<td>CNTFRQ, CNTPCT</td>
</tr>
<tr>
<td></td>
<td>PL0VCTEN</td>
<td>CNTFRQ, CNTVCT</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-8944.

**Traps to Undefined mode of EL0 accesses to Performance Monitors registers**

PMUSERENR. {ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to Undefined mode. For each of these controls:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

For those Performance Monitors registers that more than one PMUSERENR. {ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.
The accesses that these trap controls trap might be reads, writes, or both.

--- Note ---

- The architecture does not provide traps on Performance Monitors register accesses through the memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, the Performance Monitors registers, including PMUSERENR, are reserved.

Table G1-31 on page G1-9009 shows the registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Access type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>ER</td>
<td>PMXEVCNTR, PMEVCNTR&lt;\text{n}&gt;</td>
<td>R</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PMSELR</td>
<td>RW</td>
</tr>
<tr>
<td>CR</td>
<td>PMCCCNTR, accessed using an MRC</td>
<td>R</td>
<td></td>
</tr>
<tr>
<td>CR</td>
<td>PMCCCNTR, accessed using an MRRC</td>
<td>R</td>
<td></td>
</tr>
<tr>
<td>SW</td>
<td>PMSWINC</td>
<td></td>
<td>W</td>
</tr>
<tr>
<td>EN</td>
<td>PMCINTENSET, PMCINTENCLR, PMCR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCEID2, PMCEID3, PMCCNTR, PMXEVTYPE, PMXEVCNTR, PMOSSET, PMEVCNTR&lt;\text{n}&gt;, PMEVTYPER&lt;\text{n}&gt;, PMCCFILTER</td>
<td>RW&lt;sup&gt;a&lt;/sup&gt;</td>
<td></td>
</tr>
</tbody>
</table>

<sup>a</sup> The EL0 access is trapped only if the corresponding EL1 accesses is permitted. For example, the PMSWINC register is WO at EL1, and therefore, when the value of EN is 0:
- Write accesses to the register from EL0 are trapped.
- Read accesses to the register from EL0 are UNDEFINED, because read accesses to the register from EL1 are UNDEFINED.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-8944.

**Traps to Undefined mode of EL0 accesses to Activity Monitors registers**

AMUSERENR.EN traps EL0 accesses to the Activity Monitors System registers other than AMUSERENR to Undefined mode:

1. This control has no effect on EL0 accesses to the corresponding registers.
2. EL0 accesses to the corresponding registers are trapped to Undefined mode.

--- Note ---

- The architecture does not provide traps on Activity Monitors register accesses through the memory-mapped external interface.
- If the Activity Monitors Extension is not implemented, the Activity Monitors registers, including AMUSERENR, are reserved.
Table G1-32 on page G1-9010 shows the registers for which EL0 accesses are trapped.

**Table G1-32 Register accesses trapped to Undefined mode when disabled from EL0**

<table>
<thead>
<tr>
<th>Traps from</th>

</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>AMCFGFR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPE0&lt;n&gt;, AMEVTYPE1&lt;n&gt;, AMEVCNTR0&lt;n&gt; or AMEVCNTR1&lt;n&gt;.</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-8944.

### G1.21.3 EL2 configurable controls

These controls are ignored in Secure state when using AArch32.

Table G1-33 on page G1-9010 shows the System registers that contain these controls.

</tbody>
</table>

Also see the following:

- Register access instructions on page G1-9002.
- Instructions that fail their Condition code check.
- Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-9013.

### Instructions that fail their Condition code check

For **UNDEFINED** instructions that fail their Condition code check, see Conditional execution of undefined instructions on page G1-8966.

For an instruction that has a Hyp trap set that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Hyp Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
  - Always generate a Hyp Trap exception.
  - Always treat the instruction as a NOP.

- The IMPLEMENTATION DEFINED part of the requirements of Conditional execution of undefined instructions on page G1-8966 must be consistent with the handling of Hyp traps on instructions that fail their Condition code check. Table G1-36 on page G1-9012 shows this:

### Table G1-36 Consistent handling of instructions that fail their Condition code check

<table>
<thead>
<tr>
<th>Behavior of conditional <strong>UNDEFINED</strong> instruction(^a)</th>
<th>Hyp trap on instruction that fails its Condition code check(^b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Executes as a NOP</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Hyp Trap exception</td>
</tr>
</tbody>
</table>

\(^a\) As defined in Conditional execution of undefined instructions on page G1-8966. In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.

\(^b\) For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

---

**Note**

Hyp traps on WFE and WFI instructions generate Hyp Trap exceptions only if the instruction passes its Condition code check. See Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020.
Trapping to EL2 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Hyp Trap exception.

Note

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode must not generate a Hyp Trap exception.

Disabling or enabling EL2 use of AArch32 optional functionality

Table G1-37 on page G1-9013 shows the optional AArch32 functionality that might have disable controls in the HSCTLR:

- The SED control is implemented if the implementation supports mixed-endian operation at EL2.
- Whether the ITD control is implemented is IMPLEMENTATION DEFINED.
- Whether the CP15BEN control is implemented is IMPLEMENTATION DEFINED.
- If a control is not implemented, then the associated functionality cannot be disabled.

These HSCTLR controls apply only to execution at EL2 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL2, meaning it is undefined in Hyp mode.

Table G1-37 EL2 controls for disabling and enabling EL2 use of AArch32 optional functionality

<table>
<thead>
<tr>
<th>Optional AArch32 functionality</th>
<th>Instruction enable or disable in the HSCTLR</th>
<th>Disabled instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED&lt;sup&gt;a&lt;/sup&gt;</td>
<td>SETEND instructions</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD&lt;sup&gt;b&lt;/sup&gt;</td>
<td>See the HSCTLR.IT description</td>
</tr>
<tr>
<td>Accesses to the System register (coproc==0b1111) DMB, DSB, and ISB barrier operations</td>
<td>CP15BEN&lt;sup&gt;c&lt;/sup&gt;</td>
<td>MCR accesses to the CP15DMB, CP15DSB, and CP15ISB</td>
</tr>
</tbody>
</table>

Note

- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

Note

- These controls have no effect on instructions executed in any mode other than Hyp mode. The SCTLR provides similar controls that apply to execution in other modes.
- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.
Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

HCR.{TRVM, TVM} trap Non-secure EL1 accesses to the virtual memory control registers to Hyp mode:

**HCR.TRVM, for read accesses:**

1  Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode.
0  This control has no effect on Non-secure EL1 reads of the virtual memory control registers.

**HCR.TVM, for write access:**

1  Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode.
0  This control has no effect on Non-secure EL1 writes to the virtual memory control registers.

Table G1-38 on page G1-9014 shows the registers for which:

- Reads are trapped to Hyp mode when HCR.TRVM is 1.
- Writes are trapped to Hyp mode when HCR.TVM is 1.

The table also shows how the exceptions are reported in HSR.

Table G1-38 Register read and write accesses trapped when HCR.{TRVM, TVM} are 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR</td>

</tr>
<tr>
<td></td>
<td></td>
<td>Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>

--- Note ---

These registers are not accessible at EL0.

Disabling Non-secure state execution of HVC instructions

HCR.HCD disables Non-secure state execution of HVC instructions:

1  HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
0  HVC instruction execution is enabled at EL2 and Non-secure EL1.

--- Note ---

HVC instructions are always UNDEFINED at EL0.

HCR.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0. See the HCR register description. Table G1-39 on page G1-9014 shows how the exceptions are reported in HSR.

Table G1-39 Instruction that causes exceptions when HCR.HCD is 1

<table>
<thead>
<tr>

<td>HVC</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>
Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

The System instruction encoding space includes TLB maintenance instructions.

HCR.TTLB traps Non-secure EL1 execution of TLB maintenance instructions to Hyp mode:

1  Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to Hyp mode.
0  This control has no effect on the Non-secure EL1 execution of TLBI instructions.

Table G1-40 on page G1-9015 shows the instructions that are trapped, and how the exceptions are reported in HSR.

### Table G1-40 Instructions trapped to Hyp mode when HCR.TTLB is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TLBIALLIS, TLBIMVAIS, TLBISIDIS, TLBIMVAAIS, TLBIVALIS, TLBIVALIS, ITLBIALL, ITLBMVA, ITLBMVAS, DTLBIALL, DTLBMVA, DTLBIASID, TLBLALL, TLBLMA, TLBLMVA, TLBLISID, TLIBMVA, TLIBMVAIS, TLIBMVAL, TLIBMVAAL.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

--- Note ---

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see The scope of TLB maintenance instructions on page G5-9230.

Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

HCR.{TSW, TPC, TPU} trap cache maintenance instructions to Hyp mode:

0  The control has no effect on the execution of cache maintenance instructions.
1  Any attempt to execute one of the cache maintenance instructions shown in Table G1-42 on page G1-9015 at Non-secure EL1 is trapped to Hyp mode.

Table G1-41 Controls for trapping cache maintenance instructions to Hyp mode

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Trapped instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TSW</td>

<td></td>
</tr>
<tr>
<td></td>
<td>TPU</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAC</td>
<td></td>
</tr>
</tbody>
</table>
Note
These instructions are always UNDEFINED at EL0.

For more information about these instructions, see Cache maintenance system instructions on page K17-11905.

Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

HCR.TAC traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode:

1   Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to Hyp mode.
0   This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.

Table G1-43 on page G1-9016 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR:

Table G1-43 Register accesses trapped to Hyp mode when HCR.TAC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>ACTLR and, if implemented, ACTLR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111) access, using EC value 0x03</td>
</tr>
</tbody>
</table>

Note
The ACTLR and ACTLR2 are not accessible at EL0.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR.TIDCP traps the execution of System register access instructions that access these registers, as follows:

1   At Non-secure EL1, any attempt to execute an MCR or MRC instruction with a reserved register encoding shown in Table G1-44 on page G1-9017 is trapped to Hyp mode.
    At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute MCR or MRC instructions with reserved register encodings are:
    • Trapped to Hyp mode.
    • UNDEFINED, and the PE takes the Undefined Instruction exception to Non-secure Undefined mode.
    Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.
0   This control has no effect on Non-secure EL0 and EL1 System register access instructions with reserved register encodings shown in Table G1-44 on page G1-9017.

Note
This means that a Hyp Trap exception taken from Non-secure EL1 to Hyp mode, generated because of a configuration setting in HCR.TIDCP is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because the register is never accessible at EL1. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-8933 shows, this is an exception to the general exception prioritization rules that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2.
Table G1-44 on page G1-9017 shows the register encodings for which accesses are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-44 Encodings trapped to Hyp mode when HCR.TIDCP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register encodings</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>An access to any of the following encodings:</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>• CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</td>
<td></td>
</tr>
</tbody>
</table>

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

Arm expects the trapping of Non-secure User mode accesses to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. Arm strongly recommends that unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

HCR.TSC traps Non-secure EL1 execution of SMC instructions to Hyp mode:

1  Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

0  This control has no effect on Non-secure EL1 execution of SMC instructions.

Table G1-45 on page G1-9017 shows how the exceptions are reported in HSR:

Table G1-45 SMC Instruction trapped to Hyp mode when HCR.TSC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>SMC on page F5-7900</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

The architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

Note

• This trap is implemented only if the implementation includes EL3.
• SMC instructions are always UNDEFINED at EL0.
• HCR.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap and SMC exceptions have different preferred return addresses.

