatQ(element - count, esize, unsigned);
Z[dn, VL] = result;
Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.508  SQDECW (scalar)

Determines the number of active 32-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.510   SQDMLALB (indexed)

Multiply then double the even-numbered signed elements within each 128-bit segment of the first source vector and
specified signed element in the corresponding second source vector segment. Each intermediate value is saturated
to the double-width N-bit value's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. Then destructively add to the overlapping
double-width elements of the addend and destination vector. Each destination element is saturated to the
double-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$.

The elements within the second source vector are specified using an immediate index which selects the same
element position within each 128-bit vector segment. The index range is from 0 to one less than the number of
elements per 128-bit segment, encoded in 2 or 3 bits depending on the size of the element.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.521   SQDMULH (vectors)

Multiply then double the corresponding signed elements of the first and second source vectors, and place the most
significant half of the results in the corresponding elements of the destination vector register. Each result element is
saturated to the N-bit element's signed integer range \(-2^{(N-1)} - 1\). This instruction is unpredicated.

```
integer res = 2 * element1 * element2;
Elem[result, e, esize] = SignedSat(res, esize);

Z[d, VL] = result;
C8.2.526   SQINCB

Determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the source general-purpose register’s signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

#uimm5 when pattern = 1xx00
MUL4 when pattern = 11101
MUL3 when pattern = 11110
ALL when pattern = 11111

<imm> Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer count = DecodePredCount(pat, esize);
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, e, esize], unsigned);
  (Elem[result, e, esize], -) = SatQ(element1 + (count + imm), esize, unsigned);
Z[dn, VL] = result;

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.529   SQINCH (scalar)

Determines the number of active 16-bit elements implied by the named predicate constraint, multiplies that by an
immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is
saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then
sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than
Undefined Instruction exception.

MUL3 when pattern = 11110
ALL when pattern = 11111

<imm> Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer count = DecodePredCount(pat, esize);
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, e, esize], unsigned);
  (Elem[result, e, esize], -) = SatQ(element1 + (count * imm), esize, unsigned);
Z[dn, VL] = result;

Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.535 SQNEG

Negate the signed integer value in each active element of the source vector, and place the results in the corresponding elements of the destination vector. Each result element is saturated to the N-bit element’s signed integer range \(-2^{(N-1)}\) to \((2^{(N-1)})-1\). Inactive elements in the destination vector register remain unmodified.

Encoding

SQNEG <Zd>.<T>, <Pg>/M, <Zn>.<T>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Zd);

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:
    B when size = 00
    H when size = 01
    S when size = 10
    D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(VL) result = Z[d, VL];
for e = 0 to elements-1
    if Elem[mask, e, esize] == '1' then
        integer element = SInt(Elem[operand, e, esize]);
        element = -element;
        Elem[result, e, esize] = SignedSat(element, esize);
Z[d, VL] = result;
Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.536  SQRDCMLAH (indexed)

Multiply without saturation the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding second source vector segment rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

Then double and add the products to the corresponding components of the complex numbers in the addend vector. Destructively place the most significant rounded half of the results in the corresponding elements of the addend vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.537 SQRDCMLAH (vectors)

Multiply without saturation the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in the first source vector by the corresponding complex number in the second source vector rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

Then double and add the products to the corresponding components of the complex numbers in the addend vector. Destructively place the most significant rounded half of the results in the corresponding elements of the addend vector. Each result element is saturated to the N-bit element's signed integer range \(-2^{(N-1)}\) to \((2^{(N-1)})-1\). This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

## Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.538  SQRDMLAH (indexed)

Multiply then double all signed elements within each 128-bit segment of the first source vector and the specified signed element of the corresponding second source vector segment, and destructively add the rounded high half of each result to the corresponding elements of the addend and destination vector. Each destination element is saturated to the N-bit element's signed integer range \(-2^{(N-1)}\) to \((2^{(N-1)})-1\).

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 3 bits depending on the size of the element.

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.571  SRSRA

Shift right by immediate each signed element of the source vector, preserving the sign bit, and add the rounded
intermediate result destructively to the corresponding elements of the addend vector. The immediate shift amount
is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
D when size = 11
The encoding size = 00 is reserved.

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.
<Tb> Is the size specifier, encoded in the "size" field. It can have the following values:
B when size = 01
H when size = 10
S when size = 11
The encoding size = 00 is reserved.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = SInt(Elem[operand1, e, esize]);
  integer element2 = SInt(Elem[operand2, 2*e + 1, esize DIV 2]);
\[ \text{Elem}[\text{result}, e, \text{esize}] = (\text{element1} - \text{element2})\text{<esize-1:0>}; \]

\[ Z[d, VL] = \text{result}; \]

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.581  ST1B (scalar plus immediate)

Contiguous store of bytes from elements of a vector register to the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements are not written to memory.

Encoding

\[
\text{ST1B \{ <Zt>.<T>, <Pg>, [<Xn|SP>{, #<imm>, MUL VL}] \}
\]

Decode for this encoding

\[
\text{if !HaveSVE() \&\& !HaveSME() then UNDEFINED;} \\

```
C8.2.588   ST1D (vector plus immediate)

Scatter store of doublewords from the active elements of a vector register to the memory addresses generated by a vector base plus immediate index. The index is a multiple of 8 in the range 0 to 248. Inactive elements are not written to memory.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Encoding

ST1D {<Zt>.D}, <Pg>, [<Zn>.D{, #<imm>}]

Decode for this encoding

if !HaveSVE() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Zn);
integer g = UInt(Pg);
constant integer esize = 64;
constant integer msize = 64;
integer offset = UInt(imm5);

Assembler symbols

<Zt> Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zn> Is the name of the base scalable vector register, encoded in the "Zn" field.
<imm> Is the optional unsigned immediate byte offset, a multiple of 8 in the range 0 to 248, defaulting to 0, encoded in the "imm5" field.

Operation

CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];

### Assembler symbols

- `<Zt>` Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
- `<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Zm>` Is the name of the offset scalable vector register, encoded in the "Zm" field.
<mod> Is the index extend and shift specifier, encoded in the "xs" field. It can have the following values:

- **UXTW** when `xs = 0`
- **SXTW** when `xs = 1`

### Operation for all encodings

```c
CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(64) base;
bits(PL) mask = P[g, PL];
bits(VL) offset;
bits(VL) src;
constant integer mbytes = msize DIV 8;

            bits(64) addr = base + (off << scale);
            Mem[addr, mbytes, AccType_SVE] = Elem[src, e, esize]<msize-1:0>;
```
C8.2.596   ST1W (vector plus immediate)

Scatter store of words from the active elements of a vector register to the memory addresses generated by a vector base plus immediate index. The index is a multiple of 4 in the range 0 to 124. Inactive elements are not written to memory.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

C8.2.620   ST4W (scalar plus scalar)

Contiguous store four-word structures, each from the same element number in four vector registers to the memory address generated by a 64-bit scalar base and a 64-bit scalar index register scaled by the element size (LSL option) and added to the base address. After each structure access the index value is incremented by four. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive words in memory which make up each structure. Inactive structures are not written to memory.

Encoding

ST4W { <Zt1>.S, <Zt2>.S, <Zt3>.S, <Zt4>.S }, <Pg>, [<Xn|SP>, <Xm>, LSL #2]

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;

### C8.2.621  STNT1B (scalar plus immediate)

Contiguous store non-temporal of bytes from elements of a vector register to the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

![Hexadecimal and binary representation](image)

**Encoding**

STNT1B { <Zt>.B }, <Pg>, [<Xn|SP>{, #<imm>, MUL VL}]

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
n = UInt(Rn);
g = UInt(Pg);
offset = SInt(imm4);
```

**Assembler symbols**

- `<Zt>`: Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
- `<Pg>`: Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<imm>`: Is the optional signed immediate vector offset, in the range -8 to 7, defaulting to 0, encoded in the "imm4" field.

**Operation**

```c
CheckSVEEnabled();
VL = CurrentVL;
PL = VL DIV 8;
elements = (VL DIV esize);
mask = P[g, PL];
if HaveMTEExt() then SetTagCheckedInstruction(n != 31);
if !AnyActiveElement(mask, esize) then
    CheckSPAlignment();
else
    if n == 31 then CheckSPAlignment();
    base = if n == 31 then SP[] else X[n, 64];
    src = Z[t, VL];
for e = 0 to elements-1
```

---

**Note:**

- **Encoding:** The encoding provided includes fields for the scalable vector register `<Zt>`, the governing predicate register `<Pg>`, the base register `<Xn|SP>`, and an optional signed immediate vector offset `<imm>`. The encoding also includes a multiplication by the vector's in-memory size (MUL VL).
- **Operation:** The operation involves checking the enabled state for SVE and SVE, then decoding the instructions based on the provided fields. It includes checks for active elements, base and source addresses, and a loop to process each element.
if `Elem[mask, e, esize] == '1'` then
    integer eoff = (offset * elements) + e;
    bits(64) addr = base + eoff * mbytes;
    Mem[addr, mbytes, AccType_SVESTREAM] = Elem[src, e, esize];
C8.2.622   STNT1B (scalar plus scalar)

Contiguous store non-temporal of bytes from elements of a vector register to the memory address generated by a 
64-bit scalar base and scalar index which is added to the base address. After each element access the index value is 
incremented, but the index register is not updated. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

Encoding

C8.2.630  STNT1W (scalar plus immediate)

Contiguous store non-temporal of words from elements of a vector register to the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

Encoding

        bits(64) addr = ZeroExtend(Elem[base, e, esize], 64) + offset;
        Mem[addr, mbytes, AccType_SVESTREAM] = Elem[src, e, esize]<msize-1:0>;
```

C8.2.633 STR (predicate)

Store a predicate register to a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 which is multiplied by the current predicate register size in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, each containing 8 consecutive predicate bits in ascending element order, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then a general-purpose base register must be aligned to 2 bytes.

Encoding

STR <Pt>, [<Xn|SP>{, #<imm>, MUL VL}]

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Pt);
integer n = UInt(Rn);
integer imm = SInt(imm9h:imm9l);

Assembler symbols

<Pt> Is the name of the scalable predicate transfer register, encoded in the "Pt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm> Is the optional signed immediate vector offset, in the range -256 to 255, defaulting to 0, encoded in the "imm9h:imm9l" fields.

Operation

CheckSVEEnabled();
constant integer PL = CurrentVL DIV 8;
constant integer elements = PL DIV 8;
bits(PL) src;
bits(64) base;
integer offset = imm * elements;

if n == 31 then
    CheckSPAlignment();
    if HaveMTEExt() then SetTagCheckedInstruction(FALSE);
    base = SP[];
else
    if HaveMTEExt() then SetTagCheckedInstruction(TRUE);
    base = X[n, 64];
src = P[t, PL];
boolean aligned = AArch64.CheckAlignment(base + offset, 2, AccType_SVE, TRUE);
for e = 0 to elements-1
    AArch64.MemSingle[base + offset, 1, AccType_SVE, aligned] = Elem[src, e, 8];
    offset = offset + 1;
C8.2.634   STR (vector)

Store a vector register to a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 which is multiplied by the current vector register size in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

```
| 31 30 29 28|27 26 25 24|23 22 21 | 16|15 14 13 12| 10 9 |  5 4 |  0 |
| 1 1 1 0 0 1 0 1 1 0| imm9h    | 0 1 0| imm9l | Rn  | Zt  |
```

**Encoding**

STR <Zt>, [<Xn|SP>{, #<imm>, MUL VL}]

**Decode for this encoding**

if !HaveSVE() && !HaveSME() then UNDEFINED;
integer t = UInt(Zt);
integer n = UInt(Rn);
integer imm = SInt(imm9h:imm9l);

**Assembler symbols**

<Zt> Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>  Is the optional signed immediate vector offset, in the range -256 to 255, defaulting to 0, encoded in the "imm9h:imm9l" fields.

**Operation**

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV 8;
bits(VL) src;
bits(64) base;
integer offset = imm * elements;
if n == 31 then
    CheckSPAlignment();
    if HaveMTEExt() then SetTagCheckedInstruction(FALSE);
    base = SP[];
else
    if HaveMTEExt() then SetTagCheckedInstruction(TRUE);
    base = X[n, 64];
src = Z[t, VL];
boolean aligned = AArch64.CheckAlignment(base + offset, 16, AccType_SVE, TRUE);
for e = 0 to elements-1
    AArch64.MemSingle[base + offset, 1, AccType_SVE, aligned] = Elem[src, e, 8];
    offset = offset + 1;
### C8.2.635 SUB (immediate)

Subtract an unsigned immediate from each element of the source vector, and destructively place the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is ";#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

**Encoding**

```plaintext
SUB <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

**Decode for this encoding**

```plaintext
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
```

**Assembler symbols**

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - `B` when size = 00
  - `H` when size = 01
  - `S` when size = 10
  - `D` when size = 11
- `<imm>` Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when sh = 0
  - LSL #8 when sh = 1

**Operation**

```plaintext
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
  bits(esize) element1 = Elem[operand1, e, esize];
```

```plaintext
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|  | 5 4 | 0]
0 0 1 0 0 1 0 1 size 1 0 0 0 0 1 1 1 sh imm8 Zdn
```
Elem[result, e, esize] = element1 - imm;
Z[dn, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.636   SUB (vectors, predicated)

Subtract active elements of the second source vector from corresponding elements of the first source vector and
destructively place the results in the corresponding elements of the first source vector. Inactive elements in the
destination vector register remain unmodified.

```
<table>
<thead>
<tr>

Z[d, VL] = result;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.639   SUBHNT

Subtract each vector element of the second source vector from the corresponding vector element in the first source vector, and place the most significant half of the result in the odd-numbered half-width destination elements, leaving the even-numbered elements unchanged. This instruction is unpredicated.

Encoding

SUBHNT <Zd>.<T>, <Zn>.<Tb>, <Zm>.<Tb>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);

Assembler symbols

<Zd>  Is the name of the destination scalable vector register, encoded in the "Zd" field.
<T>  Is the size specifier, encoded in the "size" field. It can have the following values:
    B  when size = 01
    H  when size = 10
    S  when size = 11
    The encoding size = 00 is reserved.
<Zn>  Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Tb>  Is the size specifier, encoded in the "size" field. It can have the following values:
    H  when size = 01
    S  when size = 10
    D  when size = 11
    The encoding size = 00 is reserved.
<Zm>  Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result = Z[d, VL];
constant integer halfesize = esize DIV 2;
for e = 0 to elements-1
    integer element1 = UInt(Elem[operand1, e, esize]);
integer element2 = UInt(Elem[operand2, e, esize]);
integer res = (element1 - element2) >> halfesize;
Elem[result, 2*e + 1, halfesize] = res<halfesize-1:0>;
Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C8.2.640 SUBR (immediate)

Reversed subtract from an unsigned immediate each element of the source vector, and destructively place the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

<td></td>
</tr>
</tbody>
</table>
```

### Encoding

```
SUBR <Zdn>,<T>, <Zdn>,<T>, #<imm>{, <shift>}
```

### Decode for this encoding

```
if !HaveSVE() && !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
```

### Assembler symbols

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<imm>` Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when sh = 0
  - LSL #8 when sh = 1

### Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = UInt(Elem[operand1, e, esize]);
```
Elem[result, e, esize] = (imm - element1)<esize-1:0>;
Z[dn, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.641 SUBR (vectors)

Reversed subtract active elements of the first source vector from corresponding elements of the second source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

Encoding

SUBR <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);

Assembler symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:
B when size = 00
H when size = 01
S when size = 10
D when size = 11
<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand1 = Z[dn, VL];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m, VL] else Zeros(VL);
bits(VL) result;
for e = 0 to elements-1
    bits(esize) element1 = Elem[operand1, e, esize];
    bits(esize) element2 = Elem[operand2, e, esize];
    if Elem[mask, e, esize] == '1' then
        Elem[result, e, esize] = element2 - element1;
    else
        Elem[result, e, esize] = Elem[operand1, e, esize];
Z[dn, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

- The MOVPRFX instruction must specify the same destination register as this instruction.

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.642  SUDOT

The signed by unsigned integer indexed dot product instruction computes the dot product of a group of four signed 8-bit integer values held in each 32-bit element of the first source vector multiplied by a group of four unsigned 8-bit integer values in an indexed 32-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3. This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

SVE
(FEAT_I8MM)

Encoding

Decode for this encoding
if (!HaveSVE() && !HaveSME()) || !HaveInt8MatMulExt() then UNDEFINED;
constant integer esize = 32;
integer index = UInt(i2);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);

Assembler symbols
<Zda> Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.
<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm> Is the name of the second source scalable vector register Z0-Z7, encoded in the "Zm" field.
<imm> Is the immediate index of a 32-bit group of four 8-bit values within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field.

Operation
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;

Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
— The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.646   TBL

Reads each element of the second source (index) vector and uses its value to select an indexed element from a table of elements consisting of one or two consecutive vector registers, where the first or only vector holds the lower numbered elements, and places the indexed table element in the destination vector element corresponding to the index vector element. If an index value is greater than or equal to the number of vector elements then it places zero in the corresponding destination vector element.

Since the index values can select any element in a vector this operation is not naturally vector length agnostic.

        Elem[result, e, esize] = if idx < table_elements then Elem[table, idx, esize] else Zeros(esize);

    Z[d, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.647   TBX

Reads each element of the second source (index) vector and uses its value to select an indexed element from a table of elements in the first source vector, and places the indexed element in the destination vector element corresponding to the index vector element. If an index value is greater than or equal to the number of vector elements then the corresponding destination vector element is left unchanged.

Since the index values can select any element in a vector this operation is not naturally vector length agnostic.

Encoding

TBX <Zd>.<T>, <Zn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE2() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:
    B when size = 00
    H when size = 01
    S when size = 10
    D when size = 11

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result = Z[d, VL];

for e = 0 to elements-1
    integer element2 = UInt(Elem[operand2, e, esize]);
    if element2 < elements then
        Elem[result, e, esize] = Elem[operand1, element2, esize];
    Z[d, VL] = result;
Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.663  UCVTF

Convert to floating-point from the unsigned integer in each active element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified.

If the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.665  UDIVR

Unsigned reversed divide active elements of the second source vector by corresponding elements of the first source vector and destructively place the quotient in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

Encoding

UDIVR <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
if size IN {'0x'} then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
boolean unsigned = TRUE;

Assembler symbols

<Zdn>  Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.
<T>  Is the size specifier, encoded in the "size<0>" field. It can have the following values:
S  when size<0> = 0
D  when size<0> = 1
<Pg>  Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
<Zm>  Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.666 UDOT (indexed)

The unsigned integer indexed dot product instruction computes the dot product of a group of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the first source vector multiplied by a group of four unsigned 8-bit or 16-bit integer values in an indexed 32-bit or 64-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit or 64-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. This instruction is unpredicated.

32-bit

[31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 14 13 12 11 10 9 | 5 4 | 0]

  - S when size = 10
  - D when size = 11
- `<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

#### Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand1 = Z[dn, VL];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m, VL] else Zeros(VL);
bits(VL) result;
integer element1;
integer element2;
for e = 0 to elements-1
  if ElemP[mask, e, esize] == '0' then
    Elem[result, e, esize] = Elem[operand1, e, esize];
  else
    if IsEven(e) then
      element1 = UInt(Elem[operand1, e + 0, esize]);
      element2 = UInt(Elem[operand1, e + 1, esize]);
    else
      element1 = UInt(Elem[operand2, e - 1, esize]);
```

element2 = UInt(Elem[operand2, e + 0, esize]);
integer res = Max(element1, element2);
Elem[result, e, esize] = res<esize-1:0>;

Z[dn, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.
• The MOVPRFX instruction must specify the same destination register as this instruction.
• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.674   UMAXV

Unsigned maximum horizontally across all lanes of a vector, and place the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as zero.

Encoding

UMAXV <V><d>, <Pg>, <Zn>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer n = UInt(Zn);
integer d = UInt(Vd);
boolean unsigned = TRUE;

Assembler symbols

<V>    Is a width specifier, encoded in the "size" field. It can have the following values:
   B      when size = 00
   H      when size = 01
   S      when size = 10
   D      when size = 11

<d>    Is the number [0-31] of the destination SIMD&FP register, encoded in the "Vd" field.

<Pg>   Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn>   Is the name of the source scalable vector register, encoded in the "Zn" field.

<T>    Is the size specifier, encoded in the "size" field. It can have the following values:
   B      when size = 00
   H      when size = 01
   S      when size = 10
   D      when size = 11

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
integer maximum = if unsigned then 0 else -(2^(esize-1));
for e = 0 to elements-1
   if Elem[mask, e, esize] == '1' then

  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C8.2.675  UMIN (immediate)

Determine the unsigned minimum of an immediate and each element of the source vector, and destructively place the results in the corresponding elements of the source vector. The immediate is an unsigned 8-bit value in the range 0 to 255, inclusive. This instruction is unpredicated.

Encoding

UMIN <Zdn>.<T>, <Zdn>.<T>, #<imm>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
boolean unsigned = TRUE;
integer imm = Int(imm8, unsigned);

Assembler symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:
  B when size = 00
  H when size = 01
  S when size = 10
  D when size = 11
<imm> Is the unsigned immediate operand, in the range 0 to 255, encoded in the "imm8" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, e, esize], unsigned);
  Elem[result, e, esize] = Min(element1, imm)<esize-1:0>;
Z[dn, VL] = result;

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
The response of this instruction to asynchronous exceptions does not vary based on:

— The values of the data supplied in any of its registers.

— The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

• The MOVPRFX instruction must be unpredicated.

• The MOVPRFX instruction must specify the same destination register as this instruction.

• The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.676   UMIN (vectors)

Determine the unsigned minimum of active elements of the second source vector and destructively place the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

Encoding

UMIN <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer dn = UInt(Zdn);
integer m = UInt(Zm);
boolean unsigned = TRUE;

Assembler symbols

<Zdn>     Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.
<T>       Is the size specifier, encoded in the "size" field. It can have the following values:
            B    when size = 00
            H    when size = 01
            S    when size = 10
            D    when size = 11

<Pg>      Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm>      Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];

```

**Encoding**

UMLALT <Zda>.<T>, <Zn>.<Tb>, <Zm>.<Tb>

**Decode for this encoding**

```cpp
if !HaveSVE2() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer da = UInt(Zda);
```

**Assembler symbols**

- `<Zda>` Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - H when size = 01
  - S when size = 10
  - D when size = 11
  The encoding size = 00 is reserved.
- `<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.
- `<Tb>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 01
  - H when size = 10
  - S when size = 11
  The encoding size = 00 is reserved.
- `<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

**Operation**

```cpp
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result = Z[da, VL];
for e = 0 to elements-1
  integer element1 = UInt(Elem[operand1, 2*e + 1, esize DIV 2]);
  integer element2 = UInt(Elem[operand2, 2*e + 1, esize DIV 2]);
  bits(esize) product = (element1 * element2)<esize-1:0>;
  Elem[result, e, esize] = Elem[result, e, esize] + product;
```
Z[da, VL] = result;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is **UNPREDICTABLE**:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.683 UMLSLB (indexed)

Multiply the even-numbered unsigned elements within each 128-bit segment of the first source vector by the specified unsigned element in the corresponding second source vector segment and destructively subtract from the overlapping double-width elements of the addend vector.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 2 or 3 bits depending on the size of the element.

C8.2.687 UMMLA

The unsigned integer matrix multiply-accumulate instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of unsigned 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

SVE

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.692  UMULLT (indexed)

Multiply the odd-numbered unsigned elements within each 128-bit segment of the first source vector by the specified unsigned element in the corresponding second source vector segment, and place the results in the overlapping double-width elements of the destination vector register.

The elements within the second source vector are specified using an immediate index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 2 or 3 bits depending on the size of the element.

Z[d, VL] = result;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.694 **UQADD (immediate)**

Unsigned saturating add of an unsigned immediate to each element of the source vector, and destructively place the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to \((2^N)-1\). This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

---

**Encoding**

UQADD <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}

**Decode for this encoding**

```c
if !HaveSVE() & !HaveSME() then UNDEFINED;
if size:sh == '001' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
boolean unsigned = TRUE;
```

**Assembler symbols**

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<imm>` Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when sh = 0
  - LSL #8 when sh = 1

**Operation**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
```
for e = 0 to elements-1
  integer element1 = Int(Elem[operand1, e, esize], unsigned);
  (Elem[result, e, esize], -) = SatQ(element1 + imm, esize, unsigned);

Z[dn, VL] = result;

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.695   UQADD (vectors, predicated)

Add active unsigned elements of the first source vector to corresponding unsigned elements of the second source vector and destructively place the results in the corresponding elements of the first source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. Inactive elements in the destination vector register remain unmodified.

**Encoding**

UQADD <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>

**Assembler symbols**

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

**Operation**

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[<Pg>, PL];
bits(VL) operand1 = Z[<Zdn>, VL];

Elem[result, e, esize] = res<esize-1:0>;
else
Elem[result, e, esize] = Elem[operand1, e, esize];
Z[dn, VL] = result;

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.696   UQADD (vectors, unpredicated)

Unsigned saturating add all elements of the second source vector to corresponding elements of the first source vector and place the results in the corresponding elements of the destination vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to \((2^N)-1\). This instruction is unpredicated.

Encoding

UQADD <Zd>.<T>, <Zn>.<T>, <Zm>.<T>

Decode for this encoding

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
boolean unsigned = TRUE;
```

Assembler symbols

- `<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Zn>` Is the name of the first source scalable vector register, encoded in the "Zn" field.
- `<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[n, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;

for e = 0 to elements-1
    integer element1 = Int(Elem[operand1, e, esize], unsigned);
    integer element2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], -) = SatQ(element1 + element2, esize, unsigned);

Z[d, VL] = result;
```
C8.2.697   UQDECB

Determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

  - `ALL` when `pattern = 11111`

- `<imm>`  
  Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

**Operation for all encodings**

```c
CheckSVEEnabled();
integer count = DecodePredCount(pat, esize);
bits(ssize) operand1 = X[dn, ssize];
bits(ssize) result;

integer element1 = Int(operand1, unsigned);
(result, -) = SatQ(element1 - (count * imm), ssize, unsigned);
X[dn, 64] = Extend(result, 64, unsigned);
```
C8.2.699  UQDECD (vector)

Determines the number of active 64-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement all destination vector elements. The results are saturated to the 64-bit unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

Encoding

UQDECD <Zdn>.D{, <pattern>{, MUL #<imm>}}

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 64;

bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
    integer element1 = Int(Elem[operand1, e, esize], unsigned);
    (Elem[result, e, esize], -) = SatQ(element1 - (count * imm), esize, unsigned);
Z[dn, VL] = result;
```

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.702 UQDECP (scalar)

Counts the number of true elements in the source predicate and then uses the result to decrement the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

32-bit

\[
\begin{array}{cccccccccccccccccc}
0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & \text{Pm} & \text{Rdn} \\
\end{array}
\]

Encoding

UQDECP <Wdn>, <Pm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Rdn);
boolean unsigned = TRUE;
integer ssize = 32;

64-bit

\[
\begin{array}{cccccccccccccccccc}
0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & \text{Pm} & \text{Rdn} \\
\end{array}
\]

Encoding

UQDECP <Xdn>, <Pm>.<T>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Rdn);
boolean unsigned = TRUE;
integer ssize = 64;

Assembler symbols

<Wdn> Is the 32-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.
<Xdn> Is the 64-bit name of the source and destination general-purpose register, encoded in the "Rdn" field.
<Pm> Is the name of the source scalable predicate register, encoded in the "Pm" field.
<T> Is the size specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
- D when size = 11
Operation for all encodings

CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(ssize) operand1 = X[dn, ssize];
bits(PL) operand2 = P[m, PL];
bits(ssize) result;
integer count = 0;
for e = 0 to elements-1
   if ElemP[operand2, e, esize] == '1' then
      count = count + 1;
   integer element = Int(operand1, unsigned);
   (result, -) = SatQ(element - count, ssize, unsigned);
   X[dn, 64] = Extend(result, 64, unsigned);

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is
dependent on the general-purpose register written by this instruction might be significantly delayed.
### C8.2.703 UQDECP (vector)

Counts the number of true elements in the source predicate and then uses the result to decrement all destination vector elements. The results are saturated to the element unsigned integer range.

The predicate size specifier may be omitted in assembler source code, but this is deprecated and will be prohibited in a future release of the architecture.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 8 | 5 4 | 0 ]
0 0 1 0 0 1 0 1 | size 1 0 1 0 1 | 1 0 0 0 0 0 0 0 | Pm | Zdn
```

#### Encoding

Z[dn, VL] = result;
```

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.706   UQINCB

Determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

| 0 0 1 0 0 1 0 1 | size 1 0 1 0 0 1 1 0 0 0 0 0 0 | Pm | Zdn |
```

**Encoding**

UQINCP <Zdn>.<T>, <Pm>.<T>

**Decode for this encoding**

if !HaveSVE() && !HaveSME() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = $ << UInt(size);
integer m = UInt(Pm);
integer dn = UInt(Zdn);
boolean unsigned = TRUE;

**Assembler symbols**

- `<Zdn>` Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - H when size = 01
  - S when size = 10
  - D when size = 11
  - The encoding size = 00 is reserved.
- `<Pm>` Is the name of the source scalable predicate register, encoded in the "Pm" field.

**Operation**

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(PL) operand2 = P[m, PL];
bits(VL) result;
integer count = 0;
for e = 0 to elements-1
  if ElemP[operand2, e, esize] == '1' then
    count = count + 1;
for e = 0 to elements-1
  integer element = Int(Elem[operand1, e, esize], unsigned);
  Elem[result, e, esize], -) = SatQ(element + count, esize, unsigned);
Z[dn, VL] = result;
```
Operational information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.713  UQINCW (scalar)

Determines the number of active 32-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

32-bit

#uimm5 when pattern = 11101
#uimm5 when pattern = 11110
#uimm5 when pattern = 11111

<imm> Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

Operation for all encodings

CheckSVEEnabled();
integer count = DecodePredCount(pat, esize);
bits(ssize) operand1 = X[dn, ssize];
bits(ssize) result;

integer element1 = Int(operand1, unsigned);
(result, -) = SatQ(element1 + (count * imm), ssize, unsigned);
X[dn, 64] = Extend(result, 64, unsigned);
C8.2.714  UQINCW (vector)

Determines the number of active 32-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment all destination vector elements. The results are saturated to the 32-bit unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

Encoding

UQINCW <Zdn>.S{, <pattern>{, MUL #<imm>}}

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;

<imm>  Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

**Operation**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer count = DecodePredCount(pat, esize);
bits(VL) operand1 = Z[dn, VL];
bits(VL) result;
for e = 0 to elements-1
   integer element1 = Int(Elem[operand1, e, esize], unsigned);
   (Elem[result, e, esize], -) = SatQ(element1 + (count * imm), esize, unsigned);

Z[dn, VL] = result;
```

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.715  UQRSHL

Shift active unsigned elements of the first source vector by corresponding elements of the second source vector and destructively place the rounded results in the corresponding elements of the first source vector. A positive shift amount performs a left shift, otherwise a right shift by the negated shift amount is performed. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. Inactive elements in the destination vector register remain unmodified.

Encoding

```
UQRSHL <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer g = UInt(Pg);
integer m = UInt(Zm);
integer dn = UInt(Zdn);
```

Assembler symbols

- `<Zdn>` Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<Zm>` Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
bits(PL) mask = P[g, PL];
bits(VL) operand1 = Z[dn, VL];
bits(VL) operand2 = if AnyActiveElement(mask, esize) then Z[m, VL] else Zeros(VL);
bits(VL) result;
for e = 0 to elements-1
  if Elem[mask, e, esize] == '1' then
    integer element = UInt(Elem[operand1, e, esize]);
    integer shift = ShiftSat(SInt(Elem[operand2, e, esize]), esize);
    integer round_const = 1 << (-shift - 1); // 0 for left shift, 2^(n-1) for right shift
    integer res = (element + round_const) << shift;
    Elem[result, e, esize] = UnsignedSat(res, esize);
  else
```
$\text{Elem}[\text{result}, e, \text{esize}] = \text{Elem}[\text{operand1}, e, \text{esize}]$;

$Z[dn, VL] = \text{result}$;

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.716 UQRSHLR

Shift active unsigned elements of the second source vector by corresponding elements of the first source vector and destructively place the rounded results in the corresponding elements of the first source vector. A positive shift amount performs a left shift, otherwise a right shift by the negated shift amount is performed. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. Inactive elements in the destination vector register remain unmodified.

**Operational information**

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated, or be predicated using the same governing predicate register and source element size as this instruction.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.722 UQSHRN

Shift each unsigned integer value in the source vector elements right by an immediate value, and place the truncated results in the even-numbered half-width destination elements, while setting the odd-numbered elements to zero. Each result element is saturated to the half-width N-bit element's unsigned integer range 0 to (2^N)-1. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

Encoding

UQSHRN <Zd>.<T>, <Zn>.<Tb>, #<const>

Decode for this encoding

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
bite(3) tsize = tszh:tszl;
integer esize;
case tsize of
    when '000' UNDEFINED;
    when '001' esize = 8;
    when '01x' esize = 16;
    when '1xx' esize = 32;
integer n = UInt(Zn);
integer d = UInt(Zd);
integer shift = (2 * esize) - UInt(tsize:imm3);
```

Assembler symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in the "tszh:tszl" field. It can have the following values:

- `B` when tszh = 0, tszl = 01
- `H` when tszh = 0, tszl = 1x
- `S` when tszh = 1, tszl = xx

The encoding tszh = 0, tszl = 00 is reserved.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

<Tb> Is the size specifier, encoded in the "tszh:tszl" field. It can have the following values:

Z[d, VL] = result;
C8.2.724   UQSUB (immediate)

Unsigned saturating subtract an unsigned immediate from each element of the source vector, and destructively place the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to \(2^N-1\). This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<imm>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

Encoding

\[
\text{UQSUB} \quad \langle\text{Zdn}\rangle.<\text{T}>., \langle\text{Zdn}\rangle.<\text{T}>., \#<\text{imm}>, \langle\text{shift}\rangle\
\]

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.737 USDOT (indexed)

The unsigned by signed integer indexed dot product instruction computes the dot product of a group of four
unsigned 8-bit integer values held in each 32-bit element of the first source vector multiplied by a group of four
signed 8-bit integer values in an indexed 32-bit element of the second source vector, and then destructively adds
the widened dot product to the corresponding 32-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index which selects the same group
position within each 128-bit vector segment. The index range is from 0 to 3. This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

  - The values of the NZCV flags.
C8.2.741 USMMLA

The unsigned by signed integer matrix multiply-accumulate instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of signed 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

Assembler symbols

- `<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Pn>` Is the name of the first source scalable predicate register, encoded in the "Pn" field.
- `<Pm>` Is the name of the second source scalable predicate register, encoded in the "Pm" field.
Operation for all encodings

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer pairs = VL DIV (esize * 2);
bits(PL) operand1 = P[n, PL];
bits(PL) operand2 = P[m, PL];
bits(PL) result;

for p = 0 to pairs - 1
    Elem[result, p, esize DIV 8] = Elem[operand1, 2*p+part, esize DIV 8];

for p = 0 to pairs - 1
    Elem[result, pairs+p, esize DIV 8] = Elem[operand2, 2*p+part, esize DIV 8];

P[d, PL] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.751  UZP1, UZP2 (vectors)

Concatenate adjacent even or odd-numbered elements from the first and second source vectors and place in elements of the destination vector. This instruction is unpredicated. The 128-bit element variant of this instruction requires that the current vector length is at least 256 bits, and if the current vector length is not an integer multiple of 256 bits then the trailing bits are set to zero.

ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant of the instruction is implemented.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.752 WHILEGE

Generate a predicate that starting from the highest numbered element is true while the decremented value of the first, signed scalar operand is greater than or equal to the second scalar operand and false thereafter down to the lowest numbered element.

If the second scalar operand is equal to the minimum signed integer value then a condition which includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

Encoding

WHILEGE <Pd>.<T>, <R><n>, <R><m>

C8.2.758 WHILELS

Generate a predicate that starting from the lowest numbered element is true while the incrementing value of the first, unsigned scalar operand is lower or same as the second scalar operand and false thereafter up to the highest numbered element.

If the second scalar operand is equal to the maximum unsigned integer value then a condition which includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is incremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. Sets the FIRST (N), NONE (Z), !LAST (C) condition flags based on the predicate result, and the V flag to zero.

Encoding

WHILELS <Pd>.<T>, <R><n>, <R><m>

Decode for this encoding

if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
constant integer rsize = 32 << UInt(sf);

integer diff = (operand2 - operand1) DIV (esize DIV 8);
for e = 0 to elements-1
   if diff <= 0 || e < diff then
      ElemP[result, e, esize] = '1';
   else
\textbf{Operational information}

If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
WRFFR

Read the source predicate register and place in the first-fault register (FFR). This instruction is intended to restore a saved FFR and is not recommended for general use by applications.

This instruction requires that the source predicate contains a MONOTONIC predicate value, in which starting from bit 0 there are zero or more 1 bits, followed only by 0 bits in any remaining bit positions. If the source is not a monotonic predicate value, then the resulting value in the FFR will be UNPREDICTABLE. It is not possible to generate a non-monotonic value in FFR when using SETFFR followed by first-fault or non-fault loads.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled at the current Exception level.

**Encoding**

WRFFR <Pn>.B

**Decode for this encoding**

if !HaveSVE() then UNDEFINED;
integer n = UInt(Pn);

**Assembler symbols**

<Pn> Is the name of the source scalable predicate register, encoded in the "Pn" field.

**Operation**

CheckNonStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
bits(PL) operand = P[n, PL];

constant integer hsb = HighestSetBit(operand);
if hsb < 0 || IsOnes(operand<hsb:0>) then
    FFR[PL] = operand;
else // not a monotonic predicate
    FFR[PL] = bits(PL) UNKNOWN;

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.763   XAR

Bitwise exclusive OR the corresponding elements of the first and second source vectors, then rotate each result element right by an immediate amount. The final results are destructively placed in the corresponding elements of the destination and first source vector. This instruction is unpredicated.

```
0 0 0 0 0 1 0 0 | tszh 1 | tszl | imm3 | 0 0 1 1 0 1 | Zm | Zdn
```

**Encoding**

XAR <Zdn>.<T>, <Zdn>.<T>, <Zm>.<T>, #<const>

**Decode for this encoding**

```
if !HaveSVE2() && !HaveSME() then UNDEFINED;
bits(4) tsize = tszh:tszl;
integer esize;
  case tsize of
    when '0000' UNDEFINED;
    when '0001' esize = 8;
    when '001x' esize = 16;
    when '01xx' esize = 32;
    when '1xxx' esize = 64;
  integer m = UInt(Zm);
  integer dn = UInt(Zdn);
  integer rot = (2 * esize) - UInt(tsize:imm3);
```

**Assembler symbols**

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in the "tszh:tszl" field. It can have the following values:

- B when tszh = 00, tszl = 01
- H when tszh = 00, tszl = 1x
- S when tszh = 01, tszl = xx
- D when tszh = 1x, tszl = xx

The encoding tszh = 00, tszl = 00 is reserved.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<const> Is the immediate shift amount, in the range 1 to number of bits per element, encoded in "tsz:imm3".

**Operation**

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
bits(VL) operand1 = Z[dn, VL];
bits(VL) operand2 = Z[m, VL];
bits(VL) result;
for e = 0 to elements-1
  bits(esize) element1 = Elem[operand1, e, esize];
bits(esize) element2 = Elem[operand2, e, esize];
```
\[
\text{Elem}(\text{result, e, esize}) = \text{ROR}(\text{element1 EOR element2, rot});
\]
\[
Z[dn, VL] = \text{result};
\]

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX instruction must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is UNPREDICTABLE:

- The MOVPRFX instruction must be unpredicated.
- The MOVPRFX instruction must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.
C8.2.764 ZIP1, ZIP2 (predicates)

Interleave alternating elements from the lowest or highest halves of the first and second source predicates and place in elements of the destination predicate. This instruction is unpredicated.

**High halves**

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 14 13 12|11 10 9 8] 5 4 3 0

integer m = UInt(Pm);
integer d = UInt(Pd);
integer part = 1;
```

**Low halves**

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 14 13 12|11 10 9 8] 5 4 3 0
0 0 0 0 0 1 0 1 | Pm 0 1 0 0 0 0 | Pn 0 | Pd 0
```

**Encoding**

ZIP1 <Pd>.<T>, <Pn>.<T>, <Pm>.<T>

**Decode for this encoding**

```c
if !HaveSVE() && !HaveSME() then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Pn);
integer m = UInt(Pm);
integer d = UInt(Pd);
integer part = 0;
```

**Assembler symbols**

- `<Pd>` Is the name of the destination scalable predicate register, encoded in the "Pd" field.
- `<T>` Is the size specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  - D when size = 11
- `<Pn>` Is the name of the first source scalable predicate register, encoded in the "Pn" field.
- `<Pm>` Is the name of the second source scalable predicate register, encoded in the "Pm" field.
**Operation for all encodings**

```c
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer pairs = VL DIV (esize * 2);
bits(PL) operand1 = P[n, PL];
bits(PL) operand2 = P[m, PL];
bits(PL) result;

integer base = part * pairs;
for p = 0 to pairs-1
    Elem[result, 2*p+0, esize DIV 8] = Elem[operand1, base+p, esize DIV 8];
    Elem[result, 2*p+1, esize DIV 8] = Elem[operand2, base+p, esize DIV 8];

P[d, PL] = result;
```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C8.2.765 ZIP1, ZIP2 (vectors)

Interleave alternating elements from the lowest or highest halves of the first and second source vectors and place in elements of the destination vector. This instruction is unpredicated. The 128-bit element variant of this instruction requires that the current vector length is at least 256 bits, and if the current vector length is not an integer multiple of 256 bits then the trailing bits are set to zero.

ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant of the instruction is implemented.

Chapter C9
SME Instruction Descriptions

This chapter describes the SME instructions.

It contains the following sections:
• About the SME instructions on page C9-4542.
• Alphabetical list of SME instructions on page C9-4543.
C9.1  About the SME instructions

This section is added for ease of reference. For more information, see, Arm® Architecture Reference Manual Supplement, The Scalable Matrix Extension (SME), for Armv9-A (ARM DDI 0616).

Alphabetical list of SME instructions on page C9-4543 gives full descriptions of the SME instructions.

A64 instruction set encoding on page C4-388 in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.
C9.2 Alphabetical list of SME instructions

This section lists every section in the SME category of the A64 instruction set. For details of the format used, see Structure of the A64 assembler language on page C1-228.
C9.2.1 ADDHA

Add each element of the source vector to the corresponding active element of each horizontal slice of a ZA tile. The tile elements are predicated by a pair of governing predicates. An element of a horizontal slice is considered active if its corresponding element in the second governing predicate is TRUE and the element corresponding to its horizontal slice number in the first governing predicate is TRUE. Inactive elements in the destination tile remain unmodified.

ID_AAA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

<Pn> Is the name of the first governing scalable predicate register P0-P7, encoded in the "Pn" field.
Is the name of the second governing scalable predicate register P0-P7, encoded in the "Pm" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

**Operation for all encodings**

```c
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer dim = VL DIV esize;
bits(PL) mask1 = P[a, PL];
bits(PL) mask2 = P[b, PL];
bits(VL) operand_src = Z[n, VL];
bits(dim*dim*esize) operand_acc = ZAtile[da, esize, dim*dim*esize];
bits(dim*dim*esize) result;

for col = 0 to dim-1
    bits(esize) element = Elem[operand_src, col, esize];
    for row = 0 to dim-1
        bits(esize) res = Elem[operand_acc, row*dim+col, esize];
        if ElemP[mask1, row, esize] == '1' && ElemP[mask2, col, esize] == '1' then
            res = res + element;
        Elem[result, row*dim+col, esize] = res;
ZAtile[da, esize, dim*dim*esize] = result;
```

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C9.2.2 ADDSPL

Add the Streaming SVE predicate register size in bytes multiplied by an immediate in the range -32 to 31 to the 64-bit source general-purpose register or current stack pointer and place the result in the 64-bit destination general-purpose register or current stack pointer.

This instruction does not require the PE to be in Streaming SVE mode.

— The values of the NZCV flags.
C9.2.4   ADDVA

Add each element of the source vector to the corresponding active element of each vertical slice of a ZA tile. The tile elements are predicated by a pair of governing predicates. An element of a vertical slice is considered active if its corresponding element in the first governing predicate is TRUE and the element corresponding to its vertical slice number in the second governing predicate is TRUE. Inactive elements in the destination tile remain unmodified.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

C9.2.5  BFMOPA

The BFloat16 floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile.

This instruction multiplies the SVLS×2 sub-matrix of BFloat16 values held in the first source vector by the 2×SVLS sub-matrix of BFloat16 values in the second source vector.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting SVLS×SVLS single-precision floating-point sum of outer products is then destructively added to the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVLS×2 sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVLS sub-matrix.

This instruction follows SME BFloat16 numerical behaviors.

\end{verbatim}
C9.2.7   FMOPA (non-widening)

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. In case of the single-precision variant, the first source is SVL₅×1 vector and the second source is 1×SVL₅ vector. In case of the double-precision variant, the first source is SVL₆×1 vector and the second source is 1×SVL₆ vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, SVL₅×SVL₅ in case of single-precision variant or SVL₆×SVL₆ in case of double-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented.

C9.2.8 FMOPA (widening)

The half-precision floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile.

This instruction widens the SVLS×2 sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened 2×SVLS sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting SVLS×SVLS single-precision floating-point sum of outer products is then destructively added to the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVLS×2 sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVLS sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

C9.2.9  FMOPS (non-widening)

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. In case of the single-precision variant, the first source is SVLS×1 vector and the second source is 1×SVLS vector. In case of the double-precision variant, the first source is SVLD×1 vector and the second source is 1×SVLD vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, SVLS×SVLS in case of single-precision variant or SVLD×SVLD in case of double-precision variant, is then destructively subtracted from the destination tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented.

    else
      Elem[result, row*dim+col, esize] = element3;
  
ZAtile[da, esize, dim*dim*esize] = result;
C9.2.10 FMOPS (widening)

The half-precision floating-point sum of outer products and subtract instruction works with a 32-bit element ZA tile.

This instruction widens the SVLS×2 sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened 2×SVLS sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting SVLS×SVLS single-precision floating-point sum of outer products is then destructively subtracted from the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVLS×2 sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVLS sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

  offset = offset + 1;

ZAslice[t, esize, vertical, slice, VL] = result;
C9.2.16 LDR

The ZA array vector is selected by the sum of the vector select register and an immediate, modulo the number of bytes in a Streaming SVE vector. The immediate is in the range 0 to 15. The memory address is generated by scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

SME

(FEAT_SME)

Encoding

LDR ZA[<Wv>, <imm>], [<Xn|SP>{, #<imm>, MUL VL}]

Decode for this encoding

if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer v = UInt('011':Rv);
integer imm = UInt(imm4);

Assembler symbols

<Wv> Is the 32-bit name of the vector select register W12-W15, encoded in the "Rv" field.
<imm> Is the vector select offset and optional memory offset, in the range 0 to 15, defaulting to 0, encoded in the "imm4" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

CheckSMEAndZAEnabled();
constant integer svl = SVL;
constant integer dim = svl DIV 8;

    Elem[result, e, 8] = AArch64.MemSingle(base + offset, 1, AccType_SME, aligned);
    offset = offset + 1;

ZAvector[vec, svl] = result;
C9.2.17 MOV (tile to vector)

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and an immediate, modulo the number of such elements in a vector. The immediate is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This instruction is an alias of the MOVA (tile to vector) instruction. This means that:

- The encodings in this description are named to match the encodings of MOVA (tile to vector).
- The description of MOVA (tile to vector) gives the operational pseudocode for this instruction.

128-bit Encoding

MOV <Zd>.Q, <Pg>/M, <ZAn><HV>.Q[<Ws>, <imm>]

is equivalent to

MOVA <Zd>.Q, <Pg>/M, <ZAn><HV>.Q[<Ws>, <imm>]

and is always the preferred disassembly.

**Assembler symbols**

- `<Zd>` Is the name of the destination scalable vector register, encoded in the "Zd" field.
- `<Pg>` Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- `<ZAn>` For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.
  - For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.
  - For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.
  - For the 128-bit variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAn" field.
<HV> Is the horizontal or vertical slice indicator, encoded in the "V" field. It can have the following values:
H when V = 0
V when V = 1

<W> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<imm> For the 8-bit variant: is the slice index offset, in the range 0 to 15, encoded in the "imm4" field.
For the 16-bit variant: is the slice index offset, in the range 0 to 7, encoded in the "imm3" field.
For the 32-bit variant: is the slice index offset, in the range 0 to 3, encoded in the "imm2" field.
For the 64-bit variant: is the slice index offset, in the range 0 to 1, encoded in the "i1" field.
For the 128-bit variant: is the slice index offset 0.

**Operation for all encodings**

The description of MOV A (tile to vector) gives the operational pseudocode for this instruction.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
### C9.2.18 MOV (vector to tile)

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and an immediate, modulo the number of such elements in a vector. The immediate is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination slice remain unmodified.

This instruction is an alias of the MOVA (vector to tile) instruction. This means that:

- The encodings in this description are named to match the encodings of MOVA (vector to tile).
- The description of MOVA (vector to tile) gives the operational pseudocode for this instruction.

integer s = UInt('011':Rs);
integer n = UInt(Zn);
integer d = UInt(ZAd);
integer imm = 0;
constant integer esize = 128;
boolean vertical = V == '1';

**Assembler symbols**

<ZAd> For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field.
For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field.
For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.
For the 128-bit variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAd" field.

<HV> Is the horizontal or vertical slice indicator, encoded in the "V" field. It can have the following values:
H when V = 0
V when V = 1

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<imm> For the 8-bit variant: is the slice index offset, in the range 0 to 15, encoded in the "imm4" field.
For the 16-bit variant: is the slice index offset, in the range 0 to 7, encoded in the "imm3" field.
For the 32-bit variant: is the slice index offset, in the range 0 to 3, encoded in the "imm2" field.
For the 64-bit variant: is the slice index offset, in the range 0 to 1, encoded in the "i1" field.
For the 128-bit variant: is the slice index offset 0.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.
Operation for all encodings

`CheckStreamingSVEAndZAEnabled();`

C9.2.22   SMOPA

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $\text{SVLS} \times 4$ sub-matrix of signed 8-bit integer values, and the second source holds $4 \times \text{SVLS}$ sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds $\text{SVLD} \times 4$ sub-matrix of signed 16-bit integer values, and the second source holds $4 \times \text{SVLD}$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $\text{SVLS} \times \text{SVLS}$ widened 32-bit integer or $\text{SVLD} \times \text{SVLD}$ widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $\text{SVLS} \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times \text{SVLS}$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $\text{SVLD} \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times \text{SVLD}$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

C9.2.23 SMOPS

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVLS×4 sub-matrix of signed 8-bit integer values, and the second source holds 4×SVLS sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVLĐ×4 sub-matrix of signed 16-bit integer values, and the second source holds 4×SVLĐ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVLS×SVLS widened 32-bit integer or SVLĐ×SVLĐ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLS×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLS sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLĐ×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLĐ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

C9.2.29   STR

The ZA array vector is selected by the sum of the vector select register and an immediate, modulo the number of bytes in a Streaming SVE vector. The immediate is in the range 0 to 15. The memory address is generated by scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

C9.2.30  SUMOPA

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVLS×4 sub-matrix of signed 8-bit integer values, and the second source holds 4×SVLS sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVLD×4 sub-matrix of signed 16-bit integer values, and the second source holds 4×SVLD sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVLS×SVLS widened 32-bit integer or SVLD×SVLD widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLS×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLS sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLD×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLD sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

**Operational information**

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then when PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
C9.2.33 UMOPS

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVLS×4 sub-matrix of unsigned 8-bit integer values, and the second source holds 4×SVLS sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVLD×4 sub-matrix of unsigned 16-bit integer values, and the second source holds 4×SVLD sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVLS×SVLS widened 32-bit integer or SVLD×SVLD widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLS×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLS sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVLD×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVLD sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  — The values of the NZCV flags.
C9.2.36 ZERO

Zeroes all bytes within each of the up to eight listed 64-bit element tiles named ZA0.D to ZA7.D, leaving the other
64-bit element tiles unmodified.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will
not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

For programmer convenience an assembler must also accept the names of 32-bit, 16-bit, and 8-bit element tiles
which are converted into the corresponding set of 64-bit element tiles.

In accordance with the architecturally defined mapping between different element size tiles:

- Zeroing the 8-bit element tile name ZA0.B, or the entire array name ZA, is equivalent to zeroing all eight
  64-bit element tiles named ZA0.D to ZA7.D.
- Zeroing the 16-bit element tile name ZA0.H is equivalent to zeroing 64-bit element tiles named ZA0.D,
- Zeroing the 16-bit element tile name ZA1.H is equivalent to zeroing 64-bit element tiles named ZA1.D,
- Zeroing the 32-bit element tile name ZA0.S is equivalent to zeroing 64-bit element tiles named ZA0.D and
  ZA4.D.
- Zeroing the 32-bit element tile name ZA1.S is equivalent to zeroing 64-bit element tiles named ZA1.D and
  ZA5.D.
- Zeroing the 32-bit element tile name ZA2.S is equivalent to zeroing 64-bit element tiles named ZA2.D and
  ZA6.D.
- Zeroing the 32-bit element tile name ZA3.S is equivalent to zeroing 64-bit element tiles named ZA3.D and
  ZA7.D.

The preferred disassembly of this instruction uses the shortest list of tile names that represent the encoded
immediate mask.