For more information about SMC instructions, see SMC on page F5-7900.
Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers

Other than the MIDR, MPIDR, and PMCR.N, the ID registers are divided into groups, with a trap control in the HCR for each group.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Register group</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TID0</td>
<td>ID group 0, Primary device identification registers on page G1-9019</td>
</tr>
<tr>
<td>HCR.TID1</td>
<td>ID group 1, Implementation identification registry on page G1-9019</td>
</tr>
<tr>
<td>HCR.TID2</td>
<td>ID group 2, Cache identification registers on page G1-9019</td>
</tr>
<tr>
<td>HCR.TID3</td>
<td>ID group 3, Detailed feature identification registers on page G1-9020</td>
</tr>
</tbody>
</table>

These controls trap register accesses from Non-secure EL0 or EL1 to Hyp mode, as follows:

**HCR.TID0**
- 0: This control has no effect on Non-secure EL1 reads of the ID group 0 registers.
- 1: Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to Hyp mode.

**HCR.TID1**
- 0: This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
- 1: Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to Hyp mode.

**HCR.TID2**
- 0: This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.
- 1: Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the CSSELR, is trapped to Hyp mode.

**HCR.TID3**
- 0: This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
- 1: Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to Hyp mode.

For the MIDR and MPIDR, and for PMCR.N, the architecture provides read/write aliases. The original register becomes accessible only from Hyp mode and Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR</td>
<td>VPIDR</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR</td>
<td>VMPIDR</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR.N</td>
<td>HDCR.HPMN</td>
</tr>
</tbody>
</table>

Reads of the MIDR, MPIDR, or PMCR.N from Hyp mode or Secure state are unchanged by the implementation of EL2, and access the physical registers.

**Note**

- If the optional Performance Monitors Extension is not implemented, HDCR.HPMN is RES0 and PMCR is reserved.
- HDCR.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.
• **PMCR** contains other fields that identify the implementation. For more information about trapping accesses to the PMCR, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-9029.

A reset into AArch32 state sets **VPIDR** to the **MIDR** value, **VMPIDR** to the **MPIDR** value, and **HDCR.HPMN** to the **PMCR.N** value.

**ID group 0, Primary device identification registers**

These registers identify some top-level implementation choices.

Table G1-48 on page G1-9019 shows the registers that are in ID group 0 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>FPSID</td>
<td>Trapped VMRS access, for ID group traps, using EC value 0x08</td>
</tr>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>JIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

--- Note ---

The **FPSID** is not accessible at EL0.

If **HCPTR.\{TCP11, TCP10\}** traps accesses to SIMD and floating-point functionality, then for a read of **FPSID**, that trap has priority over this trap.

When the **FPSID** is accessible, a **VMSR** **FPSID**, <Rt> instruction is permitted but is ignored. The execution of this **VMSR** instruction is not trapped by the ID group 0 trap.

**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table G1-49 on page G1-9019 shows the registers that are in ID group 1 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table G1-50 on page G1-9019 shows the registers that are in ID group 2 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>CTR, CCSIDR, CLIDR, CSSELR, and, if implemented, CCSIDR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>
ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

--- Note ---

These registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See The CPUID identification scheme on page G4-4993.

Table G1-51 on page G1-9020 shows the registers that are in ID group 3 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>MVFR0, MVFR1, MVFR2.</td>
<td>Trapped VMRS access for ID group traps, using EC value 0x88</td>
</tr>
<tr>
<td></td>
<td>ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ID_MMFRO, ID_MMFRO, ID_MMFRO, ID_MMFRO.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ID_ISRAR0, ID_ISRAR1, ID_ISRAR2, ID_ISRAR3, ID_ISRAR4, ID_ISRAR5.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ID_MMFR4, ID_ISRAR6, ID_DFR1 are trapped, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether HCR.TID3 traps accesses.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>It is IMPLEMENTATION DEFINED whether HCR.TID3 traps MRC accesses to registers with coproc==0b1111 to encodings in the following range that are not already mentioned in this table CRn == c0, opc1 == 0, CRn == {c2-c7}, opc2 == {0-7}.</td>
<td></td>
</tr>
</tbody>
</table>

If HCPTR traps accesses to SIMD and floating-point functionality, then for reads of MVFR0, MVFR1, and MVFR2, that trap has priority over this trap.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions

HCR. {TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to Hyp mode:

HCR.TWE:

1  Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.

0  This control has no effect on Non-secure EL0 or EL1 execution of WFE instructions.

HCR.TWI:

1  Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.

0  This control has no effect on Non-secure EL0 or EL1 execution of WFI instructions.

Table G1-52 on page G1-9020 shows how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>WFE</td>
<td>Trapped WFE or WFI instruction, using EC value 0x01</td>
</tr>
<tr>
<td></td>
<td>WFI</td>
<td></td>
</tr>
</tbody>
</table>
The attempted execution of a conditional \texttt{WFE} or \texttt{WFI} instruction is only trapped if the instruction passes its Condition code check.

\begin{quote}
\underline{Note}
\end{quote}

Since a \texttt{WFE} or \texttt{WFI} can complete at any time, even without a \texttt{Wakeup} event, the traps on \texttt{WFE} of \texttt{WFI} are not guaranteed to be taken, even if the \texttt{WFE} or \texttt{WFI} is executed when there is no \texttt{Wakeup} event. The only guarantee is that if the instruction does not complete in finite time in the absence of a \texttt{Wakeup} event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
\begin{itemize}
  \item \textit{Wait For Event and Send Event} on page \pageref{Wait For Event and Send Event}.
  \item \textit{Wait For Interrupt} on page \pageref{Wait For Interrupt}.
\end{itemize}

\section*{Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Activity Monitors registers}

If the Activity Monitors Extension is implemented, \texttt{HCPTR.TAM} traps Non-secure EL0 and EL1 accesses to the Activity Monitors registers to Hyp mode:

\begin{itemize}
  \item \texttt{1} Non-secure EL0 and EL1 accesses to all Activity Monitors registers are trapped to Hyp mode.
  \item \texttt{0} This control has no effect on Non-secure EL0 and EL1 accesses to the Activity Monitors registers.
\end{itemize}

\begin{quote}
\underline{Note}
\end{quote}

\begin{itemize}
  \item EL2 does not provide traps on Activity Monitor register accesses through the optional memory-mapped external interface.
  \item If the Activity Monitors Extension is not implemented, \texttt{HCPTR.TAM} is \texttt{RES0}.
\end{itemize}

Table \ref{Table G1-53} on page \pageref{Table G1-53} shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

\begin{table}[h]
\centering
\caption{Register accesses trapped to Hyp mode when \texttt{HDCR.(TPM, TPMCR)} are \texttt{1}}
\begin{tabular}{|l|l|l|}

\end{tabular}
\label{Table G1-53}
\end{table}

\section*{General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers}

\texttt{HCPTR.(TCP11, TCP10)} trap Non-secure accesses to the SIMD and floating-point registers to Hyp mode:

\begin{itemize}
  \item \texttt{0b11} All Non-secure accesses to the SIMD and floating-point registers are trapped to Hyp mode. Trapped instructions generate:
    \begin{itemize}
      \item \texttt{Hyp Trap} exceptions, if the exception is taken from Non-secure EL0 or EL1.
      \item Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
    \end{itemize}
  \item \texttt{0b00} This control has no effect on Non-secure accesses to the SIMD and floating-point registers.
\end{itemize}
Note

Software must set HCPTR.TCP11 and HCPTR.TCP10 to the same value.

Table G1-54 on page G1-9022 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-54 Register accesses trapped to Hyp mode when HCPTR.{TCP11, TCP10} are both 0b11

| Traps from Non-secure state | Registers FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-8998. | Syndrome reporting in HSR Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07

---

a. VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, then HCPTR.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-8996.

Enabling access to the SIMD and floating-point registers

FPEXC.EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

• VMSR accesses to the FPEXC or FPSID.
• VMSR accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

FPEXC.EN is a PL1 control that also applies at EL2. See Enabling access to the SIMD and floating-point registers on page G1-9007.

Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

If implemented as an RW field, HCPTR.TASE can trap Non-secure execution of Advanced SIMD instructions to Hyp mode, as follows. This trap applies only when HCPTR.{TCP11, TCP10} are both 0:

1 Any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode. Trapped instructions generate:
   • Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
   • Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0 This control has no effect on Non-secure execution of Advanced SIMD instructions.

When the control is not implemented, meaning the HCPTR.TASE field is RAZ/WI, the HCPTR does not provide a trap to Hyp mode of the Non-secure execution of Advanced SIMD instructions, other than the HCPTR.{TCP11, TCP10} trap that applies to Non-secure execution of both Advanced SIMD and floating-point instructions.
Table G1-55 Instructions trapped to Hyp mode when HCPTR.TASE is set to 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>All Advanced SIMD instructions that are not also floating-point instructions.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07</td>
</tr>
</tbody>
</table>

Table G1-56 Register accesses trapped to Hyp mode when HCPTR.TCPAC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>CPACR</td>
<td>Trapped MCR or MRC access to System register with coproc==0b1111, using EC value 0x03</td>
</tr>
</tbody>
</table>

---

**Note**

- The CPACR is not accessible at EL0.
- *In Armv7 and earlier versions of the Arm architecture, one use of the CPACR is to identify what coprocessor, or conceptual coprocessor, functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism. See *Background to the System register interface* on page G1-8994 for more information about this functionality.*

---

**Traps to Hyp mode of Non-secure System register accesses to trace registers**

If implemented, the HCPTR.TTA control traps System register accesses to the trace registers from Non-secure state to Hyp mode, as follows:

1. Non-secure System register accesses to the trace registers are trapped to Hyp mode. Trapped instructions generate:
   - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
   - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
2. This control has no effect on Non-secure System register accesses to the trace registers.

If the HCPTR.TTA control is not implemented, then HCPTR.TTA is RAO/WI. See the register description for more information.

---

**Note**

- System register accesses to the trace registers use the System register (coproc==0b1110) encoding space.
The ETMv4 architecture does not permit EL0 to access the trace registers. If the architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than an HCPTR.TTA Hyp Trap exception.

EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page G1-9002.

Table G1-57 on page G1-9024 shows the registers for which accesses are trapped to Hyp mode when HCPTR.TTA is 1, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>System register accesses to all implemented</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td>trace registers</td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, then HCPTR.TTA behaves as RAO/WI, regardless of its actual value. This behavior applies, also, when the HCPTR.TTA control is not implemented.

Traps to Hyp mode of Non-secure System register accesses to trace filter control registers

If implemented, the HDCR.TTRF control traps System register accesses to the trace filter control registers from Non-secure state to Hyp mode, as follows:

1 Non-secure System register accesses at EL1 to the trace filter control registers are trapped to Hyp mode. Trapped instructions generate Hyp Trap exceptions.