For example:

- An immediate which encodes 64-bit element tiles ZA0.D, ZA1.D, ZA4.D, and ZA5.D is disassembled as
  \{ZA0.S, ZA1.S\}.
  \{ZA0.H\}.
- An all-ones immediate is disassembled as \{ZA\}.
- An all-zeros immediate is disassembled as an empty list \{\}.

Part D

The AArch64 System Level Architecture
This chapter describes the AArch64 system level programmers’ model. It contains the following sections:

- Exception levels on page D1-4632.
- Exceptions on page D1-4638.
- Registers for instruction processing and exception handling on page D1-4636.
- Process state, PSTATE on page D1-4670.
- Resets and power domains on page D1-4673.
- Mechanisms for entering a low-power state on page D1-4676.
- Self-hosted debug on page D1-4681.
- Event monitors on page D1-4683.
- Interprocessing on page D1-4684.
D1.1 Exception levels

The architecture defines four Exception levels: EL0, EL1, EL2, and EL3.

EL3 is the highest Exception level and EL0 the lowest. Therefore, EL3 is higher than EL2, EL2 is higher than EL1, and EL1 is higher than EL0.

Unprivileged execution is any execution that occurs at EL0.

An implementation includes EL0 and EL1.

It is IMPLEMENTATION DEFINED whether EL2 is implemented, or not.

If implemented, EL2 provides support for the virtualization of EL0 and EL1.

It is IMPLEMENTATION DEFINED whether EL3 is implemented, or not.

A PE is not required to implement a contiguous set of Exception levels.

The current Exception level changes only when any of the following occur:
- Taking an exception.
- Returning from an exception.
- Processor reset.
- Exiting from Debug state.
- If in Debug state, executing a DCPS\(^x\) instruction.
- If in Debug state, executing a DRPS instruction.

The target Exception level is the Exception level to which an exception is taken.

Each exception type has a target Exception level that is either:
- Implicit in the type of the exception.
- Defined by configuration bits in the System registers.

An exception cannot be taken to EL0.

An exception cannot cause entry to a lower Exception level.

D1.1.1 Execution state

The architecture defines two Execution states. The AArch32 Execution state uses 32-bit processing. The AArch64 Execution state uses 64-bit processing.

The AArch32 Execution state is compatible with Armv7-A operation.

An Exception level is described as:
- Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
- Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

The PE can only change Execution state at reset, or when changing Exception level.

If an Exception level is using AArch32, then all lower Exception levels are using AArch32.

If an Exception level is using AArch64, then all higher Exception levels are using AArch64.

Interaction between the AArch64 and AArch32 Execution states is called interprocessing.

In this chapter, the described behavior assumes the highest implemented Exception level is using AArch64.

D1.1.2 Security state

The architecture defines two Security states, called Secure state and Non-secure state.
The architecture defines two physical address spaces, Secure and Non-secure.

If in Non-secure state, the PE can only access the Non-secure physical address space.

If in Secure state, the PE can access both the Secure physical address space and the Non-secure physical address space.

EL3 is in Secure state.

The Security state of EL2, EL1, and EL0 is determined by the Effective value of SCR_EL3.NS. If the Effective value of SCR_EL3.NS is 0, the PE is in Secure state. If the Effective value of SCR_EL3.NS is 1, the PE is in Non-secure state.

EL2 can only be in Secure state if all the following are true:
- FEAT_SEL2 is implemented.
- The Effective value of SCR_EL3.EEL2 is 0b1.
- The Effective value of SCR_EL3.NS is 0b0.

Otherwise, EL2 is in Non-secure state.

The state of SCR_EL3.NS can only change in EL3.

**D1.1.3 Effect of not implementing an Exception level**

An exception cannot be taken to an unimplemented Exception level.

Any configurable instruction control that defines an exception to an unimplemented Exception level does not cause that exception to the unimplemented Exception level. The Effective value of the configurable exception control is the value that does not cause an exception to that Exception level.

System calls made to an unimplemented Exception level from a lower Exception level are UNDEFINED.

The translation regime associated with an unimplemented Exception level is not implemented.

Any exception return that targets an unimplemented Exception level is an illegal return.

Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

**Behavior when EL3 is not implemented**

If EL3 is not implemented, SCR_EL3.NS has a fixed Effective value that is IMPLEMENTATION DEFINED.

An implementation can provide a configuration input that determines the Effective value of SCR_EL3.NS at reset.

If EL3 is not implemented, and the Effective value of SCR_EL3.NS is 0b0, all of the following are true:
- The Effective value of MDCR_EL3.EPMAD is 0b1.
- The Effective value of MDCR_EL3.EDAD is 0b1.
- The Effective value of MDCR_EL3.SPME is 0b1.
- The Effective value of MDCR_EL3.NSPB is 0b01.
- The Effective value of MDCR_EL3.SPD32 is 0b11.
- The Effective value of MDCR_EL3.STE is 0b1.

If EL3 is not implemented, the Effective value of MDCR_EL3.STE is the inverse of the Effective value of SCR_EL3.NS.

If all of the following are true, the Effective value of SCR_EL3.EEL2 is 0b1:
- EL3 is not implemented.
- EL2 is implemented.
- The Effective value of SCR_EL3.NS is 0b0.
Behavior when EL2 is not implemented

If EL2 is not implemented, all of the following are true:
- Virtual interrupts are disabled.
- The Effective value of CNTHCTL_EL2[1:0] is 0b11.
- The Effective value of HCR_EL2.E2H is 0b0.
- The Effective value of HCR_EL2.TGE is 0b0.
- The Effective value of MDCR_EL2.HPMN is the value of PMCR_EL0.N

Behavior when EL2 is not implemented and EL3 is implemented

If EL2 is not implemented and EL3 is implemented, all of the following are true:
- Except for any of the following registers, every accessible register associated with EL2 is RES0:
  - If EL1 can use AArch32, then the following registers are not RES0:
    - DACR32_EL2.
    - DBGVCR32_EL2.
    - FPEXC32_EL2.
    - IFSR32_EL2.
  - For VPIDR_EL2:
    - Reads return the value of MIDR_EL1.
    - Writes to VPIDR_EL2 are ignored.
  - For VMPIDR_EL2:
    - Reads return the value of MPIDR_EL1.
    - Writes to VMPIDR_EL2 are ignored.
- The Effective value of HCR_EL2.RW is the value of SCR_EL3.RW.
- SCR_EL3.HCE is RES0.
- The following Address translation and TLB invalidation instructions are UNDEFINED:
  - AT S1E2R.
  - AT S1E2W.
  - TLBI VAE2.
  - TLBI VALE2.
  - TLBI VAE2IS.
  - TLBI VALE2IS.
  - TLBI VALE2OS.
  - TLBI VAE2OS.
  - TLBI RVAE2.
  - TLBI RVALE2.
  - TLBI RVAE2IS.
  - TLBI RVALE2IS.
  - TLBI RVAE2OS.
  - TLBI RVALE2OS.
Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>Applications.</td>
</tr>
<tr>
<td>EL1</td>
<td>OS kernel and associated functions that are typically described as privileged.</td>
</tr>
<tr>
<td>EL2</td>
<td>Hypervisor.</td>
</tr>
<tr>
<td>EL3</td>
<td>Secure monitor.</td>
</tr>
</tbody>
</table>
D1.2 Registers for instruction processing and exception handling

In the Arm architecture, registers are split into two main categories:

- Registers that provide system control or status reporting.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions.

For more information, see Chapter D17 AArch64 System Register Descriptions.

D1.2.1 The general-purpose registers

The general-purpose register bank comprises the 31 general-purpose registers, R0-R30.

The general-purpose register bank is associated with instructions in the base instruction set.

The general-purpose registers can be accessed as either of the following:

- 31 64-bit registers, X0-X30.
- 31 32-bit registers, W0-W30.

When a Warm reset is asserted, the general-purpose registers are reset to an architecturally UNKNOWN value.

For more information, see Register size on page C6-1166 and Registers in AArch64 state on page B1-137.

D1.2.2 The stack pointer registers

If in AArch64 state, each implemented Exception level has a dedicated stack pointer register. The stack pointer registers are:

- SP_EL0.
- SP_EL1.
- If EL2 is implemented, SP_EL2.
- If EL3 is implemented, SP_EL3.

When a Warm reset is asserted, the stack pointers are reset to an architecturally UNKNOWN value.

For more information, see Special-purpose registers on page C5-671 and SP alignment checking on page D1-4668.

Stack pointer register selection

The PE uses the following stack pointers:

- If executing at EL0, then the PE uses the EL0 stack pointer, SP_EL0.
- If executing at EL1, EL2, or EL3, then the PE uses the stack pointer determined by the PSTATE.SP bit:
  - If PSTATE.SP is 0, then the PE uses the EL0 stack pointer, SP_EL0.
  - If PSTATE.SP is 1, then the PE uses the stack pointer for the current Exception level.

When an exception is taken, the stack pointer for the target Exception level is selected.

The selected stack pointer can be indicated by a suffix to the Exception level:

- The t suffix, referring to thread, indicates use of the SP_EL0 stack pointer.
- The h suffix, referring to host, indicates use of the SP_ELx stack pointer.
The following are the AArch64 stack pointer options:

<table>
<thead>
<tr>
<th>Exception level (EL)</th>
<th>Stack pointer (SP) options</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>SP_EL0t</td>
</tr>
<tr>
<td>EL1</td>
<td>SP_EL1t, SP_EL1h</td>
</tr>
<tr>
<td>EL2</td>
<td>SP_EL2t, SP_EL2h</td>
</tr>
<tr>
<td>EL3</td>
<td>SP_EL3t, SP_EL3h</td>
</tr>
</tbody>
</table>

**D1.2.3 The SIMD and floating-point registers**

- The SIMD and floating-point register bank comprises the 32 quadword (128-bit) SIMD and floating-point registers, V0-V31.
- The SIMD and floating-point register bank is used for floating-point, vector, and other SIMD-related scalar operations.
- The SIMD and floating-point registers can be accessed as any of the following:
  - 32 quadword (128-bit) registers, Q0-Q31.
  - 32 doubleword (64-bit) registers, D0-D31.
  - 32 word (32-bit) registers, S0-S31.
  - 32 halfword (16-bit) registers, H0-H31.
  - 32 byte (8-bit) registers, B0-B31.
  - 128-bit vectors of elements.
  - 64-bit vectors of elements.
- When a Warm reset is asserted, the SIMD and floating-point registers are reset to an architecturally UNKNOWN value.

For more information, see *Registers in AArch64 state* on page B1-137.

**D1.2.4 Saved Program Status Registers**

- In AArch64 state, each implemented Exception level to which an exception can be taken has a Saved Program Status Register (SPSR). The following are the SPSRs:
  - For exceptions taken to EL1 using AArch64, SPSR_EL1.
  - For exceptions taken to EL2 using AArch64, SPSR_EL2.
  - For exceptions taken to EL3 using AArch64, SPSR_EL3.
- When a Warm reset is asserted, the SPSRs are reset to an architecturally UNKNOWN value.

For more information, see *Process state, PSTATE* on page D1-4670.

**D1.2.5 Exception Link Registers**

- Exception Link Registers hold preferred exception return addresses.
- In AArch64 state, each implemented Exception level to which an exception can be taken has an Exception Link Register (ELR). The following are the ELRs:
  - For exceptions taken to EL1, ELR_EL1.
  - For exceptions taken to EL2, ELR_EL2.
  - For exceptions taken to EL3, ELR_EL3.
- When a Warm reset is asserted, the ELRs are reset to an architecturally UNKNOWN value.

For more information, see *Preferred exception return address* on page D1-4640.
D1.3 Exceptions

D1.3.1 Exception entry terminology

*Taken, taken from, and taken to*

When the PE responds to an exception, an exception is *taken*.

The PE state immediately before taking the exception is the state the exception is *taken from*.

The PE state immediately after taking the exception is the state the exception is *taken to*.

**Exception producing instructions**

Instructions that intentionally cause an exception to be taken are called exception producing instructions.

The following are exception producing instructions:

- HVC.
- SMC.
- SVC.

Exception producing instructions produce a precise exception at the point in the instruction stream immediately after the exception producing instruction.

**Synchronous and asynchronous exceptions**

If all of the following apply, an exception is *synchronous*:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The preferred exception return address has an architecturally defined relationship with the instruction that caused the exception.
- The exception is precise.

An exception is *asynchronous* if it is not synchronous.

Asynchronous exceptions taken to AArch64 state are also known as interrupts.

**Definition of a precise exception and imprecise exception**

An exception is *precise* if on taking the exception, the PE state and the memory system state is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken from, and none afterwards. However, for an instruction executing immediately at the point in the instruction stream that the exception was taken from, the definition of precise also permits any of the following:

- For synchronous Data Abort and Watchpoint exceptions that are taken to AArch64 state generated by an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instructions can be UNKNOWN, if all of the following apply:
  - The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
  - The registers are not involved in the calculation of the memory address used by the instruction.
- For synchronous Data Abort and Watchpoint exceptions that are generated from load or store instructions executed in AArch64 state, all the following can occur:
  - If the instruction was a load to either the base address register or the offset register, that register is restored to the original value, and any other destination registers become UNKNOWN.
  - If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
For implementations that include synchronous exception generation for floating-point exceptions, when a floating-point exception is taken, it is permitted that the cumulative floating-point exception bits are not restored.

For a synchronous exception that is taken from AArch64 state during an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instructions can be UNKNOWN, if all of the following apply:
- The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
- The registers are not involved in the calculation of the memory address used by the instruction.

For a synchronous exception or synchronous debug state entry, generated by a Memory Copy and Memory Set instruction, and for an asynchronous exception or asynchronous debug state entry part way through the execution of a Memory Copy and Memory Set instruction:
- The values of PSTATE.\{N,Z,C,V\} are UNKNOWN on exception entry. The values held in
  SPSR_ELx.\{N,Z,C,V\} on exception entry, and DSISR_EL0.\{N,Z,C,V\} on debug state entry, are the initial values for the instruction.
- All memory locations written by the pseudocode at the point at which the exception is taken are updated.
- If the memory locations that are not written by the pseudocode at the point at which the exception is taken are within the set of locations to be read by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception, then those memory locations are not updated.
- For CPYF*T* and SET{G}*T* instructions, no memory locations that are not written by the pseudocode at the point at which the exception is taken are updated.
- For Memory Copy and Memory Set instructions other than CPYF*T* and SET{G}*T*, any memory location that does not itself generate a synchronous exception on a write becomes UNKNOWN if all of the following apply:
  - The memory location is within the set of locations to be written by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception.
  - The memory location is not within the set of locations to be read by the instruction on that restart.
- Only for a synchronous exception or synchronous debug state entry, generated by a Memory Copy and Memory Set instruction:
  - On taking the exception, the X[n], X[d], and, as appropriate, X[s] register values hold a self-consistent set of values that correspond to the first element that was not copied or set, such that return to the instruction enables resumption of the memory copy or memory set. That first element does not need to be the element with a watchpoint, but can be an earlier element, including the first element.
  - If a memory location that generates a synchronous exception on a write is within the set of locations to be written by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception, and if the memory location is not within the set of locations to be read by the instruction on that restart, then the memory location is unchanged.
  - For a synchronous exception, ELR_ELx points to the instruction that generated the exception.
  - For a synchronous debug state entry, DLR_EL0 points to the instruction that generated the debug state entry.
- Only for an asynchronous exception or asynchronous debug state entry part way through the execution of a Memory Copy and Memory Set instruction:
  - On taking the exception, the values of the registers that are updated by the instruction are presented as a self-consistent set of values that correspond to the first element that was not copied or set.

R\textsubscript{ZNCXP} An exception is imprecise if it is not a precise exception.
Except for SError interrupts, all exceptions taken to AArch64 state are precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

An asynchronous Data Abort exception generated by a load that causes an SError exception to be taken at some point later in the instruction stream than the load that generated the exception, is usually imprecise. The SError exception is usually imprecise because the data returned from the load is UNKNOWN, and so can have corrupted the state that is presented at the time that the exception is taken.

**Preferred exception return address**

The preferred exception return address is an address that software might return to after handling an exception in order to resume execution.

The preferred exception return address is determined by the type of the exception.

For an exception taken to an Exception level, ELx, using AArch64, the Exception Link Register for that Exception level, ELR_ELx, is set to the preferred exception return address.

For asynchronous exceptions, the preferred exception return address is the address of the instruction following the instruction boundary at which the interrupt occurs.

For synchronous exceptions other than exception producing instructions, the preferred exception return address is the address of the instruction that generates the exception.

For an exception producing instruction that is executed, the preferred exception return address is the address of the instruction that follows the exception producing instruction.

For an exception producing instruction that is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception producing instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level, ELx, using AArch64, ELR_ELx[63:32] are 0.

**Exception vectors**

When an exception is taken to an Exception level that is using AArch64, execution starts at the exception vector.

The memory at the exception vector for an exception is expected to contain the handler code that corresponds to that exception category.

The vector base address for an Exception level, ELx, is defined by the Vector Base Address Register, VBAR_ELx.

Each exception category has an exception vector at a fixed offset from the vector base address.

Exceptions taken to AArch64 are categorized for the purpose of assigning exception vectors based on the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.
- Information about the Exception level that the exception came from.
- Information about the SP in use.
- The state of the register file.
The AArch64 System Level Programmers’ Model

D1.3 Exceptions

RKYXCL The following table describes the offsets that are added to the vector base address to describe the exception vector:

<table>
<thead>
<tr>
<th>Exception taken from</th>
<th>Offset for exception type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Synchronous (including synchronous External aborts if SCR_EL3.EASE is 0)</td>
</tr>
<tr>
<td>Current Exception level with SP_EL0.</td>
<td>0x000</td>
</tr>
<tr>
<td>Current Exception level with SP_ELx, x&gt;0.</td>
<td>0x200</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.</td>
<td>0x400</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch32.</td>
<td>0x600</td>
</tr>
</tbody>
</table>

For the preceding table, the implemented Exception level immediately lower than the target Exception level is defined by RFSZTB.

If EL3 is implemented, the Exception level immediately lower than the target Exception level is determined by whether the exception was taken from an Exception level in Secure or Non-secure state.

For an exception taken to EL3 from a lower Exception level, if EL2 is implemented and enabled for the security state of Exception level the exception was taken from, the Exception level immediately lower than EL3 is EL2.

For an exception taken to EL3 from a lower Exception level, if EL2 is not implemented and enabled for the security state of Exception level the exception was taken from, the Exception level immediately lower than EL3 is EL1.

D1.3.2 Exception entry

RDQXFW When an exception is taken to an Exception level, ELx, that is using AArch64 state, all of the following occur:

- The contents of PSTATE immediately before the exception was taken is written to SPSR_ELx.
- The preferred exception return address is written to ELR_ELx.
- The contents of PSTATE immediately after the exception is taken is as described in rule RWTXBY.
- For synchronous exceptions and SError interrupts, exception syndrome information is written to ESR_ELx.
- Execution starts from the exception vector at the target Exception level.

RWTXBY When an exception is taken to an Exception level, ELx, that is using AArch64 state, after recording the previous values in SPSR_ELx, the following PSTATE bits are set:

- PSTATE.EL is set to the target Exception level.
- All of PSTATE. {D, A, I, F, SP, TCO} are set to 1.
- PSTATE.SSBS is set to the value of SCTLR_ELx.DSSBS.
- PSTATE. {IL, nRw, UAO} are set to 0.
- PSTATE.BTYPE is set to 0b0.
- PSTATE.SS is set according to the rules in Chapter D2 AArch64 Self-hosted Debug.
- For any of the following situations, PSTATE.PAN is set to 1:
  - The target Exception level is EL1 and SCTLR_EL1.SPN is 0.
The exception is taken from EL0, the target Exception level is EL2 using AArch64, Secure EL2 is enabled, HCR_EL2.{TGE, E2H} is {1, 1}, and SCTLR_EL2.SPAN is 0.

- PSTATE.ALLINT is set to the inverse value of SCTLR_ELx.SPINTMASK.

If the Effective value of SCTLR_ELx.IESB is 1 at the target Exception level, an exception taken to AArch64 state is an error synchronization event.

If SCTLR_ELx.EIS is 1, exception entry is a context synchronization event. If SCTLR_ELx.EIS is 0, exception entry is not a context synchronization event, but the indirect writes to ESR_ELx, FAR_ELx, SPSR_ELx, ELR_ELx, and HPFAR_EL2 due to exception entry are synchronized so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.

The ordering of error synchronization and context synchronization on exception entry is described in the pseudocode.

Memory copy and memory set operations are guaranteed to function correctly only if the prologue, main, and epilogue Memory Copy and Memory Set instructions are executed in succession and are placed consecutively in memory. Failure to execute the three instructions in succession can result in the instructions causing exceptions. Software exception handlers are expected to require that the three instructions are placed consecutively in memory. If the three instructions are not placed consecutively in memory, exception returns to the wrong instructions might occur.

### Synchronous exception entry

For any of the following synchronous exceptions taken from an Exception level using AArch64, PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then PSTATE.BTYPE is set to 0:

- Software Step exception.
- PC Alignment Fault exception.
- Instruction Abort exception.
- Breakpoint exception.
- Address Matching Vector Catch exception.
- Illegal Execution state exception.
- Software Breakpoint exception.
- Branch Target exception.

When taking any other synchronous exception from an Exception level using AArch64, it is CONSTRAINED UNPREDICTABLE whether:

- SPSR_ELx.BTYPE is set to the value of PSTATE.BTYPE.
- SPSR_ELx.BTYPE is set to 0.

PSTATE.BTYPE is then set to 0.

For any of the following synchronous exception types, when an exception is taken to an Exception level, ELx, a virtual address that characterizes the exception is captured in FAR_ELx:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

For synchronous External aborts that are not caused by translation table walks, it is CONSTRAINED UNPREDICTABLE whether the FAR_ELx contains a virtual address that characterizes the exception. The ESR_ELx.FnV bit in the ISS encoding for the External abort indicates the validity of the virtual address in FAR_ELx:

- If ESR_ELx.FnV in the ISS encoding for the External abort is 1, the Faulting Virtual Address in FAR_ELx is UNKNOWN.
- If ESR_ELx.FnV in the ISS encoding for the External abort is 0, the Faulting Virtual Address in FAR_ELx is valid.

For all other exceptions taken to ELx, FAR_ELx is UNKNOWN.
For Instruction Abort or Data Abort exceptions caused by any of the following faults, when an exception is taken to EL2, an intermediate physical address that characterizes the exception is captured in HPFAR_EL2:

- A Translation fault on a stage 2 translation.
- An Access Flag fault on a stage 2 translation.
- A stage 2 Address Size fault.
- A fault on stage 2 translation of an address accessed in a stage 1 translation table walk.

For all other exceptions taken to EL2 using AArch64, HPFAR_EL2 is UNKNOWN.

If an Instruction Abort or Breakpoint exception is generated part way through execution of a Memory Copy and Memory Set instruction, presentation of the exception state is as described in R_TNVSL for a synchronous exception or synchronous debug state entry from a watchpoint, generated by a Memory Copy and Memory Set instruction.

For a CPy Memory Copy instruction, if both the read and write generate the Data Abort or Watchpoint exception, it is CONSTRAINED UNPREDICTABLE whether the exception on the read or the exception on the write is presented. ESR_ELX.ISS.WnR is set to be consistent with whether the exception was on the read or the write.

**SVE MOVPRFX exception entry behavior**

When a MOVPRFX instruction pairs legally with another instruction and the execution of the pair generates a synchronous exception, the return address that is stored in ELR_ELx is one of the following:

- When the MOVPRFX instruction did not cause a change to the architectural state, the address of the MOVPRFX instruction is stored.
- When the MOVPRFX instruction caused a change to the architectural state, the address of the prefixed instruction is stored.

When a MOVPRFX instruction pairs illegally with another instruction and execution of the pair causes entry to Debug state, the return address that is stored in DLR_EL0 is one of the following:

- When the MOVPRFX instruction did not cause a change to the architectural state, the address of the MOVPRFX instruction is stored.
- When the MOVPRFX instruction caused a change to the architectural state, the address of the prefixed instruction is stored.

When a prefixed instruction generates an Instruction Abort due to an MMU fault or synchronous External abort and the MOVPRFX does not generate an Instruction Abort, then the address of the prefixed instruction is recorded in the appropriate FAR_ELx or HPFAR_EL2 register and the address of the MOVPRFX instruction is recorded in the appropriate ELR_ELx register.

When a prefixed instruction generates an Instruction Abort due to an MMU fault or synchronous External abort and the MOVPRFX also generates an Instruction Abort, then the address of the MOVPRFX instruction is recorded in the appropriate FAR_ELx or HPFAR_EL2 register and the appropriate ELR_ELx register.
Asynchronous exception entry

When an asynchronous exception is taken from an Exception level using AArch64, PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then PSTATE.BTYPE is set to 0.

If any of the following apply, when a physical SError interrupt exception is taken to AArch64 state, the pending state of the physical SError is cleared:

- FEAT_DoubleFault is implemented.
- If the Reliability, Availability, and Serviceability Extension (RAS Extension) is implemented, and on taking the SError interrupt, the syndrome recorded in ESR_ELx indicates an SError other than IMPLEMENTATION DEFINED or uncategorized SError interrupt syndrome.

Otherwise, it is IMPLEMENTATION DEFINED whether the pending state of the physical SError is cleared. This IMPLEMENTATION DEFINED behavior might vary according to the type of the SError interrupt.

When a virtual SError interrupt exception is taken to AArch64 state, HCR_EL2.VSE is set to 0.

An asynchronous exception or asynchronous debug state entry part way through the execution of a Memory Copy and Memory Set instruction is permissible. For an asynchronous exception, ELR_ELx points to the instruction that the exception was taken on. For an asynchronous debug state entry, DLR_EL0 points to the instruction that the debug state entry was taken on.

For an imprecise asynchronous exception part way through the execution of a Memory Copy and Memory Set instruction, the following are UNKNOWN:

- The state of the X[n], X[d], and X[s] registers.
- The state of memory that was being written to by the instruction.

D1.3.3 Exception return terminology

Return, return from, return to

An exception return is caused by the execution of an exception return instruction.

The PE state immediately before an exception return instruction is executed is the state the exception returns from.

The PE state immediately after the execution of an exception return instruction is the state the exception returns to.

D1.3.4 Exception return

In AArch64 state, the Exception return instructions are ERET, ERETAA, and ERETAB.

The Exception return instructions are UNDEFINED in EL0.

An exception return is either legal or illegal.

Legal exception returns from AArch64 state

On a legal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, and the Exception return instruction does not generate an exception, the PE inserts an error synchronization event before the Exception return instruction.
- The PC is set to the value in ELR_ELx.
- If returning to an Exception level using AArch32 state, all of the following apply:
  - If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for setting the PC.
  - If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for setting the PC.
- The contents of PSTATE are set to the values held in SPSR_ELx.
• If the PSTATE.IL bit copied from SPSR_ELx is 1 and the target Exception level for the return is using AArch32 state, the PSTATE.\{IT,T\} bits are determined by an IMPLEMENTATION DEFINED choice of one of the following:
  — Set to 0.
  — For returns initiated by an Exception return instruction or DRPS instruction, copied from SPSR_ELx.
  — For debug exits, copied from DSPSR_EL0.

The IMPLEMENTATION DEFINED choice might vary dynamically within the implementation. Software must regard the value as being an UNKNOWN choice between the two values.

• The Event Register for the PE executing the Exception return instruction is set.

• The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.

• After the PC is set to the value held in ELR_ELx and the contents of PSTATE are set to the values held in SPSR_ELx, ELR_ELx and SPSR_ELx become UNKNOWN.

• If the Effective value of SCTLR_ELx.EOS is 1, the exception return is a context synchronization event.

• If the Effective value of SCTLR_ELx.EOS is 0, the exception return is not a context synchronization event.

**Illegal exception returns from AArch64 state**

If in AArch64 state, any of the following situations can cause an illegal exception return:

• A return is made to an Exception level higher than the current Exception level.

• A return is made to an Exception level that is not implemented.

• If all of the following are true, and a return is made to EL1:
  — EL2 is implemented and enabled in the current Security state
  — HCR_EL2.TGE is 1.

• If all of the following are true, and a return is made to EL2:
  — EL3 is implemented.
  — SCR_EL3.NS is 0.
  — FEAT_SEL2 is not implemented.

• If all of the following are true, and a return is made to EL2:
  — EL3 is implemented.
  — SCR_EL3.NS is 0.
  — FEAT_SEL2 is implemented.
  — SCR_EL3.EEL2 is 0.

• A return where the saved PSTATE.M[4] is 0 and at least one of the following is true:
  — M[1] is 1.
  — M[3:0] are 0b0001.
  — The Exception level being returned to is using AArch32 state, as determined by SCR_EL3.RW, HCR_EL2.RW, or as configured from reset.

• A return where the saved PSTATE.M[4] bit is 1, indicating a return to AArch32 state, and at least one of the following are true:
  — AArch32 state is not supported at any Exception level.
  — The M field value is not a valid AArch32 state PE mode.
  — The Exception level being returned to is using AArch64 state, as determined by SCR_EL3.RW, HCR_EL2.RW, or as configured from reset.
On an illegal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, the PE inserts an error synchronization event before the Exception return instruction.
- The PC is set to the value in ELR_ELx. If the saved PSTATE.M[4] bit is 1, for illegal exception returns to AArch32 state, all of the following are true:
  - The PC bits[31:2] are set to the value in ELR_ELx.
  - The PC bits[63:32, 1:0] are UNKNOWN.
- PSTATE.IL is set to 1.
- PSTATE.{EL, nRW, SP} are unchanged.
- PSTATE.{N, Z, C, V, D, A, I, F, PAN} are set to the associated values in SPSR_ELx.
- PSTATE.SS is handled as if the return is a legal exception return.
- PSTATE.{TCO, DIT, UAO, SSBS, BTYPE, ALLINT} are UNKNOWN.
- If PSTATE.nRW is 1, indicating a return to AArch32 state, then the following PSTATE bits are also set:
  - PSTATE.{Q, IT, GE, E} are set to the associated values in SPSR_ELx.
  - It is CONSTRAINED UNPREDICTABLE whether PSTATE.T is 0 or set to the contents of SPSR_ELx.
- The Event Register for the PE executing the Exception return instruction is set.
- The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.
- After the PC has been set to the value held in ELR_ELx and the contents of PSTATE have been set to the value held in SPSR_ELx, the ELR_ELx and SPSR_ELx become UNKNOWN.
- If the Effective value of SCTLR_ELx.EOS is 1, the exception return is a context synchronization event.
- If the Effective value of SCTLR_ELx.EOS is 0, the exception return is not a context synchronization event.

**D1.3.5 Synchronous exception types**

All of the following are Synchronous exceptions:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that are not allocated.
- Any exception caused by attempts to execute an instruction when the value of PSTATE.IL is 1. These are called Illegal Execution State exceptions.
- Any exception caused by the use of a misaligned SP. These are called SP Alignment Fault exceptions.
- Any exception caused by attempting to execute an instruction with a misaligned PC. These are called PC Alignment Fault exceptions.
- If executing inside a guarded memory region and PSTATE.BTYPE does not equal 0, any exception caused by executing an instruction that is not compatible with the current value of PSTATE.BTYPE. These are called Branch Target exceptions.
- Any exception caused by a pointer authentication instruction authentication failure. These are called PAC Fail exceptions.
- Any exception caused by the exception producing instructions SVC, HVC, or SMC. These are respectively called Supervisor Call (SVC) exceptions, Hypervisor Call (HVC) exceptions, or Secure Monitor Call (SMC) exceptions.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. These are called Trap exceptions.
- Any exception caused by Instruction Aborts that were generated by the memory address translation system that was associated with attempts to execute instructions from areas of memory that generate faults. These are called Instruction Abort exceptions.
• Any exception caused by Data Aborts that were generated by the memory address translation system that are associated with attempts to read or write memory that generate faults. These are called Data Abort exceptions.

• Any exception caused by Data Aborts because of a misaligned address. These are called Data Abort exceptions.

• If FEAT_MTE2 is implemented, any exception caused by a Data Abort as a result of a Tag Check Fault. These are called Data Abort exceptions.

• Memory Copy exceptions and Memory Set exceptions. For more information, see Memory Copy and Memory Set exceptions on page D1-4654.

• All of the debug exceptions:
  — Breakpoint Instruction exceptions.
  — Breakpoint exceptions.
  — Watchpoint exceptions.
  — Vector Catch exceptions.
  — Software Step exceptions.

• In an implementation that supports the trapping of floating-point exceptions, any exception caused by trapped floating-point exceptions. These are called Trapped Floating-point exceptions.

• An IMPLEMENTATION DEFINED set of exceptions caused by External aborts.

The architecture permits, but does not require, synchronous or asynchronous handling of External aborts.

The RAS architecture specifies some situations that must be handled synchronously.

Taking synchronous exceptions from EL0

If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 1, when any of the following exceptions are taken from EL0, they are taken to EL2. If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 0, when any of the following exceptions are taken from EL0, they are taken to EL1:

• Stage 1 Data Abort.
• Stage 1 Instruction Abort.
• PC Alignment Fault.
• SP Alignment Fault.
• Tag Check Fault.
• Branch Target Exception.
• Illegal Execution State Exception.
• Trapped Floating-point Exception.
• Supervisor Call.
• Undefined Instruction Exception.
• SVE Access Trap.
• PAC Fail Exception.
• WFE Trap.
• WFI Trap.
• Advanced SIMD and Floating-point access Trap.
• Synchronous External Aborts.
• Memory Copy and Memory Set Exceptions.

If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when any of the following debug exceptions are taken from EL0, they are taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, when any of the following debug exceptions are taken from EL0, they are taken to EL1:

• Breakpoint Exception.
• Software Breakpoint Exception.
• Software Step Exception.
• Watchpoint Exception.
If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when a Vector Catch exception is taken from EL0, it is taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, a Vector Catch exception cannot be taken.

For an exception that is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1:

- If the exception would have been reported in ESR_EL1 using any EC value other than 0x07, then the EC value and corresponding ISS encoding that would have been used to report the exception in ESR_EL1 are used to report the exception in ESR_EL2.
- If the exception would have been reported in ESR_EL1 using the EC value 0x07, then the EC value 0x00 and ISS encoding value 0x00 are reported in ESR_EL2.

Exception levels for taking a synchronous External abort

A synchronous external abort is taken to EL1 if executing at EL0 or EL1 and none of the following scenarios cause the synchronous external abort to be taken to EL2 or EL3. A synchronous external abort is taken to EL2 only if all of the following are true:

- SCR_EL3.EA is 0.
- EL2 is enabled and implemented in the current Security state.
- Execution is at an Exception level below EL3.
- If any of the following is true:
  - HCR_EL2.TEA is 1.
  - HCR_EL2.TGE is 1.
  - Execution is at EL2.

A synchronous external abort is taken to EL3 if any of the following are true:

- If executing at any Exception level and SCR_EL3.EA is 0b1.
- If executing at EL3.

SVE synchronous memory faults

In this section, the term Memory fault refers to the detection of an erroneous condition or debug event as a result of performing a data memory access for an SVE load or store instruction.

When an SVE load or store instruction results in a data memory access, the detection of any of the following conditions is considered to be a Memory fault:

- MMU fault.
- Alignment fault, excluding the SP alignment fault.
- Synchronous External abort, including synchronous parity error or ECC error.
- Watchpoint debug event.

For more information, see Memory aborts on page D8-5180.

The detection or generation of a Memory fault by an SVE load or store instruction may or may not cause a synchronous Data Abort or Watchpoint exception to be taken.

Unless otherwise specified in this section, SVE vector load and store instructions that detect a Memory fault cause a Data Abort or Watchpoint exception to be taken, as described in SVE Data Abort and Watchpoint exceptions on page D1-4649.

A Memory fault detected for a memory location that can only be accessed by an Inactive element of a predicated SVE vector load or store instruction is ignored and does not cause a Data Abort or Watchpoint exception to be taken by that instruction.
**SVE Data Abort and Watchpoint exceptions**

**RKJPTS**

Unless otherwise specified in this section, a Data Abort and Watchpoint exception caused by an SVE load or store instruction follows the behaviors described in Definition of a precise exception and imprecise exception on page D1-4638, Exception entry on page D1-4641, and Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.

**IDGSNC**

SVE load and store instructions can generate a sequence of single-copy atomic memory accesses that might not be completed due to a Memory fault causing a Data Abort or Watchpoint exception to be taken during the memory access sequence.

**RZKBRX**

When the execution of an SVE load or store instruction detects multiple Memory faults caused by different single-copy atomic memory accesses, the Memory faults are not prioritized by the architecture.

**IMSVYK**

When an SVE load or store instruction that has not been architecturally executed is restarted after an exception return, any memory locations that it accessed before taking the exception might be accessed again. Therefore, SVE load or store instructions might perform multiple accesses to memory locations that do not cause a Memory fault but which are sensitive to the number of accesses, or have been modified between the accesses.

**RZNXNXT**

When execution of an SVE load instruction causes a Data Abort or Watchpoint exception to be taken and the destination is not a vector register that is also used as a base or index register by the instruction, then all elements of the destination register become UNKNOWN.

**RSNQJR**

When execution of an SVE load instruction causes a Data Abort or Watchpoint exception to be taken and the destination is a vector register that is also used as a base or index register by the instruction, then all elements of the destination vector register are restored to their original value prior to execution of the load instruction.

**RDWYCY**

When execution of an SVE predicated vector store instruction causes a Data Abort or Watchpoint exception to be taken, one or more of the following occurs:

- Memory locations that are associated with Active elements and which do not generate a Memory fault become UNKNOWN.
- Memory locations that are associated with Active elements and which generate a Memory fault are unchanged.
- Memory locations that are only associated with Inactive elements are unchanged.

**SVE First-fault and Non-fault loads**

**IJBGW**

When a memory access performed for the First active element of an SVE First-fault vector load instruction detects a Memory fault, this causes a synchronous exception to be taken as described in SVE Data Abort and Watchpoint exceptions.

**IDXING**

When a memory access performed for the First active element of an SVE First-fault vector load instruction does not detect a Memory fault, the other elements are handled in the same way as the elements of an SVE Non-fault vector load instruction.

**RJKGJY**

A Data Abort or Watchpoint exception is not generated when a Memory fault is detected by a memory access performed for any of the following elements:

- Any Active element of an SVE Non-fault vector load.
- Any Active element of an SVE First-fault vector load except for the First active element.

**RMNKNV**

The PE can choose to suppress a memory access performed for any of the following elements:

- Any Active element of an SVE Non-fault vector load.
- Any Active element of an SVE First-fault vector load except for the First active element.

**RHYFRN**

When a memory access performed for any of the following elements detects a Memory fault or is suppressed for any other reason, the FFR predicate elements starting from that element number, up to and including the highest-numbered element, are set to FALSE:

- Any Active element of an SVE Non-fault vector load.
- Any Active element of an SVE First-fault vector load except for the First active element.
An FFR predicate element is never set to TRUE by an SVE vector load, therefore the fault indications are cumulative.

After an SVE Non-fault vector load or First-fault vector load is executed, each destination vector element contains one of the values listed in the following table:

<table>
<thead>
<tr>
<th>Corresponding FFR element</th>
<th>Vector element status</th>
<th>Content of destination vector element</th>
</tr>
</thead>
</table>
| FALSE                     | Active                | Each byte of the element contains an independently CONSTRAINED UNPREDICTABLE choice of one of the following:  
  • 0.  
  • The previous value of that byte in the destination vector register.  
  • If and only if all of the following apply, the value read from memory:  
    — The memory access for that byte was not an access to any type of Device memory.  
    — The memory access for that byte does not return information that cannot be accessed at the current or a lower level of privilege. |
| FALSE                     | Inactive              | A CONSTRAINED UNPREDICTABLE choice of:  
  • 0.  
  • The previous value of that vector element. |
| TRUE                      | Active                | The value read from memory. |
| TRUE                      | Inactive              | 0. |

In the previous table, watchpoints are not a mechanism for preventing access to memory.

**Priority of Synchronous exceptions taken to AArch64 state**

The following list shows the priorities for Synchronous exceptions taken to an Exception level using AArch64. The highest priority is 1. The AArch64 Priority numbers correlate with the equivalent AArch32 and Debug prioritization lists.

<table>
<thead>
<tr>
<th>Priority</th>
<th>Synchronous exception type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Reset Catch debug event. See Reset Catch debug events on page H3-10293.</td>
</tr>
<tr>
<td>2</td>
<td>Exception Catch debug event if it has a priority of 2. See Reset Catch debug events on page H3-10293.</td>
</tr>
<tr>
<td>3</td>
<td>Halting Step debug event. See Halting Step debug events on page H3-10276.</td>
</tr>
<tr>
<td>4</td>
<td>Software Step Exception used during Debug. See Software Step exceptions on page D2-4742.</td>
</tr>
<tr>
<td>5</td>
<td>Exception Catch debug events. See Exception Catch debug event on page H3-10287.</td>
</tr>
<tr>
<td>6</td>
<td>PC alignment fault exception. See PC alignment checking on page D1-4668.</td>
</tr>
<tr>
<td>7</td>
<td>Instruction Abort exceptions, including exceptions generated by a Translation Table Walk not prioritized as 29. See MMU fault prioritization from a single address translation stage on page D8-5190.</td>

<td>Software Breakpoint exceptions, caused by execution of a Breakpoint instruction.</td>
</tr>
</tbody>
</table>
D1.3 Exceptions

11 Branch Target exception. See PSTATE.BTYPE on page D8-5133.

12 Exceptions taken from EL1 to EL2 because of the configuration of one of the following:
   • HSTR_EL2.Tn.
   • HCR_EL2.TIDCP.
   • If FEAT_NV is implemented, HCR_EL2.{NV1, NV}.
Exceptions taken from EL0 to EL1 or EL2 because of the configuration of the following:
   • If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP.
Exceptions taken from EL0 to EL2 because of the configuration of the following:
   • If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP.

13 Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons:
   • Attempting to execute a uDF instruction.
   • Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   • Attempting to execute an instruction that is defined to never be accessible at the current Exception level and Security state, regardless of any enables or traps.
   • Debug state execution of an instruction encoding that is not accessible in Debug state.
   • Non-debug state execution of an instruction encoding that is not accessible in Non-debug state.
   • If HVC instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD, attempting to execute an HVC instruction.
   • If SPSel.SP is 0, attempting to execute an MSR or MRS instruction to SP_EL0.
   • If HCR_EL2.E2H is 0, attempting to execute an MSR or MRS instruction using an _EL12 register name.
   • If FEAT_FGT and FEAT_PMUv3 are implemented, attempting to execute an MSR or MRS instruction in AArch64 state, or an MCR or MRC instruction in AArch32 state, that accesses a register associated with an unimplemented event counter.
   • If HLT instructions are disabled by EDSCR.HDE or halting is prohibited, attempting to execute an HLT instruction.
   • If in Debug state:
     — If HCR_EL2.TGE is 1, attempting to execute a DCPS1 instruction in Non-secure EL0.
     — If EL2 is disabled in the current Security state or is not implemented, attempting to execute a DCPS2 instruction in EL1 or EL0.
     — If EDSCR.SDD is 1 or EL3 is not implemented, attempting to execute a DCPS3 instruction.
     — If EDSCR.SDD is 1, attempting to execute in EL2, EL1, or EL0 an instruction that is configured by EL3 control registers to trap to EL3. It is IMPLEMENTATION DEFINED whether this type of exception is prioritized at this level or has the priority of the original trap exception.
   • If in AArch32 state:
     — If SCTLR_EL1.ITD is 1, attempting to execute an instruction in an IT block.
     — If SCTLR_EL1.SED is 1, attempting to execute a SETEND instructions.
     — If SCTLR_EL1.CP15BEN is 0, attempting to execute a CP15DSB, CP15SDB, or CP15SBE barrier instruction.
   • Attempting to execute an instruction that is UNDEFINED because all of the following apply:
     — EL0 is using AArch32.
     — EL1 is using AArch64.
     — Programming FPCR. {Stride, Len} to nonzero values is supported.
     — One or more of FPCR. {Stride, Len} is nonzero.

14 If all of the following apply, any exception that is generated by a configurable trap or enable:
   • The exception is not already covered by priorities 4-13.
   • The exception is taken to EL1, or if HCR_EL2.TGE is 1, is taken to EL2.
15 As the result of a configuration control in one of the following registers, an exception taken from EL0 to EL2:
   • When the exception is taken to AArch64 state:
     — HSTR_EL2.T
     — HCR_EL2.TIDCP.
   • When the exception is taken to AArch32 state:
     — HSTR.Tn.
     — HCR.TIDCP.

16 As the result of a configuration control in one of the following registers, an exception taken to EL2:
   • When the exception is taken to AArch64 state: CPTR_EL2.
   • When the exception is taken to AArch32 state: in HCPTR.

17 As the result of a configuration control in one of the following registers, an exception taken to EL2:
   • When the exception is taken to AArch64 state:
     — HCR_EL2: Other than a setting made in the {TIDCP, NV} fields, and MRS/MSR instruction using an _EL12
     register name with HCR_EL2.E2H is 0.
     — CNTHCTL_EL2: Any setting.
     — MDCR_EL2: Any setting.
     — Any of the following fine-grained traps:
       — HAFGRTR_EL2.
       — HDFGRTR_EL2.
       — HDFGWTR_EL2.
       — HFGITR_EL2.
       — HFGTR_EL2.
       — HFGWTR_EL2.
   • When the exception is taken to AArch32 state:
     — HCR: Other than the TIDCP bit.
     — CNTHCTL: Any setting.
     — HDCR: Any setting.

18 Other than an exception defined by priorities 4-17 inclusive, any exception that is the result of a configurable access to
instructions, and the exception is taken to EL2.

19 An exception caused by the SMC instruction being UNDEFINED because SCR_EL3.SMD is 1.

20 An exception caused by any of the following Exception producing instructions:
   • HVC.
   • SMC.
   • SVC.
For AArch64 State, see Branches, Exception generating, and System instructions on page C3-248.

21 An exception taken to EL3 as the result of configuration controls in CPTR_EL3. It is IMPLEMENTATION DEFINED whether
the exception is prioritized as an UNDEFINED instruction or has the priority of the original Trap exception.

22 Exceptions Trapped to EL3 from Secure EL1 using AArch32.

23 An Exception taken to EL3 from EL0, EL1, or EL2 as a result of configuration controls in MDCR_EL3. It is
IMPLEMENTATION DEFINED whether the exception is prioritized as an UNDEFINED instruction or has the priority of the
original Trap exception.

24 Other than an exception defined by priorities 4-23, inclusive, any exception taken to EL3 because of a configurable
access to an instruction. It is IMPLEMENTATION DEFINED whether the exception is prioritized as an UNDEFINED instruction
or has the priority of the original Trap exception.
Trapping of floating-point exceptions

Execution of a floating-point instruction, or execution of an Advanced SIMD or SVE instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

The architecture does not support asynchronous reporting of floating-point exceptions. If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements on when that synchronous exception is generated do not apply.

For any of the implemented floating-point exceptions listed in \texttt{R\textsubscript{BBSGN}}, FPCR provides control bits to enable synchronous exception generation.
The Exception level that a Trapped Floating-point exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

If an implementation includes synchronous exception generation for floating-point exceptions in AArch64 state, when the execution of separate operations in separate SIMD or SVE elements causes multiple floating-point exceptions, the ESR_ELx reports only the exceptions associated with one element that the instruction uses. The architecture does not specify which element is reported.

When a floating-point exception is trapped, all of the following apply:

- When the trapped floating-point exception is taken, it is IMPLEMENTATION DEFINED whether the FPSR is restored to the value of the FPSR immediately before the instruction that generated the trapped floating-point exception. When the trapped floating-point exception is taken, if the FPSR is not restored, it is CONSTRAINED UNPREDICTABLE which untrapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative floating-point exception bits having the value 1.
- In ESR_ELx at the target Exception level, all of the following apply:
  - The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
  - If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
  - If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is CONSTRAINED UNPREDICTABLE whether the floating-point exception trapped bit is set to 1.

For trapped floating-point exceptions from Advanced SIMD or SVE instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction.

**Memory Copy and Memory Set exceptions**

If an exception is taken during the execution of Memory Copy and Memory Set instructions, and execution of these instructions restarts on a physical hardware PE implementation that is different from where the exception was taken from, then a Memory Copy or Memory Set exception can be generated.

For CPYE*, CPYFE*, CPYFM*, and CPYM* instructions, if the instruction algorithm option indicated by the value of PSTATE.C is different from the PSTATE.C value of the implementation, then a Memory Copy exception is generated.

For SETE*, SETGE*, SETGM*, and SETM* instructions, if the instruction algorithm option indicated by the value of PSTATE.C is different from the PSTATE.C value of the implementation, then a Memory Set exception is generated.

For CPYE*, CPYFE*, CPYFM*, and CPYM* instructions, if the instruction alignment and size requirements of the implementation that an exception is taken from are different from the alignment and size requirements of the implementation that is returned to, then a Memory Copy exception is generated.

For SETE*, SETGE*, SETGM*, and SETM* instructions, if the instruction alignment and size requirements of the implementation that an exception is taken from are different from the alignment and size requirements of the implementation that is returned to, then a Memory Set exception is generated.

The Memory Copy and Memory Set exceptions that are caused by alignment and size requirement differences can be avoided if the following apply:

- The CPYFP*, CPYP*, SETGP*, or SETP* instruction is executed before the appropriate CPYFM*, CPYM*, SETGM*, or SETM* on the same implementation.
• The CPYFM*, CPYM*, SETGM*, or SETM* instruction is executed before the appropriate CPYFE*, CPYE*, SETGE*, or SETE* on the same implementation.

The generic return routine for Memory Copy and Memory Set exceptions is to adjust the register arguments to be consistent with performing a new memory copy or memory set, and then to return to the CPYFP*, CPYP*, SETGP*, or SETP* instruction to restart the memory copy or memory set.

The generic return routine for Memory Copy and Memory Set exceptions can be used by relying on the Memory Copy and Memory Set instructions being placed consecutively in memory - prologue, then main, and then epilogue.

The generic return routine for Memory Copy exceptions is shown in the following pseudocode:

```c
if OptionA && WrongOption || OptionB && !WrongOption then
    // format is from option B
    if SPSR_ELx.N=='1' then
        // backward copy
        DestReg = DestReg - SizeReg;
        SrcReg = SrcReg - SizeReg;
    else // format is from option A;
        if SizeReg<63>=='1' then
            // forward copy
            DestReg = DestReg + SizeReg;
            SrcReg = SrcReg + SizeReg;
            SizeReg = -1*SizeReg;
            if FromEpilogue then
                ReturnAddress = ELR_ELx - 8;
            else
                ReturnAddress = ELR_ELx - 4;
        end
    end
end
```

The generic return routine for Memory Set exceptions is shown in the following pseudocode:

```c
if !OptionA && WrongOption || (OptionA && !WrongOption) then
    // format is from Option A
    // forward set
    DestReg = DestReg + SizeReg;
    SizeReg = -1*SizeReg;
    if FromEpilogue then
        ReturnAddress = ELR_ELx - 8;
    else
        ReturnAddress = ELR_ELx - 4;
end
```

The information in the ESR_ELx.ISS field is sufficient to allow the diagnosis of the reason for a Memory Copy or Memory Set exception being generated and to allow a generic emulation of the memory copy or memory set.

The Exception levels that Memory Copy and Memory Set exceptions are taken to are as follows:

• From EL0, to EL1 if HCR_EL2.TGE is 0. Otherwise, they are taken to EL2.
• From EL1, to either EL1 or EL2, depending on the value of HCRX_EL2.MCE2.
• From EL2 or EL3, to the same Exception level.

The HCRX_EL2.MCE2 control bit allows Memory Copy and Memory Set exceptions to be handled in a system where Memory Copy and Memory Set instructions might be used at EL1 at times when taking an exception to EL1 is not acceptable. This is necessary only if there is a possibility of the migration of EL1 code between different physical hardware PE implementations when EL1 is not tolerant of taking an exception.
D1.3.6 Asynchronous exception types

The Arm architecture exception model distinguishes two classes of asynchronous exceptions:

- Physical Interrupts
- Virtual Interrupts

There are three types of physical interrupt:

- SError (also described as a System Error).
- IRQ.
- FIQ.

There are three types of virtual interrupt:

- vSError (also described as a Virtual System Error).
- vIRQ.
- vFIQ.

IRQ, FIQ, vIRQ, and vFIQ interrupts are precise asynchronous exceptions.

If FEAT_NMI is implemented and SCTLR_ELx.NMI is 1, IRQ, FIQ, vIRQ, and vFIQ interrupts can have Superpriority as an additional attribute. When SCTLR_ELx.NMI is 0, the denotation of Superpriority has no effect on these interrupts. See also R_MHWHB, R_GFXXY, R_SNLHR, and R_XSPSG.

The mechanism by which Superpriority is assigned is IMPLEMENTATION DEFINED.

Each physical interrupt type can be assigned a target Exception level of EL1, EL2, or EL3.

ISR_EL1 shows the pending status of interrupts as follows:

- When read from EL2 or EL3, ISR_EL1 shows the pending status of each of the physical interrupts IRQ, FIQ, and SError.
- When read from EL1, ISR_EL1 shows:
  - The pending status of the virtual interrupts, vIRQ, vFIQ, and vSError if they are enabled by the Effective values of the corresponding HCR_EL2.{IMO, FMO, AMO} enables.
  - The pending status of the physical interrupts, IRQ, FIQ, and SError if the corresponding virtual interrupts are not enabled by the Effective values of the HCR_EL2.{IMO, FMO, AMO} enables.

An implementation might support other mechanisms for signaling a virtual interrupt.

The mechanism by which physical interrupts are signaled to the PE are IMPLEMENTATION DEFINED and might be either edge or level sensitive. A common implementation choice is that the IRQ and FIQ interrupts are level sensitive, and this is supported by the Generic Interrupt Controller (GIC).

The physical SError interrupt is often used, amongst other things, for communicating External aborts from the memory system that are to be taken asynchronously.

For an External abort generated by the memory system that is taken asynchronously using the SError interrupt, the SError interrupt always behaves as an edge-triggered interrupt. For any other sources of SError interrupts, it is IMPLEMENTATION DEFINED whether they are edge-triggered or level-sensitive.

When taking an SError or a vSError interrupt to an Exception level using AArch64, ESR_ELx at the target Exception level is updated to describe an SError interrupt. If the RAS extension is implemented, when taking a vSError interrupt to an Exception level using AArch64, ESR_ELx at the target Exception level is updated with exception syndrome information from VESER_EL2.

When taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, ESR_ELx at the target Exception level is not updated.
Virtual interrupts

Each virtual interrupt type can be independently enabled from EL2. If a virtual interrupt type is enabled from EL2, the target Exception level for the corresponding physical interrupt is not EL1.

Each virtual interrupt type can be set to the pending state by EL2 using controls in HCR_EL2.

Pending vIRQ and vFIQ interrupts can be assigned Superpriority by using controls in HCRX_EL2.

If HCR_EL2.TGE is 0, setting an HCR_EL2.{FMO, IMO, AMO} routing control bit to 1 enables the corresponding virtual interrupt. If HCR_EL2.TGE is 1, all virtual interrupts are disabled and the Effective values of HCR_EL2{FMO, IMO, AMO} are 0.

If a virtual interrupt type is enabled, that type of interrupt can be generated by any one of the following:
- Execution at EL0 or EL1 if the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, is 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller.

If a virtual interrupt is disabled, the virtual interrupt cannot be taken.

The following table describes the bits that enable virtual interrupts, the bits that cause virtual interrupts to be pending in HCR_EL2, and the bits that enable signaling of pending virtual interrupts with Superpriority in HCRX_EL2:

<table>
<thead>
<tr>
<th>Virtual interrupt type</th>
<th>Enable control</th>
<th>Cause a virtual interrupt to be pending</th>
<th>Pending virtual interrupt has Superpriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSError</td>
<td>HCR_EL2.AMO</td>
<td>HCR_EL2.VSE</td>
<td>n/a</td>
</tr>
<tr>
<td>vIRQ</td>
<td>HCR_EL2.IMO</td>
<td>HCR_EL2.VI</td>
<td>HCRX_EL2.VINMI</td>
</tr>
<tr>
<td>vFIQ</td>
<td>HCR_EL2.FMO</td>
<td>HCR_EL2.VF</td>
<td>HCRX_EL2.VFNMI</td>
</tr>
</tbody>
</table>

When taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in HCR_EL2 retains its state.

If the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

When taking a vSError interrupt, HCR_EL2.VSE is cleared to 0.

Establishing the target Exception level of an asynchronous exception

The terms used in the table in this section have the following meanings:

<table>
<thead>
<tr>
<th>Term</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3</td>
<td>The Effective value of a field in SCR_EL3.</td>
</tr>
<tr>
<td>EEL2</td>
<td>If EL3 is not implemented, the Effective value of SCR_EL3.EEL2 is 1.</td>
</tr>
<tr>
<td>FIQ</td>
<td>The Effective value of the field that configures the asynchronous exception type in SCR_EL3. The Effective value of the field is one of the following:</td>
</tr>
<tr>
<td>IRQ</td>
<td>• If EL3 is implemented, the FIQ/IRQ/EA fields are taken from SCR_EL3.</td>
</tr>
<tr>
<td>EA</td>
<td>• If EL3 is not implemented, the Effective value of these fields is 0.</td>
</tr>
<tr>
<td>RW</td>
<td>If EL3 is not implemented, the Effective value of SCR_EL3.RW is 1.</td>
</tr>
<tr>
<td>HCR</td>
<td>If EL2 is using AArch32, this is the Effective value of a field in HCR. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.</td>
</tr>
</tbody>
</table>
The AArch64 System Level Programmers' Model

### D1.3 Exceptions

#### RNMMXK

The following table describes the routing of physical interrupts if the highest implemented Exception level is using AArch64.

<table>
<thead>
<tr>
<th>Term</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TGE</td>
<td>If EL2 is not implemented, the Effective value of HCR.TGE or HCR_EL2.TGE is 0.</td>

</tbody>
</table>
Asynchronous exception masking

An interrupt can be masked. A masked interrupt is not taken and remains pending.

Whether an interrupt is masked is determined by all of the following:
- The PSTATE.{A, I, F, ALLINT, SP} bits.
- The value of AllIntMask, as described in RXZPDT.
- Whether an IRQ or FIQ interrupt has Superpriority.
- The implemented Exception levels.
- The configuration of the Hypervisor Configuration Register.
- The configuration of the Secure Configuration Register.

If in AArch64 state and the target Exception level of an interrupt is lower than the current Exception level, the interrupt is masked.

If FEAT_NMI is implemented and SCTLR_ELx.NMI is 1, all of the following apply:
- The AllIntMask variable is created and is defined as follows:

  \[
  \text{AllIntMask} = \text{PSTATE.ALLINT} || (\text{PSTATE.SP} \&\& \text{SCTLR_ELx.SPINTMASK})
  \]
- When AllIntMask is 1 and execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx is masked regardless of Superpriority.
- When AllIntMask is 0 and execution is at ELx:
  - An IRQ or FIQ interrupt with Superpriority that is targeted to ELx is not masked by PSTATE.I or PSTATE.F, respectively.
  - An IRQ or FIQ interrupt without Superpriority that is targeted to ELx is masked by PSTATE.I or PSTATE.F, respectively, in the same way as when the Effective value of SCTLR_ELx.NMI is 0.

AllIntMask does not affect the masking or routing of interrupts to a higher Exception level.

If FEAT_NMI is not implemented or SCTLR_ELx.NMI is 0, the Effective value of AllIntMask is 0.
Physical interrupt masking

If the target Exception level of a physical IRQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

<table>
<thead>
<tr>
<th>PSTATE.I</th>
<th>SCTLR_ELx.NMI</th>
<th>AllIntMask</th>
<th>IRQ</th>
<th>IRQ with Superpriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>x</td>
<td>Not masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>0 1</td>
<td>0</td>
<td>Not masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>0 1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
<tr>
<td>1 0</td>
<td>x</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
<tr>
<td>1 1</td>
<td>0</td>
<td>Masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>1 1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
</tbody>
</table>

If the target Exception level of a physical FIQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

<table>
<thead>
<tr>
<th>PSTATE.F</th>
<th>SCTLR_ELx.NMI</th>
<th>AllIntMask</th>
<th>FIQ</th>
<th>FIQ with Superpriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>x</td>
<td>Not masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>0 1</td>
<td>0</td>
<td>Not masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>0 1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
<tr>
<td>1 0</td>
<td>x</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
<tr>
<td>1 1</td>
<td>0</td>
<td>Masked</td>
<td>Not masked</td>
<td></td>
</tr>
<tr>
<td>1 1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
<td></td>
</tr>
</tbody>
</table>

If the target Exception level of a physical SError interrupt is the current Exception level, the PSTATE.A control determines whether the interrupt is masked. However, if all of the following are true, the PSTATE.A control is ignored, and the interrupt is taken:

- The target Exception level is the current Exception level.
- FEAT_DoubleFault is implemented.
- SCR_EL3.NMEA is 1.

If the target Exception level of a physical interrupt is higher than the current Exception level, all of the following apply:

- If the target Exception level is EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2 and any of the following are true, the interrupt cannot be masked by the PSTATE.{A, I, F} bits:
  - HCR_EL2.E2H is 0.
  - HCR_EL2.TGE is 0.
- If the target Exception level is EL2 and all of the following are true, the interrupt can be masked by the PSTATE.{A, I, F} bits:
  - HCR_EL2.E2H is 1.
  - HCR_EL2.TGE is 1.
  - The interrupt does not have Superpriority or SCTLR_EL2.NMI is 0.
• If the target Exception level is EL1 and the interrupt does not have Superpriority or SCTLR_EL1.NMI is 0, the interrupt can be masked by the PSTATE. {A, I, F} bits.

The ability to execute in EL0 with interrupts taken to EL1 masked is required by some user level driver code.

The terms used in the table in this section have the following meanings:

<table>
<thead>
<tr>
<th>Term</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3</td>
<td>This is the Effective value of a field in SCR_EL3.</td>
</tr>
<tr>
<td>EEL2</td>
<td>If EL3 is not implemented, the Effective value of SCR_EL3.EEL2 is 1. If FEAT_SEL2 is not implemented, the Effective value of SCR_EL3.EEL2 is 0.</td>
</tr>
<tr>
<td>FIQ</td>
<td>The Effective value of the field that configures the asynchronous exception type in SCR_EL3. If EL3 is implemented, the FIQ/IRQ/EA field are taken from SCR_EL3. If EL3 is not implemented, then the Effective value of these fields is 0.</td>
</tr>
<tr>
<td>IRQ</td>
<td></td>
</tr>
<tr>
<td>EA</td>
<td></td>
</tr>
<tr>
<td>RW</td>
<td>If EL3 is not implemented, the Effective value of SCR_EL3.RW is 1.</td>
</tr>
<tr>
<td>HCR</td>
<td>If EL2 is using AArch32, this is the Effective value of a field in HCR. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.</td>
</tr>
<tr>
<td>TGE</td>
<td>If EL2 is not implemented, the Effective value of HCR.TGE or HCR_EL2.TGE is 0.</td>
</tr>
<tr>
<td>E2H</td>
<td>If EL2 is not implemented, the Effective value of HCR.E2H or HCR_EL2.E2H is 0.</td>
</tr>
<tr>
<td>FMO</td>
<td>The Effective value of the mask override field for the asynchronous exception type in HCR or HCR_EL2. The Effective value of the field is one of the following:</td>
</tr>
<tr>
<td>IMO</td>
<td>• If EL2 is implemented, the FMO/IMO/AMO fields are taken from HCR_EL2.</td>
</tr>
<tr>
<td>AMO</td>
<td>• If EL2 is not implemented, the Effective value of these fields is 0.</td>
</tr>
<tr>
<td>A</td>
<td>When the interrupt is pending, it is taken regardless of the value of the PSTATE. {A, I, F, ALLINT, SP} interrupt masks.</td>
</tr>
<tr>
<td>B</td>
<td>When the interrupt is pending, it might be subject to masking, as defined in RMHWBP. If the interrupt is masked, it is not taken. If the interrupt is not masked, it is taken.</td>
</tr>
<tr>
<td>A/B</td>
<td>SEError interrupts behave as A. FIQ and IRQ interrupts behave as B.</td>
</tr>
<tr>
<td>C</td>
<td>When the interrupt is pending, it is not taken, regardless of the value of the PSTATE. {A, I, F, ALLINT, SP} interrupt masks.</td>
</tr>
<tr>
<td>n/a</td>
<td>Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.</td>
</tr>
</tbody>
</table>

The following table describes the target and masking of physical interrupts, if the highest implemented Exception level is using AArch64.

<table>
<thead>
<tr>
<th>SCR_EL3</th>
<th>HCR</th>
<th>Effect of the interrupt mask when executing at:</th>
</tr>
</thead>

</tbody>
</table>
Virtual interrupt masking

If the target Exception level of a virtual IRQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

<table>
<thead>
<tr>
<th>PSTATE.I</th>
<th>SCTLR_ELx.NMI</th>
<th>AllIntMask</th>
<th>vIRQ</th>
<th>vIRQ with Superpriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 x</td>
<td></td>
<td></td>
<td></td>
<td>Not Masked</td>
</tr>
<tr>
<td>0 1 0</td>
<td></td>
<td></td>
<td></td>
<td>Not Masked</td>
</tr>
<tr>
<td>0 1 1</td>
<td></td>
<td></td>
<td></td>
<td>Masked</td>
</tr>
<tr>
<td>1 0 x</td>
<td></td>
<td>Masked</td>
<td></td>
<td>Masked</td>
</tr>
<tr>
<td>1 1 0</td>
<td></td>
<td>Masked</td>
<td></td>
<td>Not Masked</td>
</tr>
<tr>
<td>1 1 1</td>
<td></td>
<td>Masked</td>
<td></td>
<td>Masked</td>
</tr>
</tbody>
</table>

Virtual interrupt masking
RSNLJH
If the target Exception level of a virtual FIQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

<table>
<thead>
<tr>
<th>PSTATE.F</th>
<th>SCTLR_ELx.NMI</th>
<th>AllIntMask</th>
<th>vFIQ</th>
<th>vFIQ with Superpriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>x</td>
<td>Not Masked</td>
<td>Not Masked</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>Not Masked</td>
<td>Not Masked</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
</tr>
<tr>
<td>1</td>
<td>0</td>

<td>0</td>
<td>Masked</td>
<td>Not Masked</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Masked</td>
<td>Masked</td>
</tr>
</tbody>
</table>

Virtual interrupts can only be taken from EL0 or EL1 and can only be taken to EL1. If EL2 is not enabled in the current Security state, all types of virtual interrupts are always masked. If executing at EL2 or EL3, all types of virtual interrupts are always masked.

If the target Exception level of a virtual SError interrupt is the current Exception level, ELx, the PSTATE.A control determines whether the interrupt is masked. However, if all of the following are true, the PSTATE.A control is ignored, and the interrupt is taken:

- The target Exception level is the current Exception level.
- FEAT_DoubleFault is implemented.
- SCR_EL3.NMEA is 1.

The terms used in the table in this section have the following meanings:

**Prioritization of interrupts**

The prioritization of physical interrupts and virtual interrupts is IMPLEMENTATION DEFINED.

For all of the following Context synchronization events, if an interrupt is pending before the Context synchronization event, and the interrupt remains pending and is not masked after the Context synchronization event, the interrupt is taken before the first instruction after the Context synchronization event:

- Execution of an ISB instruction.
- If FEAT_ExS is not implemented, exception entry.
- If FEAT_ExS is implemented and the appropriate SCTLR_ELx.EIS bit is set, exception entry.
- If FEAT_ExS is not implemented, exception return.
- If FEAT_ExS is implemented and the appropriate SCTLR_ELx.EOS bit is set, exception exit.
- Exit from Debug state.

If the first instruction after the context synchronizing event generates a synchronous exception, the architecture does not define whether the PE takes the interrupt or the synchronous exception first.

A RAS error synchronization event defines additional requirements for taking an SError interrupt.

Other than the behaviors described in RRBZYL, an unmasked, pending interrupt must be taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, it is CONSTRAINED UNPREDICTABLE whether or not the interrupt is taken. If the interrupt is taken, it is taken before the first context synchronization event after the interrupt was changed to be not pending.

**Taking an interrupt during a multi-access load or store**

If in AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.
Taking an interrupt during an SVE instruction

Permitting SVE instructions to be interrupted by asynchronous exceptions is IMPLEMENTATION DEFINED.

When returning from an asynchronous exception, an interrupted SVE instruction is restarted and cannot resume at the point the instruction was interrupted.

For Data Aborts taken asynchronously, see Definition of a precise exception and imprecise exception on page D1-4638.

D1.3.7 UNDEFINED instructions

An instruction which is UNDEFINED generates a synchronous exception for that instruction unless there is a higher priority exception generated for that instruction.

The Exception level that the synchronous Undefined Instruction exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

D1.3.8 Configurable instruction controls

Configurable instruction controls are control bits held in System registers that determine whether attempting to execute an instruction generates a synchronous exception at the point in the instruction stream of that instruction, and the instruction is not executed.

Configurable instruction controls might be referred to by any of the following names:

- Instruction enables.
- Instruction disables.
- Trap controls.

The definitions of each type overlap, and in some cases is historical. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported. Each configurable instruction control defines how the exception that is generated as a consequence of the configurable instruction control is handled or reported.

An exception can only be generated as a result of a configurable instruction control if all of the following apply:

- The instruction generating the exception does not also generate a higher priority exception.
- The instruction generating the exception is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed.

It is UNPREDICTABLE / CONSTRAINED UNPREDICTABLE whether configurable instruction controls generate an exception when the instruction is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed.

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of configurable instruction controls, but the architecture does not require them to do so.

Note: Many CONSTRAINED UNPREDICTABLE behaviors for instructions include an allowance that the CONSTRAINED UNPREDICTABLE instruction behaves the same way as a closely related instruction that is not CONSTRAINED UNPREDICTABLE. In those cases, the instructions enable, disable, or trap control that causes in exception on the closely related instruction will cause the same exception on the CONSTRAINED UNPREDICTABLE instruction.

An implementation might provide more controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.
When a configurable instruction control causes an exception, the exception is taken and the instruction is not executed, and therefore all of the following are true:

- The preferred exception return address of the exception is the instruction that generates the exception.
- There are no changes to the registers accessed by the instruction, including as a result of side-effects of a register access.

When a configurable instruction control causes a conditional instruction to generate an exception in AArch32 state, it is IMPLEMENTATION DEFINED whether the exception applies to conditional AArch32 instructions that fail their condition code check.

**EL0 and EL1 configurable instruction controls**

The following EL0 and EL1 System registers contain configurable instruction controls:

<table>
<thead>
<tr>
<th>Register name</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMUSERENR_EL0</td>
<td>Activity Monitors User Enable Register</td>
</tr>
<tr>
<td>CPACR_EL1</td>
<td>Architectural Feature Access Control Register</td>
</tr>
<tr>
<td>MDSCCR_EL1</td>
<td>Monitor System Debug Control Register</td>
</tr>
<tr>
<td>PMUSERENR_EL0</td>
<td>Performance Monitors User Enable Register</td>
</tr>
<tr>
<td>SCTLR_EL1</td>
<td>System Control Register (EL1)</td>
</tr>
<tr>
<td>TCR_EL1</td>
<td>Translation Control Register (EL1)</td>
</tr>
</tbody>
</table>

An exception caused by configurable instruction controls in EL1 can be taken from either AArch64 state or AArch32 state.

**EL2 configurable instruction controls**

The following EL2 System registers contain configurable instruction controls:

<table>
<thead>
<tr>
<th>Register name</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPTR_EL2</td>
<td>Architectural Feature Trap Register, EL2</td>
</tr>
<tr>
<td>HAFGRTR_EL2</td>
<td>Hypervisor Activity Monitors Fine-Grained Read Trap Register</td>
</tr>
<tr>
<td>HCR_EL2</td>
<td>Hypervisor Configuration Register</td>
</tr>
<tr>
<td>HCRX_EL2</td>
<td>Extended Hypervisor Configuration Register</td>
</tr>
<tr>
<td>HDFGRTR_EL2</td>
<td>Hypervisor Debug Fine-Grained Read Trap Register</td>
</tr>
<tr>
<td>HDFGWTR_EL2</td>
<td>Hypervisor Debug Fine-Grained Write Trap Register</td>
</tr>
<tr>
<td>HFGITR_EL2</td>
<td>Hypervisor Fine-Grained Instruction Trap Register</td>
</tr>
<tr>
<td>HFGRTTR_EL2</td>
<td>Hypervisor Fine-Grained Read Trap Register</td>
</tr>
<tr>
<td>HFGWTR_EL2</td>
<td>Hypervisor Fine-Grained Write Trap Register</td>
</tr>
<tr>
<td>HSTR_EL2</td>
<td>Hypervisor System Trap Register</td>
</tr>
</tbody>
</table>
An exception caused by configurable instruction controls in EL2 can be taken from either AArch64 state or AArch32 state.

If Secure EL2 is implemented and enabled, configurable instruction controls available at EL2 apply in Secure state. If Secure EL2 is not implemented or not enabled, the configurable instruction controls available at EL2 are ignored in Secure state.

**EL3 configurable instruction controls**

The following EL3 System registers contain configurable instruction controls:

<table>
<thead>
<tr>
<th>Register name</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL3</td>
<td>System Control Register, EL3</td>
</tr>
<tr>
<td>SCR_EL3</td>
<td>Secure Configuration Register</td>
</tr>
<tr>
<td>CPTR_EL3</td>
<td>Architectural Feature Trap Register, EL3</td>
</tr>
<tr>
<td>MDCR_EL3</td>
<td>Monitor Debug Configuration Register, EL3</td>
</tr>
<tr>
<td>TCR_EL3</td>
<td>Translation Control Register, EL3</td>
</tr>
</tbody>
</table>

An exception caused by configurable instruction controls in EL3 can be taken from either AArch64 state or AArch32 state.

**D1.3.9 Exception Producing Instructions**

The exception producing instructions are commonly called system calls and refer to any of the following synchronous exception types:

- Supervisor Call exception.
- Hypervisor Call exception.
- Secure Monitor Call exception.

A Supervisor Call is generated by executing an SVC instruction.

A Supervisor Call exception is taken to the following Exception levels:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

A Supervisor Call enables software executing at EL0 to make a call to an operating system or other software executing at EL1.

If EL2 is implemented, a Hypervisor Call is generated by executing an HVC instruction.
A Hypervisor Call exception is taken to the following Exception levels:

- If Secure EL2 is implemented and enabled in the current Security state, when taken from EL1, the exception is taken to EL2.
- When taken from EL2, the exception is taken to EL2.
- When taken from EL3, the exception is taken to EL3.

If any of the following is true, the HVC instruction is UNDEFINED:

- The PE is executing at EL0.
- If EL2 is not enabled in the current Security state, and the PE is executing at EL1.
- SCR_EL3.HCE is 0.

If EL3 is implemented, a Secure Monitor Call is generated by executing an SMC instruction. A Secure Monitor Call is a synchronous exception that is taken to EL3.

If any of the following are true, the SMC instruction is UNDEFINED:

- The PE is executing at EL0.
- EL3 is not implemented.

### D1.3.10 Program counter and stack pointer alignment

#### PC alignment checking

If bits [1:0] of the PC are not 0b00, there is a misaligned PC.

The execution of an instruction with a misaligned PC generates a synchronous PC Alignment exception on that instruction.

A PC Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  - If HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

When a PC Alignment Fault exception is taken to an Exception level, ELx, using AArch64, the ELR_ELx and the FAR_ELx both hold the entire PC in its misaligned form.

A misalignment of the PC is an indication of a serious error, for example software corruption of an address.

#### SP alignment checking

When the SP is used as the base address of a calculation, regardless of any offset applied by the instruction, if bits [3:0] of the SP are not 0b0000, there is a misaligned SP.

If SP alignment checking is enabled, then the execution of a load or store using the SP with a misaligned SP generates a synchronous SP Alignment exception on that load or store.

PRFM instructions that use the SP do not perform stack alignment checking.

The following bits enable SP alignment checking at each Exception level when that Exception level is using AArch64.

- If HCR_EL2.{E2H, TGE} is \{1, 1\}, SCTLR_EL2.SA0 controls EL0. Otherwise, SCTLR_EL1.SA0 controls EL0.
- SCTLR_EL1.SA controls EL1.
• SCTLR_EL2.SA controls EL2.
• SCTLR_EL3.SA controls EL3.

**RNCGYQ**

An SP Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  - If HCR_EL2.TGE is 0, the exception is taken to EL1
  - If HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

**RDLVL**

If SP alignment checking is enabled and an SVE predicated load or store instruction with any *Active elements* uses the current SP as the base address, then the SP register is checked for 16-byte alignment.

**RFNCJX**

If SP alignment checking is enabled and an SVE predicated load or store instruction with no *Active elements* uses the current SP as the base address, then it is CONstrained UNPredictable whether the SP register is checked for 16-byte alignment.
D1.4 Process state, PSTATE

PSTATE is an abstraction of process state information. All Arm instruction sets provide instructions that operate on elements of PSTATE. PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState.

D1.4.1 PSTATE fields that are meaningful in AArch64 state

PSTATE fields that are meaningful in AArch64 state are grouped into the following categories:

- Condition flags.
- Execution state controls.
- Exception mask bits.
- Access control bits.
- Timing control bits.
- Speculation control bits.

The following PSTATE bits are meaningful in AArch64 state:

<table>
<thead>
<tr>
<th>PSTATE field name</th>
<th>PSTATE field group</th>
<th>Required implemented feature</th>
<th>Value when a Warm reset is asserted</th>
<th>Additional details</th>
</tr>
</thead>
<tbody>
<tr>
<td>N, Negative condition flag</td>
<td>Condition flags</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Z, Zero condition flag</td>
<td>Condition flags</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>C, Carry condition flag</td>
<td>Condition flags</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>V, Overflow condition flag</td>
<td>Condition flags</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>SS, Software Step bit</td>
<td>Execution state controls</td>
<td>-</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>IL, Illegal Execution state bit</td>
<td>Execution state controls</td>
<td>-</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>nRW, Current Execution state bit</td>
<td>Execution state controls</td>
<td>-</td>
<td>0</td>
<td>If the current execution state is AArch64, the PSTATE.nRW bit is 0.</td>
</tr>
<tr>
<td>EL, Current Exception level field</td>
<td>Execution state controls</td>
<td>-</td>
<td>When a Warm reset is asserted into an Exception level using AArch64, the PSTATE.EL field holds the encoding for the highest implemented Exception level.</td>
<td>-</td>
</tr>
<tr>
<td>SP, Stack pointer register selection bit</td>
<td>Execution state controls</td>
<td>-</td>
<td>1</td>
<td>-</td>
</tr>
</tbody>
</table>
Accessing PSTATE fields

In AArch64 state, PSTATE fields are accessed using Special-purpose registers that are directly read using the `MRS` (register) instructions, and directly written using the `MSR` (register) instructions.

If in AArch64 state, the following special-purpose registers can access the PSTATE fields that hold AArch64 state:

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>
<tr>
<td>CurrentEL</td>
<td>EL</td>
</tr>
<tr>
<td>SPSel</td>
<td>SP</td>
</tr>
<tr>
<td>PAN</td>
<td>PAN</td>
</tr>
<tr>
<td>UAO</td>
<td>UAO</td>
</tr>
<tr>
<td>DIT</td>
<td>DIT</td>
</tr>
</tbody>
</table>
All other PSTATE fields do not have direct read and write access.

Software can use the MSR (immediate) instructions to directly write to PSTATE.\{D, A, I, F, SP, PAN, UAO, SSBS, TCO\}.

The following PSTATE fields can be accessed at EL0:
- PSTATE.\{N, Z, C, V, SSBS, DIT, TCO\}.
- If SCTLR_EL1.UMA is 0, PSTATE.\{D, A, I, F\}.
- All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. For side-effects caused by writes to a PSTATE field, all of the following are true:
- The side-effect is guaranteed not to be visible to earlier instructions in the Execution stream.
- The side-effect is guaranteed to be visible to later instructions in the Execution stream.

Other side-effects might occur but are not guaranteed.

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSBS</td>
<td>SSBS</td>
</tr>
<tr>
<td>TCO</td>
<td>TCO</td>
</tr>
<tr>
<td>ALLINT</td>
<td>ALLINT</td>
</tr>
</tbody>
</table>
D1.5

Resets and power domains

IDQXXZ

The PE logic is split into a Debug power domain and a Core power domain. Cold and Warm resets, reset elements in the Core power domain. An External debug reset can reset the Debug power domain. Other resets might be implemented.

D1.5.1

Power domains and reset domains

RJMTZY

The PE logic is split into two logical power domains:

• The Core power domain.
• The Debug power domain.

IQBPTS

The power domains are described as logical because the architecture does not require two physical power domains.

RPDMKB

It is IMPLEMENTATION DEFINED whether the Core power domain and Debug power domain power up and power down separately or together.

RZDVQQ

The Core power domain contains:

• Non-debug registers and logic.
• Self-hosted debug registers and logic.
• Shared debug registers and logic.
• Some external debug registers and logic.

RGTVLN

The Debug power domain contains:

• The interface between the PE and the external debugger.
• Some external debug registers.

RMLXWM

If an external debugger is connected to the PE, the Debug power domain is powered up.

IKTSWK

For more information on access permissions for the external debug interface registers, see Access permissions for the External debug interface registers on page H8-10370 or individual register descriptions.

D1.5.2

Reset types

IHDLQB

The architecture defines the following resets:

• Warm reset.
• Cold reset.
• External debug reset.
• Trace unit reset. See Resetting the trace unit on page D4-4800.

IFMTCY

Other resets are IMPLEMENTATION DEFINED and can be mapped onto the existing resets.

RPXXYQ

Mechanisms to assert resets, other than RMR_ELx, are IMPLEMENTATION DEFINED.

RHLGGD

When a Cold reset is asserted, for each register in the Core power domain, the reset sets the register to its architecturally defined reset value.

RPJXVL

When a Warm reset is asserted, the logic on which the PE executes is reset. The Warm reset does not reset the integrated debug functionality.

RNBBKHK

When an External debug reset is asserted, the Debug power domain is reset. The Cold reset domain is not reset.

IMWTKX

If RMR_ELx is implemented, writing 1 to RMR_ELx.RR requests a Warm reset.

RDTTVZ

It is IMPLEMENTATION DEFINED whether a Warm reset can be asserted without using RMR_ELx.

ILWNC

Arm recommends that a Warm reset can be asserted independently of a Cold reset.

IQLZGF

A Warm reset allows debugging across a reset of the PE logic in the Core power domain.
It is IMPLEMENTATION DEFINED whether an External debug reset and a Cold reset can be asserted independently.

Arm recommends that when separate Core and Debug power domains are implemented, the External debug reset and Cold reset can be asserted independently.

**D1.5.3 Reset behavior**

Immediately after a reset, much of the PE state is architecturally UNKNOWN. However, some of the PE state is defined, see the individual register descriptions for more information. The state that is reset to known values is sufficient to permit predictable initial execution at the highest Exception level, such that this execution is then capable of initializing the remaining state of the system where necessary before use.

When a Cold or Warm reset is asserted, all of the following occur:

- The PE enters the highest implemented Exception level.
- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.

When a Cold or Warm reset is deasserted, execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds the address at which the PE starts execution.

When a Cold or Warm reset is deasserted, the IMPLEMENTATION DEFINED address from which the PE starts execution is typically set either by a hardwired configuration of the PE or by configuration input signals.

When a Cold or Warm reset is asserted, all of the following are UNKNOWN:

- All general-purpose, SIMD, and floating-point registers.
- The global exclusive monitor for the PE.
- The local exclusive monitor for the PE.
- System and Special-purpose registers with a reset value of UNKNOWN described in the AArch64 Registers.

When a Cold or Warm reset is asserted, PSTATE.{SS, IL, nRW, EL, SP, D, A, I, F, DIT} fields are set to known values.

When a Cold or Warm reset is asserted, the TLBs and caches are in an IMPLEMENTATION DEFINED state.

When a Cold or Warm reset has been asserted and before the memory management system is enabled, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

When a Cold or Warm reset has been asserted and before Normal memory accesses are permitted to be Cacheable, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

If IMPLEMENTATION DEFINED resets are implemented, each IMPLEMENTATION DEFINED reset can treat the cache and TLB state differently.

If IMPLEMENTATION DEFINED resets are implemented, for each IMPLEMENTATION DEFINED reset, the TLBs, caches, or both might require a different IMPLEMENTATION DEFINED invalidation sequence.

The IMPLEMENTATION DEFINED invalidation sequence might be a NOP.

**External debug access to registers in reset**

If External Debug reset is asserted, for each register that can be accessed by the external debug interface, a register access by the external debug interface has one of the following IMPLEMENTATION DEFINED results:

- The external debug interface can access the register, and the access result is IMPLEMENTATION DEFINED.
- The external debug interface cannot access the register.

If either a Cold or Warm reset is asserted, accesses of registers or register fields might be direct accesses or indirect side-effects of an access.

If either a Cold or Warm reset is asserted, external debug interface accesses of a register or register field have the following effects:
<table>
<thead>
<tr>
<th>Access</th>
<th>Register or register field reset behavior</th>
<th>Effect on register or register field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write</td>
<td>Reset by the reset signal</td>
<td>Set to CONSTRAINED UNPREDICTABLE choice of the reset value or the value written.</td>
</tr>
<tr>
<td>Write</td>
<td>Not reset by the reset signal</td>
<td>Set to the value written.</td>
</tr>
<tr>
<td>Read</td>
<td>Reset by the reset signal</td>
<td>Returns an UNKNOWN value.</td>
</tr>
<tr>
<td>Read</td>
<td>Not reset by the reset signal</td>
<td>Returns the value of the register or register field.</td>
</tr>
</tbody>
</table>
D1.6    Mechanisms for entering a low-power state

The architecture provides the following mechanisms that software can use to indicate that the PE can enter low-power state:

- Wait for Event.
- Wait for Interrupt.

D1.6.1   Wait for Event

The Wait for Event mechanism behavior depends on the interaction of all of the following:

- The Event Register for the PE. See The Event Register.
- The Wait for Event (WFE) or Wait for Event with Timeout (WFET) instruction. See The Wait for Event and Wait for Event with Timeout instructions on page D1-4677.
- WFE wake-up events. See WFE wake-up events in AArch64 state on page D1-4677.
- The Send Event instructions, SEV and SEVL, that can cause WFE wake-up events. See The Send Event instructions on page D1-4678.

Except for all or the following, the architecture does not define the exact nature of the low-power state:

- When a WFE or WFET instruction is executed, the architecture requires that memory coherency is not lost.
- If the system is configured such that the WFE or WFET instruction can be completed, then the architecture requires that the architectural state is not lost.

The Wait for Event mechanism is associated with suspending execution on a PE for power saving, therefore Arm recommends that the Event Register is set infrequently. Software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

The Event Register

The Event Register is a single bit register for each PE.

The event register is a conceptual register and cannot be explicitly accessed.

If the Event Register is set, then an event has occurred since the register was last cleared and the event might require some action by the PE.

When the PE executes a WFE or WFET instruction, all of the following apply:

- If the Event Register is clear, then the PE can enter the low-power state.
- If the Event Register is set, then all of the following apply:
  — The PE does not suspend operation.
  — The Event Register is cleared.
  — The WFE or WFET instruction completes immediately.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see Event streams on page D10-5239.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait for Event (WFE) instruction or a Wait for Event with Timeout (WFET) instruction.
The AArch64 System Level Programmers’ Model

D1.6 Mechanisms for entering a low-power state

IZXJPD Software cannot read or write the value of the Event Register directly.

The Wait for Event and Wait for Event with Timeout instructions

RQRXWZ If FEAT_WFXT is implemented, the Wait for Event with Timeout (WFET) instruction is implemented

RCSKPF If the Event Register is clear, when a WFE or WFET instruction is executed, the PE can suspend execution and enter a low-power state.

RGZZQM If the PE enters a low-power state, the PE remains in the lower-power state until one of the following occurs:
- The PE detects a WFE wake-up event.
- An IMPLEMENTATION DEFINED wake event that is architecturally permitted to occur at any time.
- A reset is asserted.

IQGHTM The architecture permits all of the following:
- The PE is permitted to leave the low-power state for any reason.
- The PE is permitted to treat WFE as a NOP, but this is not recommended for lowest power operation.

RSLQVQ If the PE is in a low-power state, when the PE detects a WFE wake-up event, or earlier if the implementation chooses, the WFE or WFET instruction completes. If the wake-up event sets the Event Register, when execution is restarted, the state of the Event Register is IMPLEMENTATION DEFINED.

IDRSIV Software using the Wait for Event mechanism must tolerate spurious wake-up events, including multiple wake-up events.

Trapping of WFE and WFET

IKMHTB The WFE and WFET instructions are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be configured to trap to a higher Exception level.

RJWKTL If FEAT_TWED is implemented, then all of the following apply:
- A delay before taking a WFE trap can be configured.
- If a delay before taking a WFE trap is configured, then the delay does not affect the priority of the traps.

IRDYQK For example, if execution is subject to a trap at EL1 because SCTLR_EL1.nTWE is 0 and HCR_EL2.TWE is 1, the only trap that will be taken is a trap to EL1, even if the delay at EL1 is longer than the delay at EL2.

WFE wake-up events in AArch64 state

IRJRLR In this section, AllIntMask refers to the value described in RXZPDT.

ILRPVP If a WFE or WFET instruction puts a PE into low-power state, a WFE wake-up event received by the PE causes that PE to exit low-power state.

IRJRLR If a WFE or WFET instruction puts a PE into low-power state, a WFE wake-up event received by the PE causes that PE to exit low-power state.

IRLPVP If a WFE or WFET instruction puts a PE into low-power state, a WFE wake-up event received by the PE causes that PE to exit low-power state.

RKBMFC All of the following are WFE wake-up events:
- The execution of an SEV instruction on any PE in a multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE that is not disabled by EDSR.INTdis and either of the following is true:
  - The interrupt is marked as A in RXSLWJ in Asynchronous exception masking on page D1-4659, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - The interrupt is marked as B in RXSLWJ in Asynchronous exception masking on page D1-4659, AllIntMask is 0, and any of the following are true:
    - The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
    - An IRQ or FIQ interrupt has Superpriority.
See RMHWBP and RGFXKY.
• If all of the following apply, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE:
  — The PE is executing at EL1 or EL0.
  — The interrupt is not disabled by EDSCR.INTdis.
  — The interrupt is marked as B in RBKHXL in Virtual interrupt masking on page D1-4662, AllIntMask is 0, and any of the following are true:
    — The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
    — A vIRQ or vFIQ interrupt has Superpriority.
    See RSNLJH and RXSPSG.
• If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited on page H2-10233 and External Debug Request debug event on page H3-10291.
• An event sent by the timer event stream for the PE. See Event streams on page D10-5239.
• An event caused by the clearing of the global monitor for the PE.
• An event sent by some IMPLEMENTATION DEFINED mechanism.
• When FEAT_WFxT is implemented, for WFET instructions, a local timeout event caused by the virtual count threshold value, expressed in CNTVCT_EL0, being equaled or exceeded.

Not all of the wake-up events in RKBMF set the Event Register.

The Send Event instructions

The Send Event instructions are:

- SEV, Send Event: Causes an event to be signaled to all PEs in a multiprocessor system.
- SEVL, Send Event Local: Causes an event to be signaled locally without requiring the event to be signaled to other PEs in a multiprocessor system.

An SEVL instruction might signal an event to other PEs by an IMPLEMENTATION DEFINED mechanism, but it is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED.

When an event is signaled by an SEV instruction, the ordering of the event with respect to the completion of memory accesses by instructions before the SEV instruction is not guaranteed.

Arm recommends that software includes a Data Synchronization Barrier (DSB) instruction before any SEV instruction. DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See Data Synchronization Barrier (DSB) on page B2-178.

The SEVL instruction appears to execute in program order relative to any subsequent WFE or WFET instruction executed on the same PE.

The behavior in RQJDQV applies without the need for any explicit insertion of barrier instructions.

D1.6.2 Wait for Interrupt mechanism

A PE can use the Wait for Interrupt mechanism to enter a low-power state.

When FEAT_WFxT is implemented, the Wait for Interrupt with Timeout (WFIT) instruction is implemented.

Software can use the Wait for Interrupt (WFI) and Wait for Interrupt with Timeout (WFIT) instructions to cause the PE to enter a low-power state.

If a Wait for Interrupt (WFI) and Wait for Interrupt with Timeout (WFIT) instructions causes the PE to enter a low-power state, the PE remains in that low-power state until any of the following occur:

- The PE detects a WFI wake-up event.
The AArch64 System Level Programmers' Model
D1.6 Mechanisms for entering a low-power state

- An IMPLEMENTATION DEFINED wake event that is architecturally permitted to occur at any time.
- A reset is asserted.

The architecture permits all of the following:
- The PE is permitted to leave the low-power state for any reason.
- The PE is permitted to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered because of a WFI or WFIT instruction, the WFI or WFIT instruction completes.

Except for all or the following, the architecture does not define the exact nature of the low-power state:
- When a WFI or WFIT instruction is executed, the architecture requires that memory coherency is not lost.
- If the system is configured such that the WFI or WFIT instruction can be completed, then the architecture requires that the architectural state is not lost.

In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wake-up events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wake-up events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

The WFI and WFIT instructions are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be configured to trap to a higher Exception level.

### WFI wake-up events

In this section, AllIntMask refers to the value described in RXZPDT.

If a WFI or WFIT instruction put a PE into low-power state, the PE remains in that low-power state until it receives a WFE wake-up event.

All of the following are WFI wake-up events:
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE that is marked as A, B or A/B in the tables in Physical interrupt masking on page D1-4660, regardless of the value of the corresponding PSTATE. {A, I, F} mask bit.
- If the PE is executing at in EL0 or EL, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in the tables in Virtual interrupt masking on page D1-4662, regardless of the value of the corresponding PSTATE. {A, I, F} mask bit.
- If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited on page H2-10233. See also External Debug Request debug event on page H3-10291.
- An event sent by an IMPLEMENTATION DEFINED mechanism.
- When FEAT_WFxT is implemented, for WFIT instructions, a local timeout event caused by the virtual count threshold value, expressed in CNTVCT_EL0, being equaled or exceeded.

WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE. {A, I, F} mask bits, or by the state of AllIntMask. If wake-up is invoked by an interrupt that is disabled or masked, the interrupt is not taken.

Because debug events are WFI wake-up events, Arm recommends that Wait for Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

The architecture does not require the WFI mechanism to drain down any pending memory activity before suspending execution, and software must not rely on the WFI mechanism operating in this way.
D1.6.3 Using WFI to indicate an idle state on bus interfaces

When all of the following are true, the IMPLEMENTATION DEFINED mechanism for entering powerdown state can be completed:

- The IMPLEMENTATION DEFINED mechanism forces quiescence on a PE.
- The IMPLEMENTATION DEFINED mechanism prevents any possible WFI wakeup events.

The mechanism for entering powerdown state is IMPLEMENTATION DEFINED.

Although the mechanism for entering powerdown state is IMPLEMENTATION DEFINED, the WFI and WFE mechanisms are often used to enter powerdown state.

If a WFI powerdown mechanism is implemented, when a WFI or WFI! instructions is executed, the PE completes all current operations and any associated bus activity also completes. When all current PE operations and associated bus activity are complete, the PE can signal to an external power controller that there is no ongoing bus activity.

After a WFI instruction is executed and all currently executing instructions and related bus activity has completed, the PE is waiting for an interrupt and is in idle state. If in idle state, the PE can process memory-mapped or external debug interface accesses to debug registers.

The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If OSDLR_EL1.DLK is 1, the PE does not signal the idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked on page H6-10346.

In a PE that implements separate Core and Debug power domains, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see Power domains and debug on page H6-10335.

The exact nature of the debug interface is IMPLEMENTATION DEFINED, but the use of Wait for Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it suitable as the preferred powerdown entry mechanism.
D1.7 Self-hosted debug

The architecture supports both of the following:

Self-hosted debug
The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the Arm Exception model.

External debug
The PE is controlled by an external debugger. The debugger programs the PE to generate debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

D1.7.1 Debug exceptions

If a debugger has programmed the PE to generate Debug exceptions, the Debug exceptions occur during normal program flow.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The debug exceptions are all of the following:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

The PE can only generate a particular debug exception if all of the following are true:

- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-4699. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
- A debugger has enabled that particular debug exception. All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls on page D2-4696.

Breakpoints and watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 About External Debug.

D1.7.2 The PSTATE debug mask bit, D

The debug exception mask bit, PSTATE.D, can mask Watchpoint, Breakpoint, and Software Step exceptions if the target Exception level is the current Exception level.

If in AArch64 state and the target Exception level of a debug exception is lower than the current Exception level, the debug exception is masked.

If the target Exception level is higher than the current Exception level, debug exceptions are not masked by PSTATE.D.

If PSTATE.D is 1 and the PE is already handling an exception in AArch64 state, the Watchpoint, Breakpoint, and Software Step exceptions are masked.

If an exception is already being handled, masking prevents software from generating another instance of an exception and prevents recursive entry into the exception handler and loss of return state.

Masking debug interrupts with PSTATE.D prevents the generation of new debug exceptions, therefore, any masked debug exceptions are not taken if PSTATE.D is later set to 0.
<table>
<thead>
<tr>
<th>IVSTYD</th>
<th>The behavior described in RNCHXS differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask prevents the interrupt from being taken, but instead the interrupt remains pending.</th>
</tr>
</thead>
<tbody>

<td>IKWFMZ</td>
<td>When an exception is taken, PSTATE.D is set to 1.</td>
</tr>
</tbody>
</table>
D1.8 Event monitors

The architecture supports the following non-invasive architectural components that allow for event monitoring:

Performance Monitors
The Performance Monitors have a wide feature set, flexible selection of counted events, and are read/write in operation.

Activity Monitors
The Activity Monitors have a narrow feature set, limited selection of counted events, and are read-only in operation.

D1.8.1 The Performance Monitors Extension

The System registers provide access to a Performance Monitoring Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of event counters. If FEAT_PMUv3p5 is implemented, the event counters are 64-bit unsigned counters, otherwise the event counters are 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events.

Chapter D11 The Performance Monitors Extension.

D1.8.2 The Activity Monitors Extension

If the OPTIONAL Activity Monitors Extension is implemented, the System registers provide access to controls and counters for the Activity Monitors Unit (AMU).

Chapter D12 The Activity Monitors Extension.
Interprocessing

Moving between the AArch64 and AArch32 Execution states is called interprocessing.

The Execution state can only change on a change of Exception level.

Therefore, Execution state can change only on taking an exception to a higher Exception level or returning from an exception to a lower Exception level. For an exception that is taken to the same Exception level or is returning from the same Exception level, the Execution state cannot change.

When taking an exception to a higher Exception level, the Execution state is one of the following:

- Unchanged.
- Changed from AArch32 state to AArch64 state.

When returning from an exception to a lower Exception level, the Execution state is one of the following:

- Unchanged.
- Changed from AArch64 state to AArch32 state.

Register mappings between AArch32 state and AArch64 state

Register mappings between AArch32 state and AArch64 state describe the following:

- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The AArch32 state register contents occupy the bottom 32 bits of the AArch64 state registers.

If in AArch32 state, the upper 32 bits of AArch64 state registers are inaccessible and are ignored.

For bits[63:32] of AArch64 registers that are not mapped to AArch32 registers, the unmapped bits are unchanged by AArch32 state execution.

Mapping of the general-purpose registers between the Execution states

The following table shows the mappings of general-purpose registers between Execution states:

<table>
<thead>
<tr>
<th>AArch32 register</th>
<th>AArch64 register</th>
</tr>
</thead>
<tbody>
<tr>
<td>R0</td>
<td>X0</td>
</tr>
<tr>
<td>R1</td>
<td>X1</td>
</tr>
<tr>
<td>R2</td>
<td>X2</td>
</tr>
<tr>
<td>R3</td>
<td>X3</td>
</tr>
<tr>
<td>R4</td>
<td>X4</td>
</tr>
<tr>
<td>R5</td>
<td>X5</td>
</tr>
<tr>
<td>R6</td>
<td>X6</td>
</tr>
<tr>
<td>R7</td>
<td>X7</td>
</tr>
<tr>
<td>R8_usr</td>
<td>X8</td>
</tr>
<tr>
<td>R9_usr</td>
<td>X9</td>
</tr>
<tr>
<td>R10_usr</td>
<td>X10</td>
</tr>
<tr>
<td>R11_usr</td>
<td>X11</td>
</tr>
</tbody>
</table>
For some exceptions, the exception syndrome given in the ESR_ELx identifies one or more register numbers from the issued instruction that generated the exception. If one of these exceptions is taken from an Exception level using AArch32, the register numbers give the AArch64 view of the register.

For example, if an exception is taken from AArch32 Abort mode and the faulting instruction specified R14, the ESR_ELx.ISS field would report this using the EC value 0b10100, because register X20 provides the AArch64 view of LR_abt, which is the copy of R14 used in Abort mode.

### Mapping of the SIMD and floating-point registers between the Execution states

The following table shows the mappings of SIMD and floating-point registers between the Execution states:

<table>
<thead>
<tr>
<th>AArch64 register</th>
<th>AArch32 register</th>
</tr>
</thead>
<tbody>
<tr>
<td>V0</td>
<td>Q0</td>
</tr>
<tr>
<td>V1</td>
<td>Q1</td>
</tr>
</tbody>
</table>
The AArch64 state registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state.

In AArch64 state, there are:
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

A smaller register occupies the least significant bytes of the corresponding larger register.

The following graphic shows the mapping of V, D, and S registers in AArch64 state:

In AArch32 state, there are:
- 16 128-bit Q registers, Q0-Q15.
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers.

The following graphic shows the mapping of Q, D and S registers in AArch32 state:

In AArch32 state:
- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15.

If software executing in AArch64 state interprets D or S registers from AArch32 state, the software must unpack the D or S registers from the V registers before it uses them.

**Mapping of the System registers between the Execution states**

For a full list of mappings of writable AArch64 System registers to the AArch32 System registers, see *Mapping of writable AArch64 System registers to the AArch32 System registers* on page K17-11840.
The relationship between the AArch64 System registers and the AArch32 System registers is architecturally defined.

Modifications made to AArch32 System registers affect only the parts of the AArch64 state registers that are mapped to the AArch32 System registers.

Supervisory code, such as a hypervisor, executing in AArch64 state, can save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

In some cases, two AArch32 System registers are packed into a single AArch64 System register.

If EL3 is implemented and is using AArch32, some System registers are banked between Secure and Non-secure states. In this type of banking, there is an instance of the register in Secure state and another instance of the register in Non-secure state.

If any of the following are true, banking between Secure and Non-secure states is not supported:

- EL3 is not implemented.
- EL3 is implemented and is using AArch64.

If EL3 is implemented and is using AArch64, the same, non-banked, registers are accessed in the following state:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

If EL3 is implemented and is using AArch64, it is not possible to architecturally determine whether an AArch64 register is mapped onto the Secure or the Non-secure instance of corresponding AArch32 register.

If EL3 is implemented and is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt that is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.

Although not required, Arm expects that implementations map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this mapping is not possible for the following registers:

- IFAR - This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.
- DFAR - This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

There are some AArch32 System registers that are only used in AArch32 state and do not have an equivalent AArch64 System register. However, there are AArch64 registers that can access, from a higher Exception level, the AArch32 registers that do not have an AArch64 state equivalent.

For a full list of AArch64 registers that access AArch32 System registers with no AArch64 equivalent, see AArch64 registers for accessing registers that are only used in AArch32 state on page K17-11845.

For a full list AArch64 registers that allow access to the AArch32 ID registers from AArch64 state, see AArch64 registers that access the AArch32 ID registers on page K17-11845.

State of the general-purpose registers on taking an exception to AArch64 state

If the general-purpose register was accessible from AArch32 state

When an exception is taken from AArch32 state to AArch64 state and the general-purpose register was accessible from AArch32 state, the upper 32 bits have one of the following IMPLEMENTATION DEFINED values and might vary dynamically within an implementation:

- The upper 32 bits retain the value that the same architectural register held before any AArch32 execution.
- The upper 32 bits are set to zero.

The IMPLEMENTATION DEFINED behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32.
For example, the IMPLEMENTATION DEFINED behavior described in RWWJWP applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

When an exception is taken from AArch32 state to AArch64 state, software must regard the value of the upper 32 bits as a CONSTRAINED UNPREDICTABLE choice between the two values described in RWWJWP.

**If the general-purpose register was not accessible from AArch32 state**

If all of the following apply, when an exception is taken from AArch32 state to AArch64 state, the X15 register is treated as if it is accessible and therefore the upper 32 bits of X15 might either be set to zero or retain their previous value:

- The target Exception level is EL3.
- EL2 is not implemented or EL1 is in Secure state.
- SCR_EL3.RW is 0.

Otherwise, when an exception is taken from AArch32 state to AArch64 state, for a general-purpose register that was not accessible from AArch32 state, the register retains the value it had before any AArch32 execution.

**Determining the upper 32 bits of AArch64 registers on taking an exception from AArch32 state**

Whether a general-purpose register has its upper 32 bits set to zero or retained on taking an exception from AArch32 to AArch64 is affected by all of the following:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES 0.

The following table shows which general-purpose registers can have their upper 32 bits set to zero on taking an exception from AArch32 state to AArch64 state. In this table, a dash (-) indicates that the RW values are not valid for the targeted Exception level.

<table>
<thead>
<tr>
<th>SCR_EL3.RW</th>
<th>HCR_EL2.RW or HCR.RW</th>
<th>Registers when the target Exception level is:</th>
<th>EL3</th>
<th>EL2</th>
<th>EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>X0-X30</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>X0-X14, X16-X30</td>
<td>X0-X14, X16-X30</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>X0-X14</td>
<td>X0-X14</td>
<td>X0-X14</td>
<td>-</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bits prevent its use, the registers that can have their upper 32 bits set to zero on taking an exception from AArch32 state to AArch64 state are the same as when HCR_EL2.RW has the same value as SCR_EL3.RW.
The following table shows which general-purpose registers can retain their upper 32 bits on taking an exception from AArch32 state to AArch64 state. In this table, a dash (-) indicates that the RW values are not valid for the target Exception level.

<table>
<thead>
<tr>
<th>SCR_EL3.RW</th>
<th>HCR_EL2.RW or HCR.RW</th>
<th>Registers when the target Exception level is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>EL3: None - EL2: - EL1: -</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>EL3: X15 EL2: X15 EL1: -</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>EL3: X15-X30 EL2: X15-X30 EL1: X15-X30</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, or SCR_EL3.NS prevents its use, the registers that can have their upper 32 bits retained on taking an exception to AArch64 state from AArch32 state are the same as when HCR_EL2.RW has the same value as SCR_EL3.RW.