0 This control has no effect on Non-secure System register accesses to the trace registers.

Table G1-58 on page G1-9024 shows the registers for which accesses are trapped to Hyp mode when HDCR.TTRF is 1, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>TRFCR</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03.</td>
</tr>
</tbody>
</table>

General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space

HSTR.\{T0-T3, T5-T13, T15\} trap Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, or MRRC instructions, to the System registers in the (coproc==0b1111) encoding space, by:

• The value of the CRn argument to the instruction, for MCR and MRC instructions.

• The value of the CRn argument to the instruction, for MCRR and MRRC instructions.

This applies for the set of CRn, or CRn, values \{c0-c3, c5-c13, c15\}. 

Table G1-57 Register accesses trapped to Hyp mode when HCPTR.TTA is 1

Table G1-58 Register accesses trapped to Hyp mode when HDCR.TTRF is 1
When an HSTR.Tn trap control is:

1  Non-secure EL1 accesses to the corresponding System registers in the (coproc == 0b1111) encoding space are trapped to Hyp mode.
   EL0 accesses to the corresponding System registers are trapped to Hyp mode if they would not be UNDEFINED if the bit was zero.

0  This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

_____ Note _____

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in HSTR.Tn, is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because a register is never accessible at Non-secure EL1. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-8933 shows, this is an exception to the general exception prioritization rules that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2. This prioritization includes any access from Non-secure EL1 to a register that is only accessible in Secure state. So, for example, an access to the SCR from Non-secure EL1:

- When the value of HSTR.T1 is 0, generates an Undefined Instruction exception.
- When the value of HSTR.T1 is 1, generates a Hyp Trap exception.

Table G1-59 on page G1-9025 shows the accesses that are trapped, and how the exceptions are reported in HSR.

Table G1-59 Accesses trapped to Hyp mode when an HSTR.Tn trap is enabled

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1 a</td>
<td>Tn</td>
<td>MCR and MRC instructions, with coproc set to 0b1111 and CRn set to n</td>
<td>Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MCRR and MRRC instructions, with coproc set to 0b1111 and CRm set to n</td>
<td>Trapped MCRR or MRRC access (coproc == 0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>

a. As described in this section, traps from EL1 apply whenever the value of HSTR.Tn is 1. Traps from EL0 apply only if the value of HSTR.Tn is 1 and the access would not be UNDEFINED if the value of HSTR.Tn was 0.

For example, when HSTR.T7 is 1, considering only accesses from Non-secure EL1:

- Any 32-bit access from a Non-secure PL1 mode using an MRC or MCR instruction with coproc set to 0b1111 and CRn set to c7, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure PL1 mode using an MRRC or MCRR instructions with coproc set to 0b1111 and CRm set to c7, is trapped to Hyp mode.

_____ Note _____

- Bits[4,14] of the HSTR are reserved, RES0. Although the Generic Timer control registers are implemented in the coproc == 0b1111 encoding space with CRn==c14 for an MRC or MCR access, EL2 does not provide a trap on accesses to the Generic Timer System registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of trapping of IMPLEMENTATION DEFINED features.
**System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0**

For a System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a HSTR.Tn control, if an access to the register from User mode is UNDEFINED when the value of the corresponding HSTR.Tn trap control is 0, then when that HSTR.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

--- Note ---

Arm expects that trapping to Hyp mode of Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize User mode operation. Arm recommends that, whenever possible, Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

---

**Traps to Hyp mode of Non-secure System register accesses to debug registers**

HDCR.(TDRA, TDOSA, TDA) trap Non-secure System register accesses to debug registers to Hyp mode, as follows:

- HDCR.(TDRA, TDA) trap Non-secure EL0 and EL1 accesses.
- HDCR.TDOSA traps Non-secure EL1 accesses.

--- Note ---

EL2 does not provide traps of debug register accesses through the optional memory-mapped external debug interface.

---

System register accesses to the debug registers can have side-effects. When a System register access is trapped to Hyp mode, no side-effects occur before the exception is taken to Hyp mode. See Register access instructions on page G1-9002.

Table G1-60 on page G1-9026 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in HSR.

**Table G1-60 Traps of Non-secure EL0 and EL1 accesses to debug registers**

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDCR.TDRA</td>
<td>Trapping Non-secure System register accesses to Debug ROM registers on page G1-9026</td>
</tr>
<tr>
<td>HDCR.TDOSA</td>
<td>Trapping Non-secure System register accesses to powerdown debug registers on page G1-9027</td>
</tr>
<tr>
<td>HDCR.TDA</td>
<td>Trapping general Non-secure System register accesses to debug registers on page G1-9027</td>
</tr>
</tbody>
</table>

--- Note ---

System register accesses to debug registers use the (coproc==0b1110) encoding space.

---

**Trapping Non-secure System register accesses to Debug ROM registers**

HDCR.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode:

1 Non-secure EL0 or EL1 System register accesses to the Debug ROM registers are trapped to Hyp mode.
This control has no effect on Non-secure EL0 and EL1 System register accesses to the Debug ROM registers.

Table G1-61 on page G1-9027 shows the register accesses that are trapped, and how the exceptions are reported in HSR:

**Table G1-61 Register accesses trapped to Hyp mode when HDCR.TDRA is 1**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
</table>
| Non-secure EL0 and EL1 | DBGDRAR, DBGDSAR | For accesses using:  

  - MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.  
  - MRRC instructions, trapped MRRC access (coproc==0b1110), using EC value 0x0C. |

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDRA is 1 other than for the purpose of a direct read.

**Trapping Non-secure System register accesses to powerdown debug registers**

HDCR.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode:

- 1 Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

- 0 This control has no effect on Non-secure EL1 System register accesses to the powerdown debug registers.

Table G1-62 on page G1-9027 shows the register accesses that are trapped, and how the exceptions are reported in HSR.

**Table G1-62 Register accesses trapped to Hyp mode when HDCR.TDOSA is 1**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR</td>
<td>Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

These registers are not accessible at EL0.

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDOSA is 1 other than for the purpose of a direct read.

**Trapping general Non-secure System register accesses to debug registers**

HDCR.TDA traps Non-secure EL0 and EL1 System register accesses to the debug registers that are not mentioned in either of the following:

- Traps to Hyp mode of Non-secure System register accesses to debug registers on page G1-9026.

- Trapping Non-secure System register accesses to powerdown debug registers.

This means that HDCR.TDA traps to Hyp mode Non-secure EL0 and EL1 System register accesses to all debug registers except the following:

- Non-secure System register accesses to DBGDRAR or DBGDSAR. The HDCR.TDRA trap traps these accesses.

- Non-secure System register access to DBGOSLSR, DBGOSLAR, DBGOSDLR, or DBGPRCR. The HDCR.TDOSA trap traps these accesses.
HDCR.TDA does not trap accesses to DBGDTRTXint or DBGDTRRXint when the PE is in Debug state.

When HDCR.TDA is:

1  Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table G1-63 on page G1-9028 are trapped to Hyp mode.

0  This control has no effect on Non-secure EL0 or EL1 System register accesses.

Table G1-63 on page G1-9028 shows how the exceptions are reported in HSR.

Table G1-63 Accesses trapped to Hyp mode when HDCR.TDA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>Accesses to the DBGIDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRXtext, DBGDTRRXext, DBGVBR&lt;n&gt;, DBGBCR&lt;n&gt;, DBGXVR&lt;n&gt;, DBGWCR&lt;n&gt;, DBGVR&lt;n&gt;, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGOSECCR</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDA is 1 other than for the purpose of a direct read.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers

CNTHCTL.{PL1PCEN, PL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to Hyp mode, as follows:

• CNTHCTL.PL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
• CNTHCTL.PL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

1  This control has no effect on Non-secure EL0 and EL1 accesses to the registers shown in Table G1-64 on page G1-9028.

0  Non-secure EL0 and EL1 accesses are trapped to Hyp mode.

Table G1-64 on page G1-9028 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-64 Register accesses trapped to Hyp mode by CNTHCTL trap controls

<table>
<thead>

• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03
• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |
| PL1PCTEN | CNTPCT | Trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x04 |
Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

If the Performance Monitors Extension is implemented, HDCR.{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to Hyp mode:

**HDCR.TPM:**
- 1: Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
- 0: This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors registers.

**HDCR.TPMCR:**
- 1: Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.

--- Note ---
The conditions for this trap are identical to those for the trap controlled by HDCR.TPM

- 0: This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers.

--- Note ---
- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, HDCR.{TPM, TPMCR} are RES0.

Table G1-65 on page G1-9029 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

**Table G1-65 Register accesses trapped to Hyp mode when HDCR.{TPM, TPMCR} are 1**

Also see the following:
- Register access instructions on page G1-9002.
- Instructions that fail their Condition code check.
- Trapping to EL3 of instructions that are UNPREDICTABLE on page G1-9032.

Instructions that fail their Condition code check

For UNDEFINED instructions that fail their Condition code check, see Conditional execution of undefined instructions on page G1-8966.

For an instruction that has a Monitor trap set that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Monitor Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Monitor trap is set on such an instruction it must either:
  - Always generate a Monitor trap exception.
  - Always treat the instruction as a NOP.

- The IMPLEMENTATION DEFINED part of the requirements of Conditional execution of undefined instructions on page G1-8966 must be consistent with the handling of Monitor traps on instructions that fail their Condition code check. Table G1-70 on page G1-9031 shows this:

Table G1-70 Consistent handling of instructions that fail their Condition code check

<table>
<thead>
<tr>
<th>Behavior of conditional UNDEFINED instruction&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Monitor trap on instruction that fails its Condition code check&lt;sup&gt;b&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Generates as a NOP</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Monitor trap exception</td>
</tr>
</tbody>
</table>

a. As defined in Conditional execution of undefined instructions on page G1-8966. In Non-secure EL0 and EL1 modes, this applies only if no Monitor trap is set for the instruction, otherwise see the behavior in the other column of the table.
b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

--- Note ---

When SCR {TWE, TWI} is set so that conditional WFE and WFI instructions are trapped to Monitor mode, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check. See Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-9032.
Trapping to EL3 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, when the instruction is disabled or trapped then it is CONstrained
UNPREDICTABLE whether execution of the instruction generates a Monitor Trap exception.

Note

UNPREDICTABLE and CONstrained UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONstrained UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE and Constrained UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode must not generate a Monitor Trap exception.

Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode

SCR{TWE, TWI} trap WFE and WFI instructions to Monitor mode:

\[
\begin{align*}
\text{SCR.TWE} & & 1 & & \text{Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.} \\
& & 0 & & \text{This control has no effect on the execution of WFE instructions.}
\end{align*}
\]

\[
\begin{align*}
\text{SCR.TWI} & & 1 & & \text{Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.} \\
& & 0 & & \text{This control has no effect on the execution of WFI instructions.}
\end{align*}
\]

For PL0 and PL1, these traps apply to WFE and WFI instruction execution in both Security states.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event](#)
- [Wait For Interrupt](#)

Traps to Monitor mode of accesses to RAS error record registers

SCR.TERR traps accesses to the RAS ER* registers from modes other than Monitor mode to Monitor mode.