SPSR, ELR, and AArch64 SP relationships on changing Execution state

The following table shows SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state:

<table>
<thead>
<tr>
<th>AArch32 register</th>
<th>AArch64 register</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_svc</td>
<td>SPSR_EL1</td>
</tr>
<tr>
<td>SPSR_hyp</td>
<td>SPSR_EL2</td>
</tr>
<tr>
<td>ELR_hyp</td>
<td>ELR_EL2</td>
</tr>
</tbody>
</table>

When an exception is taken from an Exception level using AArch32 to EL3 using AArch64 and EL2 has been using AArch32 state, the upper 32 bits of ELR_EL2 have one of the following IMPLEMENTATION DEFINED values:
- The upper 32 bits retain the value that the same architectural register held before any AArch32 execution.
- The upper 32 bits are set to zero.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state if there is execution at EL1 and EL1 is using AArch64 state.
- SPSR_abt.
- SPSR_und.
- SPSR_irq.
- SPSR_fiq.

For the purposes of context switching, the registers in RWFDMR are accessible during execution in AArch64 state at Exception levels higher than EL1.

If EL1 does not support execution in AArch32 state, the registers in RWFDMR are RES0.

If an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the AArch64 stack pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at the Exception level from which the exception was taken, retain the state that they had before AArch32 execution. This applies to the following registers:
- SP_EL0.
- SP_EL1.
- SP_EL2.
• ELR_EL1.
Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

**Introductory information**
- *About self-hosted debug* on page D2-4692.
- *The debug exception enable controls* on page D2-4696.

**The debug Exception model**
- *Routing debug exceptions* on page D2-4697.
- *Enabling debug exceptions from the current Exception level* on page D2-4699.
- *The effect of powerdown on debug exceptions* on page D2-4701.
- *Summary of the routing and enabling of debug exceptions* on page D2-4702.
- *Pseudocode description of debug exceptions* on page D2-4704.

**The debug exceptions**
- *Breakpoint Instruction exceptions* on page D2-4705.
- *Breakpoint exceptions* on page D2-4707.
- *Watchpoint exceptions* on page D2-4726.
- *Vector Catch exceptions* on page D2-4741.
- *Software Step exceptions* on page D2-4742.

**Synchronization requirements**

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a *Context synchronization event* guarantees the effects of the changes:
- *Synchronization and debug exceptions* on page D2-4755.
D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, which are taken using the exception model described in Chapter D1 The AArch64 System Level Programmers’ Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the Debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current Context ID, which is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions on page D2-4693.
- Breakpoint exceptions on page D2-4693, generated by hardware breakpoints.
- Watchpoint exceptions on page D2-4693, generated by hardware watchpoints.
- Software Step exceptions on page D2-4694.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See Routing debug exceptions on page D2-4697. Chapter G2 describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. Vector Catch exceptions on page D2-4741 describes the behavior for this case.

The PE can generate a particular debug exception only when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
   See Enabling debug exceptions from the current Exception level on page D2-4699. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.
   All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls on page D2-4696.

Note

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see *Halting allowed and halting prohibited on page H2-10233.*

The following list summarizes each of the debug exceptions:

**Breakpoint Instruction exceptions**

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

**PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see *Breakpoint Instruction exceptions on page D2-4705.*

**Breakpoint exceptions**

The A-profile architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

The A-profile architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- **Address.** Comparisons are made with the virtual address of each instruction in the program flow.
- **Context:**
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint generates a Breakpoint exception only if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State. Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions on page D2-4707.*

**Watchpoint exceptions**

The A-profile architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.
A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

- If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.
- Otherwise:
  - If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
  - If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions* on page D2-4726.

**Vector Catch exceptions**

These are not generated in an AArch64 translation regime. They can be generated only in an AArch32 translation regime. See *Vector Catch exceptions* on page D2-4741.

**Software Step exceptions**

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

**PE behavior**

Software step can be used only by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see *Software Step exceptions* on page D2-4742.

Table D2-1 on page D2-4694 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

**Table D2-1 PE behavior and pseudocode for each of the debug exceptions**

<td>Takes the exception</td>
<td>Not applicable&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

<sup>a</sup> If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.

<sup>b</sup> Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.
D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

MDSCR\_EL1.MDE, plus an enable control for each breakpoint, DBGBCR\_n\_EL1.E.

**Watchpoint exceptions**

MDSCR\_EL1.MDE, plus an enable control for each watchpoint, DBGWCR\_n\_EL1.E.

**Vector Catch exceptions**

MDSCR\_EL1.MDE.

**Software Step exceptions**

MDSCR\_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level* on page D2-4699.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
**D2.3 Routing debug exceptions**

If the OS Lock is locked, or if `DoubleLockStatus() == TRUE`, a Debug exception cannot be taken.

Debug exceptions are enabled and routed according to the following controls:

- `HCR_EL2.TGE`.
- `MDCR_EL2.TDE`.
- `MDCR_EL3.SDD`.
- The Security state when the exception is taken.
- The Exception level where the exception is taken.

Breakpoint Instructions are enabled in some situations where other Debug exceptions are disabled.

--- Note ---

If EL2 is not implemented, the Effective value of `HCR_EL2.TGE` is 0 and the Effective value of `MDCR_EL2.TDE` is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

If EL3 is not implemented, and the implementation is a Secure state only implementation, the Effective value of `MDCR_EL3.SDD` is 0.

Table D2-2 on page D2-4697 shows when debug exceptions are enabled from the current Security state.

### Table D2-2 Whether debug exceptions are enabled from the current Security state

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>Secure</td>
<td>Enabled</td>
<td>Disabled if <code>MDCR_EL3.SDD</code> is 1. See <a href="#">Disabling debug exceptions from Secure state on page D2-4699</a>. Otherwise enabled.</td>
</tr>
</tbody>
</table>

The routing of debug exceptions is as follows:

**Debug exceptions taken when EL2 is implemented and enabled in the current Security state**

The routing of debug exceptions taken depends on the values of `MDCR_EL2.TDE` and `HCR_EL2.TGE`:

- If the Effective value of `{MDCR_EL2.TDE, HCR_EL2.TGE}` is not `{0, 0}`
  - Debug exceptions are routed to EL2, EL₀ is EL2.

- Otherwise
  - Debug exceptions behave as follows:
    - Debug exceptions taken from EL1 and EL0 are routed to EL1. EL₀ is EL1
    - Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
    - All other debug exceptions are disabled from EL2 using AArch64.

**When EL3 is implemented**

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.

All other debug exceptions are disabled from EL3 using AArch64.

**Otherwise**

Debug exceptions are routed to EL1.

This means that, for all debug exceptions, the debug target Exception level, EL₀, is either EL1 or EL2. When executing in the same exception level as EL₀, see [Enabling debug exceptions from the current Exception level on page D2-4699](#).
Table D2-3, Table D2-4, and Table D2-5 show the routing of debug exceptions. In these tables:

**NS**
Means the Effective value of SCR_EL3.NS.

**EEL2**
Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.

**TDE or TGE**
Means the logical OR of the Effective value of MDCR_EL2.TDE and the Effective value of HCR_EL2.TGE.

**(ELx)**
Means EL_D is ELx. However:
- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Exception level.
- Breakpoint Instruction exceptions taken when executing in this Exception level are routed to the same Exception level. This may not be the same as the EL_D Exception level.

**ELx**
Means EL_D is ELx.

### Table D2-3 Routing when both EL3 and EL2 are implemented

### D2.3.1 Pseudocode description of routing debug exceptions

**DebugTarget()** returns the current debug target Exception level.

**DebugTargetFrom()** returns the debug target Exception level for the specified Security state.

These functions are described in Chapter J1 *Armv8 Pseudocode*. 
D2.4  Enabling debug exceptions from the current Exception level

A debug exception can be taken only if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus() == FALSE.`
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Debug exceptions are enabled from the current Exception level, where EL_D is the Exception level that Table D2-3 on page D2-4698 defines, as follows:

When executing at any Exception level that is higher than EL_D:

- Breakpoint Instruction exceptions are enabled.
- All other debug exceptions are disabled.

When executing at EL_D:

- Breakpoint Instruction exceptions are enabled.
- All other debug exceptions are disabled if either of the following is true:
  - The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.
  - The Debug exception mask bit, PSTATE.D, is 1.
- Otherwise enabled.

This means that a debugger must explicitly enable these debug exceptions from EL_D by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.

When executing at EL1, EL_D is EL2, and FEAT_NV2 is implemented:

- Watchpoint debug exceptions generated by a System register access converted to a memory access because HCR_EL2.NV2 is 1 are disabled if MDSCR_EL1.KDE is 0 and enabled if MDSCR_EL1.KDE is 1. The value of PSTATE.D is ignored.
- All other debug exceptions are enabled.

Otherwise:

- All debug exceptions are enabled.

D2.4.1  Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the Secure Debug Disable bit, MDCR_EL3.SDD, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The A-profile architecture does not support disabling debug in Non-secure state.

--- Note ---

- If the boot software executed when reset is deasserted sets MDCR_EL3.SDD to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
- The PE cannot take a debug exception unless it is enabled from the current Exception level. See Table D2-6.
- If either the OS Lock or the OS Double Lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.
- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if MDCR_EL3.SDD is 0.

D2.4.2  Pseudocode description of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.
AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in Chapter J1 Armv8 Pseudocode.
D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-10342 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

• Breakpoint exceptions.
• Watchpoint exceptions.
• Vector Catch exceptions.
• Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and DoubleLockStatus() == FALSE, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if DoubleLockStatus() == TRUE, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL3 is always routed to EL3. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to EL_D.

**All other debug exceptions**

Table D2-6 on page D2-4702 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table:

- **Lock** Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- **NS** Means the **Effective value** of SCR_EL3.NS.
- **SDD** Means the **Effective value** of MDCR_EL3.SDD. See Disabling debug exceptions from Secure state on page D2-4699.
- **EEL2** Means the **Effective value** of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.
- **TGE** Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.
- **TDE** Means the value of MDCR_EL2.TDE. If EL2 is not implemented, the PE behaves as if this is 0.
- **KDE** Means the value of MDSCR_EL1.KDE.
- **D** Means the value of PSTATE.D.
- **n/a** Means not applicable. The PE cannot be executing at this Exception level.
- **-** Means that debug exceptions are disabled from that Exception level.

D2.7 Pseudocode description of debug exceptions

`AArch64.DebugFault()` returns a `FaultRecord` object that indicates that a memory access has generated a debug exception:

The `AArch64.Abort()` function processes `FaultRecord` objects, as described in *Abort exceptions* on page D7-5076, and generates a debug exception.

Some functions called by `AArch64.Abort()` are:

- `AArch64.BreakpointException()`.
- `AArch64.WatchpointException()`.
- `AArch64.VectorCatchException()`.
- `AArch64.InstructionAbort()`.
- `AArch64.DataAbort()`.

These functions are defined in *Chapter J1 Armv8 Pseudocode*.
D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions, see:

• Breakpoint instruction in the A32 and T32 instruction sets on page G2-9051.
• BKPT instructions as the first instruction in an IT block on page G2-9052.

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

• About Breakpoint Instruction exceptions.
• Breakpoint instructions.
• Exception syndrome information and preferred return address on page D2-4706.
• Pseudocode description of Breakpoint Instruction exceptions on page D2-4706.

D2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:

• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, which this section describes, are software breakpoints. Breakpoint exceptions on page D2-4707 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked. A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

• The current Exception level.
• The current Security state.
• Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

Note

• The debug target Exception level, EL_D, is the Exception level that debug exceptions are targeting. Routing debug exceptions on page D2-4697 describes how EL_D is derived.
• Debuggers using breakpoint instructions must be aware of the rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-156.

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see BRK on page C6-1237.

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see Breakpoint instruction in the A32 and T32 instruction sets on page G2-9051.
D2.8.3 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address.

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:
• ESR_EL1.
• ESR_EL2.
• ESR_EL3.

Note
Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-7 on page D2-4706 shows the information that the PE records.

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x3C for an A64 BRK instruction.</td>
</tr>
<tr>
<td></td>
<td>• 0x38 for an A32 or T32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0 for a 16-bit T32 BKPT instruction.</td>
</tr>
<tr>
<td></td>
<td>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[24:16]</td>
<td>The PE copies the instruction Comment field value into here, zero extended as necessary.</td>
</tr>
<tr>
<td>ISS[15:0]</td>
<td></td>
</tr>
</tbody>
</table>

Note

• If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.

• For information about how debug exceptions can be routed to EL2, see Routing debug exceptions on page D2-4697.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

AArch64.SoftwareBreakpoint() generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in Chapter J1 Armv8 Pseudocode.
D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page D2-4708.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.
• Breakpoint instruction address comparisons on page D2-4718.
• Breakpoint context comparisons on page D2-4720.
• Breakpoint usage constraints on page D2-4721.
• Preferred return address on page D2-4724.
• Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-4724.

D2.9.1 About Breakpoint exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions on page D2-4705.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The Breakpoint Control Register, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, which is one of:
  — An instruction virtual address.
  — A Context ID.
  — A VMID value.
  — A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:
• DBGBCR0_EL1 and DBGBVR0_EL1 are for breakpoint number zero.
• DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
• DBGBCR2_EL1 and DBGBVR2_EL1 are for breakpoint number two.
• ...
• ...
• DBGBCR<n-1>_EL1 and DBGBVR<n-1>_EL1 are for breakpoint number (n-1).

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is generated only if both breakpoints match.
For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>_EL1.E, is 1.
- The conditions specified in the DBGBCR<n>_EL1 are met.
- The comparison with the value held in the DBGBVR<n>_EL1 is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

**Note**
The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-4696 describes the enable controls for Breakpoint debug events.

### D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - A Context ID match, with the value held in the CONTEXTIDR_EL1.
  - A VMID match, with the VMID value held in the VTTBR_EL2.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.
By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that generates a Breakpoint exception only if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a **Linked Address Match breakpoint**.
2. Program breakpoint number five to be a **Linked Context ID Match breakpoint**.
3. Link these two breakpoints together. A Breakpoint exception is generated only if both the instruction address matches and the Context ID matches.

The **Breakpoint Type** field for a breakpoint, DBGBCR<n>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See **Specifying the halfword-aligned address that an Address breakpoint matches on** on page D2-4719.

--- **Note**

Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == 0b0010 and BT == 0b0101. For information about these, see Chapter G2 **AArch32 Self-hosted Debug**. These types are reserved in stage 1 of an AArch64 translation regime. See **Reserved BT values** on page D2-4722.

---

### Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.

- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The **Linked Breakpoint Number** field, DBGBCR<n>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  
  - **DBGBCR<n>_EL1.{SSC, HMC, PMC}** for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See **Execution conditions for which a breakpoint generates Breakpoint exceptions** on page D2-4717.
  
  - **DBGBCR<n>_EL1.{SSC, HMC, PMC}** for the Linked Context breakpoint are ignored.

- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is **CONSTRAINED UNPREDICTABLE**. See **Other usage constraints for Address breakpoints** on page D2-4724.

- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

--- **Note**

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. **Watchpoint exceptions on** page D2-4726 describes watchpoints.
These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

**Note**

If FEAT_NV2 is implemented, the hypervisor must use the 0b1101, Linked CONTEXTIDR_EL2 Match breakpoint type to guarantee a linked match, see Interaction with self-hosted and External debug on page D8-5179.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-1 shows an example of permitted breakpoint and watchpoint linking.

---

**Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation**

In Figure D2-1, each Linked Address breakpoint can generate a Breakpoint exception only if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.
Breakpoint types defined by DBGBCRn_EL1.BT

The following list provides more detail about each breakpoint type:

0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.
- A successful address match, as described in Breakpoint instruction address comparisons on page D2-4718.

DBGBCR<n>_EL1.LBN for this breakpoint is ignored.

0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.
- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons on page D2-4718.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.
- A successful Context ID match, as described in Breakpoint context comparisons on page D2-4720.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and HCR_EL2.E2H is set to 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-4718.
— A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

- Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

The value of DBGBVR<\text{n}>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:
- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and HCR_EL2.E2H is set to 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<\text{n}>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-4722.

0b0100, Unlinked Address Mismatch breakpoint on page G2-9059 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-4722.

0b0101, Linked Address Mismatch breakpoint on page G2-9059 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0110 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
- DBGBCR<\text{n}>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<\text{n}>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

|| Note |
---|---|
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<\text{n}>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0111 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- The implementation does not include FEAT_VHE.
In an implementation that includes FEAT_VHE, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-4718.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<\(n\)_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

\(0b1000\), Unlinked VMID Match breakpoint

\(BT == 0b1000\) is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \(DBGBCR<\(n\)>_EL1.\{SSC, HMC, BAS, PMC\}\) These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.

- A successful VMID match, as described in Breakpoint context comparisons on page D2-4720.

\(DBGBCR<\(n\)>_EL1.\{LBN, BAS\}\) for this breakpoint are ignored.

\(0b1001\), Linked VMID Match breakpoint

\(BT == 0b1000\) is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page D2-4718.
  - A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

• DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-4717.
• A successful Context ID match, as described in Breakpoint context comparisons on page D2-4720.
• A successful VMID match.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1. Breakpoint context comparisons on page D2-4720 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on all of the following:
  — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-4718.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.
  — A successful VMID match defined by this breakpoint.
• Generation of a Watchpoint exception depends on all of the following:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-4720.
  — A successful VMID match defined by this breakpoint.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1. Breakpoint context comparisons on page D2-4720 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.
0b1100, Unlinked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1100 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

0b1101, Linked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1101 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, either:
- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-4718.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-4720.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

0b1110, Unlinked Full Context ID Match breakpoint

BT == 0b1110 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.
In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \( \text{DBGBCR}^{<n>}_\text{EL1}.\{\text{SSC, HMC, PMC}\} \). These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR^{<n>}_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR^{<n>}_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

\( 0b1111 \), Linked Full Context ID Match breakpoint

- BT == \( 0b1111 \) is a reserved value if either:
  - The breakpoint is not a context-aware breakpoint.
  - FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-4718.
  - A successful Context ID match, as described in Breakpoint context comparisons on page D2-4720.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-4731.
  - A successful Context ID match, as described in Breakpoint context comparisons on page D2-4720.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR^{<n>}_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR^{<n>}_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

\( \text{DBGBCR}^{<n>}_\text{EL1}.\{\text{LBN, BAS}\} \) for this breakpoint are ignored.

--- Note ---

See Reserved DBGBCR^{<n>}_EL1.BT values on page D2-4722 for the behavior of breakpoints programmed with reserved BT values.
D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it generates Breakpoint exceptions only for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<\n>_EL1.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

--- Note ---

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

---

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-8 on page D2-4717 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

- **Y** Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row can generate Breakpoint exceptions in that Exception level and Security state.
- **-** Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row cannot generate Breakpoint exceptions in that Exception level and Security state.

A combination in Table D2-8 on page D2-4717 might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented, see *Reserved DBGBCR<\n>_EL1.{SSC, HMC, PMC} values* on page D2-4722.

### D2.9 Breakpoint exceptions

#### D2.9.4 Breakpoint instruction address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by breakpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See *Address tagging on page D8-5162*.
- 63, otherwise.

--- **Note**

When stage 1 translation is enabled, in AArch64 state, a virtual address has a maximum address width of either 48 bits or, when `FEAT_LVA` is implemented and the 64KB translation granularity is used, 52 bits. Software can configure a smaller address width for a virtual address, see *Input address size configuration on page D8-5090*. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See *Reserved DBGBCR<n>_EL1.(SSC, HMC, PMC) values on page D2-4722*.

---

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are relevant only if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.
When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED up to 52 bits, see Implemented physical address size on page D8-5088.

These faults have a higher priority than breakpoints.

An address comparison is successful if bits [AddrTop:2] of the current instruction virtual address are equal to DBGBVR<\text{n}>_EL1[AddrTop:2].

\textbf{Note}

DBGBVR<\text{n}>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR<\text{n}>_EL1[1:0] are RES0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

\textbf{Specifying the halfword-aligned address that an Address breakpoint matches on}

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the \textit{Byte Address Selection} field, DBGBCR<\text{n}>_EL1.BAS.

<table>

<td>DBGBCR&lt;\text{n}&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<\text{n}>_EL1.BAS is RES1.

Figure D2-2 on page D2-4720 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<\text{n}>_EL1.BAS programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

\textbf{Note}

To breakpoint on an A64 instruction, Arm recommends that the debugger programs DBGBCR<\text{n}>_EL1.BAS as 0b1111.
In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.
No Means that the breakpoint does not generate a Breakpoint exception.
UNP Means that it CONstrained UNPREDICTable whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page D2-4724.

a. 0 means the word-aligned address held in the DBGBVR<n>_EL1[maxAddressSize:2]:00.
The other locations are as follows:
- -2 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) –
- -1 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) –
- ... ...
- +5 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) + 5).
The solid areas show the location of the instruction.

Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

D2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>.BT determines what context comparison is required, if any. Table D2-10 on page D2-4720 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-10 Breakpoint Context ID and VMID comparison tests

<table>
<thead>
<tr>
<th>DBGBCR&lt;n&gt;.BT</th>
<th>Test required for successful context comparison</th>
</tr>
</thead>
</table>
| 0b001x       | • When FEAT_VHE is implemented, EL2 is using AArch64, the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID value.  
• Otherwise, CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value. |
| 0b011x       | CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value. |
| 0b100x       | VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value. |
| 0b101x       | CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value and VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value. |
| 0b110x       | CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32]. |
| 0b111x       | Both:  
• CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value, DBGBVR<n>_EL1[31:0].  
• CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32]. |

No Context ID or VMID comparison is required for other valid DBGBCR<n>.BT values.
Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and HCR_EL2.{E2H, TGE} == {1, 1}.
- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - Neither FEAT_VHE is implemented, nor FEAT_Debugv8p2 is implemented.
  - If the PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - The PE is executing at EL3.
  - EL2 is using AArch32.
  - EL2 is not implemented.
- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - If the PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - The PE is executing at EL2.
  - The PE is executing at EL3.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and HCR_EL2.{E2H, TGE} == {1, 1}.

**Note**
- For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.
- For Linked Context breakpoints, DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

### D2.9.6 Breakpoint usage constraints

See the following sections:

- *Reserved DBGBCR<n>_EL1.BT values* on page D2-4722.
- *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-4722.
- *Reserved DBGBCR<n>_EL1.BAS values* on page D2-4723.
- *Reserved DBGBCR<n>_EL1.LBN values* on page D2-4724.
- *Other usage constraints for Address breakpoints* on page D2-4724.
- *Other usage constraints for Context breakpoints* on page D2-4724.
Reserved DBGBCR<\text{n}>_EL1.BT values

Table D2-11 on page D2-4722 shows when particular DBGBCR<\text{n}>_EL1.BT values are reserved.

<table>
<thead>
<tr>

<td>Full Context ID Match</td>
<td></td>
</tr>
</tbody>
</table>

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<\text{n}>_EL1.

- For a direct or external read of DBGBCR<\text{n}>_EL1, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<\text{n}>_EL1.{SSC, HMC, PMC} values

Table D2-12 on page D2-4722 shows when particular combinations of DBGBCR<\text{n}>_EL1.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00, or combinations when SSC is set to 0b11.</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.</td>
<td>When EL2 is not implemented.</td>
</tr>
</tbody>
</table>
For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR<\texttt{n}>_EL1.{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR<\texttt{n}>_EL1.{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:
- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of DBGBCR<\texttt{n}>_EL1.{SSC, HMC, PMC} returns UNKNOWN values.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

### Reserved DBGBCR<\texttt{n}>_EL1.BAS values

In an AArch64-only implementation, DBGBCR<\texttt{n}>_EL1.BAS for all breakpoints is RES1.

Otherwise:

**For all Context breakpoints**

DBGBCR<\texttt{n}>_EL1.BAS is RES1 and is ignored.

**For all Address breakpoints**

Table D2-9 on page D2-4719 gives the valid values of the DBGBCR<\texttt{n}>_EL1.BAS field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of DBGBCR<\texttt{n}>_EL1.

- A direct or external read of DBGBCR<\texttt{n}>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.
Reserved DBGBCR<n>_EL1.LBN values

For all Context breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<n>_EL1.LBN return an unknown value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
  - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  - If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, Arm recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

AArch64.BreakpointValueMatch() tests the value in DBGBVR<n>_EL1.
AArch64.StateMatch() tests the values in DBGBCR<n>_EL1.\{SSC, HMC, PMC\} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch64.StateMatch() tests the values in DBGWCR<n>_EL1.\{SSC, HMC, PAC\} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch64.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch64.CheckBreakpoint() generates a Breakpoint exception if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-4699.
- All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page D2-4707.

Note

AArch64.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

AArch64.BreakpointException() is called to generate a Breakpoint exception.

These functions are defined in Chapter J1 Armv8 Pseudocode.
**D2.10 Watchpoint exceptions**

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- About Watchpoint exceptions.
- Watchpoint types and linking of watchpoints on page D2-4727.
- Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-4728.
- Watchpoint data address comparisons on page D2-4731.
- Determining the memory location that caused a Watchpoint exception on page D2-4734.
- Watchpoint behavior on other instructions on page D2-4735.
- SVE Watchpoint exceptions on page D2-4737.
- Watchpoint usage constraints on page D2-4737.
- Exception syndrome information and preferred return address on page D2-4739.
- Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-4740.

**D2.10.1 About Watchpoint exceptions**

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRP shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The Watchpoint Control Register, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
- The Watchpoint Value Register, DBGWVR<n>_EL1. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- DBGWCR0_EL1 and DBGWVR0_EL1 are for watchpoint number zero.
- DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
- DBGWCR2_EL1 and DBGWVR2_EL1 are for watchpoint number two.
- ...
- ...
- DBGWCR<n-1>_EL1 and DBGWVR<n-1>_EL1 are for watchpoint number (n-1).

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a Linked Context breakpoint, so that a Watchpoint debug event is generated only if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<n>_EL1.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page D2-4732.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

A debugger uses the MASK field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page D2-4733.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page D2-4738.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>_EL1.E, is 1.
- The conditions specified in the DBGWCR<n>_EL1 are met.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See Figure D2-1 on page D2-4710. See also Breakpoint context comparisons on page D2-4720.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization on page D8-5175 and one of the following is true:
  - EDSCR.HDE is set to 1 and halting is allowed.
  - Debug exceptions are enabled at EL2.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:
- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

--- Note ---

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

---

**D2.10.2 Watchpoint types and linking of watchpoints**

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.
When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a Linked VMID Match breakpoint.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is generated only if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, DBGWCR<\text{\textless}n\text{\textgreater}>_EL1.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<\text{\textless}n\text{\textgreater}>_EL1.WT is 1, the watchpoint is enabled for linking.

**Rules for linking watchpoints**

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGWCR<\text{\textless}n\text{\textgreater}>_EL1.LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<\text{\textless}n\text{\textgreater}>_EL1.{SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See *Execution conditions for which a watchpoint generates Watchpoint exceptions*.
  - DBGBCR<\text{\textless}n\text{\textgreater}>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See *Watchpoint usage constraints* on page D2-4737.
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in *Enhanced support for nested virtualization* on page D8-5175, and the watchpoint is linked to a context-aware breakpoint that is programmed to match the value held in CONTEXTIDR_EL1, then it is CONSTRAINED UNPREDICTABLE whether there is a watchpoint match.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

---

**Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. *Breakpoint exceptions* on page D2-4707 describes breakpoints.

---

Figure D2-1 on page D2-4710 shows an example of permitted watchpoint linking.

### D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it generates Watchpoint exceptions only for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only for Non-secure EL2 accesses.
DBGWCR<\textsubscript{\textasciitilde}>_EL1.\{SSC, HMC, PAC\} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

--- Note ---
This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

**Higher Mode Control, HMC, and Privileged Access Control, PAC**

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made:

- Load unprivileged or Store unprivileged instructions executed at EL1, or executed at EL2 when HCR\_EL2.E2H is 1, are treated as EL0 accesses.
- System register accesses executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization on page D8-5175 are treated as EL2 accesses.

--- Note ---
This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are LDTR and STTR.

Table D2-13 on page D2-4730 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

**Y or -**

Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:

- **Y** Can generate Watchpoint exceptions in that Exception level and Security state.
- **-** Cannot generate Watchpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see Reserved DBGWCR<\textsubscript{\textasciitilde}>_EL1.\{SSC, HMC, PAC\} values on page D2-4737.

</table>

<sup>a</sup> Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are relevant only if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Watchpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See *Reserved DBGWCR<sub>n</sub> EL1 {SSC, HMC, PAC} values* on page D2-4737.
D2.10.4 Watchpoint data address comparisons

In this subsection, the term \textit{AddrTop} represents the most significant bit of a virtual address used by watchpoint data address comparisons. \textit{AddrTop} is:

\begin{itemize}
  \item 55, if address tagging is used for the address. See \textit{Address tagging} on page D8-5162.
  \item 63, otherwise.
\end{itemize}

\begin{note}
When stage 1 translation is enabled, in AArch64 state, a virtual address has a maximum address width of either 48 bits or, when \textit{FEAT_LVA} is implemented and the 64KB translation granule is used, 52 bits. Software can configure a smaller address width for a virtual address. See \textit{Input address size configuration} on page D8-5090. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.

When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is \textit{IMPLEMENTATION DEFINED} up to 52 bits. See \textit{Implemented physical address size} on page D8-5088.

These faults have a higher priority than watchpoints.
\end{note}

An address comparison is successful if bits \([\textit{AddrTop}:2]\) of the current data address are equal to \texttt{DBGWVR}_\texttt{n}\_EL1[\textit{AddrTop}:2], taking into account all of the following:

\begin{itemize}
  \item The size of the access. See \textit{Size of the data access}.
  \item If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.
  \item The bytes selected by \texttt{DBGWVR}_\texttt{n}\_EL1.BAS. See \textit{Programming a watchpoint with eight bytes or fewer} on page D2-4732.
  \item Any address ranges indicated by \texttt{DBGWVR}_\texttt{n}\_EL1.MASK. See \textit{Programming a watchpoint with eight or more bytes} on page D2-4733.
\end{itemize}

\begin{note}
\begin{itemize}
  \item \texttt{DBGWVR}_\texttt{n}\_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits.
  \item \texttt{DBGWVR}_\texttt{n}\_EL1[1:0] are \texttt{RES0} and are ignored.
\end{itemize}
\end{note}

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See \textit{Example D2-1}.

\begin{example}
1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address \texttt{0x1009} is accessed.
2. The PE accesses the unaligned doubleword starting at address \texttt{0x1003}.

In this scenario, the watchpoint must generate a Watchpoint exception.
\end{example}

The size of data accesses initiated by \texttt{DC ZVA} instructions is the DC ZVA block size that \texttt{DCZID\_EL0.BS} defines.

The size of data accesses initiated by \texttt{DC IVAC} instructions is an \textit{IMPLEMENTATION DEFINED} size that is both:

\begin{itemize}
  \item From the inclusive range between:
    \begin{itemize}
      \item The size that \texttt{CTR\_EL0.DminLine} defines.
      \item 2KB.
    \end{itemize}
\end{itemize}
• A power-of-two.

For both of these instructions:

• The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

• The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions on page D2-4736.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>_EL1.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<n>_EL1 the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<n>_EL1 is:

• Doubleword-aligned:
  — All eight bits of DBGWCR<n>_EL1.BAS are used, and the descriptions given in Table D2-14 apply.

• Word-aligned but not doubleword-aligned:
  — Only DBGWCR<n>_EL1.BAS[3:0] are used, and the descriptions given in Table D2-15 on page D2-4733 apply. In this case, DBGWCR<n>_EL1.BAS[7:4] are RES0.

### Table D2-14 Supported BAS values when the DBGWVRn_EL1 address alignment is doubleword

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000000000</td>
<td>Watchpoint never generates a Watchpoint exception.</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:000 is accessed.</td>
</tr>
<tr>
<td>BAS[1] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:001 is accessed.</td>
</tr>
<tr>
<td>BAS[2] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:010 is accessed.</td>
</tr>
<tr>
<td>BAS[3] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:011 is accessed.</td>
</tr>
<tr>
<td>BAS[4] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:100 is accessed.</td>
</tr>
<tr>
<td>BAS[5] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:101 is accessed.</td>
</tr>
<tr>
<td>BAS[6] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:110 is accessed.</td>
</tr>
<tr>
<td>BAS[7] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;n&gt;_EL1[AddrTop:3]:111 is accessed.</td>
</tr>
</tbody>
</table>
If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page D2-4739.

When programming the BAS field with anything other than 0b11111111, a debugger must program DBGWCR<\n>_EL1.MASK to be 0b00000. See Programming dependencies of the BAS and MASK fields on page D2-4738.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<\n>_EL1[AddrTop:3]. See Example D2-1 on page D2-4731.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<\n>_EL1 with 0x1000.
  - DBGWCR<\n>_EL1.BAS to be 0b00001000.

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR<\n>_EL1 with 0x2000.
  - DBGWCR<\n>_EL1.BAS to be 0b00111000.

- If the address programmed into the DBGWVR<\n>_EL1 is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<\n>_EL1.BAS to be 0b00001011.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<\n>_EL1[31:3]:100 is accessed, program DBGWCR<\n>_EL1.BAS to be 0b11110000.

Note

Arm deprecates programming a DBGWVR<\n>_EL1 with an address that is not doubleword-aligned.

### Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, DBGWCR<\n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.
— A minimum of eight bytes.
— A maximum of 2GB.

- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>

If \( n \) least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address \( \text{DBGWVR}^{n}\_\text{EL1}[:\text{AddrTop}:n]:000… \)
- Address \( \text{DBGWVR}^{n}\_\text{EL1}[:\text{AddrTop}:n]:111… \)
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between \( \text{DBGWVR}^{n}\_\text{EL1}[:\text{AddrTop}:4]:0000 \) and \( \text{DBGWVR}^{n}\_\text{EL1}[:\text{AddrTop}:4]:1111 \), including these addresses.

--- Note ---

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see Reserved \( \text{DBGWCR}^{n}\_\text{EL1}.\text{MASK} \) values on page D2-4739.

---

When masking address bits, a debugger must both:

- Program \( \text{DBGWCR}^{n}\_\text{EL1}.\text{BAS} \) to be \( 0b11111111 \). See Programming dependencies of the BAS and MASK fields on page D2-4738.
- In the \( \text{DBGWVR}^{n}\_\text{EL1} \), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see Other usage constraints on page D2-4739.

### D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a Fault Address Register that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- \( \text{FAR\_EL1} \), if the exception is taken to EL1.
- \( \text{FAR\_EL2} \), if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

For more information, see the subsections that follow. These are:

- Address recorded for Watchpoint exceptions generated by Memory Copy and Memory Set instructions on page D2-4735.
- Address recorded for Watchpoint exceptions generated by data cache maintenance instructions on page D2-4735.
- Address recorded for Watchpoint exceptions generated by other instructions on page D2-4735.
Address recorded for Watchpoint exceptions generated by Memory Copy and Memory Set instructions

The address recorded is within an address range of the size defined by the DCZID_EL0.BS field. The start of the range is aligned to the size defined by the DCZID_EL0.BS field and its end is not greater than the address that triggered the watchpoint.

Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

Address recorded for Watchpoint exceptions generated by other instructions

Note

Despite their mnemonics, the DC ZVA, DC GVA, and DC GZVA instructions are not data cache maintenance instructions.

For Watchpoint exceptions generated by a DC ZVA, DC GVA, or DC GZVA instruction, the address recorded is an address accessed by the instruction that triggered the watchpoint.

Otherwise, the address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
  - The highest watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than the DC ZVA block size.
  - Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

D2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
• Prefetch memory instructions.
• All data cache maintenance instructions except DC IVAC.

Note

Despite their mnemonics, the DC ZVA, DC GVA, and DC GZVA instructions are not data cache maintenance instructions.

However, the debug architecture allows for implementation defined controls, such as those in ACTLR registers, to enable watchpoints on an implementation defined subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are implementation defined.

The access size of the implementation defined instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are implementation defined.

See also the following subsections:
• Watchpoint behavior on accesses by Store-Exclusive instructions.
• Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:
• If the store fails because an Exclusives monitor does not permit it, it is implementation defined whether the watchpoint generates a Watchpoint exception.
• Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions

DC ZVA, DC GVA and DC GZVA operations can generate Watchpoint exceptions. If the Point of Coherency is before any level of cache, it is implementation defined whether a DC IVAC instruction can generate a Watchpoint exception. Otherwise, DC IVAC operations can generate Watchpoint exceptions.

DC IVAC, DC ZVA, DC GZVA and DC GVA operations are treated as data stores by DBGWCR<\text{n}>_EL1.LSC.

Note

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see Watchpoint data address comparisons on page D2-4731. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.
D2.10.7 SVE Watchpoint exceptions

**RZRWTZ**
For SVE predicated vector load or store instructions which are not First-fault vector loads or Non-fault vector loads, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element*, a *Watchpoint debug event* is generated.

**RGRRCD**
For SVE predicated vector load or store instructions, if the instruction performs an access due to an *Inactive element*, a *Watchpoint debug event* is not generated.

**RDYGMS**
For SVE Non-fault vector load instructions, when the instruction performs an access, a *Watchpoint debug event* is not generated.

**RLLKQG**
For SVE Non-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element*, the access is reported in the FFR.

**RTLSCX**
For SVE First-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to the *First active element*, a *Watchpoint event* is generated.

**RXBBLW**
For SVE First-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element* that is not the *First active element*, a *Watchpoint debug event* is not generated and the access is reported in the FFR.

**RCKZFP**
Watchpoints are not a mechanism for preventing access to memory.

**IZHXGG**
For SVE Non-fault and First-fault vector load instructions that do not generate a *Watchpoint debug event*, an access that matches a configured watchpoint can return the data and set the appropriate FFR elements to FALSE.

D2.10.8 Watchpoint usage constraints

See the following:

- *Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values*.
- *Reserved DBGWCR<n>_EL1.LBN values* on page D2-4738.
- *Programming dependencies of the BAS and MASK fields* on page D2-4738.
- *Reserved DBGWCR<n>_EL1.BAS values* on page D2-4738.
- *Reserved DBGWCR<n>_EL1.MASK values* on page D2-4739.
- *Other usage constraints* on page D2-4739.

**Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values**

Table D2-16 on page D2-4737 shows when particular combinations of DBGWCR<n>_EL1.{SSC, HMC, PAC} are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PAC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00 or combinations with SSC set to 0b11.</td>
<td>When both EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PAC set to 0b00.</td>
<td>When EL2 is not implemented.</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 except the combination with HMC set to 1, SSC set to 0b11, and PAC set to 0b00.</td>
<td>When Secure EL2 is not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01, and PAC set to 0b00.</td>
<td>When Secure EL2 is not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table D2-13 on page D2-4730.</td>
<td>Always.</td>
</tr>
</tbody>
</table>
If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of 
    DBGWCR<n>_EL1.
- For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC 
    is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read 
    back is the value written. This permits software to save and restore the combination so that the 
    watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions 
of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGWCR<n>_EL1.LBN values**

**For Linked Watchpoints**

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any 
DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, 
then reads of DBGWCR<n>_EL1.LBN return an UNKNOWN value and the behavior is 
CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is 
either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked Watchpoints** For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is 
ignored.

**Programming dependencies of the BAS and MASK fields**

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the 
  DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b000000, so that the MASK field does not indicate any address 
  ranges.

If an enabled watchpoint has a MASK field that is nonzero and a BAS field that is not set to 0b11111111, then for 
each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception 
is generated.

**Reserved DBGWCR<n>_EL1.BAS values**

The BAS field must be programmed with a value \( \text{Zeros}(8-n-m):\text{Ones}(n):\text{Zeros}(m) \), where:

- \( n \) is a nonzero positive integer less-than-or-equal-to 8.
- \( m \) is a positive integer less-than 8.
- \( n+m \) is less-than-or-equal-to 8.
All other values are reserved.

Note

If \( x \) is zero, then \( \text{Zeros}(x) \) is an empty bitstring.

If \( \text{DBGWVR}_{n}\_\text{EL1}[2] \) is 1, \( \text{DBGWCR}_{n}\_\text{EL1}.\text{BAS}[7:4] \) are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the \( \text{DBGWVR}_{n}\_\text{EL1} \).
- A direct or external read of \( \text{DBGWCR}_{n}\_\text{EL1}.\text{BAS} \) returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved \( \text{DBGWCR}_{n}\_\text{EL1}.\text{MASK} \) values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of \( \text{DBGWCR}_{n}\_\text{EL1} \).
- A direct or external read of \( \text{DBGWCR}_{n}\_\text{EL1}.\text{MASK} \) returns an UNKNOWN value.

Other usage constraints

For all watchpoints:

- \( \text{DBGWVR}_{n}\_\text{EL1}[1:0] \) are RES0 and are ignored.
- If \( \text{DBGWCR}_{n}\_\text{EL1}.\text{MASK} \) is nonzero, and any masked bits of \( \text{DBGWVR}_{n}\_\text{EL1} \) are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if \( \text{DBGWCR}_{n}\_\text{EL1}.\text{LSC} \) is 0b00.

D2.10.9 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address on page D2-4740.

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the \( \text{Exception Syndrome Register} \) (\( \text{ESR}_{\text{EL}x} \)) at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a \( \text{Fault Address Register} \) (\( \text{FAR} \)).

The ESR and FAR used is either:

- \( \text{ESR}_{\text{EL1}} \) and \( \text{FAR}_{\text{EL1}} \), if the exception is taken to EL1.
- \( \text{ESR}_{\text{EL2}} \) and \( \text{FAR}_{\text{EL2}} \), if the exception is taken to EL2.
--- Note ---

Watchpoint exceptions cannot be taken to EL3 using AArch64.

See *ISS encoding for an exception from a Watchpoint exception* on page D17-5697 for more information.

**Preferred return address**

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

### D2.10.10 Pseudocode description of Watchpoint exceptions taken from AArch64 state

*AArch64.WatchpointByteMatch()* tests an individual byte accessed by an operation.

*AArch64.StateMatch()* tests the values in DBGWCR<n>_EL1.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

*AArch64.WatchpointMatch()* tests the value in DBGWVR<n>_EL1.

*AArch64.CheckWatchpoint()* generates a FaultRecord that *AArch64.Abort()* raises a Watchpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level* on page D2-4699.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions* on page D2-4726.

--- Note ---

*AArch64.CheckWatchpoint()* might halt the PE and cause it to enter Debug state. External debug uses Debug state.

*AArch64.WatchpointException()* is called to generate a Watchpoint exception.

These functions are defined in *Chapter J1 Armv8 Pseudocode*. 

---
D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

Note

This means that they are never taken to EL1 using AArch64 and are supported only if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See Routing debug exceptions on page D2-4697.

AArch64.VectorCatchException() is called to generate a Vector Catch exception.

Vector Catch exceptions on page G2-9093 describes Vector Catch exceptions.
D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine.
- Entering the active-not-pending state on page D2-4744.
- Behavior in the active-not-pending state on page D2-4747.
- Entering the active-pending state on page D2-4749.
- Behavior in the active-pending state on page D2-4750.
- Stepping T32 IT instructions on page D2-4750.
- Exception syndrome information and preferred return address on page D2-4751.
- Additional considerations on page D2-4752.
- Pseudocode description of Software Step exceptions on page D2-4754.

D2.12.1 About Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions. For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See The debug exception enable controls on page D2-4696.
   b. Executes an exception return instruction, to branch to the instruction to be single-stepped in the software being debugged.

2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can take a Software Step exception only if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-4699.

A state machine describes the behavior of software step, shown in The software step state machine. Throughout this Software Step exceptions section, including in all subsections, EL_D means the Exception level that Software Step exceptions are targeting. Routing debug exceptions on page D2-4697 defines EL_D as the debug target Exception level.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.

D2.12.3 The software step state machine

In Figure D2-3 on page D2-4743:

- The OS Lock is unlocked and DoubleLockStatus() == FALSE.
The PE is not in Secure state with MDCR_EL3.SDD set to 1. That is, the PE is in Non-secure state, or is in Secure state with MDCR_EL3.SDD set to 0, or the implementation does not include EL3.

**Figure D2-3 Software step state machine**

For a description of when debug exceptions are enabled or disabled from an Exception level, see *Enabling debug exceptions from the current Exception level* on page D2-4699.

For more information about how a step is completed, see *Behavior in the active-not-pending state* on page D2-4747.
The software step states are:

**Inactive**

Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- MDSCR_EL1.SS is 0.
- ELD is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

**Active-not-pending**

None of the conditions mentioned in *Inactive* are true, therefore software step is active. The current instruction is the instruction to be stepped.

**Active-pending**

None of the conditions mentioned in *Inactive* are true, therefore software step is active. A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not-pending state or the active-pending state depends on PSTATE.SS. Table D2-17 on page D2-4744 shows this.

<table>
<thead>

</tr>
</tbody>
</table>

**D2.12.4 Entering the active-not-pending state**

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an Exception return instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 1. See *Exiting Debug state on page H2-10271*.

An Exception return instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- ELD is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the Exception return instruction targets.

Otherwise, Exception return instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS. Table D2-18 on page D2-4745 shows this. In the table:

- **Lock**  Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- **NS**  Means the *Effective value of SCR_EL3.NS.*
SDD Means the Effective value of MDCR_EL3.SDD. See Disabling debug exceptions from Secure state on page D2-4699.

EEL2 Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.

TGE Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.

TDE Means the Effective value of MDCR_EL2.TDE. See Routing debug exceptions on page D2-4697.

**EL1 is using** The Execution state when the ELD is EL1.

**EL2 is using** The Execution state when the ELD is EL2.

For:

- If ELD is EL1 using AArch64, Table D2-19 on page D2-4746 shows the value an Exception return instruction writes to PSTATE.SS.
If ELₐ is EL2 using AArch64, Table D2-20 on page D2-4747 shows the value an Exception return instruction writes to PSTATE.SS.

In both tables:

- **From EL**: Means the Exception level at which the PE executes the Exception return instruction.
- **Target EL**: Is the target Exception level of the Exception return instruction.

--- **Note** ---

If the Exception return instruction is an illegal exception return, the target Exception level of the Exception return instruction is the current Exception level. See *Illegal exception returns from AArch64 state* on page D1-4645.

**KDE**

Is MDSCR_EL1.KDE. See *Enabling debug exceptions from the current Exception level* on page D2-4699.

a. Because MDSCR_EL1.SS == 1, it means that the Exception return instruction is itself being stepped.
b. Depends on SPSR_EL2.D.

---

**Note**

No AArch32 instruction can set PSTATE.SS to 1.

### D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:
- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
• Enters Debug state because of a Halting debug event.

If the PE executes the instruction without taking any exceptions, then the PE sets `PSTATE.SS` to 0, meaning that after the instruction has been executed:

• If the instruction has disabled debug by setting `PSTATE.D` to 1 then software step advances to the inactive state.

• If the instruction disables software step by a direct write to a System register, for example a write to `MDSCR_EL1.KDE` or `MDSCR_EL1.SS`, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine on page D2-4753.

• Otherwise, software step advances to the active-pending state. See Behavior in the active-pending state on page D2-4750.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

• If the PE takes an exception to an Exception level that is using AArch64.

• If the PE takes an exception to an Exception level that is using AArch32 on page D2-4749.

If the PE enters Debug state because of a Halting debug event, behavior is as described in Entering Debug state and Software Step on page H2-10241.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

• Sets `SPSR_ELx.SS` to 0 or 1, depending on the exception. See Table D2-21 on page D2-4748.

• It is UNPREDICTABLE whether `SPSR_ELx.SS` to 0 or 1 when an SError interrupt is taken to ELx without executing the instruction.

• Sets `PSTATE.SS` to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
  - Enabled  Software step enters the active-pending state.
  - Disabled  Software step enters the inactive state.
  - In either case, on taking the exception, a step is complete.

• Sets `PSTATE.D` to 1.

### Table D2-21 Categorization of exceptions, for setting `SPSR_ELx.SS` to 0 or 1

<table>
<thead>
<tr>
<th>Exception description</th>
<th>Exceptions</th>
<th>SPSR_ELx.SS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.</td>
<td>Supervisor Call (SVC) exceptions, Hypervisor Call (HVIC) exceptions, Secure Monitor Call (SMC) exceptions.</td>
<td>0</td>
</tr>
<tr>
<td>Exceptions whose preferred return address is the address of the instruction to be stepped.</td>
<td>All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.</td>
<td>1</td>
</tr>
</tbody>
</table>

--- Note ---

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because `HCR_EL2.TSC` is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so `SPSR_ELx.SS` is set to 1, not 0.
If the PE takes an exception to an Exception level that is using AArch32

This can happen only when all of the following is true:

- EL2 is implemented and is using AArch64, and the Effective value of MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, ELD is EL2.
- The exception is taken to EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

--- Note ---
- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because ELD is EL2, and debug exceptions are always enabled from Exception levels that are lower than ELD.
- AArch32 SPSRs have no SS bit.

a. For the No exception rows, this column shows the effect of the event. For the Exception rows, this column shows the exception taken.
b. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-3 on page D2-4743.

D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.
While software step is in the active-pending state
The PE takes an asynchronous exception.

While software step is in the inactive state
The PE executes either:
• An Exception return instruction when SPSR_ELx.SS is 0.
• An instruction that enables debug by setting PSTATE.D to 0.

Note
If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to EL1 when MDCR_EL2.TDE is 1 and EL2 is implemented and enabled in the current Security state. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:
• After a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine on page D2-4753.
• On exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0. See Exiting Debug state on page H2-10271.

D2.12.7 Behavior in the active-pending state
When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction. The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:
• Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.
• Prioritization of interrupts on page D1-4664.
• Architectural requirements for taking asynchronous exceptions on page G1-8935.

D2.12.8 Stepping T32 IT instructions
The A-profile architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:
• The PE considers this combination to be one instruction.
• The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, which can disable some uses of the IT instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:
• The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
• The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
• The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:
• SCTLR_EL1.ITD if execution is at EL0 using AArch32 when EL1 is using AArch64.
• SCTLR.ITD if execution is at EL0 or EL1 when EL1 is using AArch32.
• HSCTRL.ITD if execution is at Non-secure EL2 using AArch32.

D2.12.9 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address on page D2-4752.

Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to. See ISS encoding for an exception from a Software Step exception on page D17-5697 for more information.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, then ESR_ELx.ISV, EX are set to 0.

When an instruction has been stepped, if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test, then ESR_ELx.ISV is set to 1 and ESR_ELx.EX is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1.

When an instruction has been stepped, if the stepped instruction was an Exception return instruction or an ISB, then ESR_ELx.ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1, and ESR_ELx.EX is set to 0.

If the Effective value of MDCR_EL2.TDE == 1, EL2 is implemented and enabled in the current Security state, and a different exception is taken before the Software Step exception, then ESR_ELx.ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1. In this case:
• If ESR_ELx.ISV is set to 1, then ESR_ELx.EX is set to the correct value for the instruction.
• If ESR_ELx.ISV is set to 0, then ESR_ELx.EX is set to zero.

Other than for the cases described above, when an instruction has been stepped:
• ESR_ELx.ISV is set to 1, to indicate that the EX bit is valid.
• The value of ESR_ELx.EX is set according to the instruction stepped. When:
  — The instruction stepped was an instruction other than a Load-Exclusive instruction, an Exception Return instruction, or an ISB, and no other exception was taken before the Software Step exception, ESR_ELx.EX is set to 0.
  — The instruction stepped was a Load-Exclusive instruction that was either not conditional or did not fail its Condition code test, ESR_ELx.EX is set to 1.

Note

If the PE cannot determine the correct value of ESR_ELx.EX for the stepped instruction, then it sets ESR_ELx.{ISV, EX} to {0, 0}. For example, the exception is taken before the PE decodes the stepped instruction, or the exception means the PE has no valid stepped instruction to decode.

Note

A Load-Exclusive instruction is any one of the following:
• In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
• In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

Note

An implementation that always sets ISV to 0 and never sets EX is not compliant.
Table D2-23 on page D2-4752 summarizes the possible values that the PE can record in ESR_ELx.{ISV, EX}.

**Preferred return address**

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

### D2.12.10 Additional considerations

This section contains the following:

- Behavior when an Exception return instruction is an illegal exception return.
- Behavior when the instruction stepped writes a misaligned PC value on page D2-4753.
- Stepping code that uses Exclusives monitors on page D2-4753.
- Synchronization and the software step state machine on page D2-4753.

**Behavior when an Exception return instruction is an illegal exception return**

If the conditions for entering the active-not-pending state in Entering the active-not-pending state on page D2-4744 are met, but the PE executes an Exception return instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the Exception return instruction, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.
   - PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.
2. The PE executes an Exception return instruction.
3. The intended target of the Exception return instruction is EL2. This means that the Exception return instruction is an illegal exception return because the intended target is higher than the Exception level the Exception return instruction it is executed at. In this case, the Exception return instruction must target EL1 instead of EL2.

If SPSR_EL1.D is 0, then on the Exception return instruction PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.
  In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.

- If SPSR_ELx.SS is 0, software step advances to the active-pending state.
  In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650 shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A PC alignment fault exception is generated.

AArch32 The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

Stepping code that uses Exclusives monitors

The A-profile architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see Exception syndrome information and preferred return address on page D2-4751.

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
• A write to an external debug register.

The software step state machine indirectly reads some of these registers and so is not guaranteed to observe any new values until after a *Context synchronization event* has occurred.