Table G1-71 Register accesses trapped to EL3 when SCR.TERR is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
</table>
| AArch32 state | ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTLR, ERXCTLR2, ERXFRI, ERXFRI2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, ERXMISC4, ERXMISC5, ERXMISC6, ERXMISC7, ERXSTATUS. | For accesses using:
|             |           | • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |
|             |           | • MCR or MRC instructions, trapped MCR or MRC access, (coproc==0b1111) using EC value 0x04 |
This trap control applies to accesses from both Security states.

**Enabling EL2 and Non-secure EL1 execution of HVC instructions**

SCR.HCE enables EL2 and Non-secure EL1 execution of HVC instructions:

1  
HVC instruction execution is enabled at EL2 and Non-secure EL1.

0  
HVC instructions are:

- **Undefined** at Non-secure EL1. The Undefined Instruction exception is taken to Undefined mode.
- **Constrained Unpredictable** at EL2. The behavior must be one of the following:
  - The instruction is **undefined**.
  - The instruction executes as a NOP.

---

**Note**

- If EL2 is not implemented, SCR.HCE is RES0 and HVC is undefined.
- HVC instructions are always **Undefined** at EL0 and in Secure state.

**Disabling SMC instructions**

SCR.SCD disables SMC instructions:

1  
In Non-secure state

SMC instructions are **Undefined**. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

In Secure state

Behavior is one of the following:

- The instruction is **undefined**.
- The instruction executes as a NOP.

0  
SMC instructions are enabled.

---

**Note**

- SMC instructions are always **Undefined** at EL0.
- When the value of HCR.TSC is 1, any attempted execution of an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR.SCD, see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions* on page G1-9017. As *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-8933* shows, this is an exception to the general exception prioritization rules that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to a higher Exception level.

**Disabling Non-secure System register access to the trace registers**

NSACR.NSTRCDIS disables Non-secure System register accesses to the trace registers, from all Privilege levels:

1  
Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:

- CPACR.TRCDIS behaves as RAO/WI, regardless of its actual value. See *Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers* on page G1-9005. This behavior applies even if the CPACR.TRCDIS control is not implemented. See the referenced section for more information.

- HCPTR.TTA behaves as RAO/WI, regardless of its actual value. See *Traps to Hyp mode of Non-secure System register accesses to trace registers* on page G1-9023.

0  
There is no effect on accesses to CPACR.TRCDIS and HCPTR.TTA.
Note

- System register accesses to the trace registers use the \textit{(coproc==0b1111)} encoding space.
- \texttt{NSACR.NSTRCDIS} might be implemented as RAZ/WI. See the \texttt{NSACR} register description for more information.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the Armv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

Traps to Monitor mode of System register accesses to the trace filter control registers

\texttt{SDCR.TTRF} traps any System register accesses to trace filter control registers to Monitor mode:

\begin{itemize}
  \item \texttt{1}: Any attempt to access a trace filter control register in any mode other than Monitor mode is trapped to Monitor mode.
  \item \texttt{0}: This control has no effect.
\end{itemize}

Enabling Non-secure access to SIMD and floating-point functionality

\texttt{NSACR.{cp11, cp10}} enable Non-secure access to the SIMD and floating-point registers, from all Privilege levels:

\begin{itemize}
  \item \texttt{0b11}: All accesses, from both Security states, are enabled.
  \item \texttt{0b00}: Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
    \begin{itemize}
      \item \texttt{CPACR.{cp11, cp10}} behave as RAZ/WI. See \textit{Enabling PL0 and PL1 accesses to the SIMD and floating-point registers} on page G1-9006.
      \item \texttt{HCPTR.{TCP11, TCP10}} behave as RAO/WI. See \textit{General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers} on page G1-9021.
    \end{itemize}
\end{itemize}

Note

Software must set \texttt{NSACR.cp11} and \texttt{NSACR.cp10} to the same value.

For more information about SIMD and floating-point support, see \textit{Advanced SIMD and floating-point support} on page G1-8996.

Disabling Non-secure access to Advanced SIMD functionality

\texttt{NSACR.NSASEDIS} disables Non-secure accesses to the Advanced SIMD functionality, from all Privilege levels:

\begin{itemize}
  \item \texttt{1}: Non-secure state accesses are disabled. Secure accesses are enabled. If the PE is in Non-secure state:
    \begin{itemize}
      \item \texttt{CPACR.ASEDIS} behaves as RAO/WI. See \textit{Disabling PL0 and PL1 execution of Advanced SIMD instructions} on page G1-9007.
      \item \texttt{HCPTR.TASE} behaves as RAO/WI. See \textit{Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality} on page G1-9022.
    \end{itemize}
\end{itemize}

These behaviors apply even if one or both of the \texttt{CPACR.ASEDIS} and \texttt{HCPTR.TASE} controls is not implemented. See the referenced sections for more information.

\begin{itemize}
  \item \texttt{0}: There is no effect on \texttt{CPACR.ASEDIS} and \texttt{HCPTR.TASE}.
\end{itemize}

Pseudocode description of configurable instruction enables, disables, and traps

The pseudocode function \texttt{AArch32.CheckITEnabled()} checks whether the T32 IT instruction is enabled.
The pseudocode function `AArch32.CheckSETENDEnabled()` checks whether the SETEND instruction is disabled.

The pseudocode function for `AArch32.CheckForSMCF indefOrTrap()` checks for traps on an SMC instruction.

The `AArch32.CheckForWFxTrap()` pseudocode function checks for traps on WFE and WFI instructions:

**Pseudocode description of enabling SIMD and floating-point functionality**

The `AArch32.CheckAdvSIMDoorFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The `CheckAdvSIMDoorVFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEnabled()` wrapper functions support the `AArch32.CheckAdvSIMDoorFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` functions.

The `AArch32.CheckAdvSIMDoorFPEnabled()`, `AArch32.CheckFPAdvSIMDTrap()`, `CheckAdvSIMDoorVFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEnabled()` functions are described in Chapter J1 *Armv8 Pseudocode.*
G1.21 Configurable instruction enables and disables, and trap controls
Chapter G2
AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates debug exceptions. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

Introductory information
- About self-hosted debug on page G2-9038.
- The debug exception enable controls on page G2-9042.

The debug Exception model
- Routing debug exceptions on page G2-9043.
- Enabling debug exceptions from the current Privilege level and Security state on page G2-9045.
- The effect of powerdown on debug exceptions on page G2-9047.
- Summary of permitted routing and enabling of debug exceptions on page G2-9048.
- Pseudocode description of debug exceptions on page G2-9050.

The debug exceptions
- Breakpoint Instruction exceptions on page G2-9051.
- Breakpoint exceptions on page G2-9054.
- Watchpoint exceptions on page G2-9079.
- Vector Catch exceptions on page G2-9093.

Synchronization requirements
The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context synchronization event guarantees the effects of the changes:
- Synchronization and debug exceptions on page G2-9100.
G2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in:

- Chapter D1 The AArch64 System Level Programmers’ Model, if the exception is taken to AArch64 state.
- Chapter G1 The AArch32 System Level Programmers’ Model, if the exception is taken to AArch32 state.

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.

G2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

G2.1.2 Context ID and Process ID

In AArch32 state, the CONTEXTIDR identifies the current Context ID, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

When using the Long-descriptor translation table format, the CONTEXTIDR has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical when using this translation table format.

When using the Short-descriptor translation table format:

- CONTEXTIDR[31:0] defines the Context ID, that is used for breakpoint and watchpoint matching.
- CONTEXTIDR[31:8] defines the Process ID.
- CONTEXTIDR[7:0] defines the ASID. See Global and process-specific translation table entries on page G5-9216. This means that, when using the Short-descriptor translation table format, the ASID is always bits[7:0] of the Context ID.

G2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 stage 1 translation regime are:

- Breakpoint Instruction exceptions on page G2-9039.
- Breakpoint exceptions on page G2-9039, generated by hardware breakpoints.
- Watchpoint exceptions on page G2-9040, generated by hardware watchpoints.
- Vector Catch exceptions on page G2-9040.

Note

In addition, Software Step exceptions can be generated in stage 1 of an AArch32 translation regime. However, these are always taken to AArch64 state. Software Step exceptions on page D2-4694 describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.

   See Enabling debug exceptions from the current Privilege level and Security state on page G2-9045.

   Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
2. A debugger has enabled that particular debug exception.

All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the DBGDSCRext. See The debug exception enable controls on page G2-9042.

——— Note ————
If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see Halting allowed and halting prohibited on page H2-10233.

——— Note ————
When a debug exception is taken to an Exception level that is using AArch32:
• If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
• Otherwise, it is taken as a Prefetch Abort exception.

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

PE behavior
Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:
• The current Privilege level and AArch32 mode.
• The current Security state.

For more information, see Breakpoint Instruction exceptions on page G2-9051.

Breakpoint exceptions

The architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

The architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:

• Address:
  — Address Match.
  — Address Mismatch.

Comparisons are made with the virtual address of each instruction in the program flow.

• Context:
  — Context ID Match. Matches with the Context ID value held in the CONTEXTIDR.
  — VMID Match. Matches with the VMID value held in the VTTBR.
  — Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior
If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.
Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page G2-9054.

**Watchpoint exceptions**

The architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions* on page G2-9079.

**Vector Catch exceptions**

These are used to trap exceptions. The architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the DBGVCR. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

**PE behavior**

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see *Vector Catch exceptions* on page G2-9093.

Table G2-1 on page G2-9041 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.
### Table G2-1 PE behavior and pseudocode for each of the debug exceptions

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Breakpoint Instruction exception</td>
<td>Takes Prefetch Abort exception</td>
<td>Takes Prefetch Abort exception</td>
</tr>
<tr>
<td>Breakpoint exception</td>
<td>Takes Prefetch Abort exception^a</td>
<td>Ignored</td>
</tr>
<tr>
<td>Watchpoint exception</td>
<td>Takes Data Abort exception^a</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exception</td>
<td>Takes Prefetch Abort exception</td>
<td>Ignored</td>
</tr>
</tbody>
</table>

^a If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.
The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**
None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**
DBGDSCRext.MDBGen, plus an enable control for each breakpoint, DBGBCR<n>.E.

**Watchpoint exceptions**
DBGDSCRext.MDBGen, plus an enable control for each watchpoint, DBGWCR<n>.E.

**Vector Catch exceptions**
DBGDSCRext.MDBGen.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Privilege level and Security state* on page G2-9045.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
G2.3 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, if EL2 is implemented, the routing of debug exceptions depends on the **Effective values** of HDCR.TDE and HCR.TGE:

**If the Effective value of {HDCR.TDE, HCR.TGE} is not {0, 0}**

Debug exceptions taken from Non-secure state are routed to Hyp mode.