Between a write to the register and the next *Context synchronization event*, it is CONstrained UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a *Context synchronization event*, the state machine must use the state of the PE after the write.

**Example D2-3 Example of synchronization and software step state machine changing states**

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During step 2, it is CONstrained UNPREDICTABLE whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:
   • Inactive state, then after the *Context synchronization event*, it must enter the active-pending state.
   • Active-pending state, the PE might take a Software Step exception before the *Context synchronization event*.

---

**Note**

A direct write to a Special-purpose register does not require explicit synchronization.

---

**D2.12.11 Pseudocode description of Software Step exceptions**

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See *Entering the active-not-pending state on page D2-4744*.

These functions are defined in Chapter J1 *Armv8 Pseudocode*.
**D2.13 Synchronization and debug exceptions**

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context synchronization event* has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a *Context synchronization event* has occurred.

For any instructions executed between the time when the change is made and the time when the next *Context synchronization event* occurs, it is **CONSTRAINED UNPREDICTABLE** whether debug uses the state of the PE before the change, or the state of the PE after the change.

**Example D2-4 Example of synchronization and Breakpoint exception generation**

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A *Context synchronization event* occurs.

In this case, it is **CONSTRAINED UNPREDICTABLE** whether the instruction generates a Breakpoint exception.

**Example D2-5 Example of synchronization and debug exceptions generation**

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During the time when the PE is executing some instructions, step 2, it is **CONSTRAINED UNPREDICTABLE** whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

**Note**

Some register updates are self-synchronizing. Others require an explicit *Context synchronization event*. For more information, see:

- *Accessing PSTATE fields* on page D1-4671.
- *Synchronization requirements for AArch64 System registers* on page D17-5547.
- *Synchronization of changes to the external debug registers* on page H8-10358.
Chapter D3
AArch64 Self-hosted Trace

This chapter describes the AArch64 self-hosted trace:

Introductory information:
- About self-hosted trace on page D3-4758.
- Trace sinks on page D3-4758.
- Register controls to enable self-hosted trace on page D3-4758.

Prohibited regions in trace:
- Controls to prohibit trace at Exception levels on page D3-4759.
- Self-hosted trace and visibility of virtual data on page D3-4760.

Timestamps and Synchronization:
- Self-hosted trace timestamps on page D3-4761.
- Synchronization in self-hosted trace on page D3-4762.
D3.1 About self-hosted trace

A trace unit generates trace data to describe the program flow of the PE.

The trace unit may be an implementation of any of the following:

- In Armv9, the Embedded Trace Extension (ETE). See Chapter D4 The Embedded Trace Extension.
- An IMPLEMENTATION DEFINED trace function.

If an Armv8.4-compliant PE implements an ETM Architecture trace unit that includes the ETM System register interface, FEAT_TRF must be implemented.

If an Armv8.4-compliant PE implements a trace unit that is either not an ETM Architecture trace unit or does not implement the ETM System register interface, Arm recommends that FEAT_TRF is implemented, but this is not mandatory. This is not applicable in Armv9.

If an Armv9-compliant PE implements FEAT_ETE, FEAT_TRF must be implemented.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The trace unit and the PE must have the same view of the debug authentication interface. If FEAT_TRF is implemented, ExternalNoninvasiveDebugEnabled() is always TRUE.

D3.1.1 Trace sinks

The trace unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

If FEAT_TRBE is implemented, the PE includes a Trace Buffer Unit. Trace data is written directly to memory by the Trace Buffer Unit. See Chapter D6 The Trace Buffer Extension.

In Armv8, Arm recommends that a system that includes FEAT_TRF incorporates an ETR, and follows the system architecture described by the CoreSight Base System Architecture (CS-BSA).

D3.1.2 Register controls to enable self-hosted trace

If FEAT_TRF is implemented, self-hosted trace is enabled if one of the following is true:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, EL3 is implemented, MDCR_EL3.STE == 1 and ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- EDSCR.TFO == 1, EL3 is not implemented, the PE executes in Secure state and ExternalSecureNoninvasiveDebugEnabled() = FALSE.

The pseudocode function SelfHostedTraceEnabled() shows these rules.

If FEAT_TRF is not implemented, SelfHostedTraceEnabled() returns FALSE.

While SelfHostedTraceEnabled() is FALSE, ExternalNoninvasiveDebugAllowed() controls whether tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the trace unit external debug interface.
D3.2  Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited in Secure state when MDCR_EL3.STE == 0.

D3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled()` == TRUE, TRFCR_EL1 and TRFCR_EL2 control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled()` == FALSE, the registers TRFCR_EL1 and TRFCR_EL2 are ignored.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL0 if one of the following is true:
- The Effective value of HCR_EL2.TGE == 0 and TRFCR_EL1.E0TRE == 0.
- The Effective value of HCR_EL2.TGE == 1 and TRFCR_EL2.E0HTRE == 0.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL1 if TRFCR_EL1.E1TRE == 0.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL2 if TRFCR_EL2.E2TRE == 0.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL3 if one of the following is true:
- EL3 is using AArch64 state.
- EL3 is using AArch32 state and TRFCR.E1TRE == 0.

The pseudocode `TraceAllowed()` shows the above rules.

If `SelfHostedTraceEnabled()` == TRUE, no events are exported to the trace unit when tracing is prohibited.

If `SelfHostedTraceEnabled()` == FALSE, no events are exported to the trace unit when the PE is in Secure state and counting in Secure state is prohibited.

If FEAT_ETE is not implemented, when PMCR_EL0.X==0 or PMCR.X==0, no PMU events are exported to the trace unit.

Otherwise, PMU events are exported to the trace unit.

If `SelfHostedTraceEnabled()` == TRUE, Table D3-1 on page D3-4760 shows the prohibited regions by Exception level and state.

In the table:

- **STE** Means the Effective value of MDCR_EL3.STE or SDCR.STE, as applicable.
- **EEL2** Means the Effective value of SCR_EL3.EEL2.
- **TGE** Means the Effective value of HCR_EL2.TGE.
- **P** Means prohibited.
- **E2TRE** Means prohibited if TRFCR_EL2.E2TRE == 0.
- **E1TRE** Means prohibited if TRFCR_EL1.E1TRE == 0.
- **E0HTRE** Means prohibited if TRFCR_EL2.E0HTRE == 0.
- **E0TRE** Means prohibited if TRFCR_EL1.E0TRE == 0.
- **n/a** Not applicable.

If FEAT_TRBE is not implemented, trace is allowed unless otherwise prohibited in Table D3-1 on page D3-4760.
If FEAT_TRBE is implemented, the requirements in this section are extended. See *The owning translation regime* on page D6-5010.

#### D3.2.2 Self-hosted trace and visibility of virtual data

A hypervisor can use TRFCR_EL2.CX to control visibility of CONTEXTIDR_EL2 and VTTBR_EL2.VMID. If SelfHostedTraceEnabled() == TRUE and TRFCR_EL2.CX == 0, or if EL2 is not implemented:

- The values of CONTEXTIDR_EL2 and VTTBR_EL2.VMID are not traced.
- Comparisons between CONTEXTIDR_EL2 and VTTBR_EL2.VMID do not match and results of comparison are not exposed through the comparators.

The trace unit may either prohibit trace for these values, or may record a CONTEXTIDR_EL2 or VTTBR_EL2.VMID value of zero in the trace.
D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While `SelfHostedTraceEnabled()` == FALSE, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When `SelfHostedTraceEnabled()` == TRUE, the trace timestamp is one of the following:

- Physical time, which is defined by the physical count value returned by `PhysicalCountInt()`.
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of (`PhysicalCountInt()` - CNTPOFF_EL2).
- Virtual time, which is defined as the value of (`PhysicalCountInt()` - CNTVOFF_EL2). The virtual offset is always CNTVOFF_EL2, including when a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

The fields TRFCR_EL2.TS, HTRFCR.TS, TRFCR_EL1.TS and TRFCR.TS control which counter is used for self-hosted trace.

The timestamp used for trace is shown in Table D3-2 on page D3-4761.

In Table D3-2 on page D3-4761, if any of the following are true, the value of physical offset is zero, otherwise the value of physical offset is the value of CNTPOFF_EL2:

- EL3 is using AArch32.
- EL2 is not implemented.
- FEAT_ECV is not implemented.
- The Effective value of SCR_EL3.{NS,RW} is {1,0}.
- CNTHCTL_EL2.ECV is 0.
- SCR_EL3.ECVEn is 0.

Note

The counter value used for the trace timestamp is not affected by the value of HCR_EL2.E2H, or whether EL2 is enabled or disabled in the current Security state.

</table>
D3.4 Synchronization in self-hosted trace

The trace unit is an indirect observer of the System registers.

If FEAT_TRBE is implemented, the requirements in this section are extended. See Synchronization and the Trace Buffer Unit on page D6-5026.

While SelfHostedTraceEnabled() == TRUE, indirect reads of the trace filter control fields, TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced. For these register fields, in addition to the standard requirements for synchronization of System register accesses, when a trace filter control value is changed and synchronization is not explicitly specified, one of the following occurs:

- The behavior of the PE must be consistent with the control value having the old value.
- The behavior of the PE must change the control value at a point in the simple sequential execution of the program, so that before that point, the behavior of the PE is consistent with the control value having the old value, and after that point the behavior of the PE is consistent with the control value having the new value.

If there are multiple direct writes to the register without explicit synchronization, the behavior is consistent with the writes occurring in program order.

The TSB CSYNC operation is used to ensure that a trace operation, due to a trace unit generating trace for an instruction has completed. The TSB CSYNC operation may be reordered with respect to other instructions, so must be combined with at least one Context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR_EL1 or TRFCR_EL2 is guaranteed to be observed by the trace unit only after a subsequent Context synchronization event. For more information, see Trace Synchronization Barrier (TSB CSYNC) on page B2-177.

While SelfHostedTraceEnabled() == FALSE, the trace unit might impose stronger synchronization requirements.
Chapter D4
The Embedded Trace Extension

This chapter describes the Embedded Trace Extension (ETE). It contains the following sections:

- About the Embedded Trace Extension on page D4-4764.
- Programmers’ model on page D4-4771.
- Trace elements on page D4-4775.
- Instruction and exception classification on page D4-4791.
- About the ETE trace unit on page D4-4800.
- Resource operation on page D4-4843.
D4.1 About the Embedded Trace Extension

FEAT_ETE describes the operation of a trace unit. The trace unit provides details about software control flow running on a PE which can be used to aid debugging or optimization. The trace unit provides filtering functionality to allow the targeting of the information to specific code regions or periods of operation.

FEAT_ETE overlaps with the ETMv4 architecture, while also providing support for new architecture features. For more information on the ETMv4 architecture, see the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064). FEAT_ETE does not support all the features of ETMv4. For more information on the differences between FEAT_ETE and the ETMv4 architecture, see Differences between ETM and ETE on page K4-11671.

D4.1.1 Attributes of tracing

The attributes of PE tracing are:

Trace is generated in real time.

Trace provides a means of observing the PE operation while the PE is running. For diagnostic purposes, this is useful as some types of erroneous behavior are only solvable by observing the system during runtime. In addition, because the PE trace can include cycle counts, trace can be used for PE profiling purposes.

Trace has a minimal effect on functional performance of the PE.

Usually, trace has no effect on the functional performance of the PE. This attribute does depend on the market use of the PE being debugged, however, and on the trace requirements for the PE and the trace solution that is adopted to meet those requirements. For some markets, some impact on PE performance is acceptable but for others, most notably in real-time systems, an impact on PE performance might be unacceptable.

Trace is available for self-hosted analysis.

The trace from a PE or process is available for analysis by software running on the target. See Self-hosted Trace.

Trace is deeply embedded in an SoC.

Trace provides a method of debugging software executing on PEs that are deeply embedded within an SoC.

Trace is available for external analysis.

The trace from a PE or process can be exported off chip for analysis by external tools.

D4.1.2 Self-hosted Trace

Self-hosted trace is used for various purposes, including:

Non-invasive single stepping:

The trace provides a history of execution similar to that obtained by single-stepping through code.

Failure logging:

This is similar to a stack trace dump when a failure occurs.

Performance analysis:

The trace might be used with other trace sources or performance analysis units to analyze program performance.

D4.1.3 External debug

External debug is commonly used in trace applications that require long-term logging of behavior. In addition, external debug is more likely to be used when the impact of PE tracing on system performance must be minimized.

For example, external debug might be used:

• For debugging real-time systems.
• When analyzing programs that do not frequently vary their behavior.
• For debugging software, where a history of execution is required up to the point of failure.

Exporting the trace off-chip usually involves one of the following methodologies:

**Real-time continuous export**

This can be done using either:

- A dedicated trace port capable of sustaining the bandwidth of the trace.
- An existing interface on the SoC, such as a USB or other high-speed port.

Use of a dedicated trace port means that the trace can be exported off-chip with zero or minimum effect on system behavior. An existing interface is usually used when system constraints, such as cost or package size, mean that a dedicated trace port is not possible. However, use of an existing interface might affect system behavior, because both trace and normal interface traffic use the same port.

**Short-term on-chip capture with subsequent low speed export**

This option is used when a low-cost method of exporting the trace is required, or when system constraints prevent real-time continuous export. The trace output from the trace unit is stored temporarily on-chip, and then exported using either:

- An existing debug port on the SoC, such as a JTAG-DP or SW-DP.
- Another existing interface on the SoC, such as USB.

Typically, the temporary storage is a circular buffer. If the buffer is full, newer trace overwrites older trace, which means that the buffer always contains the most recent trace. In SoCs that employ Arm CoreSight technology, a dedicated Embedded Trace Buffer (ETB) is provided for the on-chip capture of trace.

**D4.1.4 Trace output**

The trace unit outputs the trace byte stream to one or more of the following:

- The Trace Buffer Unit.
- A CoreSight subsystem, through an AMBA ATB interface.
- One or more IMPLEMENTATION DEFINED interfaces.

If the Trace Buffer Unit is enabled, the trace byte stream is output solely to the Trace Buffer Unit.

If the Trace Buffer Unit is disabled, the trace byte stream is output to one or more of the other interfaces.

If the trace output is captured by a single capture point dedicated to a PE, and does not mix with any other trace streams, then the value programmed into TRCTRACEIDR.TRACEID does not need to be unique among all values programmed into all trace units in the system. For example, the value 0x01 could be programmed into all trace units that have their own dedicated trace capture point.

- One example of a dedicated trace capture point is the Trace Buffer Unit. When FEAT_TRBE is implemented and enabled, the value of TRCTRACEIDR.TRACEID can be the same for all PEs that are using the Trace Buffer Extension. For more information, see Chapter D6 *The Trace Buffer Extension*.
- Another example of a dedicated trace capture point is a CoreSight ETR connected through an AMBA ATB interface and dedicated to a PE. If the AMBA ATB interface connects to the ETR without mixing with any other trace streams, TRCTRACEIDR.TRACEID does not need to be unique when using the ETR, and when ensuring the trace does not go to any other trace capture points.

If an AMBA ATB interface is implemented, the trace unit must support all of the following:

- ATB triggers, indicated by TRCIDR5.ATBTRIG.
- A 7-bit trace ID, indicated by TRCIDR5.TRACEIDSIZE.

Arm recommends that if the trace unit implements either an AMBA ATB interface, or an IMPLEMENTATION DEFINED interface for trace output, then the path from the interface is not affected by a Warm reset of the PE. This ensures tracing is possible through a Warm reset of the PE, which is useful for low level debugging scenarios.
While all trace outputs are disabled, the trace unit considers any generated trace data as having been output.

### D4.1.5 Trace sessions

At any one time, the trace unit is either enabled or disabled. For more information on the possible states of the trace unit, see *Trace unit programming states*.

A *trace session* is the period between the trace unit becoming enabled, and when the trace unit next becomes disabled.

While the trace unit is enabled, the ViewInst() function is either *active* or *inactive*. While ViewInst() is *active*, the trace unit generates trace for instructions that are executed, unless trace generation is *inoperative*.

Trace generation is *operative* while neither of the following are true:
- The trace unit is disabled.
- The trace unit is recovering from a trace unit buffer overflow.

Whether ViewInst() is *active* or *inactive* is independent of whether trace generation is *operative* or *inoperative*.

Trace generation *becomes operative* when trace generation transitions from being *inoperative* to *operative*, and occurs when any of the following occur:
- When the trace unit transitions from being disabled to being enabled.
- When the trace unit recovers from a trace unit buffer overflow.

Trace generation *becomes inoperative* when trace generation transitions from being *operative* to *inoperative*, and occurs either:
- When the trace unit transitions from being enabled to being disabled.
- When the trace unit encounters a trace unit buffer overflow.

When the trace unit is unable to generate at least one trace packet which is required by the architecture, a *trace unit buffer overflow* occurs.

A trace unit buffer overflow is typically caused when any buffering in the trace unit is unable to receive more trace packets. Inability to receive trace packets is often caused by being unable to sustain output of trace packets to any trace capture infrastructure.

Note: A trace unit buffer overflow is independent of the Trace Buffer Unit filling or wrapping a trace buffer in memory. However a trace unit buffer overflow might be caused by the Trace Buffer Unit rejecting trace data due to insufficient capacity, and the limit of any trace unit internal buffers is subsequently reached.

### D4.1.6 Trace unit programming states

The trace unit is always in one of the states shown in Figure D4-1 on page D4-4767 and Table D4-1 on page D4-4767.
When the trace unit becomes enabled, the trace unit transitions from the Idle state to the Enabling state.

The trace unit transitions from the Enabling state to the Running state in a finite amount of time.

When the trace unit becomes disabled, the trace unit transitions from the Running state to the Unstable state.

The trace unit transitions from the Unstable state to the Stable state in a finite amount of time.

While the trace unit is in the Stable and Idle states, the states of the following fields do not change other than by direct writes or external writes:

- TRCVICTLR.SSSTATUS.
- TRCSEQSTR.STATE.
- TRCCNTVR<\<n>.VALUE.
- TRCSSCSR<\<n>.STATUS.
- TRCRSR.EVENT.
- TRCRSR.EXTIN.
- TRCRSR.TA.

The trace unit programmers’ model state can be safely read when in any of the Stable or Idle states.
When the trace unit becomes fully idle and both of the following are true, the trace unit transitions from the Stable state to the Idle state:

- The trace unit is drained of any trace.
- With the exception of the programming interfaces, all external interfaces on the trace unit are quiescent.

While the trace unit is not in the Idle state, direct writes and external writes to the trace unit registers are constrained unpredictable, except for the following registers:

- TRCPRGCTRL.
- TRCLAIMSET.
- TRCLAIMCLR.

This constrained unpredictable behavior is one of the following:

- The write is ignored.
- The register takes an unknown value.

The trace byte stream might also be corrupted and analysis of the byte stream might be impossible.

While the trace unit is not in the Idle or Running states, changing the value of TRCPRGCTRL.EN is constrained unpredictable.

This constrained unpredictable behavior is one of the following:

- The write is ignored.
- The register takes an unknown value.

For more information, see:

- Behavior on enabling on page D4-4800.
- Behavior on disabling on page D4-4801.
- Access permissions on the corresponding register page.

Figure D4-2 on page D4-4769 shows the procedure that must be used when programming the trace unit registers using the External Debugger interface.
Figure D4-2 External Debugger Interface programming procedure

Figure D4-3 on page D4-4770 shows the procedure that is used when programming the trace unit registers using the System instruction interface.
Figure D4-3 System instruction programming procedure
D4.2 Programmers’ model

D4.2.1 Accessing ETE registers

The ETE architecture provides registers for programming the ETE trace unit and reading back the programmed settings. These registers can be accessed by using one or more of the following access mechanisms:

• An external debugger interface, for use by an external debugger.
• System instructions, for use by self-hosted software running on the PE being traced.

When register accesses occur simultaneously from multiple access mechanisms, the trace unit behaves as if all accesses occur atomically in any order.

External debugger interface

The external debugger interface defines an address-mapped peripheral that occupies 4KB of address space.

Note: The PE does not have to be in Debug state to program the ETE registers.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

The trace unit supports the following access sizes:

• Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
• Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations. The order in which the two halves are accessed is not specified.

Note: This means that a system implementing the Debug registers using a 32-bit bus, such as AMBA APB in CoreSight systems, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity.

The trace unit does not support the following accesses:

• Byte.
• Halfword.
• Unaligned word. These accesses are not single-copy atomic at word granularity.
• Unaligned doubleword. These accesses are not single-copy atomic at doubleword granularity.
• Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
• Quadword or higher.
• Exclusives.

The behavior of the accesses that are unsupported by the trace unit is CONSTRAINED UNPREDICTABLE and is one of the following:

• Accesses generate an External abort, and writes set the accessed register or registers to an UNKNOWN value or values.
• Reads return UNKNOWN data and writes are ignored.
• Reads return UNKNOWN data and writes set the accessed register or registers to an UNKNOWN value. This is the Arm preferred behavior.

For accesses from the external debugger interface which return an error response when AllowExternalTraceAccess() returns FALSE, EDPRSR.STAD is only set to 1 when this is the highest priority cause of the error. The following causes are higher priority than AllowExternalTraceAccess():

• The trace unit Core power domain is powered down.
• The OS Lock is locked and the register is defined to return an error response due to the OS Lock being locked.
RKQMKX

Accesses from the external debugger interface to unimplemented or Reserved registers behave as follows:

- For accesses in the range of offsets 0xF00 to 0xFFC, the access behaves as RES0H.
- For accesses in the range of offsets 0x000 to 0xEFC when the OS Lock is locked, the access behaves as RES0H or returns an error.
- For accesses in the range of offsets 0x000 to 0xEFC when the OS Lock is unlocked and MDCR_EL3.ETAD is 0, the access behaves as RES0H.
- For Secure accesses in the range of offsets 0x000 to 0xEFC when the OS Lock is unlocked and MDCR_EL3.ETAD is 1, the access behaves as RES0H.
- For Non-secure accesses in the range of offsets 0x000 to 0xEFC when the OS Lock is unlocked and MDCR_EL3.ETAD is 1, the access behaves as RES0H or returns an error.

RWXKDP

Reads of write-only registers are Reserved.

RSVSNR

Writes to read-only registers are Reserved.

IWTJFD

For accesses that return an error, see Behavior of a not permitted memory-mapped access on page H8-10363 for more details on how this error is handled.

System instructions

RJVLBN

MRS instructions with op0 == 0b10 and op1 == 0b001 read from trace unit registers.

RFYRRX

MSR instructions with op0 == 0b10 and op1 == 0b001 write to trace unit registers.

RVGVTS

Instructions with Crn >= 0b1000 are not allocated for accessing trace unit registers.

RSGPQB

While the PE is in EL0, all System instruction accesses to trace unit registers are UNDEFINED.

IWCXDT

For consistency with the Arm architecture, System instruction accesses to registers which are not implemented generate an Undefined Instruction exception. These accesses include:

- Writes to read-only registers.
- Reads from write-only registers.
- Accesses to registers which are not present due to the configuration of the trace unit.

D4.2.2 Synchronization of register updates

AArch64 System registers

IKWCGH

As defined in Synchronization requirements for AArch64 System registers on page D17-5547, direct writes to trace unit registers are only guaranteed to be visible to execution after a subsequent Context synchronization event.

IFNZZH

Direct reads of trace unit registers while the trace unit is not in the Stable or Idle states are not guaranteed to contain the results of the trace operation of execution previous to the direct read operation.

IOPVJQ

As defined in Synchronization requirements for AArch64 System registers on page D17-5547, a direct write to a register using the same register number that was used by a previous System instruction to write it, the final result is the value of the second write, without requiring any context synchronization between the two write instructions.

IWLGQK

As defined in Synchronization requirements for AArch64 System registers on page D17-5547, a direct read of a register using the same register number that was used by an earlier direct write is guaranteed to observe the value that was written, without requiring any context synchronization between the write and read instructions.

SHSXGZ

Context synchronization events are important when changing the value of TRCPRGCTRL.EN or when changing the OS Lock. After writing to TRCPRGCTRL to change the value of TRCPRGCTRL.EN, one read of TRCSTATR is required before programming any other registers. A Context synchronization event is required between writing to TRCPRGCTRL and reading TRCSTATR. If multiple reads of TRCSTATR are required, a Context synchronization event is required between each read of TRCSTATR to ensure any change to the trace unit state is observed.
When indirect writes or external writes to the registers in Table D4-2 on page D4-4773 occur, both of the following can observe the writes:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

### Table D4-2 Registers with a guarantee of observability

<table>
<thead>
<tr>
<th>Register</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRCCLAIMSET</td>
<td>Claim Tag Set Register</td>
</tr>
<tr>
<td>TRCCLAIMCLR</td>
<td>Claim Tag Clear Register</td>
</tr>
<tr>
<td>TRCCNTVR&lt;n&gt;</td>
<td>Counter Value Register &lt;n&gt;</td>
</tr>
<tr>
<td>TRCSEQSTR</td>
<td>Sequencer State Register</td>
</tr>
<tr>
<td>TRCSSCSR&lt;n&gt;</td>
<td>Single-shot Comparator Control Status Register</td>
</tr>
</tbody>
</table>

When the trace unit becomes enabled or disabled as a result of a direct write, for any instruction in program order before the direct write, the new state of the trace unit does not affect trace operations.

When the trace unit becomes enabled or disabled as a result of a direct write, for any instruction after a Context synchronization event in program order after the direct write, the new state of the trace unit takes effect for any trace operations.

Note: The registers which control whether the trace unit is enabled or disabled are:

- TRCPRGCTRLR.
- OSLAR_EL1.

Arm recommends that a Context synchronization event is executed after programming the Trace Unit registers, to ensure that all updates are synchronized to the trace unit before normal code execution resumes.

When a Context synchronization event occurs while the trace unit is in the Idle or Stable states, and at no other time, indirect writes to the trace unit registers are guaranteed to be visible to direct reads.

When either of the following events occurs, and at no other time, indirect writes to the trace unit registers are guaranteed to be visible to indirect reads or external reads:

- The trace unit transitions into the Stable state.
- The trace unit transitions into the Idle state.

The trace unit functions perform indirect writes to the registers and indirect reads from the registers in architectural order.

### External debugger registers

As defined in the *Synchronization of changes to the external debug registers on page H8-10358*, this section refers to accesses from the external debug interface as *external reads* and *external writes*.

As defined in *Synchronization of changes to the external debug registers on page H8-10358*, explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, so explicit synchronization is never required for registers that are accessible only in the external debug interface.

As defined in *Synchronization of changes to the external debug registers on page H8-10358*, when an external write to a register using the same register number that was used by a previous external write is performed, the final result is the value of the second write, without requiring any context synchronization between the two write accesses.

The trace unit does not require explicit synchronization for an external write to be visible to indirect reads.
RDYRZC  The trace unit does not require explicit synchronization for an external write to be visible to subsequent external reads.

IRDFSX  As defined in Synchronization of changes to the external debug registers on page H8-10358, explicit synchronization is required for an external write to be visible to direct reads.

RMMYRJ  While the trace unit is in the Stable or Idle states, the trace unit does not require explicit synchronization for indirect writes to be visible to external reads.

**Synchronization and the authentication interface**

RWYWMJ  Changes to the authentication interface are indirect writes to TRAUTHSTATUS by the controller of the authentication interface. It is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external read of the register only after a Context synchronization event or in finite time.
D4.3 Trace elements

Trace elements form an AST which is used to describe the control flow of program execution. Different sequences of the trace elements can be used to imply the same operation. In this way FEAT_ETE can be used by different micro-architectures. This is similar to the approach used in previous trace protocols. For more information, see the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064).

A trace unit compresses the information on the execution of the PE and outputs a trace byte stream that comprises multiple packets of encoded data. The compression techniques that are used include:

- **Not having a trace element for every executed instruction in the instruction trace element stream**
  - Instead, the trace unit generates *P0 elements* in the trace element stream when certain types of instruction are executed. These certain types of instructions are known as *P0 instructions*. A *P0 element* acts as a signpost in the program flow, indicating that execution is proceeding along a given path.
  - Consequently, the stream of *P0 elements* implies the execution of a greater number of instructions, and a trace analyzer can reconstruct the stream of instructions that are executed between *P0 elements* by using the *P0 element stream* and the program image.

- **Multiple trace elements in single packets**
  - Common sequences of trace elements are encoded into single packets.

- **Removal of program addresses from the trace element stream**
  - The trace analyzer can infer the addresses from the program image and previous history. This includes the targets of direct branch instructions, where the target address is encoded in the instruction itself.

- **Removal of predictable trace elements**
  - Some trace elements can be removed from the AST representation if the contents of the trace element can be predicted by previous control flow choices in the software flow. For example the Target Address element for returning from a subroutine might not be required if the branch to the subroutine has been traced.

D4.3.1 Layer model

FEAT_ETE is based on a layer model. Each layer deals with a unique aspect of tracing the PE.

![Layer model for compression and decompression](image)

The transport layer either provides either:
- A path off chip.
- A path to a memory buffer for trace to be stored.

Layer 1
Layer 1 provides compression by:
- Grouping trace elements together to form packets.
- Removing trace elements that can be implied.
- Compression against previous values.
- Leading zero compression.
- Reordering of trace elements.

**Layer 2**
Layer 2 provides:
- Speculation resolution.
- Transactional Memory resolution.

**Layer 3**
At layer 3:
- PE behavior is converted into trace elements.
- Compression is achieved by removing the trace elements which can be predicted using the program image:
  - Direct branch target addresses.
  - Return stack optimization.
- Knowledge of the application is required in order to decompress. Processes that modify the instruction opcodes require additional information to allow debugging.

**D4.3.2 Trace protocol synchronization**

The trace byte stream of a trace unit is typically stored in a circular buffer where, if the buffer is full, newer trace overwrites older trace. To ensure that a trace stream can be analyzed when the trace has been stored in a circular buffer, a trace unit must periodically generate trace protocol synchronization points in the trace byte stream.

The following trace elements or packets are used to provide synchronization information in the different layers.

<table>
<thead>
<tr>
<th>Layer</th>
<th>Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layer 3</td>
<td>Context element and Target Address element</td>
</tr>
<tr>
<td>Layer 2</td>
<td>Trace Info element</td>
</tr>
<tr>
<td>Layer 1</td>
<td>Trace Info packet</td>
</tr>
<tr>
<td>Transport Layer</td>
<td>Alignment Synchronization packet</td>
</tr>
</tbody>
</table>

Whenever a trace analyzer receives a Trace Info packet, the trace analyzer receives information about the current state of the trace. However, the trace analyzer cannot begin analysis of program execution until it knows the context in which instructions are being executed and it has an instruction address to start analysis from.

When a Trace Info element is generated, the trace unit generates a Context element and a Target Address element soon after the Trace Info element.

Note: There are common use cases where the ratio between the number of bytes associated with trace protocol synchronization and other trace bytes increases significantly, resulting in a degradation of the usability of the trace. Therefore Arm recommends that trace protocol synchronization only occurs when required.

**Non-periodic trace protocol synchronization**

When the trace unit becomes operative, non-periodic trace protocol synchronization occurs.
When non-periodic trace protocol synchronization occurs, the trace unit generates an Alignment Synchronization packet in the trace byte stream before any other trace packets are generated.

When non-periodic trace protocol synchronization occurs, the trace unit generates a *Trace Info element* in the trace element stream before any other trace elements are generated, except *Event elements*.

Arm recommends that if a trace protocol synchronization request occurs while ViewInst() is inactive, the Alignment Synchronization packet is not output in the trace byte stream until just before either:

- ViewInst() becomes active.
- An Event packet is output.

### Periodic trace protocol synchronization

The trace unit can be programmed to generate trace protocol synchronization requests on a periodic basis, so that the trace element streams and the trace byte streams can be analyzed when stored in a circular trace buffer. TRCSYNCPR.PERIOD controls periodic trace protocol synchronization requests.

Periodic trace protocol synchronization can also be requested by the trace capture infrastructure, for example if a trace protocol synchronization request is received on an Arm AMBA ATB interface. For more information on the Arm AMBA ATB interface, see the *AMBA® ATB Protocol Specification (ARM IHI 0032)*.

When periodic trace protocol synchronization is requested, either by TRCSYNCPR.PERIOD or by other sources, the trace unit performs periodic trace protocol synchronization.

When periodic trace protocol synchronization occurs, the trace unit generates an Alignment Synchronization packet and then generates a *Trace Info element*.

Arm recommends that an Alignment Synchronization packet is only output in the trace byte stream if other trace packets have been output since the previous Alignment Synchronization packet. This reduces the risk of a circular buffer filling and overwriting trace.

If two or more periodic trace protocol synchronization requests occur, and no trace is generated between these two requests, then Arm recommends that a non-periodic trace protocol synchronization occurs before any further trace is generated. This ensures that when tracing has been inactive for a long period of time, the trace stream is fully synchronized when tracing is re-activated.

### Synchronization of instruction trace

When non-periodic trace protocol synchronization occurs, the trace unit generates a *Context element* and a *Target Address element* before any *P0 elements* are generated, to provide the trace analyzer with *Context information* and *Address information*.

When periodic trace protocol synchronization occurs, and ViewInst() is active when the corresponding *Trace Info element* is generated, the trace unit generates a *Context element* and a *Target Address element* which provide the *Context information* and *Address information* for the target of the most recent non-canceled *P0 elements*.

Note: If the trace unit generates the *Context element* and *Target Address element* immediately after the *Trace Info element*, then the most recent non-canceled *P0 elements* might have occurred before the *Trace Info element*. 
When periodic trace protocol synchronization occurs, and ViewInst() is inactive when the corresponding Trace Info element is generated, when ViewInst() becomes active and a Trace On element is generated, the trace unit generates a Context element and a Target Address element before any Atom elements, Q elements, or Exception elements are generated. This provides the trace analyzer with Context information and Address information.

If a Cancel element cancels any P0 elements before a Trace Info element, then the trace analyzer discards all of the following:

- The canceled P0 elements.
- The Trace Info element.
- All elements after the Trace Info element, up to and including the Cancel element. This includes any Context elements or Target Address elements.
Note: In this scenario, information from the canceled Trace Info element can still be used.

**Figure D4-7 Example of Target Address element after Trace Info element in a mispredicted region.**

When a Cancel element is generated which cancels any P0 elements before a Trace Info element, the trace unit generates a new Context element and a new Target Address element, which indicate the target of the most recent P0 element that has not been canceled.

The Target Address element and Context element might indicate the target of a P0 element from before the Trace Info element, or might be delayed until after the next P0 element, and therefore indicate the target of that P0 element.

Note: If the trace unit generates the new Context element and Target Address element prior to the next new P0 element, then this might prevent the indication of execution of some instructions before the Trace Info element.

If the Cancel element cancels all P0 elements after a Trace Info element, but no P0 elements prior to the Trace Info element, then it might be necessary for the trace unit to immediately generate a Context element and Target Address element. This is because a Context element and Target Address element might have been present in the trace element stream after the Trace Info element, and those Context element and Target Address element are now discarded.

### D4.3.3 Speculation in the trace element stream

FEAT_ETE supports the correction of trace. This might be because of:

- The tracing of speculative execution of instructions by a PE.
- For some implementations, the tracing of the Transactional Memory Extension.

A FEAT_ETE trace unit traces speculatively-executed instructions in the same way as all other instructions, so that both speculatively-executed instructions and architecturally-executed instructions appear in the instruction trace element stream. This means that some of the program execution information that is shown in the trace element stream might be incorrect, because some of the speculatively executed instructions might be mis-speculated.

Note: The level of speculation that is revealed in the trace is IMPLEMENTATION SPECIFIC.
The Embedded Trace Extension
D4.3 Trace elements

IXLLKT The trace unit resolves this speculation by generating trace elements to confirm the status of each instruction in the instruction trace element stream. That is, the trace unit generates trace elements to show whether each instruction has been committed for execution, or canceled because of mis-speculation. This means that a trace analyzer does not know the status of a traced instruction until the trace analyzer receives a trace element that indicates whether the instruction has been committed for execution, or canceled because the instruction was mis-speculated.

RZJKY When speculatively-executed instructions are traced, the trace unit subsequently generates trace elements that indicate whether the instructions have been committed for execution, or have been canceled.

IKYXKZ A trace analyzer takes the appropriate action, which might involve canceling some trace elements, to determine the actual program execution.

IGGFML Trace elements that resolve the status of a traced instruction are called speculation resolution elements. For more information on speculation elements, see Speculation Resolution Elements on page D4-4787.

RKYGRF When trace is generated for speculative execution, for mis-speculated execution, the trace unit does not trace any information that cannot be accessed by software executing at the same or at a lower level of privilege than the mis-speculated execution.

ROHQLY When a Context synchronization event is speculated as being taken or executed, the trace unit does not generate trace for any speculative execution after the Context synchronization event until the Context synchronization event is resolved.

RLWICQ When a speculated Context synchronization event is resolved as being not taken or not executed, the trace unit does not generate trace for mis-speculated execution that occurred after the Context synchronization event.

RYGSGJ When an exit from a Trace Prohibited region is speculated as being taken, the trace unit does not generate trace for any speculative execution after the exit from the Trace Prohibited region, until the exit from the Trace Prohibited region is resolved.

RSRLCG When a speculated exit from a Trace Prohibited region is resolved as being not taken, the trace unit does not generate trace for mis-speculated execution that occurred after the exit from a Trace Prohibited region.

Tracing transactions

IKBTIL The Transactional Memory Extension defines the Transactional state. For instructions executed in Transactional state, the trace stream indicates which instructions are executed in Transactional state, and provides indicators for a trace analyzer to determine whether the transaction was successful or failed.

IFWGBM If the instruction is executed in Transactional state then the result of the instruction is not known until the transaction succeeds or fails. Transactions can be of an arbitrary length and can be nested, so the ETE architecture does not guarantee an entire transaction is traced, if any of the transactions is traced.

IVJTLG The execution of transactions is represented in the trace element stream by 3 elements:

1. Transaction Start element.
2. Transaction Commit element.
3. Transaction Failure element.

These provide markers in the trace element stream to indicate the sections which represent transactions. The Transaction Start element indicates that any following instructions are executed in Transactional state. When the PE leaves Transactional state, either the Transaction Commit element or Transaction Failure element are traced to indicate the resolution of the transaction.

IQZNBZ An entry to Transactional state might be traced using a Transaction Start element and the subsequent exit from Transactional state might be traced, without tracing any execution in Transactional state. There might have been no execution in Transactional state, or the trace unit might have been programmed to not trace such execution.

Implementation flexibility

RVVFQZ If no speculation in the trace element stream is implemented, then TRCIDR8.MAXSPEC is 0 and TRCIDR0.COMMTRANS indicates that the Transaction Start element is a P0 element.
Filtering of trace

The ETE architecture supports filtering of the trace within a transaction.

Filtering of a transaction can be due to any of the following:

- The ViewInst function.
- Prohibited regions.
- Asynchronous events.

Due to filtering the start of the transaction might not necessarily be traced. See the Transaction Start element for details.

Due to filtering the end of a transaction might not necessarily be traced. See the Transaction Commit element and Transaction Failure element for details.

If an instruction is traced which was executed in Transactional state, then the trace analyzer must be aware, so that the effect of the instructions executed in the Transactional state can be determined.

When an instruction is traced and the PE is in Transactional state, the trace unit traces the result of the transaction unless any of the following occur:

- The trace unit becomes disabled.
- A trace unit buffer overflow occurs.
- The PE enters a Trace Prohibited region.

In the above scenarios, the trace unit generates a Transaction Failure element, and the resolution of the transaction is UNKNOWN.

Trace element stream

A Trace element stream is a sequence of elements which describe:

- The software control path of PE execution traced by the trace unit.
- Event-based trace.
- Temporal information.

A Trace Info element provides a point in the trace element stream where analysis of the trace element stream can begin.

Trace Info elements include setup information about:

- The static trace programming that does not change during a trace session, including:
  - Whether cycle counting is enabled, and if enabled, the cycle count threshold.
- Dynamic information that might change during a trace session, such as:
  - The speculation depth. This indicates how many unresolved P0 elements were traced before the Trace Info element.
  - Whether the trace unit has traced that the PE is executing in Transactional state.

P0 element

P0 elements imply the execution of instructions.

P0 elements are generated speculatively and must be either committed or canceled. For more information on speculation elements, see Speculation Resolution Elements on page D4-4787.

P0 elements must be generated in sequential execution order.
Atom element

An Atom element implies that one or more instructions have been executed, up to and including the next P0 instruction. Only certain instructions generate an Atom element. See Instruction and exception classification on page D4-4791 for more information on these instructions.

The Atom element is one of the following types:
- E Atom.
- N Atom.

The meaning of the type of an Atom element depends on the instruction it is encoding. For example, branch instructions are represented as an E Atom element if the branch was taken and an N Atom element if not taken.

Exception element

An Exception element indicates a change in program flow which cannot be calculated by the analysis of the program image, or which is caused by an instruction which is not a P0 instruction. Such a change in program flow is described as an Exceptional occurrence.

An Exceptional occurrence consists of the following:
- PE Architectural exceptions.
- ETE defined exceptions.
- IMPLEMENTATION DEFINED exceptions.

Note: Transaction failure is not classified as an Exceptional occurrence, although it is traced using an Exception packet.

An Exception element indicates:
- That an Exceptional occurrence has occurred.
- The type of Exceptional occurrence.
- The virtual address where the Exceptional occurrence was taken from, also known as the preferred exception return address.

The instruction set for the preferred exception return address for an Exception element is one of the following:
- AArch64 A64.
- AArch32 A32.
- AArch32 T32.

An Exception element is a P0 element.

PE Architectural exceptions

The following exception types are used to indicate PE Architectural exceptions:
- IRQ.
- FIQ.
- Trap.
- Call.
- Inst fault.
- Data fault.
- Inst debug.
- Data debug.
- Alignment.
- System Error.
- Debug halt.
See *Instruction and exception classification* on page D4-4791 for information on the mapping between the PE Architectural exceptions and these exception types.

Table D4-4 on page D4-4783 defines the preferred exception return address for each exception type for PE Architectural exceptions.

Table D4-4 Preferred exception return address for PE Architectural exceptions

<table>
<thead>
<tr>
<th>Exception type</th>
<th>Preferred exception return address</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRQ</td>
<td>Instruction after the last executed instruction</td>
</tr>
<tr>
<td>FIQ</td>
<td>Instruction after the last executed instruction</td>
</tr>
<tr>
<td>Trap</td>
<td>For a trapped instruction or UNDEFINED instruction, the preferred exception return address is the address of the instruction. For a trapped exception, the preferred exception return address is the address of the instruction that caused the exception.</td>
</tr>
<tr>
<td>Call</td>
<td>Instruction after the call instruction</td>
</tr>
<tr>
<td>Inst fault</td>
<td>Instruction that caused the exception</td>
</tr>
<tr>
<td>Data fault</td>
<td>Instruction that caused the exception</td>
</tr>
<tr>
<td>Inst debug</td>
<td>Instruction that caused the exception</td>
</tr>
<tr>
<td>Data debug</td>
<td>Instruction that caused the exception</td>
</tr>
<tr>
<td>Alignment</td>
<td>Instruction that caused the alignment exception</td>
</tr>
<tr>
<td>System Error</td>
<td>Instruction after the last executed instruction</td>
</tr>
<tr>
<td>Debug halt</td>
<td>The instruction after the last executed instruction, that is, the value loaded into the DLR register.</td>
</tr>
</tbody>
</table>

The nature of System Error means that execution might not complete up to the preferred exception return address, or it might perform some operations after the preferred exception return address. This behavior is IMPLEMENTATIONDEFINED and might vary depending on the cause of the exception.

When an imprecise System Error exception occurs, the preferred exception return address is the address stored in the relevant ELR when the exception is taken.

When a System Error exception occurs, the trace analyzer must be aware that the preferred exception return address might not indicate the exact point at which program execution was interrupted. The trace analyzer should not rely on the preferred exception return address for inferring exactly which instructions were executed. This behavior only occurs for imprecise System Error exceptions.

When an imprecise Debug halt exception occurs, the preferred exception return address is the address stored in DLR or DLR_EL0 when the exception is taken.

When an imprecise Debug halt exception occurs, the trace analyzer must be aware that the preferred exception return address might not indicate the exact point at which program execution was interrupted. The trace analyzer should not rely on the preferred exception return address for inferring exactly which instructions were executed. An imprecise Debug halt exception can only occur under direct control of a debugger, usually by controlling EDRCR.CBRRQ.

**ETE defined exceptions**

In addition to the Arm Architectural exceptions, the ETE specifies the following Exceptional occurrences that are traced using Exception elements:

- PE Reset, which indicates that a PE Warm reset has occurred.
Table D4-5 on page D4-4784 defines the preferred exception return address for each exception type for ETE defined exceptions.

### Table D4-5 Preferred exception return address for ETE defined exceptions

<table>
<thead>
<tr>
<th>Exception type</th>
<th>Preferred exception return address</th>
</tr>
</thead>
<tbody>
<tr>
<td>PE Reset</td>
<td>UNKNOWN</td>
</tr>
</tbody>
</table>

When a PE Reset occurs, the preferred exception return address and context are UNKNOWN. Therefore for an Exception element indicating a PE Reset the preferred exception return address and context are UNKNOWN. No instruction execution is indicated between the previous P0 element and the Exception element.

When an Exception element indicating a PE Reset occurs:
- The target address and target context of the previous P0 element might be UNKNOWN.
- If there are no P0 elements between a Trace On element and the Exception element, then the initial address and context after the previous Trace On element might be UNKNOWN.

**IMPLEMENTATION DEFINED exceptions**

ETE defines some exception types which are IMPLEMENTATION DEFINED, including but not limited to:
- ECC error correction.
- Generic replay of program execution.

The use of the IMPLEMENTATION DEFINED exceptions is optional and IMPLEMENTATION DEFINED. IMPLEMENTATION DEFINED exceptions are not required to be traced but are intended to be used to simplify tracing of certain micro-architectural situations.

In general, the preferred exception return address is the address of the instruction after the last executed instruction, before the exception occurs.

**Source Address element**

The Source Address element indicates execution up to and including a provided P0 instruction address, and indicates the P0 instruction is taken. All P0 instructions except the final P0 instruction are not taken, which means that explicit N Atom elements are not required to be traced for those P0 instructions. A Source Address element indicates both of the following for the final P0 instruction:
- The instruction set.
- The virtual address of the instruction.

The instruction set for a Source Address element is one of the following:
- AArch64 A64.
- AArch32 A32.
- AArch32 T32.

A Source Address element is a P0 element.

**Q element**

A Q element belongs to the P0 element group in the instruction trace element stream, and must be explicitly resolved or canceled.

A Q element can optionally include a number, M. The number is a count of the instructions that are executed since the most recent P0 element, which might be a Q element. If it does not include a count of instructions, then the number of instructions that are executed since the most recent P0 element is UNKNOWN.

The trace unit generates Q elements in the program order in which they occur, and the trace protocol encode and decode process maintains this order.
A Q element does not imply Exceptional occurrences.

When a Q element implies an Exception return instruction which is taken, that instruction is the last instruction that is implied by the Q element.

When a Q element implies an executed ISB instruction, this is the last instruction implied by the Q element if execution continues from a new context after the ISB.

When execution continues from a new context after a Q element is generated, the trace unit generates a Context element after the Q element.

The Context element might be generated before or after the Target Address element that is also required after the Q element.

If a context change occurs at a point that is not a Context synchronization event, then the last instruction that is implied by a Q element must be the last instruction that is executed with the old context. The trace unit can then generate a Context element after the Q element to indicate the new context.

Transaction Start Element

TRCIDR0.COMMTRANS indicates whether the Transaction Start element is a P0 element. See Transaction Start element on page D4-4790 for more information about the Transaction Start element.

Virtual Address Space Element

Trace On element

A Trace On element indicates a discontinuity in the trace element stream. The trace unit inserts a Trace On element after a gap in the generation of the trace element stream:

• When the trace generation becomes operative and before any P0 elements.
• If some instructions are filtered out of the trace.
• The first traced instructions after:
  — A Trace Prohibited region.
  — The PE leaves Debug state.
• When instruction trace is lost because a trace unit buffer overflow occurs.

When a Trace On element is generated, the trace unit generates a Target Address element before the next P0 element.

When a Trace On element is generated, the trace unit generates a Context element before the next Atom element, Exception element or Q element, to indicate where tracing starts, unless the context has not changed since the previous Context element was output.

When the first Trace On element is generated, the trace unit outputs the corresponding Context element before the first P0 element.

Target Address element

A Target Address element indicates both of the following for the next instruction to be executed:

• The instruction set.
• The virtual address of the instruction.

The instruction set for a Target Address element is one of the following:

• AArch64 A64.
• AArch32 A32.
• AArch32 T32.

The trace unit generates Target Address elements in program order relative to other P0 elements.
The Embedded Trace Extension

**D4.3 Trace elements**

Target Address element values can be corrected by another Target Address element if both Target Address elements are generated before the next P0 element or Trace On element.

**Context element**

The Context element indicates the execution context for the next instruction to be executed.

The Context element provides the following Context information:

- The Security state.
- The Exception level.
- Whether the PE is executing in AArch64 state or AArch32 state.

The Context element can optionally provide the following Context information:

- The Context identifier.
- The Virtual context identifier.

The trace unit generates Context elements in program order relative to P0 elements.

**D4.3.7 Temporal elements**

Temporal elements provide information about the passage of time within the trace element stream. The following temporal elements are supported by ETE:

*The Cycle Count element*

Indicates the passage of PE clock cycles within the trace element stream.

*The Timestamp element*

Indicates the passage of time within the trace element stream.

*The Timestamp Marker element*

Indicates that the most recent P0 element or Event element has been timestamped and that a subsequent Timestamp element contains the timestamp value.

**Cycle Count element**

Each Cycle Count element is associated with a Commit element, and when a Commit element is generated, a Cycle Count element might also be generated.

Each Cycle Count element is associated with the most recent Commit element.

A Cycle Count element indicates the number of PE clock cycles between the two most recent Commit elements that both have an associated Cycle Count element.

Not every Commit element is required to have an associated Cycle Count element.

Cycle Count elements are generated in order relative to Commit elements.

**Timestamp element**

The Timestamp element inserts a global timestamp value into the trace element stream.

The source for timestamp reported in the timestamp element is controlled by:

- TRFCR_EL1.TS.
- TRFCR_EL2.TS.

A timestamp value of zero indicates that the timestamp value is UNKNOWN.

An UNKNOWN timestamp value might occur if the system does not support timestamping or if the timestamp is temporarily unavailable.
The Embedded Trace Extension
D4.3 Trace elements

The source for the payload of Timestamp elements is controlled by the TRFCR registers and the virtual timers. It is expected that these registers will be changed by context switch software. As a result it is possible that payloads of Timestamp elements might appear to have discontinuities, and even go backwards, if the source of the timestamp changes, or any context switching changes the System registers which control the timestamp value.

If FEAT_ETEv1p1 is implemented, when there has been a Timestamp Marker element before the Timestamp element, the Timestamp element contains the timestamp value of the most recent P0 element or Event element before the Timestamp Marker element.

If FEAT_ETEv1p1 is not implemented or if there has not been a Timestamp Marker element before the Timestamp element, the Timestamp element contains the timestamp value of the most recent P0 element or Event element before the Timestamp element.

If TRCIDR0.TSMARK is 1 and there is no previous Timestamp Marker element, the Timestamp element is for a P0 element or Event element which is before the start of the trace. This scenario might occur when trace analysis starts at a Trace Info element which is not the first Trace Info element, and the Timestamp Marker element was generated before the Trace Info element.

The requirement for a Timestamp Marker element for every Timestamp element is to avoid needing to indicate if there has been a Timestamp Marker element at a Trace Info point. This allows a trace analyzer to assume there is a Timestamp Marker element (or not) before the Trace Info, based on a static piece of information.

**Timestamp Marker element**

The Timestamp Marker element indicates the most recent P0 element or Event element has been timestamped, and that a Timestamp element will follow containing the timestamp value.

Timestamp Marker elements are generated in order with respect to P0 elements and Event elements.

Timestamp Marker elements are not canceled by Cancel elements.

A Cancel element might cause a P0 element to be canceled and if there is a Timestamp Marker element that is associated with that P0 element then the Timestamp Marker element is not associated with any P0 element. The Timestamp element which is associated with the Timestamp Marker element is unaffected, and is still usable for timestamping the approximate position in the trace stream.

If 2 Timestamp Marker elements occur without a Timestamp element between them, the oldest Timestamp Marker element is ignored.

If an Overflow element or Discard element occurs after a Timestamp Marker element and before a Timestamp element, the Timestamp Marker element is ignored.

If Timestamp Marker elements are generated by the trace unit, every Timestamp element must have a corresponding Timestamp Marker element generated before the Timestamp element.

The generation of Timestamp Marker elements is indicated in TRCIDR0.TSMARK.

**Speculation Resolution Elements**

The ETE architecture allows trace to be generated speculatively and then later committed or removed by the decompression process. Each P0 element is traced and is considered speculative until either committed by a Commit element or canceled by a Cancel element. This method of generating speculative trace allows for the tracing of speculative execution, including the tracing of transactions when the Transactional Memory Extension is implemented in the PE.

Speculation resolution elements provide a trace analyzer with information about which trace elements were correctly or incorrectly generated, and ensure the trace analyzer can reconstruct the program execution. The following speculation resolution elements are supported by ETE:

**The Mispredict element**

Corrects the most recent Atom element.
The **Cancel element**
Indicates that one or more P0 elements are canceled.

The **Commit element**
Indicates that one or more P0 elements are resolved for execution.

The **Discard element**
Removes all speculative P0 elements.

TRCIDR8.MAXSPEC specifies the maximum number of uncommitted P0 elements which can be discarded at a later stage using **Cancel elements**.

**Commit element**
A Commit element indicates that a number of unresolved P0 elements have been resolved for execution. The resolved P0 elements are the oldest P0 elements.

The Commit element resolves all types of P0 element.

Commit elements might be merged if the total number of P0 elements resolved is less than TRCIDR8.MAXSPEC. Commit elements are merged by adding their respective commit count values together.

Figure D4-8 shows an example operation for a Commit element:

![Figure D4-8 Commit Operation Example](image)

**Cancel element**
The Cancel element indicates the number of youngest unresolved and uncanceled P0 elements that are canceled from execution. A trace unit might cancel elements because of many reasons, including but not limited to:

- A P0 instruction is mis-speculated.
- An exception occurs.

The Cancel element cancels all types of P0 element.

Cancel elements might be merged if no P0 elements have been generated in between. Cancel elements are merged by adding their respective cancel numbers together.

Figure D4-9 on page D4-4789 shows an example operation for a Cancel element:
**Discard element**

A **Discard element** is generated if uncommitted **P0 elements** remain when trace generation becomes inoperative or if the resolution of uncommitted **P0 elements** cannot be output by the trace unit.

If trace generation remains inoperative, the outcomes of instructions that are traced by **P0 elements**, such as conditional **P0 instructions**, cannot be resolved, and therefore a **Discard element** indicates that all uncommitted **P0 elements** must be discarded.

**Mispredict element**

The **Mispredict element** indicates that the most recent non-canceled **Atom element** has the incorrect E or N status.

For example, if a branch instruction is predicted as taken, it is traced with an E **Atom element**. If the prediction becomes incorrect, then a **Mispredict element** is traced to indicate to a trace analyzer that the E **Atom element** changes to an N **Atom element**.

**D4.3.9 Other elements**

**Event element**

The **Event element** indicates when a programmed **ETEEvent** occurs and its payload contains a number to identify the **ETEEvent** number. See TRCEVENTCTRL0R, and TRCEVENTCTRL1R, for information about the programming of arbitrary **ETEEvents**.

**Overflow element**

The **Overflow element** indicates that the trace unit buffer has overflowed, and at least one trace element might have been lost.

**D4.3.10 Transactional Memory**

The **TSTART** instruction is a **P0 instruction**.
**Transaction Start element**

The *Transaction Start element* indicates that subsequent elements are within a transaction, until any of the following are traced:

- A *Transaction Failure element*.
- A *Transaction Commit element*.
- A *Cancel element* which cancels the *Transaction Start element*.

When the PE enters Transactional state, a *Transaction Start element* is generated before any instructions are traced. This indicates to the trace analyzer that subsequent elements have been executed in Transactional state.

Only a single *Transaction Start element* is generated for each outer transaction, unless the trace unit indicated the transaction had finished by generating a *Transaction Failure element*.

An example of when the trace unit generates a *Transaction Failure element* without the PE leaving Transactional state is when a trace unit buffer overflow occurs. In this example, tracing might resume after the trace unit buffer overflow, and if the PE is still in the same outer transaction then a new *Transaction Start element* would be generated.

The *Transaction Start element* appears in program order relative to other P0 elements.

When a TSTART instruction for an outer transaction is traced and tracing continues in Transactional state, the trace unit generates a *Transaction Start element* after the P0 element that is generated by the TSTART instruction, and before any subsequent P0 element.

When a TSTART instruction for an outer transaction is not traced and tracing becomes active while the PE is in Transactional state, the trace unit generates a *Transaction Start element* after the Trace On element and before any P0 elements.

**Transaction Commit element**

The *Transaction Commit element* indicates that the PE has exited Transactional state, that the transaction has completed successfully, and that all execution since the most recent *Transaction Start element* has been executed.

**Transaction Failure element**

The *Transaction Failure element* indicates that the transaction did not complete successfully and the trace analyzer discards all the execution since the most recent *Transaction Start element*, including any P0 elements which have been committed by Commit elements.

A sophisticated trace analyzer might be able to use the discarded elements to create a heuristic on why the transaction failed.
D4.4 Instruction and exception classification

D4.4.1 P0 instructions

This section defines all of the P0 instructions.

P0 instructions comprise all of the following:

• All direct P0 instructions.
• All indirect P0 instructions.

Direct P0 instructions comprise all of the following:

• All direct branch instructions.
• ISB instructions.
• TSTART instructions.
• WFE, WFET, WFI, and WFIT instructions, when indicated by TRCIDR2.WFXMODE.

Indirect P0 instructions comprise all of the following:

• All indirect branch instructions.

All uses of ISB in this section apply to all variants of the ISB instruction, including the CP15ISB instruction.

D4.4.2 AArc64 instructions

Direct P0 instructions

The following table describes the A64 direct P0 instructions.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Unconditional Branch.</td>

D4.5 About the ETE trace unit

Figure D4-10 shows the stages of trace generation:

![Stages of trace generation](image)

D4.5.1 Resetting the trace unit

A trace unit includes a trace unit reset, which resets all of the:

- Trace unit trace registers.
- Trace unit management registers.

When the trace unit Core power domain is powered up, a trace unit reset is applied.

It is IMPLEMENTATION DEFINED whether the system has a mechanism to initiate a trace unit reset on demand.

In a PE with FEAT_TRF, a PE Cold reset causes EDSCR.TFO to be reset to 0 which means that tracing is prohibited after the Cold reset until explicitly permitted by software. If tracing from a Cold reset is required, the debugger needs to ensure any relevant controls, including EDSCR.TFO, are programmed to permit tracing. Programming such registers might involve causing the PE to enter Debug state to ensure the registers can be programmed before the PE starts executing instructions.

When a trace unit reset is applied, the trace unit resets the values of all trace unit registers to the values described in the individual register descriptions.

Some other Arm trace architectures support multiple types of reset for the trace unit.

D4.5.2 System behaviors

The trace unit outputs all of the trace byte stream, without external stimulus, within finite time.

Behavior on enabling

While both of the following are true, the trace unit is enabled:

- TRCPRGCTRLR.EN is set to 1.
- The OS Lock is unlocked.

Some Arm trace architectures have a dedicated trace unit OS Lock, whereas ETE depends on the PE OS Lock.

While the trace unit is enabled, the trace unit can trace all PE execution, except when any of the following are true:

- A trace unit buffer overflow occurs.
- The authentication interface prohibits the tracing of certain pieces of code.
- FEAT_TRF or FEAT_TRBE prohibit the tracing of certain pieces of code.

No sequences of code or PE operations are exempt from this requirement. However, while the trace unit is transitioning from an enabled to a disabled state, or from a disabled to an enabled state, some loss of trace is permitted.

While the trace unit is enabled, writes to most trace unit trace registers might be ignored. It is UNKNOWN whether writes to these registers succeed. When the writes are successful, the behavior of the trace unit is UNPREDICTABLE.

Trace analyzers must not write to most trace unit trace registers while the trace unit is enabled, or if TRCSTATR.IDLE indicates that the trace unit is not idle.
While the trace unit is enabled or idle, all resources that are visible in the programmers’ model might have unstable values. Therefore, a trace analysis tool must be aware that the following values might be dynamically changing as they are being read:

- The Counter values, indicated by the TRCCNTVR<n>.
- The Sequencer state, indicated by TRCSEQSTR.
- The ViewInst start/stop function, indicated by TRCVICTLR.
- The Single-shot Comparator Control status, indicated by the TRCSSCSR<n>.

When the trace unit becomes enabled, the trace unit does not reset the state of any of the resources in the trace unit, including the Counters, the Sequencer, and the ViewInst start/stop function.

While the trace unit is disabled, and before it is enabled, a trace analyzer ensures the trace unit resources are programmed with a valid initial state.

### Behavior on disabling

While the trace unit is disabled:

- The trace unit cannot generate trace.
- The trace unit resources are disabled.

For more information, see [Behavior of the resources while in the Pausing state](#) on page D4-4844.

While either of the following is true, the trace unit is disabled:

- TRCPRGCTRLR.EN is 0.
- The OS Lock is locked.

Some Arm trace architectures have a dedicated trace unit OS Lock. ETE depends on the PE OS Lock.

When the trace unit becomes disabled, the trace unit stops generating trace and empties the trace buffers by outputting any data in them.

When the trace buffers are empty, after the trace unit has become idle after becoming disabled, TRCSTATR.IDLE indicates that the trace unit is idle.

When the trace unit becomes disabled, all resources that are visible in the programmers’ model retain their values and become stable at those values.

When the trace unit becomes disabled, when the resources are stable, TRCSTATR.PMSTABLE indicates that the programmers’ model is stable.

When the trace unit becomes disabled after the trace unit has generated Event elements, the trace unit outputs the Event elements before TRCSTATR.IDLE indicates that the trace unit is idle.

While the trace unit is disabled, the following are true:

- No trace is generated.
- All trace unit resources and ETEEvents are disabled.

### Behavior on flushing

The trace unit is allowed to buffer the trace byte stream to make efficient use of system infrastructure.

As the trace unit is allowed to delay the output of the trace byte stream to the system infrastructure, there are system events that require all of the trace byte stream to be observable to other observers in the system.

Making the trace byte stream visible to other observers is known as a trace unit flush.

When any of the following occur, a trace unit flush is requested:

- The trace unit transitions from an enabled to a disabled state.
- The trace capture infrastructure requests a trace unit flush.
• A TSB `CSYNC` instruction is executed in a Trace Prohibited region while the Trace Buffer Extension is implemented and enabled.

A trace unit flush might be requested for IMPLEMENTATION DEFINED reasons. For example:

• Before the trace unit enters either:
  — The low-power state.
  — A powerdown state.
• The PE enters Debug state.

An example of a trace unit flush is one requested on an Arm AMBA ATB interface. For more information on the Arm AMBA ATB interface, see the *AMBA® ATB Protocol Specification (ARM IHI 0032)*.

When a trace unit flush is requested, the trace unit performs the following tasks before responding to the flush request:

1. Encode any remaining elements into trace packets.
2. Complete any packets that are in the process of being generated.
3. Output all trace packets for all PE execution that occurred before the flush request was received.

An example of when the trace unit might need to encode remaining elements into trace packets before a trace unit flush is when there are Commit elements that are not yet encoded.

When a trace unit flush occurs while the trace unit is recovering from a trace unit buffer overflow, the trace unit outputs the corresponding Overflow element before responding to the flush request.

When a trace unit flush occurs, the trace unit either continues to generate trace or stops generating trace, depending on what condition caused the trace flush. For example, if a flush occurs because the trace unit is entering a disabled state, then tracing becomes inactive after the trace flush.

When a condition causes both a trace unit flush and the trace unit to stop generating trace, the trace unit stops generating trace before responding to the flush request, and before indicating that the trace unit is idle.

On entry to Debug state, Arm recommends that the Exception element indicating entry to Debug state is included in the flushed trace data if tracing is active.

When a trace unit flush is requested, the trace unit outputs the data within a finite period.

When a trace unit flush is requested and the cause of the flush request requires an acknowledgment, the trace unit generates the acknowledgment within a finite period.

The flush request mechanism on AMBA ATB is an example of a cause of a flush request that also requires an acknowledgment.

**Low-power state**

The low-power state in the trace unit is a mechanism to improve energy efficiency during periods where trace generation is limited.

Scenarios where the trace unit might be in the low-power state are any of the following:

• The PE is in a low-power state.
• The PE is in Debug state.

The trace unit is only permitted to be in the low-power state when any of the following are true:

• The PE is in a low-power state due to the Wait for Event mechanism.
• The PE is in a low-power state due to the Wait for Interrupt mechanism.
• The PE is in Debug state.
• The trace unit is Disabled.
**Trace unit behavior when the PE is in a low-power state**

The PE that is being traced might support a low-power state where no execution occurs. This low-power state might be invoked, for example, when the PE executes a `WFI`, `WFIT`, `WFE`, or `WFET` instruction.

When the PE is in a low-power state, it might be advantageous if the trace unit also enters a low-power state.

It is IMPLEMENTATION DEFINED whether a trace unit supports the low-power state.

While the trace unit is in the disabled state, the trace unit does not stop the PE from entering a low-power state.

While the trace unit is in Low-power Override Mode, the trace unit does not affect the operation of the PE.

**Trace unit behavior in the low-power state**

While the trace unit is enabled, when the trace unit enters the low-power state, the trace unit continues to appear enabled throughout the time it is in the low-power state.

When the trace unit enters or leaves the low-power state, the trace unit does not lose resource events that are in transition through the trace unit, except those permitted when moving through the Pausing state of the resources. For more information on the resource events that are permitted to be lost when in the Pausing state, see *Behavior of the resources while in the Pausing state* on page D4-4844.

Observation of resource events that are in transition through the trace unit when it enters the low-power state might not occur until after the trace unit leaves the low-power state.

While the trace unit is not in the low-power state, and before it enters the low-power state, the resources enter the Paused state. For more information on the pausing of resources, see *Behavior of the resources while in the Paused state* on page D4-4844.

If `WFI` and `WFE` instructions are classified as P0 instructions, see TRCIDR2.WFXMODE, and the trace unit enters the low-power state as a result of a `WFI` or `WFE` instruction, Arm strongly recommends that the following elements are generated before the trace unit enters the low-power state:

- The *Atom element* that represents a `WFI`, `WFIT`, `WFE`, or `WFET` instruction.
- Any pending *Commit elements*.

While the trace unit is in the low-power state, the trace unit does not generate trace, including ETEEEvent trace.

While the trace unit is in the low-power state, the resources remain in the state that they were in before the trace unit entered the low-power state.

The resources are:

- The Counters.
- The Sequencer.
- The ViewInst start/stop function.
- The Single-shot Comparator Controls.

While the trace unit is in the low-power state, the trace unit drives all External Outputs low.

While the trace-unit is in the low-power state, the PE and external debuggers ability to access the trace unit trace registers and trace unit management registers is unaffected.

While the trace unit is in the low-power state, when a trace protocol synchronization request occurs, the trace unit handles the trace protocol synchronization request correctly. For more information on how the trace unit handles trace protocol synchronization requests, see *Trace protocol synchronization* on page D4-4776.

While the trace unit is in a retention state, external debugger accesses to the trace unit behave as if there is no power to the trace unit Core power domain.

While the trace unit is in the low-power state, the trace unit might not recognize external events, such as the assertion of any External Inputs.
While the trace unit is in the low-power state, it is IMPLEMENTATION DEFINED whether the cycle counter continues to count or not.

While the trace unit is in the low-power state, timestamp requests might be ignored.

It is possible that the trace unit might intermittently leave and reenter the low-power state while the PE is in a low-power state. If this happens, the trace unit resources might become intermittently active during this time. In addition, trace generation might also become intermittently active, and this means that the trace unit might output some packets. This behavior is IMPLEMENTATION DEFINED.

There is no additional requirement for the trace unit to generate a Trace Info element or Trace On element when leaving the low-power state. However, if the trace unit entered the low-power state because the PE was in Debug state, the normal requirements for restarting trace after leaving Debug state apply, including generation of a Trace On element. For more information on the PE Debug state, see Trace unit behavior while the PE is in Debug state.

The trace unit can be programmed so that it does not enter the low-power state, by enabling Low-power Override Mode. Low-power Override Mode is selected using TRCEVENTCTL1R.LPOVERRIDE.

When Low-power Override Mode is enabled, the resources continue operating and the trace unit can generate trace.

Low-power Override Mode does not affect the operation of the PE, however it is not required to prevent the PE from entering a low-power state. This means that even though the trace unit can generate trace, it might only generate Event elements.

D4.5.3 Trace unit behavior while the PE is in Debug state

While ViewInst is active, when the PE enters Debug state, the trace unit generates an Exception element which indicates that the PE has entered Debug state.

When the PE enters Debug state, ViewInst becomes inactive, and remains inactive throughout the time the PE is in Debug state.

While the PE is in Debug state, the trace unit does not trace instructions that are executed.

When the PE exits Debug state and ViewInst becomes active, the trace unit generates a Trace On element.

While the PE is in Debug state, the ViewInst start/stop function maintains its state.

If an Exceptional occurrence occurs between the PE exiting Debug state and the PE executing the first instruction, the value of TRCRSR.TA is used to determine if the Exceptional occurrence is traced. In general, if the entry to Debug state was traced then TRCRSR.TA will be set to 1, and therefore this Exceptional occurrence on exit from Debug state is traced.

If a PE Reset occurs when the PE is in Debug state this is treated as leaving Debug state. This means that a Trace On element and an Exception element indicating a PE Reset are traced if tracing is not prohibited and either of the following are true:

- TRCRSR.TA is 1.
- Forced tracing of PE Resets is active.

D4.5.4 Trace unit behavior on a trace unit buffer overflow

When a trace unit buffer overflow occurs, trace generation becomes inoperative until the trace unit can recover from the overflow.

When a trace unit buffer overflow occurs, the trace unit does not output a partial trace packet, that is, the trace unit can only output complete packets.

The Overflow element indicates to a trace analyzer that a trace unit buffer overflow has occurred. For more details on the generation of an Overflow element, see Overflow element on page D4-4830.

When the trace unit recovers from a trace unit buffer overflow, the following occur:

- Trace protocol synchronization is requested.
• Trace protocol synchronization occurs before the trace unit outputs any packets.

When an Overflow packet is generated, the trace unit might output any of the following packets before it outputs an Alignment Synchronization packet:
• Event packet.
• Overflow packet.
• Discard packet.
• Ignore packet.

Arm recommends that the Alignment Synchronization packet is the first packet output after the Overflow packet.

D4.5.5 Trace unit power states

The Arm architecture defines the following power states:

Normal
The trace unit Core power domain is fully powered up and the trace unit registers are accessible.

Standby
The trace unit Core power domain is on, but there are measures to reduce energy consumption. Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention
The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. Trace unit registers cannot be accessed. A trace unit reset does not occur on leaving retention.

Powerdown
The OS takes some measures to reduce energy consumption by turning the trace unit Core power domain off. Trace registers cannot be accessed. A trace unit reset occurs on leaving powerdown.

A trace unit might support a low-power state, which is equivalent to the standby state.

A trace unit might support a retention state or a powerdown state, and both of these states are considered to be a state where the trace unit Core power domain is powered down.

If the trace unit is implemented in a power domain which is separate from the PE power domain, all of the following are true:
• The trace unit Core power domain might be able to be powered down without powering down the PE power domain.
• The trace unit Core power domain is always powered down when the PE power domain is powered down.

A read of TRCPDSR returns information about the current state of the trace unit.

Table D4-21 on page D4-4805 describes the meanings of the returned value.

<table>
<thead>
<tr>
<th>STICKYPD</th>
<th>POWER</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>The trace unit Core power domain is powered and the trace unit registers are accessible.</td>
</tr>
<tr>
<td>0b1</td>
<td>0b1</td>
<td>The trace unit Core power domain is powered and the trace unit registers are accessible. A trace unit reset or power interruption has occurred so the trace unit register state might not be valid.</td>
</tr>
</tbody>
</table>

When the trace unit Core power domain transitions from powered down to powered up, if the trace unit register state has been preserved over the powerdown, then TRCPDSR.STICKYPD is restored to the value before powerdown.

When the trace unit Core power domain transitions from powered down to powered up, if the trace unit register state has not been preserved over the power down then TRCPDSR.STICKYPD is set to 0b1.
Note: ETE only supports a single power domain and therefore TRCPDSR.POWER is always 0b1.

A system might support a Debug power domain that contains the interface between the trace unit and the external debugger. The Debug power domain usually needs to be powered up when the external debugger needs to connect to the system. Such a Debug power domain is described in *Resets and power domains on page D1-4673.*

If the trace unit Core power domain can be powered down independently of the Debug power domain, Arm recommends that the system implements an external debug component with a powerup request mechanism which can request the trace unit Core power domain to be powered up.

Arm strongly recommends the powerup request mechanism is a CoreSight Class 0x9 ROM Table containing a parent entry for the trace unit. A parent entry of a component is one of:

- An entry in the ROM table that locates the component.
- An entry in a first ROM table that locates a second ROM table that includes a parent entry for the component.

The second ROM table is a descendant of the first ROM table.

This definition of a parent entry is recursive, and therefore the powerup request mechanism might be high up in a hierarchy of ROM tables. The ROM table and any descendants might describe other debug components, including debug components for other PEs. The ROM table might have parent entries in other ROM tables, and those parent entries might also have a powerup request mechanism in those ROM tables.

If the powerup request mechanism is implemented, in the Class 0x9 ROM Table containing the powerup request mechanism for the trace unit:

- The POWERIDVALID bit in the parent entry must be 0b1.
- The POWERID field in the parent entry has an IMPLEMENTATION DEFINED value.

It is IMPLEMENTATION DEFINED whether the trace unit Core power domain is the PE Core power domain or some other power domain. For more information on the CoreSight Class 0x9 ROM Table, see the Arm® CoreSight® Architecture Specification (ARM IHI 0029).

### D4.5.6 Visibility of the PE operation

This section describes the ability of the trace unit to trace the execution of the operation of the PE.

When the trace unit performs indirect reads of PE System registers, the trace unit complies with the rules associated with Context synchronization events.

When the trace unit performs indirect reads of PE System registers, the trace unit complies with the rules associated with the TSB CSYNC instruction as defined in *Chapter D6 The Trace Buffer Extension.*

When instructions are executed outside of any Trace Prohibited region, the trace unit observes the execution.

When observable instructions are executed, the trace unit observes all execution before a PE Context synchronization event occurs, as defined in *Chapter D6 The Trace Buffer Extension.*

When an Exceptional occurrence occurs outside of any Trace Prohibited region, the trace unit observes the Exceptional occurrence.

Executing a TSB CSYNC instruction generates a Trace synchronization event as defined in *Chapter D6 The Trace Buffer Extension.*

When a TSB CSYNC instruction is executed in a Trace Prohibited region, the TSB CSYNC instruction does not become microarchitecturally-finished until the resources are in the Paused state or the trace unit is in the Idle or Stable state.

While the PE is outside a transaction, after a TSB CSYNC instruction executed inside a Trace Prohibited region generates a Trace synchronization event, the Trace synchronization event is microarchitecturally-finished when the trace operation has microarchitecturally-finished for every instruction before the Context synchronization event before the TSB CSYNC instruction that generated the Trace synchronization event.

For more details on the TSB CSYNC instruction, see RMRVPT.
While the PE is inside a transaction, when a Trace synchronization event occurs, the Trace synchronization event becomes microarchitecturally-finished within a finite period.

While the PE is inside a transaction, the completion of a Trace synchronization event is not dependent on the resolution of the transaction. It might still depend on other aspects of the trace operation.

When a T58 CSYNC instruction executed in a Trace Prohibited region becomes microarchitecturally-finished, the trace unit generates no more trace until the PE leaves the Trace Prohibited region.

When a T58 CSYNC is executed in a Trace Prohibited region, the rules around generation of a trace flush and requiring no more trace to be generated in the Trace Prohibited region mean that only whole trace packets are output, and the last byte output is the end of a packet.

These rules ensure that no new trace is generated and allows various System registers to be changed, such as those controlling the Trace Buffer Extension, without the risk of any trace being generated while those registers are being changed.

When the trace unit becomes enabled in a Trace Prohibited region, the trace unit generates no trace until the PE leaves the Trace Prohibited region.

Note: This ensures that no trace is generated until the PE leaves the Trace Prohibited region, and therefore allows various System registers to be changed, such as those controlling the Trace Buffer Extension, without the risk of any trace being generated while those registers are being changed.

The above rule ensures that no trace is generated until the PE leaves the prohibited region, and therefore allows various system registers to be changed, such as those controlling the Trace Buffer Extension, without the risk of any trace being generated while those registers are being changed.

The operation as defined in Chapter D6 The Trace Buffer Extension can be split into operations that are performed by one of the following:

- The PE.
- The ETE trace unit.
- The trace buffer.

The operation of the trace unit is defined by the ETE trace operation.

If the Trace Buffer Unit is implemented and enabled, when a Trace synchronization event occurs, and after all of the trace byte stream generated by the trace unit is flushed to the trace buffer, the Trace synchronization event completes.

Table D4-22 Labels for ordering diagrams
ETE trace operation

Each instruction has all of the following state information:

- PC.
- PSTATE.T.
- PSTATE.EL.
- The Security state.
- CONTEXTIDR_EL1.PROCID.
- CONTEXTIDR_EL2.PROCID.
- TRFCR_EL1.
- TRFCR_EL2.
- MDCR_EL3.STE.
- TxNestingLevel.

The trace information generated contains Address information in Target Address elements, Source Address elements, Exception elements, and Q elements. The Address information contains:

- The virtual address of an instruction.
- The instruction set, known as the sub_isa.

The trace information generated contains Context information in Context elements. The Context information contains:

- The current Security state.
- The current Exception level.
- The current Execution state, which is AArch32 or AArch64.
- The current Context identifier, as stored in CONTEXTIDR_EL1.PROCID.
- The current Virtual context identifier, as stored in CONTEXTIDR_EL2.PROCID.

When an instruction is executed and all the trace elements for the instruction have been generated, the trace operation for the instruction is complete.

Trace elements generated for an instruction might include:

- Global timestamp elements.
- Cycle count elements.
- Speculation resolution elements.
- Transaction resolution elements.

For example, the tracing of PE execution is where:

- Resolved instruction A is executed in program order before a Resolved instruction B.
- tA is all the trace elements that are generated due to the tracing of instruction A.
• \( t_B \) is all the trace elements that are generated due to the tracing of instruction \( B \).
• The trace elements for \( t_A \) must be observed before \( t_B \).

This is shown in Figure D4-11.

![Figure D4-11 Trace operation](image)

### Impact on PE behavior

The ETE architecture places no requirements on the impact that trace generation has on the functional performance of a PE. Arm expects that trace unit implementations are designed according to the market requirements of the PEs being traced, and according to the trace requirements for those PEs. For some markets and trace requirements, the trace solution might always have some performance impact on the PE and the ETE architecture does not prohibit this.

### Behavior on a PE Warm reset

A PE Warm reset does not cause a Trace unit reset. Note: This ensures that tracing is possible through a PE Warm reset.

A PE Warm reset might occur at the same time as a Trace unit reset, however, these are asynchronous and unrelated events.

### Instruction block

How instructions are executed can vary significantly between PE designs. To allow for these variations the ETE architecture allows some flexibility within the filtering model. Rather than applying the filtering model to individual instructions it is applied to blocks of instructions.

An instruction block contains one or more instructions.

An instruction block can contain zero or one \( P0 \) instruction.

When an instruction block is generated which contains a \( P0 \) instruction, the instruction block has the \( P0 \) instruction as the last instruction in the block.

Exceptional occurrences do not occur between instructions in an instruction block.

The addresses of the instructions within an instruction block are sequential.

The number of instructions in a block can vary from block to block and can vary each time the same sequence of instructions are executed.

For example, the tracing of an instruction block is where:
• Resolved instruction \( A \) is executed in program order before a Resolved instruction \( B \).
• \( t_A \) is all the trace elements that are generated due to the tracing of instruction \( A \).
• \( t_B \) is all the trace elements that are generated due to the tracing of instruction \( B \).

This is shown in Figure D4-12 on page D4-4810.
Exposing speculation

For some PE microarchitectures, the tracing of execution-order only might not be achievable. The ETE architecture provides the ability to trace speculatively executed instructions.

When speculative instructions are observed, the trace unit indicates whether each instruction is resolved or canceled with a resolve operation or a cancel operation.

A resolve operation indicates that one or more instructions have, or will be, architecturally executed.

A cancel operation indicates that one or more instructions, although observed by the trace unit, did not architecturally execute.

There is no requirement to expose any speculation to the trace unit.

For example, the tracing of speculation execution is where:

- $S$ is executed in speculative execution-order after a Resolved instruction $A$.
- $A$ is executed in program order before a Resolved instruction $B$.
- $S$ is not in speculative execution-order after $B$.
- $Q$ is executed in speculative execution-order after a Resolved instruction $B$.

This is shown in Figure D4-13.

Trace Prohibited Regions

Trace Prohibited regions are instruction address regions or periods of execution by the PE that are not to be traced. Instructions and Exceptional occurrences which are not prohibited are not necessarily traced because the trace unit has a number of trace filtering functions to limit the amount of trace generated to the sections or periods of interest.

An executable program might contain regions of code that are prohibited to trace. These regions might be associated with a higher Security state, or with the PE entering a privileged mode so that it can execute the instructions that are contained within them.
Tracing might be prohibited while the PE is operating in certain states or modes. For example:

- Non-invasive debug might be prohibited while the PE is in Secure state.
- FEAT_TRF might prohibit tracing.
- FEAT_TRBE might prohibit tracing.

Trace might also become prohibited if, while tracing program execution, an authentication interface changes the currently permitted level of non-invasive debug. For example, if trace is permitted and active while the PE is operating in Secure state, and then the permitted level of non-invasive debug changes from being permitted for Secure state, to not permitted, then trace becomes prohibited.

Prohibited regions in self-hosted trace on page D3-4759 and Chapter D6 The Trace Buffer Extension describe when FEAT_TRBE prohibits tracing.

If an optional authentication interface is implemented, while Secure non-invasive debug is disabled according to the optional authentication interface and while SelfHostedTraceEnabled() returns FALSE, then for execution in Secure state, the PE executes in a Trace Prohibited region.

An example of an optional authentication interface is the CoreSight Authentication interface. For more information, see the Arm® CoreSight® Architecture Specification (ARM IHI 0029).

While the PE is executing code from a Trace Prohibited region, the trace unit does not trace instructions or Exceptional occurrences, including PE Resets.

While the PE is executing code from a Trace Prohibited region, instruction Address Comparators do not match on any instructions in the Trace Prohibited region.

While cycle counting is enabled and the PE is executing code from a Trace Prohibited region, the cycle counter continues to count.

When the PE leaves a Trace Prohibited region and tracing restarts, the cycle counter includes cycles spent in the Trace Prohibited region in the cycle count.

The behavior of the resources when entering a Trace Prohibited region is defined in Behavior of the resources while in the Paused state on page D4-4844.

While the PE is executing code from a Trace Prohibited region, the trace unit does not output any trace that might provide information about the execution in the Trace Prohibited region.

Examples of information about execution in a Trace Prohibited region that trace might provide are the context of execution, instruction addresses, and the address of the first instruction in the Trace Prohibited region.

The most common cause of an entry into a Trace Prohibited region is an Exceptional occurrence or Context synchronization event.

When an Exceptional occurrence that must be traced causes the PE to enter a Trace Prohibited region, the trace unit generates an Exception element that indicates the exception type.

When the PE enters a Trace Prohibited region and there are unresolved speculative P0 elements remaining in the trace byte stream, when the resolution of the speculative elements is known the trace unit generates the appropriate Commit elements or Cancel elements.

When the PE leaves a Trace Prohibited region and ViewInst is active, that is, any filtering applied dictates that ViewInst is active, the trace unit generates a Trace On element.

The purpose of the trace unit generating a Trace On element when the PE exits a Trace Prohibited region and ViewInst is active is to indicate to the trace analyzer that there has been a discontinuity in the trace element stream.

If the PE leaves a Trace Prohibited region other than when a Context synchronization event occurs, the Trace Prohibited region is permitted to extend up to the next Context synchronization event. Typically, a PE leaves a Trace Prohibited region via a Context synchronization event, but a PE might leave a Trace Prohibited region when the authentication interface changes, or when moving from Secure to Non-secure state without an exception return.

If an Exceptional occurrence occurs between the PE exiting a Trace Prohibited region and the PE executing the first instruction, the value of TRCRSR.TA is used to determine if the Exceptional occurrence is traced.
Multi-threaded processor

Processors with multiple threads or PEs have a trace unit for each thread or PE.

The processor might support enabling and disabling of threads, either at PE Reset time or dynamically. The trace units for the threads that are disabled might behave in one of the following ways:

- The trace unit Core power domain is powered down.
- The trace unit Core power domain is held in the trace unit reset state.

Arm recommends that the trace units for threads that are permanently disabled are not visible: either they are not included, or they are marked as not present in any ROM tables that describe the system.

Sharing between multiple PEs

Previous Trace architectures have allowed the trace unit to be shared between multiple PEs.

A trace unit only traces a single PE, that is, it cannot be shared between multiple PEs.

D4.5.7 Speculation resolution

The trace unit implements a maximum speculation depth, that is, the maximum permitted number of P0 elements that can be speculative at any instance. TRCIDR8.MAXSPEC indicates the IMPLEMENTATION DEFINED maximum speculation depth.

The trace unit never outputs more speculative P0 elements than the maximum speculation depth.

If a trace unit is not exposed to any speculative execution, then Arm recommends that the trace unit implements a maximum speculation depth of zero, and in this case:

- Cancel elements are not generated.
- Commit elements are generated after each P0 element, causing each P0 element to be immediately resolved when it is generated. The instruction trace protocol implicitly generates these Commit elements for each P0 element, meaning that explicit Commit packets are not required.
- Mispredict elements are not generated.

The ETE architecture defines Commit element and Cancel elements to allow the speculation of the P0 elements to be resolved by the trace analyzer. The trace unit is required to calculate the number of P0 elements which are committed or canceled. There are many methods by which these numbers can be calculated, but in the generic case the trace unit can use the following mathematical procedure.

The PE can speculatively indicate blocks of instructions to the trace unit. Each block of instructions is given a tag where tag belongs to 0…m and m is the number of rewind points supported by the PE.

The number of instructions per block can be random from the set N and there is a maximum of one P0 instruction per block. The order in which the tags are used can be random, but a tag cannot be reused until the previous block with that tag has been resolved, canceled or merged.

This procedure generates a transform from the potentially random sequence of core tags to a more useable space. The transform T evolves over time as the tags are reused and provides the mapping onto the new space,

\[ T_t = [c_0, \ldots, c_m] \]  

(1)

c_i is the mapping for core tag i.

c_i belongs to 0…q, where q is greater than m.
Initialization

To perform the necessary calculations, the trace unit tracks the transform of the last resolved block. \( \gamma_t \) is the last committed indicator. The algorithm is initialized at \( t=0 \) to

\[
\forall i \in 0, \ldots, m : T_0[i] = \gamma_0
\]

\[
x_0 = \gamma_0
\]

New block operation

The sequence of the numbers in the transformed space, \( x_t \), is defined by the following equation:

\[
x_{t+1} = \begin{cases} 
\left| \left(x_t + 1 \right) \mod q \right| & \text{If a traced P0 instruction} \\
x_t & \text{Otherwise}
\end{cases}
\]

\[
T_{t+1}[\text{tag}_t] = \begin{cases} 
\left| \left(x_t + 1 \right) \mod q \right| & \text{If a traced P0 instruction} \\
T_t[\text{tag}_t] & \text{Otherwise}
\end{cases}
\]

Resolved operation

The PE can resolve one or more blocks in an atomic operation. This is performed by indicating the youngest block’s tag to be resolved, and by inference all older blocks.

The number required by the Commit element is calculated by

\[
n_+ = \left| (T_t[l] - \gamma_t) \mod q \right|
\]

The state of the transform is updated by

\[
\gamma_{t+1} = T_t[l]
\]

where \( l \) is the youngest block’s tag.

Cancel operation

The PE can cancel one or more blocks in an atomic operation. This is performed by indicating the oldest block to be canceled.

The number required by the Cancel element is calculated by

\[
n_- = \left| (x_t - T_t[r]) \mod q \right|
\]

The state of the transform is updated by

\[
x_{t+1} = T_t[r]
\]

where \( r \) is the oldest block’s tag.
### D4.5.8 Filtering trace generation

The amount of trace that can be generated by the trace unit can be significant. Not all the operations of the PE are always relevant. The amount of trace generated can be reduced by the use of the trace unit filter functions.

#### ViewInst function

The filtering function of the instruction trace is expressed as a calculation evaluated for each instruction.

$$\text{ViewInst}_i = \begin{cases} 
0 & \text{When Prohibited} \\
0 & \text{When in Debug state} \\
S_i \land I_i \land E_i \land N_i & \text{Otherwise} 
\end{cases}$$

(1)

- \(S_i\) = ViewInst start/stop function
- \(I_i\) = ViewInst include/exclude function
- \(E_i\) = Exception level filtering
- \(N_i\) = Resource event based filtering

While ViewInst is high, the trace unit traces all instructions.

Instructions for which ViewInst is low might be traced. This might be as a result of tracing the next P0 element or optimizations in the trace unit.

When ViewInst is high for an instruction in an instruction block, the trace unit traces the entire instruction block.

When ViewInst becomes high, the trace unit traces the next P0 instruction or Exceptional occurrence.

Some instruction types cause the trace unit to generate P0 elements, so that they are explicitly traced. Other instruction types however are not explicitly traced. The execution of these other instruction types can be inferred from the P0 elements. This means that the following scenario is possible:

- While ViewInst is high, some instructions are executed. This means that ViewInst is indicating that those instructions must be traced. However, none of the executed instructions cause the trace unit to generate a P0 element, therefore none of the instructions are traced.
- ViewInst then goes low.
- The PE then executes an instruction that, whenever ViewInst is high, causes the trace unit to generate a P0 element.

In this scenario, although ViewInst is low when the instruction in step 3 is executed, indicating that the instruction is not traced, tracing of the instruction is permitted because this is the only way that the preceding instructions can be traced.

There is no requirement for the target address of a P0 instruction or Exceptional occurrence to be traced if ViewInst has transitioned to a low state by the time program execution has moved to the target.

Unless the target instruction block is traced, any Target Address elements indicating the target address of a P0 instruction or Exceptional occurrence cannot be relied on.
Resource event based filtering

The resource event based filtering part of the ViewInst function is expressed as the following equation:

\[ N_i = F_n(\text{TRCVICTLR.EVENT.SEL}, \text{TRCVICTLR.EVENT.TYPE}) \]  (1)

Where \( F_n(\text{TRCVICTLR.EVENT.SEL}, \text{TRCVICTLR.EVENT.TYPE}) \) selects the combination of Resource Selectors used for resource event based filtering.

Exception level filtering

This function provides a simple method of filtering out information about different Exception levels without the need to use additional resources.

ViewInst start/stop function filtering

The ViewInst start/stop function is useful when the requirement is to trace a particular piece of code with all the functions that the piece of code calls.

The ViewInst start/stop function uses the Single Address Comparators and the PE Comparator Inputs to define start points and stop points.

A start point is any of the following:

- The instruction address which matches a Single Address Comparator selected for the ViewInst start/stop function using TRCVISSCTLR.START.
- The instruction address which matches a PE Comparator selected for the ViewInst start/stop function using TRCVIPCSSCTLR.START.
A stop point is any of the following:

- The instruction address which matches a Single Address Comparator selected for the ViewInst start/stop function using TRCVISSCTLR.STOP.
- The instruction address which matches a PE Comparator selected for the ViewInst start/stop function using TRCVIPCSSCTLR.STOP.

Multiple start points can be selected. Multiple stop points can be selected.

When a start point is encountered, the ViewInst start/stop function becomes active for the instruction at the start point.

When a stop point is encountered, the ViewInst start/stop function becomes inactive immediately after the instruction at the stop point.

When the ViewInst start/stop function causes ViewInst to become active, the trace unit traces the instruction at the start address.

When the ViewInst start/stop function causes ViewInst to become inactive, the trace unit traces up to and including the instruction at the stop address.

While a ViewInst start/stop function start address is the same as a stop address, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

The ViewInst start/stop function part of the ViewInst function is expressed as the following equations:

\[
\text{TRCVICTLR.SSSTATUS}_{i+1} = S_i \land \neg \text{Stop}_i
\]

\[S_i = \text{TRCVICTLR.SSSTATUS}_i \lor \text{Start}_i\]

If TRCIDR4.NUMPC == 0b0000 then

\[
\text{Start}_i = \sum_n (\text{SAC}[n] \land \text{TRCVISSCTLR.START}[n])
\]

\[
\text{Stop}_i = \sum_n (\text{SAC}[n] \land \text{TRCVISSCTLR.STOP}[n])
\]

If TRCIDR4.NUMPC != 0b0000 then

\[
\text{Start}_i = \sum_n (\text{SAC}[n] \land \text{TRCVISSCTLR.START}[n])
\lor \sum_m (\text{PECMP}[m] \land \text{TRCVIPCSSCTLR.START}[m])
\]

\[
\text{Stop}_i = \sum_n (\text{SAC}[n] \land \text{TRCVISSCTLR.STOP}[n])
\lor \sum_m (\text{PECMP}[m] \land \text{TRCVIPCSSCTLR.STOP}[m])
\]

The following have no effect on the ViewInst start/stop function:

- Exceptional occurrences.
• Execution in Debug state.
• Execution in a Trace Prohibited region.
• A trace unit buffer overflow.

When disabling the trace unit, the ViewInst start/stop function becomes static and retains its state until the trace unit is enabled again.

For each of TRCVICTLR.SSSTATUS, TRCVISSCTRL, and TRCVIPCSSCTRL, if the register is implemented, it must be programmed with an initial state when the trace unit is programmed before a trace session.

If an implementation makes speculation visible to the trace unit, the ViewInst start/stop function behaves as if no speculation has occurred. That is, when the instruction at a start or stop point is executed speculatively and is later canceled, the ViewInst start/stop function behaves as if the instruction at the start or stop point was not executed.

When the trace unit becomes disabled and there are instructions at start points or stop points which are still speculative, the behavior of the ViewInst start/stop function is IMPLEMENTATION DEFINED and one of the following:

• The ViewInst start/stop function behaves as if the instructions at the start points or stop points were incorrectly speculated. That is, the trace unit behaves as if those start points and stop points did not occur.
• The ViewInst start/stop function behaves as if the instructions at the start points or stop points were correctly speculated. That is, the trace unit updates the state of the ViewInst start/stop function as if those start points and stop points occurred.

When mis-speculation occurs and the PE returns to a point in execution before the trace unit was enabled, the ViewInst start/stop function reverts to the state it was in when the trace unit became enabled.

When a transaction failure occurs the ViewInst start/stop function reverts back to the state to point immediately after the TSTART instruction for the outer transaction.

This is the value of TRCVICTLR.SSSTATUS for the instruction block that contains the TSTART instruction for the outer transaction.

When a transaction failure causes the PE to return to a point in execution before the trace unit was enabled, the ViewInst start/stop function reverts to the state it was in when the trace unit became enabled.

When the trace unit becomes disabled and the PE is executing in Transactional state, the behavior of the ViewInst start/stop function is IMPLEMENTATION DEFINED and one of the following:

• The ViewInst start/stop function behaves as if the transaction failed. That is, the trace unit behaves as if those start points and stop points did not occur.
• The ViewInst start/stop function behaves as if the transaction was successful. That is, the trace unit updates the state of the ViewInst start/stop function as if those start points and stop points occurred.

When tracing becomes prohibited and the PE is executing in Transactional state, the behavior of the ViewInst start/stop function is IMPLEMENTATION DEFINED and one of the following:

• The ViewInst start/stop function behaves as if the transaction failed. That is, the trace unit behaves as if those start points and stop points did not occur.
• The ViewInst start/stop function behaves as if the transaction was successful. That is, the trace unit behaves as if those start points and stop points did occur.
• The ViewInst start/stop function uses the real resolution of the transaction, when that resolution is eventually known.

When the state of the ViewInst start/stop function is changed by anything other than a direct write to TRCVICTLR, the PE considers the write to be an indirect write to TRCVICTLR.SSSTATUS.

In many common usage scenarios, entry to a Trace Prohibited region or disabling of the trace unit does not occur while in a transaction.

Instruction blocks

When an instruction block that contains instructions at ViewInst start points and no instructions at ViewInst stop points is executed, the ViewInst start/stop function remains active for the entire instruction block.
While the ViewInst start/stop function is active, when an instruction block is executed that contains at least one ViewInst stop address and no ViewInst start addresses, the ViewInst start/stop function remains active for the whole instruction block and becomes inactive for the next instruction block, unless the next instruction block contains a ViewInst start address.

When an instruction block that contains at least one instruction at a ViewInst start point and at least one instruction at a ViewInst stop point is executed, the ViewInst start/stop function obeys the order of the start and stop points in the block, with the following consequences:

- The ViewInst start/stop function is active for the whole of the instruction block.
- When the final instruction in the block at a ViewInst start or stop point is at a ViewInst start point, the ViewInst start/stop function is active for the next instruction block.
- When the final instruction in the block at a ViewInst start or stop point is at a ViewInst stop point, the ViewInst start/stop function is inactive for the next instruction block, unless the next block contains an instruction at a new ViewInst start point.

The trace analyzer ensures that for all of the SACs selected for ViewInst start points or stop points, any SAC programmed with a lower address than another SAC is a lower-numbered SAC than the other SAC. That is, the SACs contain addresses in address order.

While the SACs selected for ViewInst do not contain addresses in address order, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

The trace analyzer ensures that for all of the PE Comparator Inputs selected for ViewInst start points or stop points, any PE comparator programmed with a lower address than another PE comparator is a lower-numbered PE comparator than the other PE comparator. That is, the PE comparators contain addresses in address order.

While the PE Comparator Inputs selected for ViewInst do not contain addresses in address order, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

If more than one instruction Address Comparator is programmed with the same instruction address, then programming one or more of those comparators as start comparators, and one or more as stop comparators, results in the following CONSTRAINED UNPREDICTABLE behavior of the ViewInst start/stop function:

- The ViewInst start/stop function is either active or inactive for the instruction at that address.
- The ViewInst start/stop function is either active or inactive after that instruction.

### ViewInst include/exclude function filtering

The ViewInst include/exclude function is useful if:

- Specific ranges of instructions are required to be included in the trace.
- Specific ranges of instructions are required to be excluded from the trace.
- A combination of including and excluding instruction ranges is required.

The ViewInst include/exclude function is comprised of two functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ViewInst include function</td>
<td>Includes one or more instruction address ranges</td>
</tr>
<tr>
<td>ViewInst exclude function</td>
<td>Excludes one or more instruction address ranges</td>
</tr>
</tbody>
</table>

There are between zero and eight instruction Address Range Comparators available for the ViewInst include/exclude function. Some of these comparators can be selected for the ViewInst include function, and some for the ViewInst exclude function.

For example, if all instructions in the address range from 0x00 to 0x2C are required, but no other instructions are required, an Address Range Comparator can be selected for the ViewInst include function and be programmed with these two addresses. All instructions that are in this address range, including those at the start and end addresses, are traced.
The ViewInst include/exclude function differs from the ViewInst start/stop function in the following ways:

- When the ViewInst start/stop function is used, the trace unit starts tracing on a specified start instruction address and stops tracing on a specified stop instruction address. However, if execution branches or jumps to an address between the start and stop points, without first accessing the instruction at the start address, then the instruction that it has branched or jumped to is not traced. Instructions in the start/stop range are only traced if the instruction at the start address is accessed, so that the trace unit is triggered to start tracing. When triggered, and as execution continues sequentially towards the stop address, all functions that the piece of code calls are traced.

- When the ViewInst include/exclude function is used, for example by programming an Address Range Comparator with an include address range, then if execution branches or jumps to any instruction address anywhere in that range, that instruction is always traced. This is true regardless of whether the instruction at the start address has been accessed or not.

In addition, unlike the ViewInst start/stop function, as program execution continues through the address range towards the end address, no functions that the piece of code calls are traced.

The ViewInst include/exclude function part of the ViewInst function is expressed as the following equations:

\[
I_i = \text{Include}_i \land \neg \text{Exclude}_i
\]

\[
\text{Include}_i = \sum_n (\text{ARC}[n] \land \text{TRCVIIECTLR.INCLUDE}[n]) \lor \prod_n \neg \text{TRCVIIECTLR.INCLUDE}[n]
\]

\[
\text{Exclude}_i = \sum_n (\text{ARC}[n] \land \text{TRCVIIECTLR.EXCLUDE}[n])
\]

**Instruction blocks**

- When an instruction in an instruction block is included to be traced by the ViewInst include/exclude function, the ViewInst include/exclude function includes all of the instruction block.

- When an instruction block contains at least one instruction excluded by the ViewInst include/exclude function, and only when all the instructions in the instruction block are excluded, the ViewInst include/exclude function excludes the instruction block.

- If a block of instructions is not entirely covered by at least one individual ARC selected by TRCVIIECTLR.EXCLUDE, it is CONSTRANGED UNPREDICTABLE whether the block is excluded or not. This applies even if other ARCs selected by TRCVIIECTLR.EXCLUDE cover the rest of the block.

**Guidelines for interpreting the ViewInst function result**

The result of the ViewInst function is either:

<table>
<thead>
<tr>
<th>Result</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Indicates that instructions being executed must be traced</td>
</tr>
<tr>
<td>Low</td>
<td>It is expected that instructions being executed are not traced</td>
</tr>
</tbody>
</table>

If it is expected that instructions being executed are not traced, then there are occasions when it is permitted to trace some of those instructions. This section provides guidelines for when it is permitted to trace instructions that ViewInst indicates are not traced.

**When ViewInst transitions from low to high**

If execution occurs while ViewInst is low, it is permitted for a trace unit to trace instructions in certain circumstances. For more information on ViewInst low, see *Occasions when tracing instructions when ViewInst is low is permitted on page D4-4820.*
Tracing of instructions is permitted while ViewInst is low, but if no instructions or Exceptional occurrences that occur are traced, then there is a discontinuity in the trace. When a discontinuity in the trace occurs, when ViewInst becomes high, a Trace On element must be generated.

Any instructions that are executed while ViewInst is high must be traced.

**Occasions when tracing instructions when ViewInst is low is permitted**

ETE permits tracing of instructions when ViewInst is low, in the following scenarios:

- When the instruction that ViewInst indicates is not to be traced is in the same instruction block as an instruction that ViewInst indicates must be traced. This is because the only way to trace the instruction that must be traced is to trace the whole instruction block.
- When the instruction that ViewInst indicates is not to be traced is in an instruction block that precedes or follows an instruction block containing an instruction that ViewInst indicates must be traced.

An implementation always traces the instruction block that contains an instruction that must be traced. However, additional blocks of instructions might also be traced. This is more likely to occur when many instructions are executed in close proximity.

Except for the scenarios that are mentioned, if the ViewInst function indicates that an instruction is not to be traced, then in general it is expected that it is not traced.

In Figure D4-14, the instruction block 1 is in execution order before instruction block 2. The ViewInst calculation for the second block returns true, as indicated by the transition labeled (a). As ViewInst is true for this instruction block then all the instructions in this block must be traced, as indicated by the transition labeled (b). Instruction block 1 might be traced as it is in the same PE cycle as block 2, as indicated by the transition labeled (c).
Rules for tracing Exceptional occurrences

When an Exceptional occurrence occurs, the Exceptional occurrence does not affect the comparators used by the ViewInst function, and none of the comparators used by the ViewInst function match.

The comparators used by the ViewInst function include the following:

- Single Address Comparators.
- Address Range Comparators.
- Context Identifier Comparators.
- Virtual Context Identifier Comparators.

When an Exception element is traced, it might indicate execution of instructions up to a specified address. These instructions might have an impact on the comparators, but the Exceptional occurrence itself does not. This means that when an Exceptional occurrence occurs, the ViewInst function does not indicate whether the Exceptional occurrence must be traced. However, it is useful to trace Exceptional occurrences, to determine why execution has departed from the normal program flow.

When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region, the trace unit remembers whether the instruction or Exceptional occurrence was traced. The trace unit performs indirect writes to TRCRSR.TA to store this state. When an Exceptional occurrence occurs, the trace unit uses TRCRSR.TA to determine whether to trace the Exceptional occurrence.

When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region and the instruction or Exceptional occurrence is traced, TRCRSR.TA is set to 1.

When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region and the instruction or Exceptional occurrence is not traced, TRCRSR.TA is set to 0.

When an instruction or Exceptional occurrence is canceled, TRCRSR.TA is set to the value of TRCRSR.TA immediately before the canceled instruction or Exceptional occurrence.

When an Exceptional occurrence occurs and TRCRSR.TA is 1, the Exceptional occurrence is traced.

While any of the following are true, TRCRSR.TA is unchanged by any execution:
- The PE is in Debug state.
- The PE is in a Trace Prohibited region.

When a trace unit buffer overflow occurs, the behavior of TRCRSR.TA is IMPLEMENTATION DEFINED and is one of the following:
- TRCRSR.TA is set to 0.
- TRCRSR.TA is set to the value of TRCRSR.TA for the most recent instruction or Exceptional occurrence before the trace unit buffer overflow occurred.

Forced tracing of Exceptional occurrences

The trace unit can be programmed so that it always traces certain Exceptional occurrences, regardless of whether the instruction or Exceptional occurrence immediately before the Exceptional occurrence must be traced. This option is enabled by setting either or both:
- TRCVICTLR.TRCERR to 1. This forces the trace unit to trace System Error exceptions regardless of the value of ViewInst.
- TRCVICTLR.TRCRESET to 1. This forces the trace unit to trace PE Resets regardless of the value of ViewInst.

While the PE is executing in a Trace Prohibited region, forced tracing of System Error exceptions is inactive.

While the PE is not executing a Trace Prohibited region and forced tracing of System Error exceptions is enabled, forced tracing of System Error exceptions is active.
While forced tracing of System Error exceptions is active, when a System Error exception occurs, the trace unit generates an *Exception element* indicating a System Error exception, regardless of the value of ViewInst.

While the PE is executing in a Trace Prohibited region, forced tracing of PE Resets is inactive, regardless of whether the PE Reset causes the PE to leave a Trace Prohibited region or not.

While the PE is not executing in a Trace Prohibited region, while forced tracing of PE Resets is enabled, forced tracing of PE Resets is active.