If EL2 is using AArch64 and FEAT_SEL2 is implemented, debug exceptions taken from Secure EL0 and Secure EL1 may be routed to Secure EL2. For more information, see Routing debug exceptions on page D2-4697.

**Otherwise**

In Non-secure state debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure Abort mode.
- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
- All other debug exceptions are disabled from Hyp mode.

---

**Note**

If EL2 is not implemented, the **Effective value** of HCR.TGE is 0 and the **Effective value** of HDCR.TDE is 0.

Table G2-2 on page G2-9043, Table G2-3 on page G2-9043, and Table G2-4 on page G2-9044 show the routing of debug exceptions taken from an Exception level that is using AArch32 to an Exception level that is using AArch64.

In these tables:

- **TDE** Means the logical OR of HDCR.TDE and HCR.TGE.
- **(Hyp mode)** Means:
  - All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Privilege level.
  - Breakpoint Instruction exceptions taken from this Privilege level are taken to Hyp mode.

### Table G2-2 Routing when both EL3 and EL2 are implemented

</tbody>
</table>

### G2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level. `DebugTargetFrom()` returns the debug target Exception level for the specified Security state.
G2.4 Enabling debug exceptions from the current Privilege level and Security state

A debug exception can only be taken if all of the following are true:

- The OS Lock is unlocked.
- DoubleLockStatus() == FALSE.
- The debug exception is enabled from the current Privilege level.
- The debug exception is enabled from the current Security state.

Table G2-5 on page G2-9045 shows when debug exceptions are enabled from the current Privilege level.

<table>
<thead>
<tr>
<th>Current Privilege level</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Secure</td>
<td>Enabled</td>
<td>Depends on SDCR.SPD and SDER.SUIDEN. See Disabling debug exceptions from Secure state on page G2-9045.</td>
</tr>
</tbody>
</table>

G2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can enable or disable all debug exceptions taken from Secure PL1 other than Breakpoint Instruction exceptions, by using one of:

- The Secure Privileged Debug field, SDCR.SPD, if EL3 is using AArch32.
- The AArch32 Secure Privileged Debug field, MDCR_EL3.SPD32, if EL3 is using AArch64.

If debug exceptions are disabled from Secure PL1, software executing at Secure PL1 can set the Secure User Invasive Debug Enable bit, SDER.SUIDEN, to 1 to enable all debug exceptions taken from Secure PL0 other than Breakpoint Instruction exceptions.

--- Note ---
Breakpoint Instruction exceptions are always enabled.

--- Note ---
The Armv8-A architecture does not support disabling debug in Non-secure state.

--- Note ---
If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.
G2.4.2   Pseudocode description of enabling debug exceptions

AArch64.GenerateDebugExceptions() determines whether debug exceptions are enabled from the current Exception level and Security state. AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions are enabled from the specified Exception level and Security state.
G2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-10342 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and DoubleLockStatus() == FALSE.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
### G2.6 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

#### Breakpoint Instruction exceptions

These are always enabled, regardless of the current Privilege level and Security state. Table G2-7 on page G2-9048 shows the routing of these. In the table, n/a means not applicable.

#### Table G2-7 Routing of Breakpoint Instruction exceptions

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>HDCR.TDEa:</th>
<th>Target when enabled from:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>PL0</td>
</tr>
<tr>
<td>Secure</td>
<td>X</td>
<td>Secure Abort modeb</td>
</tr>
<tr>
<td>Non-secure</td>
<td>0</td>
<td>Non-secure Abort mode</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Hyp mode</td>
</tr>
</tbody>
</table>

a. If EL2 is not implemented, behavior is as if the value of this bit is 0. Otherwise, if the value of HCR.TGE is 1, HDCR.TDE is treated as being 1 other than for a direct read of HDCR.

b. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

#### All other debug exceptions

The enabling and permitted routing is controlled by all of the following:

- SDCR.SPD.
- SDER.SUIDEN.
- HDCR.TDE.
- The IMPLEMENTATION DEFINED authentication interface.

Table G2-8 on page G2-9048 shows the valid combinations of the values of SDCR.SPD, SDER.SUIDEN, HDCR.TDE, and, in the Auth on page G2-9048 column, the input from the IMPLEMENTATION DEFINED authentication interface described by the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled(). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

a. The value of (OSLSR_EL1.OSLK == 1 || DoubleLockStatus()).
b. If EL3 is not implemented, behavior is as if SPD is 0b11 and SUIDEN is 0b0.
c. See the text that introduces this table for an explanation of the Auth column. An entry of TRUE indicates that the authentication mechanism permits the debug exceptions to be taken to their default target PE mode.
d. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.
e. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.
G2.7  Pseudocode description of debug exceptions

AArch32.DebugFault() returns a FaultRecord() that indicates that a memory access has generated a debug exception.

The AArch32.Abort() function processes FaultRecord(), as described in Abort exceptions on page G4-9144, and generates:

• Data Abort exceptions for watchpoints.
• Prefetch Abort exceptions for all other debug exceptions.
G2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

________ Note __________

When the PE is executing in EL0 using AArch32 and EL1 is using AArch64, it is using the AArch64 EL1&0 translation regime. A T32 or A32 BKPT instruction executed at EL0 can generate a Breakpoint Instruction exception that is taken to an Exception level that is using AArch64. For more information about the handling of these exceptions, see Breakpoint Instruction exceptions on page D2-4705.

It contains the following subsections:

• About Breakpoint Instruction exceptions.
• Breakpoint instruction in the A32 and T32 instruction sets.
• BKPT instructions as the first instruction in an IT block on page G2-9052.
• Exception syndrome information and preferred return address for a BKPT instruction on page G2-9052.
• Pseudocode description of Breakpoint Instruction exceptions on page G2-9053.

G2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, based on either:

• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page G2-9054 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

• The current Exception level.
• The current Security state.
• Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

________ Note __________

• EL_D is the Exception level that debug exceptions are targeting. See Enabling debug exceptions from the current Privilege level and Security state on page G2-9045.
• Debuggers using breakpoint instructions must be aware of the rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-156.

G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:

• BKPT #<immediate>

For details of the instruction encoding, see BKPT on page F5-7507.

About whether the BKPT instruction is conditional

In the T32 instruction set, BKPT instructions are always unconditional.
In the A32 instruction set:
• If the Condition code field is AL, the BKPT instruction is unconditional.
• If the Condition code field is anything other than AL, behavior is CONstrained UNPREDICTABLE, and is one of the following:
  — The instruction is UNDEFINED.
  — The instruction is treated as a NOP instruction.
  — The instruction is executed unconditionally.
  — The instruction is executed conditionally.

G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

0  The BKPT instruction generates a Breakpoint Instruction exception.

1  The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception.

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:
HSCTLR.ITD  Applies to execution at EL2 when EL2 is using AArch32.
SCTLR.ITD   Applies to execution at EL0 or EL1 when EL1 is using AArch32.
SCTLR_EL1.ITD  Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note

T32 BKPT instructions are always unconditional, even when they are inside an IT block. See:
• Disabling or enabling PL0 and PL1 use of AArch32 optional functionality on page G1-9004.
• Disabling or enabling EL2 use of AArch32 optional functionality on page G1-9013.

G2.8.4 Exception syndrome information and preferred return address for a BKPT instruction

See the following:
• Exception syndrome information for a Breakpoint Instruction exception.
• Preferred return address for a Breakpoint Instruction exception on page G2-9053.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Breakpoint Instruction exception

The PE takes a Breakpoint Instruction exception as either:
• A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
• A Hyp Trap exception, if it is taken to PL2 because either HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.
If the exception is taken to:

**PL1 Abort mode**

The PE sets all of the following:
- DBGDSCRext.MOE to 0b0011, to indicate a Breakpoint Instruction exception.
- IFSR.FS to the code for a debug, 0b00010.
- The IFAR with an UNKNOWN value.

**PL2 Hyp mode**

The PE does all of the following:
- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-9 on page G2-9053.
- Sets DBGDSCRext.MOE to 0b0011, to indicate a Breakpoint Instruction exception.
- Sets the HIFAR to an unknown value.

---

---

**Note**

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-9043.

---

**Preferred return address for a Breakpoint Instruction exception**

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

**G2.8.5 Pseudocode description of Breakpoint Instruction exceptions**

`AArch32 SoftwareBreakpoint()` generates a Prefetch Abort exception that is taken from AArch32 state.
G2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
• At EL1 or higher in an Exception level that is using AArch32.
• At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page G2-9055.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
• Breakpoint instruction address comparisons on page G2-9066.
• Breakpoint context comparisons on page G2-9071.
• Using breakpoints on page G2-9072.
• Exception syndrome information and preferred return address for a Breakpoint exception on page G2-9077.
• Pseudocode description of Breakpoint exceptions taken from AArch32 state on page G2-9078.

G2.9.1 About Breakpoint exceptions

A breakpoint is an event that results from the execution of an instruction, based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions on page G2-9051.

An implementation can include between 2-16 hardware breakpoints. DBGIDR.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The Breakpoint Control Register, DBGBCR<\text{n}>. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGBVR<\text{n}>. This holds a value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
• If EL2 is implemented, the Breakpoint Extended Value Register, DBGBXVR<\text{n}>, that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:
• DBGBCR1, DBGBVR1, and DBGBXVR1 are for breakpoint number one.
• DBGBCR2, DBGBVR2, and DBGBXVR2 are for breakpoint number two.
• ...
• ...
• DBGBCR<\text{n}>, DBGBVR<\text{n}>, and DBGBXVR<\text{n}> are for breakpoint number <\text{n}>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:
• The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<\text{n}>.E, is 1.
• The conditions specified in the DBGBCR<\text{n}> are met.
• The comparisons with the values held in one or both of the DBGBVR<\text{n}> and DBGBXVR<\text{n}>, as applicable, are successful.
• If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
• The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:
• Whether the instruction passes its Condition code check.
• The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are
• Enabled, Breakpoint debug events generate Breakpoint exceptions
• Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions. However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page G2-9042 describes the enable controls for Breakpoint debug events.

G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

• A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  — An instruction address match.
  — An instruction address mismatch.
  — A Context ID match, with the value held in the CONTEXTIDR.
  — A VMID match, with the value held in the VTTBR.
  — Both a Context ID match and a VMID match.

• A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

DBGDIDR.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:
• Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
• Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a Linked Address Match breakpoint.
2. Program breakpoint number five to be a Linked Context ID Match breakpoint.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The Breakpoint Type field for a breakpoint, DBGBCR<n>.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-9066.

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<n>.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page G2-9076.
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.
  
  __________ Note __________

  Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page G2-9079 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked Address Mismatch breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure G2-1 on page G2-9057 shows an example of permitted breakpoint and watchpoint linking.
In Figure G2-1, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn.BT**

The following list provides more detail about each breakpoint type:

0b0000, **Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- \text{DBGBCR}<n>\.\{SSC, HMC, PMC\}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions} on page G2-9063.

- A successful address match, as described in \textit{Breakpoint instruction address comparisons} on page G2-9066.