While forced tracing of PE Resets is active, when a PE Reset occurs, the trace unit generates an *Exception element* indicating a PE Reset, regardless of the value of ViewInst.

While tracing is inactive, before an *Exception element* is generated due to forced tracing of either a PE Reset or a System Error exception, the trace unit generates a *Trace On element* and then a *Target Address element*.

When an *Exception element* is generated as a result of forced tracing, the *Trace On element* generated before the *Exception element* indicates that tracing becomes active, and the *Target Address element* indicates where tracing becomes active.

When a System Error exception occurs and TRCRSR.TA is 0 and the exception is traced because forced tracing of System Error exceptions is enabled, then it is IMPLEMENTATION DEFINED whether TRCRSR.TA is set to 1 or remains at 0.

When a PE Reset occurs and TRCRSR.TA is 0 and the PE Reset is traced because forced tracing of PE Resets is enabled, then it is IMPLEMENTATION DEFINED whether TRCRSR.TA is set to 1 or remains at 0.

In scenarios where a System Error exception occurs at approximately the same time as an exit from a Trace Prohibited region, after all execution inside the Trace Prohibited region and before any instruction execution outside the Trace Prohibited region, it is UNPREDICTABLE whether the System Error exception is considered to have occurred inside or outside the Trace Prohibited region. It is also UNPREDICTABLE whether the forced tracing of System Error exceptions is active for this exception.

These scenarios do not include scenarios where the System Error exception caused the exit from a Trace Prohibited region, because the System Error exception occurred inside the Trace Prohibited region.

In scenarios where a System Error exception occurs at approximately the same time as an entry to a Trace Prohibited region, after all execution before the Trace Prohibited region and before any instruction execution inside the Trace Prohibited region, it is UNPREDICTABLE whether the System Error exception is considered to have occurred inside or outside the Trace Prohibited region. It is also UNPREDICTABLE whether the forced tracing of System Error exceptions is active for this exception.

These scenarios do not include scenarios where the System Error exception caused the entry to a Trace Prohibited region, because the System Error exception occurred outside the Trace Prohibited region.

When a System Error exception occurs immediately after the PE exits a Trace Prohibited region and the System Error exception is traced, the preferred exception return address in the *Exception element* indicating the System Error exception does not include information about the Trace Prohibited region.

In scenarios where a PE Reset occurs at approximately the same time as an exit from a Trace Prohibited region, after all execution inside the Trace Prohibited region and before any instruction execution outside the Trace Prohibited region, it is UNPREDICTABLE whether the PE Reset is considered to have occurred inside or outside the Trace Prohibited region. It is UNPREDICTABLE whether the forced tracing of PE Resets is active for this PE Reset.

These scenarios do not include scenarios where the PE Reset caused the exit from a Trace Prohibited region, because the PE Reset occurred inside the Trace Prohibited region.

In scenarios where a PE Reset occurs at approximately the same time as an entry to a Trace Prohibited region, after all execution before the Trace Prohibited region and before any instruction execution inside the Trace Prohibited region, it is UNPREDICTABLE whether the PE Reset is considered to have occurred inside or outside the Trace Prohibited region. It is UNPREDICTABLE whether the forced tracing of PE Resets is active for this PE Reset.

These scenarios do not include scenarios where the PE Reset caused the entry to a Trace Prohibited region, because the PE Reset occurred outside the Trace Prohibited region.
When a PE Reset occurs immediately after the PE exits a Trace Prohibited region and the PE Reset is traced, the preferred exception return address in the Exception element indicating the PE Reset does not include information about the Trace Prohibited region.

### D4.5.9 Element Generation

#### Trace Info element generation

When a trace protocol synchronization request is serviced, the trace unit generates a Trace Info element.

Note: There is no requirement to generate a new Trace Info element every time that ViewInst becomes active. This is because, despite the discontinuity in the trace that is caused by the filtering, the programming of the trace remains the same.

While the PE is in Transactional state and the trace unit has previously generated a Transaction Start element for this transaction, when a Trace Info element is generated, the trace unit sets the Transactional state indicator in the Trace Info element to 1.

While the PE is not in Transactional state, or the PE is in Transactional state but the trace unit has not generated a Transaction Start element for this transaction, when a Trace Info element is generated, the trace unit sets the Transactional state indicator in the Trace Info element to 0.

When the trace unit generates the first Trace Info element after an Overflow element, the Transactional state indicator is set to 0.

When an Overflow element is generated, before any subsequent P0 elements indicating execution in Transactional state are traced, the trace unit generates a new Transaction Start element, even if a Transaction Start element has previously been traced for this transaction prior to the Overflow element.

#### Atom element

When a P0 instruction is taken, the trace unit generates one of the following:

- An E Atom element.
- A Source Address element.

When a P0 instruction is not taken, the trace unit generates one of the following:

- An N Atom element.
- Nothing.

When a P0 instruction is not taken and the trace unit does not generate an N Atom element, for all future not taken P0 instructions until the next taken P0 instruction or Exceptional occurrence, the trace unit does not generate an N Atom element.

When a P0 instruction is not taken and the trace unit does not generate an N Atom element, when an Exceptional occurrence occurs before the next taken P0 instruction, the trace unit generates an Exception element.

When a P0 instruction is not taken and the trace unit does not generate an N Atom element, when no Exceptional occurrence occurs before the next taken P0 instruction, the trace unit generates a Source Address element for the next taken P0 instruction.

When a P0 instruction is not taken and the trace unit does not generate an N Atom element, and the P0 instruction is subsequently mispredicted, the trace unit generates a Source Address element and does not generate a Mispredict element.

The trace unit generates Atom elements in the program order in which they occur, and the trace protocol encode and decode process maintains this order.

For conditional branch instructions, an E Atom element indicates that the instruction passed its condition code check, and an N Atom element indicates that the instruction failed its condition code check, although a trace unit might use a Mispredict element to modify the Atom element.
The trace unit might trace unconditional P0 instructions using an E Atom element or an N Atom element.

When an unconditional P0 instruction is traced using an N Atom element, the trace unit generates either a Mispredict element or a Cancel element to correct the N Atom element.

When an ISB instruction does not pass the condition code check, and the ISB instruction does not perform a Context synchronization event, the trace unit treats the ISB instruction as a not taken instruction.

When an ISB instruction does not pass the condition code check, and the ISB instruction performs a Context synchronization event, the trace unit treats the ISB instruction as a taken instruction.

When an ISB instruction passes the condition code check, the trace unit treats the ISB instruction as a taken instruction.

Note: For an ISB instruction, a trace analyzer must not infer the value of the PSTATE condition flags from an Atom element.

It is IMPLEMENTATION DEFINED whether the trace unit classifies WFI, WFIT, WFE, and WFET instructions as P0 instructions. When WFI, WFIT, WFE, and WFET are classified as P0 instructions, execution of these instructions generates an Atom element. See Low-power state on page D4-4802 and TRCIDR2.WFXMODE.

When WFI, WFIT, WFE, and WFET instructions are classified as P0 instructions and a conditional WFE or WFI instruction is executed, if the instruction passes its condition code check then an E Atom element is generated.

Note: For a WFI, WFIT, WFE, or WFET instruction classified as a P0 instruction, a trace analyzer must not infer the value of the PSTATE condition flags from an E Atom element.

P0 instructions that fail or are predicted to fail their condition code check either generate an Undefined Instruction exception or are executed as a NOP, if the instruction is also UNDEFINED.

When a P0 instruction fails or is predicted to fail its condition code check, and the P0 instruction is executed as a NOP, the trace unit generates an N Atom element for the P0 instruction.

When a P0 instruction fails or is predicted to fail its condition code check, and the P0 instruction generates an Undefined Instruction exception, the trace unit does not generate an Atom element for the instruction and generates an Exception element instead. The preferred exception return address for the generated Exception element is the UNDEFINED instruction, which indicates that the instruction did not execute.

The trace unit generates all Atom elements speculatively, and explicitly resolves or cancels each Atom element by generating Commit elements or Cancel elements.

A trace analyzer can infer execution from an Atom element, but only after the Atom element has been resolved by a Commit element.

For taken direct P0 instructions, a trace analyzer must infer the target address and instruction set of the instruction from the opcode in the program image.

If a taken direct P0 instruction is from a branch broadcasting region, the trace analyzer does not need to infer the target address and instruction set because this is explicitly traced using a Target Address element.

**Exception element**

When an Exceptional occurrence occurs, if the Exceptional occurrence is required to be traced, the trace unit generates an Exception element.

The trace unit generates Exception elements in program order relative to other P0 elements.
To be consistent with the rules for generating Target Address elements, under the following scenarios the trace unit must generate a Target Address element before an Exception element, unless the Target Address element would be removed due to a return stack match:

- The Exceptional occurrence is taken from the target of a taken indirect P0 instruction.
- The Exceptional occurrence is taken from the target of a taken direct P0 instruction in a branch broadcasting region.
- The Exceptional occurrence is taken from the target of another Exception element.

When an Exceptional occurrence occurs, if the Context information changes at the target of the P0 element preceding the Exceptional occurrence, then the trace unit generates a Context element before the Exception element. The Context element provides Context information about the address and context where the Exceptional occurrence was taken from.

An invalid address is one where bits [63:P] are not all zeros or all ones, where P is defined as the maximum virtual address size supported by the PE.

When the PE attempts to execute an instruction at an invalid address and the trace unit generates an Exception element, the preferred exception return address in the Exception element indicates one of the following:

- The full 64-bit invalid address.
- Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

Arm recommends that when the PE attempts to execute an instruction at an invalid address and the trace unit generates an Exception element, the preferred exception return address in the Exception element indicates the full 64-bit invalid address.

**Source address element**

When a P0 instruction which must be traced is not taken and the trace unit does not generate an N Atom element, then when a subsequent P0 instruction is taken, the trace unit generates a Source Address element.

A trace unit can generate a Source Address element to imply that at least one instruction has been executed, including a taken P0 instruction.

When the trace unit generates a Source Address element to imply that a taken P0 instruction has been executed, the address associated with the Source Address element is the virtual address of the taken P0 instruction.

**Q element**

A trace unit can generate a Q element to imply that at least one instruction has been executed, possibly including P0 instructions.

When a Q element is generated, the trace unit generates a Target Address element that indicates where execution is to continue after all the instructions that are implied by the Q element have been executed.

When a Q element is generated and the last instruction implied by the Q element is a P0 instruction, the trace unit generates a Target Address element that indicates the target of the P0 instruction.

When a Q element is generated and the last instruction implied by the Q element is not a P0 instruction, the trace unit generates a Target Address element that indicates the instruction address immediately following the last instruction that is implied by the Q element.

When the PE leaves a region where Q elements are permitted, either by a P0 instruction or by sequential execution out of the region, and a Q element implies the execution of the last instruction in the region, the Q element does not imply any more instructions after the last instruction in the region.

When the PE enters a region where Q elements are permitted, either by a P0 instruction or by an Exceptional occurrence, the trace unit traces the P0 instruction or Exceptional occurrence using elements other than Q elements.

Note: Although the trace unit does not trace with Q elements a P0 instruction or Exceptional occurrence that causes the PE to enter a region where Q elements are permitted, any subsequent instructions in the region where Q elements are permitted might be traced using Q elements.
When the PE enters by sequential execution a region where $Q$ elements are permitted, any instructions that are executed since the last $P0$ element outside the permitted region might be traced using a $Q$ element. These instructions can always be inferred unambiguously from the $Q$ element.

When the PE enters by sequential execution a region where $Q$ elements are permitted, and $P0$ instructions executed since the last $P0$ element outside the permitted region are traced by a $Q$ element, the $Q$ element does not indicate execution of any $P0$ instructions outside the permitted region.

**Event element**

The trace unit generates *Event elements* independently of ViewInst.

While TRCEVENTCTL1R.INSTEN$<n>$ is 1 and the resource event selected by TRCEVENTCTL0R.EVENT$<n>$ is active, while trace generation is operative, the trace unit generates an *Event element* $<n>$ on each PE clock cycle.

When an *Event element* is generated between two $P0$ elements or at the same time as a $P0$ element that follows another, the trace unit inserts the *Event element* after the first $P0$ element but before the $P0$ element that is an IMPLEMENTATION DEFINED number of $P0$ elements after the first $P0$ element.

Arm recommends that the IMPLEMENTATION DEFINED number of $P0$ elements is less than or equal to the number of $P0$ elements the PE can process simultaneously.

While trace generation is inoperative due to a trace unit buffer overflow, when a programmed ETEEvent $<n>$ occurs, the trace unit generates at least one *Event element* $<n>$ before it generates the *Overflow element* corresponding to the trace unit buffer overflow.

**Cancel element generation**

When one or more $P0$ elements are canceled, the trace unit generates a *Cancel element*.

The trace unit generates *Cancel elements* in execution order relative to $P0$ elements.

When a *Cancel element* causes execution to return to a point in the program flow that is not adjacent to a $P0$ instruction, the trace unit generates an *Exception element* that indicates which instructions were executed up to that point in the program flow before it generates any $P0$ elements.

**Commit element generation**

When one or more traced $P0$ elements are resolved for execution, the trace unit generates a *Commit element*.

An *Atom element* might be corrected using a *Mispredict element* after it has been resolved.

The trace unit never generates more speculative $P0$ elements than the maximum speculation depth of the trace unit.

When trace generation becomes inoperative due to the trace unit being disabled, the trace unit outputs any *Commit elements* which have not been output.

If cycle counting is enabled some *Commit elements* have *Cycle Count elements* associated with them, that provide counts of processor clock cycles. The cycle count values given in *Cycle Count elements* can be used to obtain a cumulative count.

*Commit elements* with associated *Cycle Count elements* cannot be merged with later *Commit elements*.

For more information, see *Cycle Count element* on page D4-4786.

**Transaction Start element**

When the PE enters an outer transaction, before the first instruction is traced, the trace unit generates a *Transaction Start element*.

A *Transaction Start element* is not required for each *Trace On element* if the instructions are all part of the same outer transaction.
When the PE leaves Transactional state and a Transaction Start element was generated for the transaction, the trace unit traces the result of the transaction using one of the following:

- A Transaction Commit element, if the transaction was successful.
- A Transaction Failure element, if the transaction failed.
- A Cancel element which cancels the Transaction Start element.

The trace element stream only indicates that the PE is in Transactional state. It does not indicate the transactional nesting depth.

**Transaction Commit element**

When the PE exits Transactional state successfully, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Commit element.

When a Transaction Commit element is generated, the trace unit traces the Transaction Commit element after the P0 element which is generated before the TCOMMIT instruction, and before the next Transaction Start element is traced.

Arm recommends that the Transaction Commit element is generated and output as soon as possible after the PE leaves Transactional state.

The rules on the Transaction Commit element mean that a Transaction Commit element is permitted to be output later than the P0 element which implies execution of the TCOMMIT instruction.

The TCOMMIT instruction is not a P0 instruction. This means that the Transaction Commit element might be traced before the P0 element which implies execution of the TCOMMIT instruction.

**Transaction Failure element**

When a transaction failure occurs, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Failure element.

When the PE enters a Trace Prohibited region and is in Transactional state, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Failure element.

When the trace unit becomes disabled and the PE is in Transactional state, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Failure element.

When a trace unit buffer overflow occurs and the PE is in Transactional state, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Failure element.

A Transaction Failure element is encoded as an Exception packet with a type of Transaction Failure.

When a Transaction Failure element is generated, the following behavior applies:

- The target address and target context of the previous P0 element might be UNKNOWN.
- If there are no P0 elements between a Trace On element and the Transaction Failure element, the initial address and context after the previous Trace On element might be UNKNOWN.

When a PE reset occurs and the PE is in Transactional state, and a Transaction Start element was generated for the transaction, the trace unit generates a Transaction Failure element.

**Context element**

The trace unit generates a Context element in the following situations:

- While tracing is active, when any of the Context information changes, before any P0 element which indicates execution from the new context.
- After a Trace Info element is generated due to a non-periodic trace protocol synchronization request, and before any P0 element.
- After a Trace Info element is generated due to a periodic trace protocol synchronization request.
• When mis-speculation results in an incorrect Context element being output, before any P0 element which indicates execution from the correct context.

While Virtual context identifier tracing is enabled and TRFCR_EL2.CX disallows the tracing of the Virtual context identifier, when the trace unit generates a Context element, the Virtual context identifier in the Context element has the value 0x0.

A Context element might also be output at other points, which might include after all Context synchronization events, or at any other point at which the Context information changes.

If the highest implemented Exception level is using AArch64, the Context identifier value is the value of CONTEXTIDR_EL1.

Some of the Context information might change at points other than at Context synchronization events. These changes occur when system instructions are used to change a piece of Context information, including:

• Writes to the current CONTEXTIDR_EL1.
• Writes to the CONTEXTIDR_EL2.
• Changes from Secure to Non-secure state without using an exception return.
• Changes in Exception level other than due to an exception or an exception return.

When a System instruction writes to a System register and the Context information changes, the trace unit generates a Context element containing the new context value, after the P0 element prior to the System instruction but before the P0 element following a Context synchronization event after the System instruction.

Note: If the Context element is output before the first P0 element after the System instruction, this might imply that some instructions before the System instruction were executed with the new context. This is acceptable because the code which changes the context is usually executed in a state where it does not matter whether the old or new context values are used.

If the PE takes an exception after performing a write to a System register that changes the context, but a P0 element has not been generated since the write, then a Context element indicating the new context is not required to be output before the Exception element. This is because no instructions or Exceptional occurrences are indicated to have been executed from the new context. A Context element indicating the new context must be generated after the Exception element if the Exceptional occurrence is a Context synchronization event. If the Exceptional occurrence changes the context, then the Context element must indicate the new context. This might happen if, for example, the Security state changes.

When a PE reset occurs, until the relevant PE registers are updated, the trace unit traces the Context identifier and Virtual context identifier as zero.

A trace unit is not required to generate a Context element if tracing becomes inactive before any instructions are executed in the new context.

Additional Context elements might be output by a trace unit in some scenarios, but these must only be output where they do not affect the analysis of the trace element stream. Such a scenario might include when a change in the Context information is incorrectly speculated and a subsequent Context element corrects the value of a previous incorrect Context element. Arm recommends that the generation of additional unnecessary Context elements is minimized to ensure trace bandwidth is minimized.

Target Address element

When the trace analyzer cannot infer the address or instruction set from the trace, the trace unit generates a Target Address element.

Occasions when the trace analyzer might not be able to infer the address or instruction set from previous trace include:

• At the target of an indirect P0 instruction which is taken.
• At the target of a direct P0 instruction which is taken in a branch broadcasting region, see TRCBBCTRL for more information.
• At the target of an Exceptional occurrence.
• At the target of a Transaction Failure element.
• When mis-speculation occurs and the address cannot be inferred.
• After a Q element is generated.

When the trace analyzer cannot infer the address or instruction set from the trace, the trace unit generates the resulting Target Address element before the next P0 element, unless any of the following are true:
• The Target Address element can be omitted because of a return stack match.
• Tracing is inactive at the target of the P0 instruction or Exceptional occurrence.
• A transaction failure occurs and tracing is inactive at the target of the transaction failure.

When non-periodic trace protocol synchronization occurs, the trace unit generates a Target Address element after the Trace Info element and Trace On element corresponding to the non-periodic trace protocol synchronization, and before the next P0 element is generated.

When periodic trace protocol synchronization occurs, after the corresponding Trace Info element has been generated, the trace unit generates a Target Address element containing the address of the target of the most recent P0 element before the Target Address element.

When non-periodic trace protocol synchronization occurs, the Target Address element does not need to indicate the target of the most recent P0 element, since tracing might not become active at the target of a P0 element.

When periodic trace protocol synchronization occurs, the Target Address element needs to indicate the target of the most recent P0 element, since tracing is continuing from that P0 element. Furthermore, the Target Address element might indicate the target of a P0 element from before the Trace Info element.

When a Trace On element is generated, the trace unit generates a Target Address element before the next P0 element.

Typically, a Target Address element is required after an Exception element to indicate the target of the Exceptional occurrence, since a trace analyzer is not usually able to infer the target of an Exceptional occurrence.

In some scenarios, an Exception element might be generated in the trace where the Exceptional occurrence target address is the next sequential instruction from the last instruction before the Exceptional occurrence. This behavior depends on many factors and might only occur for IMPLEMENTATION DEFINED Exceptional occurrences. If an Exceptional occurrence is taken to the next sequential instruction, the trace unit is not required to output a Target Address element indicating the target address of the Exceptional occurrence because this can be inferred from the previous execution.

A trace analyzer needs both a Target Address element and a Context element before it can determine the instruction set in use, because the Target Address element provides the instruction set and the Context element provides information on whether the PE is in AArch32 or AArch64 state.

When a change of instruction set occurs that switches between AArch32 state and AArch64 state, the trace unit generates a Context element indicating the new state.

An invalid address is one where bits [63:P] are not all zeros or all ones, where P is defined as the maximum virtual address size supported by the PE.

When the PE attempts to execute an instruction at an invalid address and the trace unit generates a Target Address element, the Target Address element indicates one of the following:
• The full 64-bit invalid address.
• Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

Arm recommends that when the PE attempts to execute an instruction at an invalid address and the trace unit generates a Target Address element, the Target Address element indicates the full 64-bit invalid address.

While tagged addresses are in use, the virtual address in the trace element stream does not include the tag and is the PC value, that is, depending on the state of the PE at the address, bits[63:56] are one of the following:
• The sign-extension of bit[55].
• Zero.
The Translation Control Registers, TCR_ELx, contain the TBI field for controlling whether to ignore the top byte of an address. If the current TBI field is changed from 0 to 1, and before the next Context synchronization event the PE takes an exception because of an invalid top address byte, the branch target address to the invalid address or the preferred exception return address of the Exception element might not contain the full invalid address and might contain the address with the top byte masked. Furthermore, the branch target address might be the invalid address and therefore might be different from the preferred exception return address. Trace analysis tools must be aware that if a branch target address is substantially different from a preferred exception return address which follows, then there might have been a change in the TBI field which caused this large change in address.

When a pointer authentication check fails and an exception is taken from the resulting invalid address, the preferred exception return address is one of the following:

- The full 64-bit invalid address.
- Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

Arm recommends that when a pointer authentication check fails and an exception is taken from the resulting invalid address, the preferred exception return address is the full 64-bit invalid address.

The bottom bits of an address are ignored, in the following way:

- Bits[1:0] of addresses that are used in A64 or A32 instructions are always traced as zero.
- Bit[0] of addresses that are used in T32 instructions is always traced as zero.

Additional Target Address elements might be output by a trace unit in some scenarios, but these must only be output where they do not affect the analysis of the trace element stream. These scenarios include, but are not limited to:

- When an instruction address is incorrectly speculated, and a subsequent Target Address element corrects the value of a previous incorrect Target Address element.
- When an instruction address can be inferred by the trace analyzer, for example for the target of a direct P0 instruction, but a Target Address element is output anyway with the same address.

Arm recommends that the generation of additional unnecessary Target Address elements is minimized to ensure trace bandwidth is minimized.

Mispredict element

When the status of the last non-canceled Atom element has been changed by the PE, the trace unit generates a Mispredict element.

The trace unit only generates a Mispredict element to change the status of an Atom element.

A trace unit might generate multiple Mispredict elements for the same Atom element. A trace analyzer must use each Mispredict element to determine the final status of the Atom element. For example, if an E Atom element has two Mispredict elements, the first Mispredict element indicates the Atom element is an N Atom element and the second Mispredict element indicates it is an E Atom element.

If a PE mispredicts only the target address of a P0 element, then it does not generate a Mispredict element.

The trace unit uses a Target Address element to correct the mispredicted target address. When analyzing a Mispredict element, any Target Address elements between the mispredicted Atom element and the Mispredict element must be discarded.

Overflow element

When a trace unit buffer overflow occurs, after all trace elements that were generated prior to the trace unit buffer overflow are output, the trace unit outputs an Overflow element.

When a trace unit buffer overflow occurs, and the trace unit is disabled after recovering from the trace unit buffer overflow, the trace unit outputs the corresponding Overflow element before the trace unit becomes idle.
**Timestamp element**

*RYYWTR* While TRCCONFIGR.TS is 1 and any of the following occur, a timestamp request occurs:

- The timestamp resource event occurs, as controlled by TRCTSCCTRL.
- The trace unit generates a Trace Info element.
- The trace unit recovers from a trace unit buffer overflow.
- When not in a Trace Prohibited region and a Context synchronization event is caused by any of the following:
  - The PE takes an exception.
  - The PE returns from an exception.
  - An ISB instruction is executed.
- A trace unit flush is requested.

*RCKNFV* While TRCCONFIGR.TS is 1 and when not in a Trace Prohibited region, a timestamp request might occur when any of the following occur but do not cause a Context synchronization event:

- The PE takes an exception.
- The PE returns from an exception.
- An ISB instruction is executed.

*RNNGXNQ* The state of the ViewInst function does not affect whether a timestamp request occurs.

*RHZSVP* When a timestamp request occurs and ViewInst is inactive, the timestamp request is permitted to be delayed until after the first of the following occurs:

- A P0 element is generated.
- An Event element is generated.

*IWFXVV* There is no requirement for a Timestamp element to be generated in the trace element stream on each occasion that ViewInst becomes active.

*RDRMSV* When a timestamp request occurs and is not ignored, the trace unit generates a Timestamp element.

*RDRWCYP* When a timestamp request occurs but the trace unit does not have the capacity to generate the Timestamp element immediately, then the generation of the Timestamp element is delayed until there is capacity.

*IFTQDHY* A trace unit might not have the capacity to generate a Timestamp element for multiple reasons, including avoiding a trace unit buffer overflow. A delayed Timestamp element means that a timestamp value might not be the exact time of the incident that resulted in the timestamp request. A timestamp is only a time indicator inserted in the trace element stream somewhere near the time of the request.

*RXMSGY* When a timestamp request occurs while in a Trace Prohibited region, then the generation of the Timestamp element is delayed until the PE leaves the Trace Prohibited region.

*RCCWHIIW* When the first timestamp request occurs after trace generation becomes operative, the trace unit delays generation of the corresponding Timestamp element until after the trace unit has generated either a P0 element or an Event element.

*ISDPZZ* This is so that the timestamp value can correspond to the most recent of these elements.

*RSZNMB* A timestamp request is permitted to be ignored if a previous timestamp request has not yet generated a Timestamp element, due to a delay in the generation.

*RDWFTT* A trace unit might ignore the second request of two successive timestamp requests if all of the following are true:

- The second request is not caused as a result of a trace protocol synchronization request.
- No P0 elements or Event elements have been generated between the two requests.
- The timestamp value would be the same in both Timestamp elements.

*RZMQILT* While TRCCONFIGR.CCI is 1, each Timestamp element contains a cycle count that indicates the number of cycles between the previous Cycle Count element and the element with which the Timestamp is associated.
The cycle count associated with a Timestamp element is different from the Cycle Count element in the following ways:

- The cycle count does not affect the cumulative cycle count.
- The cycle count value can be zero.

When the cycle count associated with a Timestamp element is zero, this indicates that no cycles passed between the previous Cycle Count element and the element with which the Timestamp element is associated.

When the trace unit is first enabled, while cycle counting is enabled, when a Timestamp element is generated before any Cycle Count elements, the Timestamp element reports the cycle count as UNKNOWN.

When a Timestamp element is generated and the cycle counter has exceeded the maximum supported value, the Timestamp element reports the cycle count as UNKNOWN.

**Trace On element**

When an instruction block is traced immediately after an instruction block was not traced or a trace unit buffer overflow occurred, the trace unit generates a Trace On element.

When an Exception element indicating a PE reset is traced, the preferred exception return address is UNKNOWN. Any instructions since the most recent unresolved P0 element are not traced. If ViewInst was active for these instructions, this is not considered a gap in the trace element stream and a Trace On element is not required.

In some scenarios where mis-speculation occurs or instructions are canceled, after Cancel elements have been processed there might be Trace On elements in the trace element stream even though no trace discontinuity occurred in the architecturally-executed instruction trace. This typically only occurs when the trace is filtered using the ViewInst function, which causes the Trace On element to be inserted.

Trace analyzers must be aware that these additional Trace On elements might be traced.

**Cycle Count element**

The cycle counter has an IMPLEMENTATION DEFINED size of between 12 and 20 bits, as indicated by TRCIDR2.CCSIZE. The cycle counter therefore supports values from 1 to $2^{20} - 1$.

While TRCCONFIGR.CCI is 1 and the cycle count is equal to or greater than the value of TRCCCCTLR.THRESHOLD, when a Commit element is generated, a Cycle Count element request occurs.

While TRCCCCTLR.THRESHOLD is programmed with a value less than TRCIDR3.CCITMIN, the generation of Cycle Count elements is CONSTRAINED UNPREDICTABLE.

When a request for a Cycle Count element occurs, one of the following occurs:

- The trace unit generates a Cycle Count element immediately and before any future Commit element.
- The trace unit delays generation of the Cycle Count element until after one or more further Commit elements have been generated.

Arm recommends that when a request for a Cycle Count element occurs, the Cycle Count element is generated immediately, and that Cycle Count element generation is only delayed in rare and non-repetitive circumstances.

When a Cycle Count element is generated, the Cycle Count element contains the value of the cycle counter at the time the most recent Commit element was generated, and the cycle counter is reset to the number of cycles since the most recent Commit element was generated.

A value of 0 indicates that the cycle count value is UNKNOWN.

When the cycle counter exceeds the maximum supported value, the cycle count value is UNKNOWN.

When the trace unit becomes enabled, an UNKNOWN cycle count value occurs for the first Cycle Count element generated.

When a trace unit buffer overflow occurs, an UNKNOWN cycle count value occurs for the first Cycle Count element generated.
The first Cycle Count element after the PE clock has been restarted should have an UNKNOWN cycle count.

**Discard element**

When trace generation becomes inoperative and any of the following are true, the trace unit generates a Discard element:

- P0 elements have been generated but the trace unit is unable to output the resolution of those P0 elements.
- A Transaction Start element has been generated and trace generation becomes inoperative before the transaction either succeeds or fails.

When trace generation becomes inoperative due to the trace unit becoming disabled, and a Discard element is generated, the trace unit outputs the Discard element after all other elements.

When a PE reset occurs and any of the following are true, the trace unit generates a Discard element:

- P0 elements have been generated but the trace unit is unable to output the resolution of those P0 elements.
- A Transaction Start element has been generated and the PE reset occurs before the transaction either succeeds or fails.

A trace unit might not generate a Discard element if no P0 elements are speculative.

A trace unit might generate a Discard element even if no P0 elements are speculative.

When a Discard element is generated, all uncommitted P0 elements are discarded, that is, the current speculation depth is set to zero.

When a Discard element is generated, and a Transaction Start element has been traced but the transaction has not succeeded or failed, the trace unit does not indicate the resolution of the transaction.

When a Discard element is generated and tracing subsequently becomes operative for the same transaction, the trace unit generates a new Transaction Start element before any P0 elements are generated for the transaction.

**Trace unit features**

The architecture defines a number of optional and mandatory features that are provided to modify the trace element stream to provide additional information to aid debugging. These features include the following:

- Q element regions.
- Branch broadcasting.
- Context identifier tracing.
- Cycle counting.
- Event trace.
- No overflow.
- PE Stalling and overflow avoidance.
- Timestamping.
- Virtual context identifier tracing.

For the optional features, the inclusion of these optional features is indicated in TRCIDR0-TRCIDR13.

**Q regions**

The support for Q element is OPTIONAL, as indicated by TRCIDR0.QSUPP.

The use of Q elements must be explicitly enabled if the trace unit is to use them.

While Q elements are enabled, the trace element stream might not contain enough information to determine the complete program flow, because some changes in flow might not be explicitly indicated.
Arm recommends that *Q elements* are only used in cases where generating the full ETE instruction trace element stream might cause the performance of the PE being traced to degrade significantly.

The use of *Q elements* degrades the information that can be extracted from the trace element stream. Arm recommends that *Q element* filtering, as indicated by TRCIDR0.QFILT, is also implemented.

If TRCQCTRLR is implemented, the trace unit supports the ability to control when *Q elements* are permitted in the trace element stream using ARCs. The *Q element* filtering operates in either Exclude mode, or Include mode, selected by TRCQCTRLR.MODE.

If *Q elements* are enabled and *Q element* filtering is in Include mode, the ARCs selected by TRCQCTRLR.RANGE define where *Q elements* are permitted.

If *Q elements* are enabled and *Q element* filtering is in Exclude mode, the ARCs selected by TRCQCTRLR.RANGE define where *Q elements* are not permitted.

When an instruction block contains at least one instruction where *Q elements* are permitted, the entire instruction block is permitted to generate *Q elements*.

The following equation is calculated for each instruction block and defines when *Q elements* are permitted.

\[
Q_{PERMITTED_i} = \begin{cases} 
\sum_n ARC_i(n) \land TRCQCTRLR.RANGE[n] & \text{Include mode} \\
\sum_n ARC_i(n) \land \neg TRCQCTRLR.RANGE[n] & \text{Exclude mode}
\end{cases}
\]

While TRCCONFIGR.QE indicates that *Q elements* are disabled, the trace unit does not generate any *Q elements*.

While TRCCONFIGR.QE indicates that *Q elements* are disabled, the trace unit is able to generate all of the elements required to trace the instruction sequence.

**Branch broadcasting**

The branch broadcasting feature forces the trace unit to explicitly trace the target addresses of taken direct *P0 instructions*.

The target addresses are traced using *Target Address elements* in the instruction trace stream.

Branch broadcasting is enabled by performing both of the following actions:

- Setting TRCCONFIGR.BB to 1.
- Programming TRCBBCTLR to specify how branch broadcasting behaves. TRCBBCTLR selects Address Range Comparators to define when branch broadcasting is active, and selects the operating mode of branch broadcasting:
  - Branch broadcasting is active for all instructions inside the selected ranges. This is known as Include mode.
  - Branch broadcasting is active for all instructions outside the selected ranges. This is known as Exclude mode.

When a direct *P0 instruction* for which branch broadcasting is active is taken, the trace unit generates a *Target Address element* to explicitly trace the target of the instruction, regardless of whether the *P0 instruction* is mispredicted.

While branch broadcasting is enabled, while the return stack is enabled, the trace unit prioritizes branch broadcasting over the return stack, that is, the return stack does not match on the target of any instruction for which branch broadcasting is active.

If TRCBBCTLR is not implemented, while branch broadcasting is enabled, branch broadcasting is active for all instructions.
Context identifier tracing

The trace unit can be programmed to include information about the current execution context of the program being executed on the PE, including:

- The current process identifier, stored in CONTEXTIDR_EL1. This is known as the Context identifier.
- The current VMID, stored in CONTEXTIDR_EL2. This is known as the Virtual context identifier.

The trace unit supports tracing of the Context identifier, with TRCIDR2.CIDSIZE indicating a 32-bit Context identifier size.

Cycle counting

The use of the cycle counting feature introduces Cycle Count elements into the trace element stream to indicate the passage of PE clock cycles.

Counting the number of clock cycles the PE uses to perform a certain function can be useful as a way of measuring program performance, or for profiling the PE.

While cycle counting is enabled, the trace unit outputs Cycle Count packets that contain processor clock cycle count values.

Cycle Count elements are associated with Commit elements, so that when a Commit element is generated, a Cycle Count element might also be generated. Whether a Cycle Count element is generated when a Commit element is generated depends on what cycle count threshold has been specified when programming TRCCCCTRL.THRESHOLD.

When a Commit element is generated and the cycle count value is equal to or more than the threshold value, then a Cycle Count element is generated and a Cycle Count packet is output. The cycle count value that is contained in that packet is associated with the Commit element that triggered it.

While cycle counting is enabled, and when a Commit element is generated and the cycle count value is greater than or equal to the threshold value that is programmed in TRCCCCTRL.THRESHOLD, the trace unit generates a Cycle Count element.

Also, because cycle counting is associated with Commit elements, a Cycle Count packet might imply the generation of Commit elements, and so in addition to the cycle count value, some Cycle Count packets also contain a value for the number of Commit elements that the trace unit has generated.

The value of cycle count that is given in a new Cycle Count packet indicates the number of processor clock cycles between the new Commit element that the packet is associated with, and the most recent Commit element prior to the new Commit element that had a Cycle Count element associated with it.

This means that if there is a requirement for a cumulative cycle count total, the cycle count values from the successive Cycle Count packets can be added together to obtain this.

Event trace

The ETE architecture supports the tracing of additional information in the trace stream. These are known as ETEEvents, also known as Event trace. The trace unit supports up to 4 ETEEvents. The generation of ETEEvents is controlled by selecting resources selectors. The occurrence of ETEEvents can be communicated in the following ways:

- To the system by External Outputs on page D4-4869.
- To the trace analyzer by Event Packet.

No overflow

A trace unit might include an optional feature to prevent overflows, which is indicated by TRCIDR3.NOOVERFLOW.

TRCSTALLCTRL.NOOVERFLOW controls the no overflow feature.
Enabling the no overflow feature might have a significant impact on PE performance.

While the no overflow feature is enabled, and while the number or frequency of ETEEvents is below an IMPLEMENTATION DEFINED threshold, the trace unit does not overflow.

The threshold is greater than or equal to one of each numbered ETEEvent, for each trace session.

When TRCIDR3.SYSSTALL is 0 the Effective value of TRCSTALLCTRL.NOOVERFLOW is 0 which means the no overflow feature is disabled.

When TRCSTALLCTRL.ISTALL is 0 and TRCSTALLCTRL.NOOVERFLOW is 1, it is CONSTRAINED UNPREDICTABLE whether any stalling is disabled or whether the no overflow feature is enabled.

**Stalling the execution of the PE**

The trace unit can be programmed to reduce the likelihood of a trace unit buffer overflow. If the trace unit is configured to support PE stalling, TRCIDR3.STALLCTL indicates that PE stalling is implemented and TRCIDR3.SYSSTALL indicates that PE stalling is permitted, then the execution of the PE can be slowed.

It is permissible that the operation of the PE can be affected by the programming of the trace unit. The amount of intrusion and when stalling occurs is IMPLEMENTATION DEFINED. Additional stalling of the PE execution can be achieved by enabling this feature.

Trace unit stalling of the PE is independent of the operation of the PE.

PE operations which explicitly interact with the trace unit complete independently of the programming of the ability of the trace unit to stall the PE.

The trace unit does not stall the PE while any of the following are true:

- The trace unit is in the Disabled state.
- The PE is executing in a Trace Prohibited region (see *Trace Prohibited Regions on page D4-4810*).
- The PE is in Debug State.
- The PE does not allow stalling, that is, TRCIDR3.SYSSTALL == 0b0.
- SelfHostedTraceEnabled() == FALSE and ExternalInvasiveDebugEnabled() == FALSE.
- When TRCSTALLCTRL.ISTALL == 0b0 and TRCSTALLCTRL.NOOVERFLOW == 0b0.
- Trace output is disabled.

When all of the following are true, the trace unit is permitted to stall the PE:

- Stalling of the PE is not prohibited by SCLVV.
- TRCSTALLCTRL.ISTALL == 0b1.
- Any of the following are true:
  - TRCSTALLCTRL.NOOVERFLOW == 0b1.
  - The available space in the internal storage of the trace unit is below the level indicated in TRCSTALLCTRL.LEVEL.

Otherwise, the trace unit does not stall the PE due to the stalling feature or no overflow feature.

The trace unit does not indefinitely stall the operation of the PE.

In a multi-threaded processor, if the trace unit stalls a PE, Arm recommends that stalling or disruption of the processing of other PEs is minimized. In particular, if tracing of one or more PEs in a multi-threaded processor is enabled but tracing of other PEs in the multi-threaded processor is disabled, Arm recommends that if the PEs being traced are stalled by their respective trace units then the stall has minimal effect on the PEs which are not being traced.

The levels indicated in TRCSTALLCTRL.LEVEL are the levels of intrusion allowed.
A summary of the stalling and no overflow scenarios is shown in Table D4-23 on page D4-4837, when TRCIDR3.STALLCTL is 1 and TRCIDR3.SYSSTALL is 1.

### Timestamping

The trace unit supports timestamping, where a common global time value is inserted into the trace stream. These timestamps may be used to correlate between multiple trace streams, including those from other PEs or other sources of trace. These timestamps may be used to determine the passage of time, for analyzing performance.

When timestamping is enabled, the trace unit inserts Timestamp elements into the trace stream. Each Timestamping element indicates the time that a recent P0 element or Event element occurred, and can be used to accurately determine when that element occurred.

The time value included in Timestamp elements is selected by TRFCR_EL1 and TRFCR_EL2 and is one of:

- Physical time, as seen by the generic timers in the PE.
- Virtual time, as seen by the generic timers in the PE.
- An IMPLEMENTATION DEFINED time value, often supplied by a CoreSight system.

The insertion of Timestamp elements is controlled by TRCCONFIGR.TS and TRCTSCTRL.

### Virtual context identifier tracing

Whether an implementation supports Virtual context identifier tracing is IMPLEMENTATION DEFINED. If it does, the trace unit can be programmed to output the identifier of a virtual machine that the PE is executing.

This option is enabled by setting TRCCONFIGR.VMID to 0b1.

If the PE implements EL2, the trace unit supports a 32-bit Virtual context identifier, with TRCIDR2.VMIDSIZE indicating a 32-bit Virtual context identifier size. The source of the Virtual context identifier is CONTEXTIDR_EL2.PROCID.

If the PE does not implement EL2, the trace unit does not support a Virtual context identifier, with TRCIDR2.VMIDSIZE indicating Virtual context identifier tracing is not supported.

Note: Previous trace architectures from Arm supported the ability to select the source of the Virtual context identifier. This specification does not support Virtual context identifier selection, and only permits CONTEXTIDR_EL2.PROCID as the source of the Virtual context identifier. See TRCIDR2.VMIDOPT for more details.
D4.5.11 Compression

Additional compression of the trace byte stream is achieved by the following methods:

- Removing elements that can be implied by the trace analyzer:
  - Implying the existence of Commit elements based on the tracing of other elements.
  - Removing Target Address elements that can be calculated by the trace analyzer by analysis of previous traced PE execution.
- Combining multiple elements together into a single packet:
  - Combining Atom elements into a single packet.
  - Combining Cancel elements and Mispredict elements into a single packet.

Implied commits

The ETE trace protocol provides mechanisms to minimize the number of Commit elements which need to be explicitly output in the trace byte stream. When a P0 element is output in the trace byte stream, if the number of speculative P0 elements output exceeds TRCIDR8.MAXSPEC, then a Commit element is implied which resolves the oldest speculative P0 element.

The trace unit does not generate commit packets for Commit elements that have been implied by the trace protocol.

Atom packing

The ETE trace protocol provides packets which allow groups of consecutive Atom elements to be packed into a single trace packet. Figure D4-15 on page D4-4839 shows the decision tree for generating the different formats of Atom packets.
Cancel Packets can indicate a number of Atom elements and the Cancel element.

The Mispredict Packets can indicate a number of Atom elements and the Mispredict element.

**Address compression**

The trace unit can remove program addresses from the trace stream. The trace analyzer can infer the addresses from the program image and previous history.

This includes the targets of direct P0 instructions, where the target address is encoded in the instruction itself.

The trace unit retains the Address information of up to the last three addresses that were explicitly output in the trace protocol, as contained in:

- Target Address packets.
• Source Address packets.
• Exception packets.
• Transaction Failure packets.
• PE Reset packets.
• Q packets.

The explicitly output addresses that the trace unit retains are known as the address history buffer.

For optimized trace protocol efficiency, Arm recommends that the address history buffer is three entries deep.

When any of the following packets are generated, the trace unit pushes the address value and sub_isa to the address history buffer:
• Target Address packet.
• Source Address packet.
• Q packet that implies a Target Address element.

When an Exception packet is generated, the trace unit pushes the preferred exception return address value and sub_isa to the address history buffer.

When one of the following packets is generated with an unknown address, the trace unit pushes an address value of 0x0 and sub_isa of IS0 to the address history buffer.
• Transaction Failure packet.
• PE Reset packet.

When a Target Address packet is generated, the trace unit uses the address history buffer to identify when a Target Address Exact Match packet can be used. When a Target Address Exact Match packet cannot be used, the most recent entry in the address history buffer is used for the Target Address packet selection.

When a Source Address packet is generated, the trace unit uses the address history buffer to identify when a Source Address Exact Match packet can be used. When a Source Address Exact Match packet cannot be used, the most recent entry in the address history buffer is used for the Source Address packet selection.

When an Exception packet is generated, the trace unit uses the address history buffer to identify when an Exception Exact Match Address packet can be used. When an Exception Exact Match Address packet cannot be used, the most recent entry in the address history buffer is used for the Exception Address packet selection.

When a Q packet is generated which implies a Target Address element, the trace unit uses the address history buffer to identify when a Q with Exact Match Address packet can be used. When a Q with Exact Match Address packet cannot be used, the most recent entry in the address history buffer is used for the Q Address packet selection.

When a Trace Info packet is generated, the trace unit sets all entries of the address history buffer to have an address value of 0x0 and sub_isa of IS0.

Return stack address matching

The trace unit might contain the optional return stack function. The return stack operates when Branch with Link instructions or indirect P0 instructions are taken, and provides a mechanism to allow the trace unit to remove certain Target Address elements from the trace element stream. The trace analyzer maintains an independent copy of the return stack which is used to determine when Target Address elements have been removed and then infer the target of indirect P0 instructions.

The depth of the return stack is IMPLEMENTATION DEFINED from 0 to 15 entries.

For optimized trace protocol efficiency, Arm recommends the trace unit implements the return stack with at least 3 entries.

While TRCCONFIG.RS is 1, when a Branch with Link instruction is predicted as taken and is traced, the trace unit pushes the following Address information to the return stack:
• The instruction address + the instruction size, that is, the return address for the Branch with Link instruction.
• The sub_isa from the instruction set encoding.

When a return stack push occurs, all existing entries are shifted down one place on the return stack and the new entry is pushed to the top entry of the return stack.

While the return stack is full, when a return stack push occurs, the oldest entry on the return stack is discarded.

When a Branch with Link instruction is predicted as taken and traced with an E Atom element, when a return stack push occurs, the trace unit pushes to the return stack, even if the prediction is incorrect and is subsequently corrected to an N Atom element.

When a Branch with Link instruction is predicted as not taken and traced with an N Atom element, the trace unit does not push to the return stack, even if the prediction is incorrect and is subsequently corrected to an E Atom element.

When a Branch with Link instruction is implied by a Q element, the trace unit does not push to the return stack.

When a Branch with Link instruction is executed in a branch broadcasting region, the trace unit does not push to the return stack.

When an indirect P0 instruction is taken and traced, and the Address information in the resultant Target Address element matches the address and sub_isa on the top of the return stack, the trace unit performs a return stack pop.

When a return stack pop occurs, both of the following occur:
• The trace unit discards the Target Address element that matches the address and sub_isa on the top of the return stack.
• The trace unit removes the top entry of the return stack, and shifts each older entry up one position.

When an indirect P0 instruction is implied by a Q element, the trace unit does not perform a return stack pop.

When an indirect P0 instruction is taken, it is possible that the target address is predicted incorrectly by the PE.

When the target address of a taken indirect P0 instruction is incorrectly predicted, and the incorrect target address is traced with a Target Address element, the trace unit corrects the incorrect address by generating a new Target Address element with the correct target address, and neither of the target addresses cause a return stack pop.

When the target address of a taken indirect P0 instruction is incorrectly predicted, and the incorrect target address matches the top entry of the return stack, the trace unit subsequently generates a Target Address element with the correct target address, and neither of the target addresses cause a return stack pop.

When the final status of the Atom element corresponding to an indirect P0 instruction is E, including when one or more Mispredict elements change the status of the Atom element, the trace unit performs a return stack pop.

Note: A return stack push only occurs if the initial Atom element state for the Branch with Link instruction is E. Conversely, a return stack pop only occurs if the final Atom element state for the indirect P0 instruction is E.

When an instruction that is both a Branch with Link instruction and an indirect P0 instruction is executed, the trace unit performs the following actions on the return stack, in order:
1. Determine whether a return stack push is possible and push if required.
2. Determine whether a return stack pop is possible and pop if required.

Note: Some Arm trace architectures use a different order of operations.

When any of the following occur, the trace unit discards the contents of the return stack:
• The trace unit generates a Trace Info element.
• The trace unit generates a Trace On element.
• The PE enters a branch broadcasting region.

A trace unit might discard the contents of the return stack at any time.

When the return stack contents are discarded, there is no requirement for the trace analyzer to be aware that this discard operation has occurred. This is because even though the contents of the trace unit return stack are discarded, there are no adverse consequences if the contents of the trace analyzer return stack are retained, but never used.
After a Trace Info element, a Target Address element and a Context element are required but might not be generated immediately. If the Target Address element and the Context element are not generated before the next P0 element, then any Branch with Link instructions must not push on to the return stack until both the Target Address element and the Context element have been generated.

Note: This restriction prevents the trace unit from performing return stack pushes for instructions that the trace analyzer cannot analyze, because it is not yet fully synchronized.

**Timestamp value compression**

The trace analyzer maintains a copy of the last Timestamp element value broadcast. The Timestamp element value might be compressed relative to the last value and only the bits that have changed need to be encoded.

When a Trace Info packet is generated, the trace unit sets its maintained value of the last Timestamp element to zero, and when the trace unit generates a subsequent Timestamp packet the value is compressed relative to this new zero value. This means that the first Timestamp packet after a Trace Info packet contains all non-zero bits of the Timestamp value.

Cancel Packets can indicate a number of Atom elements and the Cancel element.

The Mispredict Packets can indicate a number of Atom elements and the Mispredict element.
### D4.6 Resource operation

FEAT_ETE has a number of resources that can be used to provide advanced filtering functionality. The resources operate in one of the following states:

- **Running**
  - All the resources are active.

- **Pausing**
  - The resources are progressing to the Paused state.

- **Paused**
  - All the resources are static and inactive except for External Input Selectors.

---

As described in *System behaviors on page D4-4800*, the trace unit can be disabled by either:

- Setting TRCPRGCTRL.EN to 0.
- Locking the OS Lock, by setting OSLAR_EL1.OSLK to 1.

While the resources are in the Running state, and when any of the following occur, the resources enter the Pausing state:

- The trace unit becomes disabled.
- The trace unit enters the low-power state.
- The PE begins executing in a Trace Prohibited region.

While the resources are in the Pausing state, the resources enter the Paused state in finite time.

While the trace unit is in the Paused state, when all of the following are true, the resources enter the Running state:

- The trace unit is enabled.
- The trace unit is not in the low-power state.
- The PE is not executing in a Trace Prohibited region.

A trace unit buffer overflow has no impact on the behavior of the resources.

### D4.6.1 Behavior of the resources while in the Running state

The time taken for the resources to operate might vary between different trace unit implementations.
D4.6.2 Behavior of the resources while in the Pausing state

When the resources enter the Pausing state, the resources perform the following procedure:

1. All resources, except for the Sequencer and any Counters, are driven low as inputs to the Resource Selector logic. The Counters and the Sequencer behave as normal.
2. The states that the inputs were at before they were driven low are propagated through the Resource Selector logic.
3. The states of the Counters and the Sequencer are propagated through the Resource Selector logic one more time. That is, the states of the Counters and the Sequencer are propagated through the Resource Selector logic for the length of time that it takes for the state of a resource to be propagated through the Resource Selector logic.
4. The resources enter the Paused state.

The procedure that the resources perform when the resources are in the Pausing state has the result that, for resource events that are activated by a resource that is not a Counter or a Sequencer, no activity is lost, because all those resource events are updated.

When Counter and Sequencer states are propagated back as resources, so that a loop is created, then the following are true:

- If a Counter at zero resource is being used to activate the Sequencer or a Counter, then that Counter at zero resource might be propagating through the Resource Selector logic at the time when the procedure ends. In this case, the Sequencer state resource or other Counter at zero resource that is activated by that Counter at zero resource might be lost.
- If a Sequencer state resource is being used to activate a Counter, then that Sequencer state resource might be propagating through the Resource Selector logic at the time when the procedure ends. In this case, the Counter at zero resource that is activated by that Sequencer state resource might be lost.

When the trace unit becomes disabled, the behavior of the resources in the Pausing state ensures that the programmers' model provides a consistent view of the state of the trace unit resources. That is, regarding the Counters and the Sequencer, the following are true:

- If the state of the Sequencer propagated back as a resource, then the view of the Sequencer as a resource event and the view of the Sequencer resource state both show the same Sequencer state.
- If the state of a Counter is propagated back as a resource, then the view of the Counter as a resource event and the view of the Counter resource state both show the same Counter state.

The Counter state might be one of the following:

- The Counter is at zero.
- The Counter is not at zero.

D4.6.3 Behavior of the resources while in the Paused state

The behavior of the resources when the PE enters the low-power state or a Trace Prohibited region differs from other trace architectures defined by Arm.

While the resources are in the Paused state and the trace unit is not disabled, the resources do not lose resource events that are in transition, except those permitted when moving through the Pausing state of the resources. See Behavior of the resources while in the Pausing state for details on the resource events that are permitted to be lost when in the Pausing state.

While the resources are in the Paused state, the resources might not observe resource events that are in transition until after the resources leave the Paused state.

While the resources are in the Paused state, the resources remain in the state they are in.

While the resources are in the Paused state, the trace unit drives all External Outputs low.

When the trace unit becomes disabled and the resources enter the Paused state, and not before, the trace unit might set TRCSTATR.PMSTABLE to 1.
While TRCSTATR.PMSTABLE is set to 1, all resources and resource events remain in a quiescent state.