\text{DBGBCR}<n>\.LBN for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>.{SSC, HMC, PMC}** for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons on page G2-9066.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<n>.LBN** for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

**BT == 0b0010** is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>.{SSC, HMC, PMC}.** These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
- A successful Context ID match, as described in Breakpoint context comparisons on page G2-9071.

The value of **DBGBVR<n>.ContextID** is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and the value of HCR_EL2.E2H is 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, **CONTEXTIDR** holds the current Context ID.

**DBGBCR<n>.{LBN, BAS}** for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

**BT == 0b0011** is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-9066.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-9083.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

The value of **DBGBVR<n>.ContextID** is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and the value of HCR_EL2.E2H is 1.
• The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
 Otherwise, CONTEXTIDR holds the current Context ID.

DBGBCR<n>.{LBN, SSC, HMC, BAS PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
• A successful address mismatch, as described in Breakpoint instruction address comparisons on page G2-9066.

DBGBCR<n>.LBN for this breakpoint is ignored.

0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
• A successful address mismatch defined by this breakpoint, as described in Breakpoint instruction address comparisons on page G2-9066.
• A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0110 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include FEAT_VHE.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

The Context ID check is made against the value in CONTEXTIDR, or CONTEXTIDR_EL1. The value of DBGBVR<n>.ContextID is compared with the Context ID value held in CONTEXTIDR or CONTEXTIDR_EL1.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0111 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include FEAT_VHE.

For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-9066.
— A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-9083.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

The Context ID check is made against the value in CONTEXTIDR, or CONTEXTIDR_EL1. The value of DBGVBR<n>.ContextID is compared with the Context ID value held in CONTEXTIDR or CONTEXTIDR_EL1.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.
• A successful VMID match, as described in Breakpoint context comparisons on page G2-9071.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, either:
• This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page G2-9066.
  — A successful VMID match defined by this breakpoint.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-9083.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-9071.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.
For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:

- \texttt{DBGBCR<n>.\{SSC, HMC, PMC\}}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions} on page \textit{G2-9063}.

- A successful Context ID match, as described in \textit{Breakpoint context comparisons} on page \textit{G2-9071}.

- A successful VMID match.

The value of \texttt{DBGBVR<n>.ContextID} is compared with \texttt{CONTEXTIDR}.

\textit{Breakpoint context comparisons} on page \textit{G2-9071} describes the requirements for a successful Context ID match and a successful VMID match.

\texttt{DBGBCR<n>.\{LBN, BAS\}} for this breakpoint are ignored.

\textbf{0b1011, Linked CONTEXTID and VMID Match breakpoint}

\texttt{BT == 0b1011} is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.

- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see \textit{Breakpoint instruction address comparisons} on page \textit{G2-9066}.
  - A successful Context ID match defined by this breakpoint, as described in \textit{Breakpoint context comparisons} on page \textit{G2-9071}.
  - A successful VMID match defined by this breakpoint.

- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see \textit{Watchpoint data address comparisons} on page \textit{G2-9083}.
  - A successful Context ID match defined by this breakpoint, as described in \textit{Breakpoint context comparisons} on page \textit{G2-9071}.
  - A successful VMID match defined by this breakpoint.

The value of \texttt{DBGBVR<n>.ContextID} is compared with \texttt{CONTEXTIDR}.

\textit{Breakpoint context comparisons} on page \textit{G2-9071} describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

\texttt{DBGBCR<n>.\{LBN, SSC, HMC, BAS, PMC\}} for this breakpoint are ignored.

\textbf{0b1100, Unlinked CONTEXTIDR_EL2 Match breakpoint}

\texttt{BT == 0b1100} is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- \texttt{FEAT_VHE} is not implemented and \texttt{FEAT_Debugv8p2} is not implemented, which means the implementation does not include \texttt{CONTEXTIDR_EL2}.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \texttt{DBGBCR<n>.\{SSC, HMC, PMC\}}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.

- A successful \texttt{CONTEXTIDR_EL2} match. The value of \texttt{DBGBVR<n>.ContextID2} is compared with the Context ID value held in \texttt{CONTEXTIDR_EL2}, as described in \textit{Breakpoint context comparisons} on page \textit{G2-9071}.
The check against CONTEXTIDR_EL2 means this breakpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<\(n\)\.\{LBN, BAS\} for this breakpoint are ignored.

**0b1101, Linked CONTEXTIDR_EL2 Match**

BT == 0b1101 is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.
- EL2 is not implemented.

For context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-9066.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page G2-9071.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-9083.
  - A successful CONTEXTIDR_EL2 match. The value of DBGBVR<\(n\)\.ContextID2 is compared with the Context ID value held in CONTEXTIDR_EL2, as described in Breakpoint context comparisons on page G2-9071.

The check against the CONTEXTIDR_EL2 means the breakpoint or watchpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<\(n\)\.\{LBN, SSC, HMC, BAS, PMC\} for this breakpoint are ignored.

**0b1110, Unlinked Full Context ID Match breakpoint**

BT == 0b1110 is a reserved value if:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<\(n\)\.\{SSC, HMC, PMC\}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons on page G2-9071.

The Context ID check is made by checking both:

- The value of DBGBVR<\(n\)\.ContextID against the value in CONTEXTIDR, or CONTEXTIDR_EL1.
The value of DBGBXVR<n>.ContextID2 against the value in CONTEXTIDR_EL2. Both comparisons must match for the check to succeed.

The check against the CONTEXTIDR_EL2 means this breakpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

---

0b1111, Linked Full Context ID Match breakpoint

- BT == 0b1111 is a reserved value if:
  - The breakpoint is not a context-aware breakpoint.
  - FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.
  - EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-9066.
  - A successful Context ID match, as described in Breakpoint context comparisons on page G2-9071.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-9083.
  - A successful Context ID match, as described in Breakpoint context comparisons on page G2-9071.

The Context ID check is made by checking both:

- The value of DBGBVR<n>.ContextID against the value in CONTEXTIDR, or CONTEXTIDR_EL1.

- The value of DBGBXVR<n>.ContextID2 against the value in CONTEXTIDR_EL2.

Both comparisons must match for the check to succeed.

The check against the CONTEXTIDR_EL2 means the breakpoint or watchpoint can be generated only if EL2 is implemented and enabled in the current Security state and EL2 is using AArch64.

--- Note ---

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

---

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

---

See Reserved DBGBCR<n>.BT values on page G2-9074 for the behavior of breakpoints programmed with reserved BT values.

---

G2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.
DBGBCR<n>.{SSC, HMC, PMC} define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

--- **Note** ---

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

Table G2-10 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

- **Y**  
  Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row can generate Breakpoint exceptions in AArch32 modes at that Privilege level.

- **-**  
  Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

A combination in Table G2-10 might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented, see *Reserved DBGBCR<n>.{SSC, HMC, PMC} values* on page G2-9075.

a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.

b. Only in User, System and Supervisor modes.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See Reserved HMC, SSC, and PMC combinations on page G2-9075.
G2.9.4 Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- Address Match breakpoints.
- Address Mismatch breakpoints.

Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS matches. That is, either:
  - DBGBCR<n>.BAS is programmed with 0b0011 or 0b1111, and the instruction is at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with 0b1100, and the instruction is not at a word-aligned address.

See Specifying the halfword-aligned address that an Address breakpoint matches on.

Note

DBGBVR<n>[1:0] are RES0 and are ignored.

Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS does not match. That is, either:
  - DBGBCR<n>.BAS is programmed with 0b0011 or 0b1111, and the instruction is not at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with 0b1100, and the instruction is at a word-aligned address.

See Specifying the halfword-aligned address that an Address breakpoint matches on.

Note

DBGBVR<n>[1:0] are RES0 and are ignored.

Address Mismatch breakpoints can be used to single-step through code. See Using an Address Mismatch breakpoint to single-step an instruction on page G2-9072.

Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the Byte Address Selection field, DBGBCR<n>.BAS, so that the address comparison is successful on one of:

- The whole word starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address ((DBGBVR<n>[31:2]:00) + 2).

Note

The address programmed into the DBGBVR<n> must be word-aligned.
DBGBCR<n>.BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, DBGBCR<n>.BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
  - The instruction address held in bits [31:2] of the DBGBVR<n>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = DBGBVR<n>[31:2] match AND BAS match.

- For an Address Mismatch breakpoint, DBGBCR<n>.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
  - The instruction address held in bits [31:2] of the DBGBVR<n>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = NOT (DBGBVR<n>[31:2] match AND BAS match).

The following subsections show the supported BAS values:

- Using the BAS field in Address Match breakpoints.
- Using the BAS field in Address Mismatch breakpoints on page G2-9069.

For Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.

**Using the BAS field in Address Match breakpoints**

The supported BAS values are:

- **0b0000**
  This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:
  - The breakpoint is disabled.
  - The breakpoint behaves as if BAS is 0b0011, 0b1100, or 0b1111.

- **0b0011**
  The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR<n>[31:2].
  - Bits [1:0] of the address are 0b00.

  This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:
  - 32-bit T32 instructions at word-aligned addresses.
  - 16-bit T32 instructions at word-aligned addresses.
  - A32 instructions. These are always at word-aligned addresses.

  However, Arm recommends that a debugger uses this BAS value only for T32 instructions.

  It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address (DBGBVR<n>[31:2]:00) - 2).

- **0b1100**
  The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR<n>[31:2].
  - Bits [1:0] of the address are 0b10.

  This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:
  - 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  - 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

  It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.
The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<\text{n}>[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<\text{n}>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<\text{n}>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<\text{n}>.BAS[3,1] ignore writes and read the same values as DBGBCR<\text{n}>[2,0] respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-2 on page G2-9069 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address ((DBGBVR<\text{n}>[31:2]:00) + 2).
- Row 6 shows that a breakpoint with a BAS value of either 0b0011 or 0b1111 generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

- **Yes** means that the breakpoint generates a Breakpoint exception.
- **No** means that the breakpoint does not generate a Breakpoint exception.
- **UNP** means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-9076.
Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

- **0b0000**: The breakpoint ignores the address held in the DBGBVR<\text{n}> and generates Breakpoint exceptions for all instruction addresses.

- **0b0011**: The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR<\text{n}>[31:2].
  - Bits [1:0] of the address are 0b00.

  This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:
  - 32-bit T32 instructions at word-aligned addresses.
  - 16-bit T32 instructions at word-aligned addresses.
  - A32 instructions. These are always at word-aligned addresses.

  However, Arm recommends that a debugger uses this BAS value only for T32 instructions.

  It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address (DBGBVR<\text{n}>[31:2]:00 - 2).

- **0b1100**: The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] equals DBGBVR<\text{n}>[31:2].
  - Bits [1:0] of the address are 0b10.

  This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
  - 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
  - 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

0b1111

The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

• Bits [31:2] of the address equals DBGBVR<n>[31:2].
• Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

• 32-bit T32 instructions at word-aligned addresses.
• 16-bit T32 instructions at word-aligned addresses.
• A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the word-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

Figure G2-3 on page G2-9071 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

• A column showing the row number, on the left.
• An instruction set and instruction size table.
• A location of instruction figure.
• A BAS field values table, on the right.

To use the figure, read across the rows. For example:

• Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the DBGBVR<n>.
• Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the DBGBVR<n>.

In the figure:

Yes Means that the breakpoint does generate a Breakpoint exception.
No Means that the breakpoint does not generate a Breakpoint exception.
UNP Means that it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-9076.
### G2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<\texttt{n}>::BT determines what context comparison is required, if any. Table G2-11 on page G2-9071 shows the BT values that require a comparison, and the match required for the comparison to be successful.

<table>
<thead>
<tr>
<th>DBGBCR&lt;\texttt{n}&gt;::BT</th>
<th>Test required for successful context comparison</th>
</tr>
</thead>
</table>
| 0b001x                 | - When FEAT\_VHE is implemented, EL2 is using AArch64, the Effective value of HCR\_EL2.E2H is 1, and either the PE is executing at EL0 with HCR\_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR\_EL2 must match the DBGVR<\texttt{n}>.ContextID value.  
- Otherwise, CONTEXTIDR must match the DBGVR<\texttt{n}>.ContextID value. |
| 0b011x                 | CONTEXTIDR, or CONTEXTIDR\_EL1, must match the DBGVR<\texttt{n}>.ContextID value. |
| 0b100x                 | VTTBR\_VMID must match the DBGXVR<\texttt{n}>.VMID value. |
| 0b101x                 | CONTEXTIDR, or CONTEXTIDR\_EL1, must match the DBGVR<\texttt{n}>.ContextID value, and VTTBR\_VMID must match the DBGXVR<\texttt{n}>.VMID value. |
| 0b110x                 | CONTEXTIDR\_EL2 must match the DBGXVR<\texttt{n}>.ContextID2 value. |
| 0b111x                 | Both:  
- CONTEXTIDR, or CONTEXTIDR\_EL1, must match the DBGVR<\texttt{n}>.ContextID value.  
- CONTEXTIDR\_EL2 must match the DBGXVR<\texttt{n}>.ContextID2 value. |

No context comparison is required for other valid DBGBCR<\texttt{n}>::BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR, or CONTEXTIDR\_EL1, and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - FEAT\_VHE is implemented, EL2 is using AArch64, EL2 is implemented and enabled in the current Security state, and HCR\_EL2.E2H.TGE == \{1, 1\}.

- The comparison uses the value of CONTEXTIDR\_EL2 and any of:
  - Neither FEAT\_VHE is implemented, nor FEAT\_Debugv8p2 is implemented.

---

*aa* 0 means the word-aligned address held in the DBGVRn. The other locations are as follows:

- -2 means ((DBGVRn[31:2]:00) - 2).
- -1 means ((DBGVRn[31:2]:00) - 1).
- ...  
- ...  
- +5 means ((DBGVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.
— EL2 is either not implemented or not enabled in the current Security state.
— EL2 is using AArch32.

• The comparison uses the current VMID value and any of:
  — EL2 is not implemented.
  — EL2 is either not implemented or not enabled in the current Security state.
  — The PE is executing at EL2.
  — FEAT_VHE is implemented, EL2 is using AArch64, EL2 is implemented and enabled in the current Security state, and HCR_EL2.{E2H, TGE} == {1, 1}.

Note
• For all Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.
• For Linked Context breakpoints, DBGBCR<n>.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

G2.9.6 Using breakpoints

This section contains the following:
• Using an Address Mismatch breakpoint to single-step an instruction.
• ITD control effects on address breakpoints on the first instruction in an IT block on page G2-9073.
• Breakpoint usage constraints on page G2-9074.

Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by DBGBCR<n>.{LBN, SSC, PMC}, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. Figure G2-4 shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address 0x1014.

![Figure G2-4 Operation of an Address Mismatch breakpoint](Image)

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in Figure G2-4:

• If the target of a branch is an instruction other than the instruction at address 0x1014, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
• If the target of a branch is the instruction at address 0x1014, the PE executes the instruction at 0x1014 and the breakpoint does not generate a Breakpoint exception until the instruction at address 0x1018 is committed for execution. The instruction at address 0x1014 is therefore single-stepped.
However, if the instruction at 0x1014 generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

— If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address 0x1014. This means that software execution steps into the exception.

— If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at 0x1014 or the instruction at 0x1018.

If the instruction at 0x1014 is single-stepped and branches to itself, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in Figure G2-4 on page G2-9072, this is 0x1014.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of an AArch64 Software Step exception.

Note

- The example shown in Figure G2-4 on page G2-9072 assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.

- Software Step exceptions are the highest priority synchronous exception. Breakpoint exceptions are lower priority. See Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650.

ITD control effects on address breakpoints on the first instruction in an IT block

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

- An IT instruction can only be used to apply to one 16-bit T32 instruction.

- Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.

- For a permitted combination, it is IMPLEMENTATION DEFINED whether the implementation treats the combination as:
  — A pair of 16-bit instructions.
  — One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in Other usage constraints for Address breakpoints on page G2-9076, an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, Arm recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.
The ITD control fields are:

**HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.

**SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.

**SCTLR_EL1.ITD** Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

--- **Note** ---

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

### Breakpoint usage constraints

See the following sections:

- **Reserved DBGBCR<n>.BT values**.
- **Reserved DBGBCR<n>.{SSC, HMC, PMC} values** on page G2-9075.
- **Reserved DBGBCR<n>.BAS values** on page G2-9075.
- **Reserved DBGBCR<n>.LBN values** on page G2-9076.
- **Other usage constraints for Address breakpoints** on page G2-9076.
- **Other usage constraints for Context breakpoints** on page G2-9077.

**Reserved DBGBCR<n>.BT values**

Table G2-12 on page G2-9074 shows when particular DBGBCR<n>.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>Context ID Match</td>
<td>If the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b010x</td>
<td>Address Mismatch</td>
<td>If EDSCR.HDE is 1 and halting is allowed</td>
</tr>
<tr>
<td>0b011x</td>
<td>CONTEXTIDR_EL1 Match</td>
<td>If FEAT_VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b100x</td>
<td>VMID Match</td>
<td>If EL2 is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b101x</td>
<td>Context ID and VMID Match</td>
<td></td>
</tr>
<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 Match</td>
<td>If FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, or if the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b111x</td>
<td>Full Context ID Match</td>
<td></td>
</tr>
</tbody>
</table>

--- **Note** ---

For these BT values, breakpoints are not generated if EL2 is using AArch32.

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>.
- For a direct or external read of DBGBCR<n>, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is **UNKNOWN**.
Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<\textless;n\textgreater;.\{SSC, HMC, PMC\} values

Table G2-13 on page G2-9075 shows when particular combinations of DBGBCR<\textless;n\textgreater;.\{SSC, HMC, PMC\} are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero.</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 and the combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00.</td>
<td>When EL2 is not implemented and EL3 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero.</td>
<td>When RME is not implemented.</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01 and PMC set to 0b00, and the combinations with SSC set to 1, SSC set to 0b11 and PMC set to 0b00.</td>
<td>When both of EL2 and EL3 are implemented, but Secure EL2 is not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table G2-10 on page G2-9064.</td>
<td>Always.</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR<\textless;n\textgreater;.\{SSC, HMC, PMC\} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR<\textless;n\textgreater;.\{SSC, HMC, PMC\} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of DBGBCR<\textless;n\textgreater;.\{SSC, HMC, PMC\} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<\textless;n\textgreater;.BAS values

For all Context breakpoints

DBGBCR<\textless;n\textgreater;.BAS is RES1 and is ignored.
For all Address breakpoints

The supported values of the BAS field for the Address Match and Address Mismatch breakpoints are shown in *Specifying the halfword-aligned address that an Address breakpoint matches on* on page G2-9066.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of DBGBCR<\textit{n}>.
- A direct or external read of DBGBCR<\textit{n}>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

**Reserved DBGBCR<\textit{n}>.LBN values**

For all Context breakpoints

DBGBCR<\textit{n}>.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<\textit{n}>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<\textit{n}>.LBN return an unknown value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<\textit{n}>.LBN reads UNKNOWN and its value is ignored.

**Other usage constraints for Address breakpoints**

For all Address breakpoints

- DBGBVR<\textit{n}>[1:0] are RES0 and are ignored.
- The DBGBXVR<\textit{n}> is ignored.

For Address Match breakpoints

- For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
- If DBGBCR<\textit{n}>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<\textit{n}>[31:2]:00) + 2). For T32 instructions, Arm recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

For Address Mismatch breakpoints

The constraints are the same as those described in *For Address Match breakpoints*, except that if two Address Mismatch breakpoints are programmed to match in the same Exception level and Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a Breakpoint debug even is generated.
Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n> and DBGBXVR<n> that are not used to specify Context ID or VMID are RES0 and are ignored.

Note

This means that for Context ID Match breakpoints, the DBGBXVR<n> is RES0 and is ignored, and for VMID Match breakpoints, the DBGBVR<n> is RES0 and is ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

G2.9.7 Exception syndrome information and preferred return address for a Breakpoint exception

See the following:

• Exception syndrome information for a Breakpoint exception.
• Preferred return address for a Breakpoint exception on page G2-9078.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Breakpoint exception

The PE takes a Breakpoint exception as either:

• A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
• A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

• DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
• IFSR_FS to the code for a debug exception, 0b00010.
• The IFAR with an UNKNOWN value.

Hyp mode

The PE does all of the following:

• Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-14 on page G2-9078.
• Sets DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
Sets the HIFAR to an unknown value.

### Preferred return address for a Breakpoint exception

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead. This means that the preferred return address is the address of the instruction that caused the exception.

#### Pseudocode description of Breakpoint exceptions taken from AArch32 state

AArch32.BreakpointValueMatch() returns a pair of results:
- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

AArch32.StateMatch() tests the values in DBGBCR<n>.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch32.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch32.CheckBreakpoint() generates a FaultRecord. A Breakpoint exception is taken if all of the following are true:
- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-9045.
- All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page G2-9054.

Note: AArch32.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The AArch32.Abort() function processes the FaultRecord object returned by AArch32.CheckBreakpoint(), as described in Abort exceptions on page G4-9144. When a Breakpoint exception is taken to AArch32 state, the AArch32.Abort() function generates a Prefetch Abort exception.
G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
• At EL1 or higher in an Exception level that is using AArch32.
• At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:
• About Watchpoint exceptions.
• Watchpoint types and linking of watchpoints on page G2-9080.
• Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-9081.
• Watchpoint data address comparisons on page G2-9083.
• Determining the memory location that caused a Watchpoint exception on page G2-9086.
• Watchpoint behavior on other instructions on page G2-9087.
• Usage constraints on page G2-9088.
• Exception syndrome information and preferred return address on page G2-9090.
• Pseudocode description of Watchpoint exceptions taken from AArch32 state on page G2-9091.