**D4.6.4 Behavior of resources on a Trace synchronization event**

When the following resources have finished calculations for all instructions prior to the previous Context synchronization event, a Trace synchronization event completes:
- Address Comparators.
- Context Identifier Comparators.
- Virtual Context Identifier Comparators.
- Single-shot Comparator Controls.

**D4.6.5 Resource organization**

There are 2 types of resources:
- Precise resources.
- Imprecise resources.

Each resource has a current state, which is output as a Resource state. The Resource state is selected by Resource Selectors, and then used by various trace unit functions as a Resource event, see Figure D4-17.

**Precise resources**

The precise resources are used in the evaluation of the ViewInst include/exclude function and the ViewInst start/stop function.

The trace unit evaluates the precise resources for each instruction block. See Instruction block on page D4-4809 for more details.

The trace unit maintains execution order of the precise resources.
Imprecise resources

If a Resource is not a precise resource, it is an imprecise resource.

![Diagram of Imprecise resource path]

Selecting a resource or a pair of resources

A resource is selected by using a Resource Selector.

Each Resource Selector uses one of the 30 TRCRSCTL<n> registers. The trace unit implements Resource Selectors in pairs, so that a maximum of 15 programmable pairs can be implemented.

Resource Selector 0 always provides a FALSE result.

While the resources are in the Running state, Resource Selector 1 provides a TRUE result.

TRCIDR4.NUMRSPAIR indicates how many pairs of Resource Selectors are implemented.

Resource Selectors can be used in pairs or used individually. When a pair of Resource Selectors is used, a Boolean function can be applied to the outputs of the combination of selected resources. See Figure D4-20 on page D4-4849.
While TRCRSCTLR<\(n\).SELECT[\(m\)] is 1, the Resource Selector selects the Resource Number \(m\) of the group selected by TRCRSCTLR<\(n\>.GROUP as described in Table D4-24 on page D4-4847.

</tbody>
</table>

While TRCRSCTLR<\(n\>.INV is set to 0 and one or more resources in a group are selected, when any of the outputs of the selected resources are high, the Resource Selector fires.

While TRCRSCTLR<\(n\>.INV is set to 1, when none of the outputs of the selected resources are high, the Resource Selector fires.

### A Resource Selector pair

The Resource Selectors are arranged in pairs, and the result of each of a pair of Resource Selectors can be combined using a Boolean function and used to drive other resources and events in the trace unit.

For each TRCRSCTLR<\(n\> register which is the lower register for a pair of Resource Selectors, the TRCRSCTLR<\(n\>.PAIRINV field.
For example:

- TRCRSCTRLR2 and TRCRSCTRLR3 constitute a Resource Selector pair. In this case:
  - TRCRSCTRLR2 is the lower register.
  - TRCRSCTRLR2.PAIRINV optionally inverts the result of the Boolean function that is applied to the outputs of the combination of selected resources.
  - TRCRSCTRLR3 is the upper register.
  - TRCRSCTRLR3.PAIRINV is RES0.

This means that, when a Resource Selector pair is used, the following scenario is possible:

- One TRCRSCTRL<n> might select only one resource within the group.
- The other TRCRSCTRL<n> might select more than one resource from the group, so that the result is a logical OR of the selected resources.
- A Boolean function, for example a logical AND, might be applied to the outputs of the combination of selected resources.
- The result of that Boolean function might be inverted by using PAIRINV.

In Figure D4-20 on page D4-4849, the Boolean function is selected by using the INV field for each Resource Selector, with the PAIRINV field for each Resource Selector pair, see Table D4-25 on page D4-4849.
D4.6.6   Address comparators

**ILGGVG**  
An ETE trace unit provides between 0 and 16 Single Address Comparators (SACs), each of which compares the instruction address with a user-programmed value.

**RYCRNP**  
The trace unit implements SACs in pairs, so that a trace unit implementation contains an even number of SACs.

**IMNTCY**  
TRCIDR4.NUMACPAIRS indicates how many pairs of SACs are implemented.

---

</tbody>
</table>
When the PE executes instructions in Debug state, Address Comparators do not match.

When the PE executes instructions in a Trace Prohibited region, Address Comparators do not match.

Address Comparators might match in failed transactions.

Address Comparators might match on Speculative execution.

**Single Address Comparators**

A SAC can be used in the following ways:

- As inputs to the ViewInst start/stop function in the ViewInst function. For more information, see *ViewInst start/stop function filtering* on page D4-4815.
- As an individual resource.
- The comparator can be programmed so that, whenever the PE is in Non-secure state, the comparator only matches in certain Exception levels.
- The comparator can be programmed so that, whenever the PE is in Secure state, the comparator only matches in certain Exception levels.

An SAC only matches on Exception levels and Security states as indicated by TRCACATR<n>.

An SAC only matches on the context indicated by TRCACATR<n>.CONTEXT and TRCACATR<n>.CONTEXTTYPE.

\[
\text{SAC}_{\text{EL}}[n] = \begin{cases}

\text{CIDCOMP}[m] & \text{type is 1} \\
\text{VMIDCOMP}[m] & \text{type is 2} \\
\text{CIDCOMP}[m] \land \text{VMIDCOMP}[m] & \text{type is 3} 
\end{cases}
\]  

\( (1) \)
When an instruction is executed, and the address of the lowest byte of the instruction exactly matches the programmed address of an SAC, the SAC matches.

\[
SAC\_ADDR_i[n] = (\text{ThisInstrAddr}(i) \equiv \text{TRCACVRn.ADDRESS}) \quad (1)
\]

For example, for a 4-byte instruction at address 0x1000:
- The lowest byte of the instruction is at 0x1000.
- The second byte of the instruction is at 0x1001.
- The third byte of the instruction is at 0x1002.
- The highest byte of the instruction is at 0x1003.

If an SAC is programmed with 0x1000, then it always matches on that instruction at address 0x1000.

It is IMPLEMENTATION DEFINED whether an SAC matches when its programmed address matches any byte of an instruction which is not the lowest byte of the instruction.

The Arm architecture supports disabling IT instructions on more than one subsequent instruction, using the ITD bits in the SCTLR, HSCTLR, and SCTLR_EL1 System registers. If any of the ITD bits are set to 1 and are affecting IT operation, and a SAC is programmed to match on the address of the instruction that is immediately after an IT instruction, when the instruction immediately after the IT instruction is executed it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

If any of the ITD bits are set to 1, Arm recommends that a SAC is programmed to match on the address of the IT instruction, instead of the instruction immediately after the IT instruction.

To avoid unexpected behavior from an SAC, Arm recommends that the SAC is always programmed with an address that is for the lowest byte of an instruction.

When the instruction immediately after a MOVPRFX instruction executes, if a SAC is programmed to match on the address of this instruction, then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

Arm recommends that a SAC is programmed to match on the address of the MOVPRFX instruction, instead of the instruction immediately after the MOVPRFX instruction.

The operation of a SAC is as follows:

\[
SAC_i[n] = \begin{cases} 
0 & \text{When Prohibited} \\
0 & \text{When in Debug State} \\
\text{SAC\_ADDR}_i[n] \land \text{SAC\_EL}_i[n] \land \text{SAC\_CONTEXT}_i[n] & \text{Otherwise}
\end{cases}
\]

**Address Range Comparators**

Pairs of SACs are arranged to form one Address Range Comparator (ARC). An ARC is programmed with an address range, so that whenever any address in that range is accessed, the ARC matches. A trace unit contains between zero and eight ARCs. ARCs can be used in the following ways:
- Selected for the ViewInst include/exclude function in the ViewInst function. See ViewInst include/exclude function filtering on page D4-4818.
- As individual resources.

An ARC is programmed by programming the SACs as follows:
- The first SAC is programmed with the start address of the instruction range.
- The second SAC is programmed with the end address of the instruction range.

The address that the second SAC is programmed with must be greater than or equal to the address that the first SAC is programmed with, that is, the end address must be greater than or equal to the start address.
While the start address of an ARC is greater than the end address, the behavior of the ARC is CONSTRAINED UNPREDICTABLE, that is, at any time the ARC might do one of the following:

- Match.
- Not match.

While the TRCACATR\(<n>\) registers for the SACs in an ARC are programmed to different values, the behavior of the ARC is CONSTRAINED UNPREDICTABLE.

While an ARC is programmed with an instruction address range, when the PE executes an instruction at an address in the following range, the ARC matches:

\[
\text{start address} = \text{TRCACVR}_n.\text{ADDRESS} \quad (1) \\
\text{end address} = \text{TRCACVR}(n+1).\text{ADDRESS} \quad (2)
\]

\[
\text{ARC}_\text{ADDR}_{\lfloor n/2 \rfloor} = (\text{ThisInstrAddr}_i \geq \text{start address}) \land (\text{ThisInstrAddr}_i \leq \text{end address})
\]

When an instruction is executed, and the address of the lowest byte of the instruction is within the programmed address range of an ARC, the ARC matches.

When an instruction is executed and the programmed address range of an ARC contains addresses for one or more bytes of the instruction, but does not contain the address for the lowest byte of the instruction, it is IMPLEMENTATION SPECIFIC whether the ARC matches.

For example, for a 4-byte instruction at address 0x1000:

- The lowest byte of the instruction is at 0x1000.
- The second byte of the instruction is at 0x1001.
- The third byte of the instruction is at 0x1002.
- The highest byte of the instruction is at 0x1003.

If the programmed address range contains 0x1000, then the ARC always matches. However, if the programmed address range starts at either 0x1001, 0x1002, or 0x1003, then it is IMPLEMENTATION SPECIFIC whether the ARC matches.

To avoid unexpected behavior from an ARC, Arm recommends that the ARC is always programmed with an address range that starts with an address for the lowest byte of an instruction.

The Arm architecture supports disabling IT instructions on more than one subsequent instruction, using the ITD bits in the SCTLR, HSCTLR, and SCTLR_EL1 System registers. If any of the ITD bits are set to 1 and are affecting IT operation, and an ARC is programmed to include the address of the instruction that is immediately after an IT instruction but not include the IT instruction, when the instruction immediately after the IT instruction is executed then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

If any of the ITD bits are set to 1, Arm recommends that an ARC is programmed to include both the IT instruction and the instruction immediately after the IT instruction.

When the instruction immediately after a MOVPRFX instruction is executed, if an ARC is programmed to include the address of the instruction that is after the MOVPRFX instruction but not the MOVPRFX instruction, then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

Arm recommends that an ARC is programmed to include both the MOVPRFX instruction and the instruction immediately after the MOVPRFX instruction.
It might be possible for multiple matches to occur simultaneously. The definition of when matches occur simultaneously is implementation specific, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place with each address in the programmed range. In this case, any of the following might occur:

- An address in the range is matched more than once.
- More than one address in the range is matched simultaneously.

When multiple ARC matches occur simultaneously for one ARC, both of the following are true:
- The ARC signals a match at least once.
- The ARC does not signal more matches than the number of instructions that are executed with an address that matches an address in the programmed range.

Each ARC can be used with one, or a combination of, the following:
- A Context Identifier Comparator.
- A Virtual Context Identifier Comparator.

An ARC only matches on Exception levels and Security states as indicated by TRCACATR<2n>.

\[
ARC_{EL_{i}}[n] = \begin{cases}
-TRCACATR<2n>.EXLEVEL_S_EL0 & \text{Secure EL0} \\
-TRCACATR<2n>.EXLEVEL_S_EL1 & \text{Secure EL1} \\
-TRCACATR<2n>.EXLEVEL_S_EL2 & \text{Secure EL2} \\
-TRCACATR<2n>.EXLEVEL_S_EL3 & \text{EL3} \\
-TRCACATR<2n>.EXLEVEL_NS_EL0 & \text{Non-Secure EL0} \\
-TRCACATR<2n>.EXLEVEL_NS_EL1 & \text{Non-Secure EL1} \\
-TRCACATR<2n>.EXLEVEL_NS_EL2 & \text{Non-Secure EL2}
\end{cases}
\]

An ARC only matches on the context indicated by TRCACATR<2n>.CONTEXT and TRCACATR<2n>.CONTEXTTYPE.

\[
m = TRCACATR<2n>.CONTEXT \\
type = TRCACATR<2n>.CONTEXTTYPE
\]

\[
ARC_{CONTEXT_{i}}[n] = \begin{cases}
1 & \text{type is 0} \\
CIDCOMP[m] & \text{type is 1} \\
VMIDCOMP[m] & \text{type is 2} \\
CIDCOMP[m]\land VMIDCOMP[m] & \text{type is 3}
\end{cases}
\]

The operation of an ARC is as follows:

\[
ARC_{i}[n] = \begin{cases}
0 & \text{When Prohibited} \\
0 & \text{When in Debug State} \\
ARC_{ADDR_{i}}[n] \land ARC_{EL_{i}}[n] \land ARC_{CONTEXT_{i}}[n] & \text{Otherwise}
\end{cases}
\]
D4.6.7 Context Identifier Comparator

An ETE trace unit provides between zero and eight Context Identifier Comparators. Each Context Identifier Comparator can be used in any of the following ways:

- Associated with a SAC.
- Associated with an ARC.
- As an individual resource.

While a Context Identifier Comparator is associated with either an SAC or an ARC, only while the PE is executing with the Context identifier that the Context Identifier Comparator is programmed with and when an address is accessed which the SAC or ARC is programmed to match on, the SAC or ARC signals a match.

While a Context Identifier Comparator is used as an individual resource, when an instruction block is executed with the Context identifier that the Context Identifier Comparator is programmed with, the Context Identifier Comparator matches.

When using a Context Identifier Comparator as an independent resource to activate a resource event, the time that the resource event is activated relative to the time that the Context Identifier Comparator becomes active might be imprecise.

It might be possible for multiple matches of a Context Identifier Comparator to occur simultaneously. The definition of when matches occur simultaneously is IMPLEMENTATION SPECIFIC, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place.

When multiple Context Identifier Comparator matches occur simultaneously for one Context Identifier Comparator, all of the following are true:

- The Context Identifier Comparator signals a match at least once.
- The Context Identifier Comparator does not signal more matches than the number of instructions that are executed with the Context identifier that the Context Identifier Comparator is programmed with.

A Context Identifier Comparator might match on Speculative execution, that is, a Context Identifier Comparator might match if the PE speculatively changes the Context identifier.

When the PE executes instructions in Debug state, Context Identifier Comparators do not match.

When the PE executes instructions in a Trace Prohibited region, Context Identifier Comparators do not match.
The Context identifier might change at points that are not Context synchronization events, for example when a System instruction is used to write to the current Context identifier register. In these scenarios, the Context Identifier Comparator might compare against the old or new Context identifier value for any instruction after the P0 element before the System instruction, up to the Context synchronization event after the System instruction.

\[
m = \begin{cases} 
\text{TRCCIDCCTL0.COMP0} & n = 0 \\
\text{TRCCIDCCTL0.COMP1} & n = 1 \\
\text{TRCCIDCCTL0.COMP2} & n = 2 \\
\text{TRCCIDCCTL0.COMP3} & n = 3 \\
\text{TRCCIDCCTL1.COMP4} & n = 4 \\
\text{TRCCIDCCTL1.COMP5} & n = 5 \\
\text{TRCCIDCCTL1.COMP6} & n = 6 \\
\text{TRCCIDCCTL1.COMP7} & n = 7 
\end{cases}
\]

\[
v = \text{TRCCIDCVRn.VALUE} \\
cid = \text{CONTEXTIDR_EL1.PROCID}
\]

\[
\text{CIDCOMP}[n] = \begin{cases} 
0 & \text{When Prohibited} \\
0 & \text{When in Debug State} \\
7 & \text{Otherwise} \\
\prod_{j=0}^{\lfloor \log_2 m \rfloor - 1} \left(v[8j + 7 : 8j] \equiv(cid[8j + 7 : 8j]) \lor m[j] \right) 
\end{cases}
\]

### D4.6.8 Virtual Context Identifier Comparators

An ETE trace unit provides between zero and eight Virtual Context Identifier Comparators. Each Virtual Context Identifier Comparator can be used in any of the following ways:

- Associated with a SAC.
- Associated with an ARC.
- As an individual resource.

While a Virtual Context Identifier Comparator is associated with either an SAC or an ARC, only while the PE is executing with the Virtual context identifier that the Virtual Context Identifier Comparator is programmed with and when an address is accessed which the SAC or ARC is programmed to match on, the SAC or ARC signals a match.

While a Virtual Context Identifier Comparator is used as an individual resource, when an instruction block is executed with the Virtual context identifier that matches the Virtual Context Identifier Comparator value, the Virtual Context Identifier Comparator matches.

While TRFCR_EL2.CX indicates that Virtual Context Identifier Comparators cannot match, Virtual Context Identifier Comparators do not match.

When the PE executes instructions in Debug state, Virtual Context Identifier Comparators do not match.

When the PE executes instructions in a Trace Prohibited region, Virtual Context Identifier Comparators do not match.

When using a Virtual Context Identifier Comparator as an independent resource to activate a resource event, the time at which the resource event is activated relative to the time at which the Virtual Context Identifier Comparator becomes active might be imprecise.

A Virtual Context Identifier Comparator is associated with an SAC by programming TRCACATR<\alpha>.CONTEXT for the SAC.
It might be possible for multiple matches of a Virtual context identifier to occur simultaneously. The definition of when matches occur simultaneously is IMPLEMENTATION SPECIFIC, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place.

When multiple Virtual Context Identifier Comparator matches occur simultaneously for one Virtual Context Identifier Comparator, both of the following are true:

• The Virtual Context Identifier Comparator signals a match at least once.
• The Virtual Context Identifier Comparator does not signal more matches than the number of instructions that are executed with the Virtual context identifier that the Virtual Context Identifier Comparator is programmed with.

A Virtual Context Identifier Comparator might signal a match on Speculative execution, that is, a Virtual Context Identifier Comparator might signal a match when the PE speculatively changes the Virtual context identifier.

The Virtual context identifier might change at points which are not Context synchronization events, for example when a System instruction is used to write to CONTEXTIDR_EL2. In these scenarios, the Virtual Context Identifier Comparator might compare against the old or new Virtual context identifier value for any instruction after the P0 element before the System instruction, up to the Context synchronization event after the System instruction.

The Counters that are employed by the ETE architecture are all decrement counters. The ETE architecture enables a trace unit to connect Counter outputs to resource events, so that a Counter at zero state can be used as a resource to activate a resource event. For example, a Counter at zero state might be used to assert an External Output or to make ViewInst active.

An ETE trace unit provides up to four 16-bit Counters. TRCIDR5.NUMCNTR indicates how many Counters are implemented. For each Counter, the following can be specified:

• The initial counter value. This can be programmed using TRCCNTVR<n>.
• The reload value. This can be programmed using TRCCNRDLVR<n>.
• The resource event that causes the Counter to reload with the reload value. This resource event is called RLDEVENT. In addition, if required, the Counter can be programmed so that it automatically reloads whenever it reaches zero.
• The resource event that enables the Counter to decrement. This resource event is called CNTEVENT. The Counter decrements whenever CNTEVENT is active.

The processor clock clocks the Counters in the trace unit.
While the PE is stalled, the Counters continue to count.

While the resources are in the Paused state, the Counters do not count.

When a Counter value is changed by anything other than a direct write to TRCCNTVR<n>, the trace unit considers the change to be an indirect write to TRCCNTVR<n>.VALUE.

Each Counter operates in one of the two following possible modes:
- Normal mode.
- Self-reload mode.

While the Counter is in Normal mode, when the Counter reaches zero, the Counter remains at zero until the reload resource event, RLDEVENT, occurs.

While the Counter is in Normal mode, the Counter-at-zero resource is active for the whole of the time that the Counter is at zero.

While the Counter is in Self-reload mode, when the Counter reaches zero, when the decrement resource event is next active, the trace unit reloads the Counter with the reload value.

While the Counter is in Self-reload mode, when the Counter value is zero, the decrement resource event is active and the reload resource event is not active, the Counter-at-zero resource is active for one cycle.

The following examples show various operating scenarios for a single Counter. Each Counter is programmed with a reload value of 0x3.

---

**Figure D4-21 Counter Example 1, Normal mode**
Figure D4-22 Counter Example 2, Normal mode

Figure D4-23 Counter Example 3, Self-reload mode

Figure D4-24 Counter Example 4, Self-reload mode
While the decrement resource event is inactive, the Counters do not decrement.

The trace unit prioritizes the reload resource event over the count decrement resource event.

Counter Operation in Normal mode

This table describes the counter operation in Normal mode:

<table>
<thead>
<tr>
<th>RLDEVENT</th>
<th>dec_action</th>
<th>Counter value</th>
<th>Action</th>
<th>Resource Active</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inactive</td>
<td>x</td>
<td>0</td>
<td>Stable</td>
<td>Yes</td>
<td>Resource is active while Counter is at zero and remains at zero</td>
</tr>
<tr>
<td>Inactive</td>
<td>0</td>
<td>&gt; 0</td>
<td>Stable</td>
<td>No</td>
<td>No activity</td>
</tr>
<tr>
<td>Inactive</td>
<td>1</td>
<td>&gt; 0</td>
<td>Decrement</td>
<td>No</td>
<td>Decrement when not zero</td>
</tr>
<tr>
<td>Active</td>
<td>x</td>
<td>0</td>
<td>Reload</td>
<td>Yes</td>
<td>Reload, but resource is active because Counter is at zero</td>
</tr>
<tr>
<td>Active</td>
<td>x</td>
<td>&gt; 0</td>
<td>Reload</td>
<td>No</td>
<td>Reload</td>
</tr>
</tbody>
</table>

Counter Operation in Self-reload mode

This table describes the counter operation in Self-reload mode:

<table>
<thead>
<tr>
<th>RLDEVENT</th>
<th>dec_action</th>
<th>Counter value</th>
<th>Action</th>
<th>Resource Active</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inactive</td>
<td>0</td>
<td>x</td>
<td>Stable</td>
<td>No</td>
<td>No activity, resource is not active even if the Counter is at zero</td>
</tr>
<tr>
<td>Inactive</td>
<td>1</td>
<td>0</td>
<td>Reload</td>
<td>Yes</td>
<td>Reload because dec_action is active and the Counter is at zero, resource is active only in this cycle</td>
</tr>
<tr>
<td>Inactive</td>
<td>1</td>
<td>&gt; 0</td>
<td>Decrement</td>
<td>No</td>
<td>Decrement when not zero</td>
</tr>
<tr>
<td>Active</td>
<td>x</td>
<td>x</td>
<td>Reload</td>
<td>No</td>
<td>Reload regardless of decrement action and the value of the Counter, resource is never active</td>
</tr>
</tbody>
</table>
Forming a larger Counter from two separate Counters

Some Counters can be chained together to form a larger counter, so that every time one Counter reloads, another Counter decrements.

The following example shows an operating scenario for 2 Counters chained together. Counter 0 is programmed with a reload value of \(0x2\).

![Figure D4-26 Chained Counter Example 1](image)

- **CLK**
  - Counter 0 Value: \(0x2, 0x1, 0x0, 0x2, 0x1, 0x0, 0x2, 0x1, 0x0, 0x2\)
  - Counter 1 Value: \(0x3, 0x2, 0x1, 0x0\)

- **Events**
  - Counter 0 RLDEVENT
  - Counter 0 CNTEVENT
  - Counter 1 RLDEVENT
  - Counter 1 CNTEVENT

- **Resources**
  - Counter 0 at zero
  - Counter 1 at zero

**Figure D4-26 Chained Counter Example 1**

Only certain Counters can be programmed to be chained together, as follows:
- Counter 1 can be programmed to decrement when Counter 0 reloads.
- Counter 3 can be programmed to decrement when Counter 2 reloads.

The decrement resource event for the higher Counter \(n\) is active when either of the following occurs:
- The lower Counter reloads due to one of the following:
  - The reload resource event that is selected by TRCCNTCTRL\(<n-1>.RLDEVENT\).
  - The Self-reload mechanism that is controlled by TRCCNTCTRL\(<n-1>.RLDSELF\).
- The decrement resource event that is selected by TRCCNTCTRL\(<n>.CNTEVENT\) is active.

While two Counters are chained together to form a larger counter, the larger counter appears as a 32-bit counter without any tearing of the values between the two Counters.

For example, if Counter 0 is in Self-reload mode and has a value of \(0x0000\) and a reload value of \(0xFFFF\), and Counter 1 is in Normal mode and has a value of \(0x1234\), then when a decrement resource event occurs on Counter 0, Counter 0 reloads to \(0xFFFF\). The reload of Counter 0 causes Counter 1 to decrement, resulting in a value of \(0x1233\).

Therefore the sequence on the Counters on consecutive cycles is \(0x12340000\) and \(0x1233FFFF\).

Note: The CounterAtZero resource might not be asserted at the same time that the Counter is at zero. For example, this could happen if the trace unit implementation pipelines some logic.
Pseudocode

EvalAllCounters()

// The counter-at-zero resources
array boolean CounterAtZero[0..3];

// EvalAllCounters() is called each clock cycle
EvalAllCounters()
    array boolean reload[0..3];
    reload[0] = EvalCounter(0, FALSE);
    reload[1] = EvalCounter(1, reload[0]);
    reload[2] = EvalCounter(2, FALSE);
    reload[3] = EvalCounter(3, reload[2]);

// EvalCounter() is called for each counter
EvalCounter(integer index, boolean lower_reloads)
    boolean dec_action;
    boolean resource_active;
    bits(16) next_value;
    boolean reload;
    boolean decrement;

    // A dec_action signal is constructed which indicates whether the counter
    // decrements. This is based on TRCCNTCTRL[n].CNTEVENT and, for counters
    // which support chaining, on TRCCNTCTRL[n].CNTCHAIN and on whether or not
    // the lower counter is reloading.
    dec_action = IsEventActive(TRCCNTCTRL[index].CNTEVENT) ||
        (TRCCNTCTRL[index].CNTCHAIN && lower_reloads);

    // The counter-at-zero resource is active if the counter is
    // currently at zero and is either in Normal mode or in
    // Self-Reload mode and dec_action is active and the reload
    // event is not active.
    resource_active = (TRCCNTVR[index] == 0) &&
        (!TRCCNTCTRL[index].RLDSELF ||
        (dec_action && !IsEventActive(TRCCNTCTRL[index].RLDEVENT))
    );

    // The counter reloads if the reload event is active or the self-reload
    // mechanism causes a reload.
    reload = IsEventActive(TRCCNTCTRL[index].RLDEVENT) ||
        (TRCCNTCTRL[index].RLDSELF && dec_action && TRCCNTVR[index] == 0);

    // The counter only decrements if it is non-zero and does not reload and
    // dec_action is active.
    decrement = !reload && (TRCCNTVR[index] != 0) && dec_action;

    // Determine the next value of the counter
    if reload then
        TRCCNTVR[index] = TRCCNTRLDVR[index].VALUE;
    else if decrement then
        TRCCNTVR[index] = TRCCNTVR[index] - 1;
    else
        TRCCNTVR[index] = TRCCNTVR[index];
    CounterAtZero[index] = resource_active;
    return reload;

D4.6.10   Sequencer

An ETE trace unit can contain a Sequencer state machine that has four states.
TRCIDR5.NUMSEQSTATE indicates whether the state machine is implemented.

If the Sequencer state machine is implemented, it has four states, numbered 0 to 3.

When the trace unit leaves the Disabled state, the Sequencer state machine starts in the state programmed in TRCSEQSTR.STATE.

The Sequencer can be connected to resource events, so that the Sequencer transitions from one state to another when certain resource events occur. The TRCSEQEVR<n> registers can be used to specify which resource events cause the state machine to transition.

Each register can be used to specify the following:

- A resource event that causes the state machine to progress to the next state.
- A resource event that causes the state machine to transition backwards to the previous state.

Different resource events can be chosen to cause the Sequencer to transition between different states. For example, a particular resource event might cause an F0 transition from state 0 to state 1 on one processor clock cycle, whereas a different resource event might cause an F1 transition from state 1 to state 2 on the next processor clock cycle. A third independent resource event might cause a B1 transition backwards from state 2 to state 1 on the third clock cycle.

The trace unit prioritizes forward transitions over backward transitions in the Sequencer state machine. That is, when two resource events occur that result in a forward transition conflicting with a backward transition in the same processor clock cycle, the trace unit gives priority to the forward transition and ignores the backward transition.

The Sequencer can progress through multiple states in a single processor clock cycle. For example, if the Sequencer is in state 0 and the resource events that cause an F0 and F1 transition to take place both become active in one clock cycle, then the Sequencer progresses from state 0 to state 2.

The Sequencer can be reset to state 0 from any other state. TRCSEQRSTEVR can be used to specify a resource event to reset the Sequencer.

When a resource event that causes an RST transition occurs, the Sequencer finishes the clock cycle in state 0 and does not progress to another state until the next clock cycle.

The trace unit prioritizes RST transitions over all other transitions. That is, when a resource event that causes an RST transition is active in the same clock cycle as resource events that cause other transitions, the trace unit gives priority to the RST transition and ignores all other transitions.

The following table defines all of the possible state transitions.

<table>
<thead>
<tr>
<th>From</th>
<th>To 0</th>
<th>To 1</th>
<th>To 2</th>
<th>To 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>RST</td>
<td>!F0</td>
<td>F0 &amp; !F1</td>
<td>F0 &amp; F1 &amp; !F2</td>
</tr>
<tr>
<td>1</td>
<td>RST</td>
<td>(B0 &amp; !F1 &amp; !F0)</td>
<td>(!B0</td>
<td>F0) &amp; !F1</td>
</tr>
<tr>
<td>2</td>
<td>RST</td>
<td>(B0 &amp; B1 &amp; !F2 &amp; !F1 &amp; !F0)</td>
<td>B1 &amp; (!B0</td>
<td>F0) &amp; !F1 &amp; !F2</td>
</tr>
</tbody>
</table>
If multiple resource events that cause transitions become active in one processor clock cycle, there is no guarantee that the order of these resource events becoming active is observed. For example, you might program:

- F0 to be active on an instruction Address Comparator at address 0x1000.
- F1 to be active on an instruction Address Comparator at address 0x1004.

If the instruction at 0x1000 and the instruction at 0x1004 are executed in the same processor clock cycle, then the transition from state 0 to state 2 occurs regardless of the program order of the two instructions.

When the Sequencer state is changed by anything other than a direct write to TRCSEQSTR, the trace unit considers the change to be an indirect write to TRCSEQSTR.STATE.

The ETE architecture provides each Sequencer state as a resource, so that states can be used to trigger other resource events in the trace unit.

When the Sequencer progresses through multiple states in a single processor clock cycle, for each state that it passes through, the resource state that the Sequencer triggers is active for that cycle.

For example, if the Sequencer is in state 0, and in one processor clock cycle it moves to state 3, then the resource events that state 1 and state 2 are connected to must be active for that clock cycle. The same rule applies if the Sequencer is transitioning backwards, so that if it is in state 3, and in one processor clock cycle B2 and B1 cause it move to state 1, then the resource event that state 2 is connected to must be active for that clock cycle.

The exception to this is when an RST transition causes the Sequencer to return to state 0. For example, if the Sequencer is in state 3, and in one processor clock cycle it moves to state 0, then the resource events that state 2 and stage 1 are connected to must not become active.
Pseudocode

_EvalSequencer()

// The sequencer state resources

D4.6.11 Single-shot Comparator Controls

IQSKXC
If a trace unit is exposed to speculative execution or execution in Transactional state, when Address Comparators
are used to activate resource events in the trace unit, then those resource events might be activated when speculative
execution occurs:

- A Single Address Comparator might signal a match on speculative execution or within a transaction.
- An Address Range Comparator might signal a match on speculative execution or within a transaction.

For example, this means that if an Address Comparator is used to activate a Counter or assert an External Output,
then that Counter might decrement, or that External Output might become asserted, as a result of speculative
execution. The Single-shot Comparator Controls for Address Comparators make it possible for resource events in
the trace unit to be activated based only on non-speculative execution, that is, only on architectural execution.

A trace unit can provide up to eight Single-shot Comparator Controls. Each Single-shot Comparator Control can be
used with one or more Address Comparators.

ITLFLF
Single-shot Comparator Controls can be used as a trace unit resource, to activate trace unit resource events. For
example, a Single-shot Comparator Control can be selected to:

- Enable or reload a trace unit Counter.
- Initiate a transition in the trace unit Sequencer state machine.
- Assert an External Output.

A Single-shot Comparator Control can therefore, if programmed to assert an External Output, be used to indicate to
a trace analyzer that a particular instruction has been resolved for execution. This means that a trace analyzer can
start or stop trace capture that is based on the architectural execution of that instruction.

IRBMXW
If a trace unit contains one or more Address Comparators, Arm recommends that at least one Single-shot
Comparator Control is implemented.

IVNBPG
A Single-shot Comparator Control works in the following way:

1. One or more Address Comparators are selected by using the TRCSSCCR<n> for the Single-shot Comparator
   Control. The selected Address Comparators can be all Single Address Comparators, all Address Range
   Comparators, or a combination of both.

2. When one of the selected Address Comparators matches, then when the instruction is confirmed to have
   architecturally executed, the Single-shot Comparator Control fires.

When a selected Address Comparator matches, but the instruction is confirmed to have not architecturally executed,
the Single-shot Comparator Control does not fire.

RXVVYX
When an instruction which matches an Address Comparator is confirmed to have architecturally executed, and the
Address Comparator is selected by TRCSSCCR<n> and TRCSSCSR<n>.STATUS is 0 or TRCSSCCR<n>.RST is
1, the Single-shot Comparator Control <n> fires.

RXFJGB
When a TSB CSYNC instruction is executed while a Single-shot Comparator Control is programmed to fire due to the
TSB CSYNC instruction, only when the related Trace synchronization event has completed, the Single-shot
Comparator fires.

RSWNFV
When a Single-shot Comparator Control fires, the trace unit considers this an indirect write to set
TRCSSCSR<n>.STATUS to 1.

RGBDCK
While the resources are in the Paused state, when the conditions for a Single-shot Comparator Control to fire are
met:

- If TRCSSCCR<n>.RST is 1 or TRCSSCSR<n>.STATUS is 0 then TRCSSCSR<n>.PENDING is indirectly
  written to 1.
- If TRCSSCCR<n>.RST is 0 and TRCSSCSR<n>.STATUS is 1 then TRCSSCSR<n>.PENDING is either
  indirectly written to 1 or is unchanged.
When one of the Address Comparators selected for a Single-shot Comparator Control matches, when the instruction that it matches on is in a Transaction which fails or is canceled, the Single-shot Comparator Control does not fire.

When the trace unit becomes disabled and an Address Comparator selected by a Single-shot Comparator Control has matched on an instruction that is still speculative, the Single-shot Comparator Control does not fire.

While the PE is executing in Transactional state, when the trace unit becomes disabled and an Address Comparator selected by a Single-shot Comparator Control has matched on an instruction in Transactional state, the Single-shot Comparator Control does not fire.

When tracing becomes prohibited and an Address Comparator selected by a Single-shot Comparator Control has matched on an instruction that is still speculative, the Single-shot Comparator Control waits until the instruction speculation is resolved and fires if the instruction is architecturally executed.

While the PE is executing in Transactional state, when tracing becomes prohibited and an Address Comparator selected by a Single-shot Comparator Control has matched on an instruction in Transactional state, the Single-shot Comparator Control does not fire.

When tracing becomes prohibited and an Address Comparator selected by a Single-shot Comparator Control has matched on an instruction that is still speculative, the Single-shot Comparator Control waits until the instruction speculation is resolved and fires if the instruction is architecturally executed.

While a Single-shot Comparator Control is used for instruction address comparisons, when the conditions for the Single-shot Comparator Control to fire are met, the Single-shot Comparator Control fires, regardless of whether either of the following are true:
- The instruction fails its condition code check.
- The instruction is a failed store-exclusive operation.

When a Single-shot Comparator Control is used to activate a resource event, the resource event might not become activated until some time after the trace unit has traced the instruction. This is because although the trace unit traces the instruction it is executed, the PE might not confirm whether the instruction was architecturally executed or canceled because of mis-speculation until some time later, and therefore the Single-shot Comparator Control might not fire until some time later.

**Single-shot Comparator Control modes**

Each Single-shot Comparator Control operates in one of the following modes:
- Single-shot mode: The Single-shot Comparator Control only fires once. That is, after it has fired, it never fires again.
- Multi-shot mode: The Single-shot Comparator Control resets after each time it fires. That is, it can fire again when a selected Address Comparator next signals an address match for an instruction is architecturally executed.

TRCSSCCR<α>.RST selects the mode.

While a Single-shot Comparator Control is in multi-shot mode, when the Single-shot Comparator Control fires, it fires for a maximum of one processor clock cycle.

While a Single-shot Comparator Control is in multi-shot mode, when multiple of the comparators selected for the Single-shot Comparator Control match in close succession, only the first match is guaranteed to cause the Single-shot Comparator Control to fire.

Examples of multiple comparator matches in close succession include:
- More than one of the Address Comparators that are selected signal an address match simultaneously.
- One Address Comparator matches multiple times while a first match is still waiting to be resolved.
Operation while in Paused state

The resolution of a speculative instruction might occur after the PE has entered a Trace Prohibited region and the resources have entered the Paused state. If the conditions for the Single-shot Comparator Control to fire are met while the resources are in the Paused state, then the Single-shot Comparator Control resource event is delayed to ensure that the Single-shot Comparator Control resource event is seen.

While the resources are in the Paused state, the Single-shot Comparator Controls do not fire.

When the resources enter the Running state while TRCSSCSR<n>.PENDING is 1, the following occur:

- If TRCSSCCR<n>.RST is 1 or TRCSSCSR<n>.STATUS is 0, the Single-shot Comparator Control fires.
- TRCSSCSR<n>.PENDING is indirectly written to 0.

D4.6.12 External Outputs

The ETE architecture supports between one and four External Outputs. The number of outputs that a trace unit has is IMPLEMENTATION DEFINED, but at least one output is always implemented.

External Outputs are used to indicate ETEEvents to a trace analyzer. ETEEvents are controlled by resources events. For example, an instruction Address Comparator can be used to drive one of the resource events.

If an External Output is programmed to be asserted based on program execution, such as an Address Comparator, the External Output might not be asserted at the same time as any trace generated by that program execution is output by the trace unit.

Typically, the generated trace might be buffered in a trace unit which means that the External Output would be asserted before the trace is output.

To program an External Output, use TRCEVENTCTL0R to select a resource.

The TRCIDR0.NUMEVENT field shows how many ETEEvents are supported for the particular implementation.

The External Outputs are connected to the CTI for the PE.

In a PE where the Trace Unit reset is independent of the PE Warm reset and the CTI reset is independent of the PE Warm reset, transmission of External Outputs to the CTI is unaffected by a PE Warm reset.

Operation while in Paused state

While the resources are in the Paused state an ETEEvent might occur, but any associated trace packets might not be generated. TRCRSR.EVENT provides a mechanism for recording this occurrence so that the trace unit state can be saved and restored.

While the resources are in the Paused state, the ETEEvent selector retains that one or more ETEEvents have been generated but not traced.

When an ETEEvent has been generated and the associated External Output has been asserted, any associated Event packets are generated.

When an ETEEvent has been generated but the associated External Output has not been asserted, any associated Event packets are not generated.

When an ETEEvent occurs while the resources are in the Paused state and the Event packet is not output, the trace unit sets the associated TRCRSR.EVENT[n] to 1.

When an ETEEvent occurs while the resources are in the Paused state, this is considered an indirect write to TRCRSR.

When the trace unit enters the Running state while TRCRSR.EVENT[n] is 1, the associated ETEEvent resource is active for a single PE clock cycle, and the trace unit clears TRCRSR.EVENT[n] to 0 and considers the action an indirect write to TRCRSR.
When the trace unit enters the Running state while TRCRSR.EVENT[n] is 1, the resource event selected by TRCEVENTCTL0R.EVENT<n> might also be active on the same PE clock cycle. If this happens, the associated ETEEvent resource is active for the single PE clock cycle and might not generate 2 separate ETEEvents for these 2 causes of the ETEEvent.

### D4.6.13 External inputs

**ITPPSC**

The trace unit uses the PMU events as External Inputs.

**RMTGBK**

If a PMU event number that is selected is not implemented, then the External Input resource event is inactive.

**RYCNCR**

Unless otherwise specified by the PMU event, the following PMU events are selectable by the trace unit:

- All PMU events required by the Performance Monitors Extension.
- If FEAT_PMUv3 is implemented, all Common architectural and microarchitectural events implemented by the Performance Monitors Extension.

Note: This includes Common events defined by other extensions, such as SVE and SPE.

**IXJBHV**

Additional ASIC-specific events can be selected by using a number in the IMPLEMENTATION DEFINED region.

**IVWHTZ**

There is no requirement that all IMPLEMENTATION DEFINED events are visible by the trace unit, PMU counters, and the PMUEVENT bus.

**RPHDQT**

For ETE, export of PMU events to the trace unit is not affected by PMCR.X or PMCR_EL0.X.

**RBFWZB**

When SelfHostedTraceEnabled() == TRUE and tracing is prohibited, only the PMU events defined by rules VBCBZ and KRSMY are exported to the trace unit.

**RWSXTC**

When SelfHostedTraceEnabled() == FALSE and the PE is in Secure state and counting in Secure state is prohibited, only the PMU events defined by rules VBCBZ and KRSMY are exported to the trace unit.

**RVCBZ**

The following PMU events are always exported to the trace unit:

- CTI_TRIGOUT4.
- CTI_TRIGOUT5.
- CTI_TRIGOUT6.
- CTI_TRIGOUT7.
- PMU_OVFS.
- TRB_WRAP.
- TRB_TRIG.

**RQPDKH**

When multiple occurrences of the same PMU event occur during the same cycle, the trace unit only observes a single occurrence of the PMU event.

**IMHHNV**

The operation of the PMU events and the generation of trace within the trace unit are not tightly coupled, and there is no guarantee that enabling ViewInst due to a PMU event will cause the instruction that caused the PMU event to be traced.

**RXGMPN**

When the PMU event SW_INCR is selected as an External Input and PMSWINC_EL0 is written from EL2 or EL3, the External Input is asserted if any bit [n] written has the value 1 and the relevant PMU counter <n> is implemented.

**R6XPZK**

When the PMU event SW_INCR is selected as an External Input and PMSWINC_EL0 is written from EL1 or EL0, the External Input is asserted if any bit [n] written has the value 1 and the relevant PMU counter <n> is implemented and any of the following are true:

- EL2 is implemented and enabled in the current Security state and <n> is less than MDCR_EL2.HPMN.
- EL2 is implemented and disabled in the current Security state.
- EL2 is not implemented.
In a PE where the trace unit reset is independent of the PE Warm reset and the CTI reset is independent of the PE Warm reset, transmission of the CTI_TRIGOUTn events from the CTI to the trace unit is unaffected by a PE Warm reset.

### Operation while in Paused state

The External Input Selectors are guaranteed to be active while in the Paused state. This is so that while the resources are Paused any cross trigger event is not lost but will occur when the resources resume running.

TRCRSR.EXTIN provides a mechanism to capture the sticky state of the External Input Selectors while in the Paused state so that the ETE state can be saved and restored.

When one or more selected External Inputs have been asserted, while the resources are in the Paused state, the trace unit retains the knowledge that one or more selected External Inputs have been asserted.

While the resources are in the Pausing or Paused states and the trace unit is not disabled and is not in the low-power state, when an External Input Selector n detects the selected External Input is asserted, the trace unit performs an indirect write to set TRCRSR.EXTIN[n] to 1.

When the resources enter the Running state while TRCRSR.EXTIN[n] is 1, the External Input Selector resource is active for a single PE clock cycle, and the trace unit clears TRCRSR.EXTIN[n] and considers the action an indirect write to TRCRSR.

### Operation while in low-power state

While the trace unit is in the low-power state, the External Input Selectors are inactive.

### D4.6.14 PE Comparator Inputs

The ETE architecture provides up to eight PE Comparator Inputs, that is, inputs that can be driven from comparators within the PE. For example, a PE might contain IMPLEMENTATION DEFINED comparators.

The number of PE Comparator Inputs is indicated by TRCIDR4.NUMPC.

While the PE is executing in a Trace Prohibited region, the PE Comparator Inputs are inactive.

The PE Comparator Inputs are only used in IMPLEMENTATION SPECIFIC code.

Each PE Comparator Input can be used in any of the following ways:

- To control the ViewInst start/stop function.
- To control the Single-shot Comparator Controls.
- As an independent resource.

The behavior of the PE Comparator Inputs on the resources and the filtering of the trace unit is IMPLEMENTATION DEFINED.
Chapter D5
ETE Protocol Descriptions

This chapter describes the ETE packets. It contains the following sections:

- *About the ETE protocol* on page D5-4874.
- *Summary list of ETE packets* on page D5-4877.
- *Alphabetical list of ETE packets* on page D5-4880.
D5.1  About the ETE protocol

An ETE trace unit generates a trace byte stream. The protocol is a byte-based packet protocol, which means that the trace byte stream is constructed of multiple packets, where each packet contains one or more bytes of data.

A packet consists of a single header byte, followed by zero or more payload bytes.

D5.1.1  Encoding schemes

Field encodings

Bit Replacement:

The packet outputs bits which update a piece of state. Bits output by the packet replace only those bits in the piece of state. Bits not output by the packet remain unchanged in the piece of state.

Unsigned LE128n:

The data is encoded as an unsigned number. The least significant bits of the number are output in the least significant bits of the packet. Bits not output by the packet are 0.

POD:

The encoding is specific to the packet.

Unary code:

The sequence for this variable is one of the following:

- A 0.
- A number of 1s followed by a 0.
- All 1s for the size of the variable, as defined by the packet.

For example, the permitted values for a 4-bit variable are:

- 0b0.
- 0b10.
- 0b110.
- 0b1110.
- 0b1111.

Instruction set encoding

For any virtual instruction address, the instruction set is output as a combination of the following two pieces of information:

- The SF bit encoded in Context packets.
- The sub_isa encoded by the type of the following groups of packets:
  - Target Address packets.
  - Exception packets.
  - Q packets.
  - Source Address packets.

The sub_isa indicates either:

- ISO.
- IS1.
Table D5-1 indicates how the combination of the SF bit and sub_isa indicate the instruction set.

<table>
<thead>
<tr>
<th>SF Bit</th>
<th>sub_isa</th>
<th>Instruction Set</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>IS0</td>
<td>AArch32 A32</td>
</tr>
<tr>
<td>0b0</td>
<td>IS1</td>
<td>AArch32 T32</td>
</tr>
<tr>
<td>0b1</td>
<td>IS0</td>
<td>AArch64 A64</td>
</tr>
</tbody>
</table>

The sub_isa also indicates the alignment of the virtual instruction addresses. Table D5-2 indicates the alignment of each sub_isa.

<table>
<thead>
<tr>
<th>sub_isa</th>
<th>Alignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS0</td>
<td>Word-Aligned</td>
</tr>
<tr>
<td>IS1</td>
<td>Halfword-Aligned</td>
</tr>
</tbody>
</table>

The following packets encode the sub_isa:

- Exception Short Address IS0 Packet.
- Exception Short Address IS1 Packet.
- Exception 32-bit Address IS0 Packet.
- Exception 32-bit Address IS1 Packet.
- Exception 64-bit Address IS0 Packet.
- Exception 64-bit Address IS1 Packet.
- Exception 32-bit Address IS0 with Context Packet.
- Exception 32-bit Address IS1 with Context Packet.
- Exception 64-bit Address IS0 with Context Packet.
- Exception 64-bit Address IS1 with Context Packet.
- Target Address Short IS0 Packet.
- Target Address Short IS1 Packet.
- Target Address 32-bit IS0 Packet.
- Target Address 32-bit IS1 Packet.
- Target Address 64-bit IS0 Packet.
- Target Address 64-bit IS1 Packet.
- Target Address with Context 32-bit IS0 Packet.
- Target Address with Context 32-bit IS1 Packet.
- Target Address with Context 64-bit IS0 Packet.
- Target Address with Context 64-bit IS1 Packet.
- Source Address Short IS0 Packet.
- Source Address Short IS1 Packet.
- Source Address 32-bit IS0 Packet.
- Source Address 32-bit IS1 Packet.
- Source Address 64-bit IS0 Packet.
- Source Address 64-bit IS1 Packet.
• Q short address IS0 Packet.
• Q short address IS1 Packet.
• Q 32-bit address IS0 Packet.
• Q 32-bit address IS1 Packet.
D5.2 Summary list of ETE packets

Table D5-3 lists the ETE packets ordered by the header byte.

<table>
<thead>

</tbody>
</table>
D5.3 Alphabetical list of ETE packets

This section lists each ETE packet and their description.
### D5.3.1 Alignment Synchronization Packet

**Purpose**

Identifies a packet boundary.

**Configurations**

All.

This packet forms a unique bit and byte pattern. Searching for this pattern allows the trace analyzer to identify packet boundaries.

**Packet Layout**

![Alignment Synchronization Packet](image)

**Additional information**

For more information about the decoding of this packet see `Parse_ExtensionPacket()` on page K4-11620.

For more information about the generation of this packet see `Trace protocol synchronization` on page D4-4776.

R\text{EXZZJ}  

Any byte that follows this unique sequence of bits is the header byte of a new packet.

R\text{VRKLP}  

This packet must be output before the first Trace Info packet.
### D5.3.2 Discard Packet

**Purpose**

Indicates a *Discard element*.

**Configurations**

All.

Indicates a *Discard element*.

**Packet Layout**

![Discard Packet](image)

**Element sequence**

This packet encodes the following sequence:

1. *Discard element.*

**Additional information**

For more information about the decoding of this packet see *DiscardPacket()* on page K4-11620.

For more information about the generation of this packet see *Trace protocol synchronization* on page D4-4776.

This packet is used to discard any speculative trace that the trace analyzer might still be holding onto.
D5.3.3 Overflow Packet

Purpose

Indicates that a trace unit buffer overflow has occurred.

Configurations

All.

Indicates that a trace unit buffer overflow has occurred and data might have been lost.

Packet Layout

```

```

Figure D5-3 Overflow Packet

Element sequence

This packet encodes the following sequence:

1. Overflow element.
2. Discard element.

Additional information

For more information about the decoding of this packet see OverflowPacket() on page K4-11620.
D5.3.4  Trace Info Packet

Purpose

Resets trace compression to a known architectural state.

Configurations

All.

The trace info packet resets the trace compression to a known state. Any fields which are not output are treated as if the value is zero.

Figure D5-11 Trace Info Packet (8)

Field descriptions

**C0**

Continuation Bit.

The encoding for this field is Unary code.

---

0b0  Last byte in this section.

0b1  At least one more byte follows in this section.

**C1**

Continuation Bit.
The encoding for this field is Unary code.

<table>
<thead>
<tr>
<th>0b0</th>
<th>Last byte in this section.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>At least one more byte follows in this section.</td>
</tr>
</tbody>
</table>

**CC**

Cycle count enable indicator.
When this field is not output, it is treated as if it is zero.
The encoding for this field is POD.

<table>
<thead>
<tr>
<th>0b0</th>
<th>Cycle counting is not enabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>Cycle counting is enabled.</td>
</tr>
</tbody>
</table>

**CYCT**

The cycle count threshold.
When this field is not output, it is treated as if it is zero.
The encoding for this field is unsigned LE128n.

**SPEC**

The number of uncommitted P0 elements in the trace.
When this field is not output, it is treated as if it is zero.
The encoding for this field is unsigned LE128n.

**T**

Transactional state indicator.
When this field is not output, it is treated as if it is zero.
The encoding for this field is POD.

<table>
<thead>
<tr>
<th>0b0</th>
<th>The PE is not currently executing in Transactional state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>The PE is currently executing in Transactional state.</td>
</tr>
</tbody>
</table>

**Element sequence**

This packet encodes the following sequence:

1. *Trace Info element.*

**Additional information**

For more information about the decoding of this packet see *TraceInfoPacket()* on page K4-11621.
D5.3.5 Trace On Packet

Purpose

Indicates that there has been a discontinuity in the trace element stream.

Configurations

All.

A Trace On packet indicates to a trace analyzer that the trace unit has generated a Trace On element.

Packet Layout

```
  7 6 5 4 3 2 1 0
0 0 0 0 0 1 0 0
```

Figure D5-12 Trace On Packet

Element sequence

This packet encodes the following sequence:

1. Trace On element.

Additional information

For more information about the decoding of this packet see TraceOnPacket() on page K4-11622.
D5.3.6 Timestamp Packet

**Purpose**
Indicates a Timestamp element.

**Configurations**
TRCIDR0.TSSIZE != 0b00000.

**Packet Layout - Variant 1**

```
0 0 0 0 0 0 1 0
C0  TS[6:0]

<tr>
<th>0b0</th>
<th>Last byte in this section.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1</td>
<td>At least one more byte follows in this section.</td>
</tr>
</tbody>
</table>

COUNT

The number of PE clock cycles between the most recent Cycle Count element and the element related to the Timestamp. When the COUNT field is not present, the cycle count value is UNKNOWN.

The encoding for this field is unsigned LE128n.

TS

Timestamp Value.

The encoding for this field is Bit replacement.

Element sequence

This packet encodes the following sequence:

1. Timestamp element.

Additional information

For more information about the decoding of this packet see TimestampPacket() on page K4-11636.
D5.3.7 Timestamp Marker Packet

Purpose

Indicates a Timestamp Marker element.

Configurations

TRCIDR0.TSSIZE \neq 0b0000 and TRCIDR0.TSMARK == 0b1

Packet Layout

Figure D5-15 Timestamp Marker Packet