G2.10.1 About Watchpoint exceptions

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:
1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, DBGDIR.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:
• The Watchpoint Control Register, DBGWCR<n>. This holds control information for the watchpoint, for example an enable control.
• The Watchpoint Value Register, DBGWVR<n>. This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:
• DBGWCR1 and DBGWVR1 are for watchpoint number one.
• DBGWCR2 and DBGWVR2 are for watchpoint number two.
• …
• …
• DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:
• Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
• Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, \texttt{DBGWCR<n>.BAS}, to select the bytes. See *Programming a watchpoint with eight bytes or fewer on page G2-9084*.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

A debugger uses the *MASK* field, \texttt{DBGWCR<n>.MASK}, to program a watchpoint with eight bytes to 2GB. See *Programming a watchpoint with eight or more bytes on page G2-9085*.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint exceptions is CONSTRAINED UNPREDICTABLE. See *Programming dependencies of the BAS and MASK fields on page G2-9089*.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, \texttt{DBGWCR<n>.E}, is 1.
- The conditions specified in the \texttt{DBGWCR<n>} are met.
- The comparison with the address held in the \texttt{DBGWVR<n>} is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See * on page G2-9057 shows this. See also Breakpoint context comparisons on page G2-9071*.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and \texttt{EDSCR.HDE} is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:
- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

_____ Note  

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions. However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page G2-9042 describes the enable controls for Watchpoint debug events.

### G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoin*:t.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, DBGWCR<n>.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<n>.WT is 1, the watchpoint is enabled for linking.

**Rules for linking watchpoints**

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGWCR<n>.LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>.WT.{SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See *Execution conditions for which a watchpoint generates Watchpoint exceptions*.
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See *Usage constraints* on page G2-9088.
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

**Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. *Breakpoint exceptions on page G2-9054* describes breakpoints.

Figure G2-1 on page G2-9057 shows an example of permitted watchpoint linking.

**G2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions**

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

DBGWCR<n>.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

**Note**

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

**Higher Mode Control, HMC, and Privileged Access Control, PAC**

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level or Privilege level at which the access was made.
This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on PL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are LDRT and STRT.

Table G2-15 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

- **Y or -** Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
  - Y Can generate Watchpoint exceptions at that Privilege level.
  - Cannot generate Watchpoint exceptions at that Privilege level.
- **Res** Means that the combination of HMC, SSC, and PAC is reserved. See Reserved DBGWCR<n>.{SSC, HMC, PAC} values on page G2-9088.

<sup>a</sup> Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at PL2 using AArch32.

<sup>b</sup> This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See Reserved \( \text{DBGWCR}<n> \cdot \{\text{SSC, HMC, PAC}\} \) values on page G2-9088.

**G2.10.4 Watchpoint data address comparisons**

An address comparison is successful if bits [31:2] of the current data virtual address are equal to \( \text{DBGWVR}<n>[31:2] \), taking into account all of the following:

- The size of the access. See *Size of the data access*.
- The bytes selected by \( \text{DBGWVR}<n> \cdot \text{BAS} \). See *Programming a watchpoint with eight bytes or fewer* on page G2-9084.
- Any address ranges indicated by \( \text{DBGWVR}<n> \cdot \text{MASK} \). See *Programming a watchpoint with eight or more bytes* on page G2-9085.

---

**Note**

\( \text{DBGWVR}<n>[1:0] \) are RES0 and are ignored.

---

**Size of the data access**

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See *Example G2-1*.

---

**Example G2-1**

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.

2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.
The size of data accesses initiated by DCIMVAC instructions is an IMPLEMENTATION DEFINED size that is both:
  • From the inclusive range between:
    — The size that CTR.DminLine defines.
    — 2KB.
  • A power-of-two.

The lowest address accessed by a DCIMVAC instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, Watchpoint behavior on accesses by DCIMVAC instructions on page G2-9088.

### Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<\text{n}>.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<\text{n}> the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<\text{n}> is:

  • Doubleword-aligned:
    — All eight bits of DBGWCR<\text{n}>.BAS are used, and the descriptions given in Table G2-16 apply.
  • Word-aligned but not doubleword-aligned:
    — Only DBGWCR<\text{n}>.BAS[3:0] are used, and the descriptions given in Table G2-17 apply. In this case, DBGWCR<\text{n}>.BAS[7:4] are RES0.

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;\text{n}&gt;[31:2]:00 is accessed</td>
</tr>
</tbody>
</table>
If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page G2-9090.

When programming the BAS field with anything other than 0b11111111, a debugger must also program DBGWCR.<n>.MASK to be 0b00000. See Programming dependencies of the BAS and MASK fields on page G2-9089.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR.<n>[31:3]. See Example G2-1 on page G2-9083.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR.<n> with 0x1000.
  - DBGWCR.<n>_EL1.BAS to be 0b00001000.

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR.<n> with 0x2000.
  - DBGWCR.<n>_EL1.BAS to be 0b00111000.

- If the address programmed into the DBGWVR.<n> is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR.<n>.BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR.<n>[31:3]:100 is accessed, program DBGWCR.<n>.BAS to be 0b11110000.

Note

Arm deprecates programming a DBGWVR.<n> with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, DBGWCR.<n>.MASK, to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.

- It starts at an address that is aligned to the size.
The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>

If \( n \) least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address \( \text{DBGWVR}<n>[31:n]:000\ldots \)
- Address \( \text{DBGWVR}<n>[31:n]:111\ldots \)
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between \( \text{DBGWVR}<n>[31:4]:0000 \) and \( \text{DBGWVR}<n>[31:4]:1111 \), including these addresses.

--- Note ---
- The most significant bit cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR<\( n \).MASK values* on page G2-9090.

When masking address bits, a debugger must both:

- Program \( \text{DBGWCR}<n>.\text{BAS} \) to be 0b11111111. See *Programming dependencies of the BAS and MASK fields* on page G2-9089.
- In the \( \text{DBGWVR}<n> \), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints* on page G2-9090.

## G2.10.5 Determining the memory location that caused a Watchpoint exception

On a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- DFAR, if the exception is taken to PL1.
- HDFAR, if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

--- Note ---
If Debug state was entered from AArch32 state, then EDWAR[63:32] is unknown and must be ignored by the debugger.

For more information, see the subsections that follow. These are:

- *Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions* on page G2-9087.
- *Address recorded for Watchpoint exceptions generated by data cache maintenance instructions* on page G2-9087.
Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
  - The highest watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than the DC ZVA block size.
  - Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example G2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:
  - 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
  - 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

G2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Preload instructions.
- All data cache maintenance instructions except DCIMVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an implementation defined subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache maintenance, address translation, and TLB maintenance instructions are implementation defined.

The access size of the IMPLEMENTATION DEFINED instruction cache maintenance, address translation, and TLB maintenance instructions that generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:

- Watchpoint behavior on accesses by Store-Exclusive instructions on page G2-9088.
- Watchpoint behavior on accesses by DCIMVAC instructions on page G2-9088.
Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by DCIMVAC instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

- Match on data stores only.
- Match on data stores and data loads.

**Note**

For the size of data accesses performed by DCIMVAC instructions, see Watchpoint data address comparisons on page G2-9083. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

### G2.10.7 Usage constraints

See the following:

- Reserved DBGWCR<n>.{SSC, HMC, PAC} values.
- Reserved DBGWCR<n>.LBN values on page G2-9089.
- Programming dependencies of the BAS and MASK fields on page G2-9089.
- Reserved DBGWCR<n>.BAS values on page G2-9089.
- Reserved DBGWCR<n>.MASK values on page G2-9090.
- Other usage constraints on page G2-9090.

Reserved DBGWCR<n>.{SSC, HMC, PAC} values

Table G2-18 on page G2-9088 shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PAC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PAC set to 0b00</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 and PAC set to 0b01 or 0b11</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01 and PAC set to 0b00</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table G2-15 on page G2-9082.</td>
<td>Always</td>
</tr>
</tbody>
</table>

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
— Programmed with a combination that is not reserved, other than for a direct or external read of \texttt{DBGWCR<n>}.

- For a direct or external read of \texttt{DBGWCR<n>}, if the reserved combination:
  — Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is \texttt{UNKNOWN}.
  — Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved \texttt{DBGWCR<n>.LBN} values**

**For Linked watchpoints**

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any \texttt{DBGWCR<n>.LBN} value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of \texttt{DBGWCR<n>.LBN} return an \texttt{UNKNOWN} value and the behavior is \texttt{CONSTRAINED UNPREDICTABLE}. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an \texttt{UNKNOWN} context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked watchpoints**

For Unlinked watchpoints, \texttt{DBGWCR<n>.LBN} reads \texttt{UNKNOWN} and its value is ignored.

**Programming dependencies of the BAS and MASK fields**

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the \texttt{DBGWVR<n>} the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be $0b11111111$, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be $0b000000$, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is nonzero and a BAS field that is not set to $0b11111111$, then for each byte in the address range, it is \texttt{CONSTRAINED UNPREDICTABLE} whether or not a Watchpoint exception is generated.

**Reserved \texttt{DBGWCR<n>.BAS} values**

The BAS field must be programmed with a value $\text{Zeros}(8-n-m) : \text{Ones}(n) : \text{Zeros}(m)$, where:

- $n$ is a nonzero positive integer less-than-or-equal-to 8.
- $m$ is a positive integer less-than 8.
- $n+m$ is less-than-or-equal-to 8.

All other values are reserved.

Note

If $x$ is zero, then $\text{Zeros}(x)$ is an empty bitstring.

If $\text{DBGWVR}<n>[2]$ is 1, $\text{DBGWCR}<n>$.BAS[7:4] are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

• It is constrained unpredictable whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the $\text{DBGWVR}<n>$.

• A direct or external read of $\text{DBGWCR}<n>$.BAS returns an unknown value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved $\text{DBGWCR}<n>$.MASK values

If a watchpoint is programmed with a reserved MASK value:

• The watchpoint must behave as if it is either:
  — Disabled.
  — Programmed with an unknown value that is not reserved, that might be $\text{0b0000}$, other than for a direct or external read of $\text{DBGWCR}<n>$.

• A direct or external read of $\text{DBGWCR}<n>$.MASK returns an unknown value.

Other usage constraints

For all watchpoints:

• $\text{DBGWVR}<n>[1:0]$ are RES0 and are ignored.

• If $\text{DBGWCR}<n>$.MASK is nonzero, and any masked bits of $\text{DBGWVR}<n>$ are not 0, it is constrained unpredictable whether the watchpoint generates a Watchpoint exception when the unmasked bits match.

• A watchpoint never generates any Watchpoint exceptions if $\text{DBGWCR}<n>$.LSC is $\text{0b00}$.

G2.10.8 Exception syndrome information and preferred return address

See the following:

• Exception syndrome information.
• Preferred return address on page G2-9091.

Exception syndrome information

The PE takes a Watchpoint exception as either:

• A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.

• A Hyp trap exception, if it is taken to PL2 because $\text{HCR.TGE}$ or $\text{HDCR.TDE}$ is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

• $\text{DBGDSCRext}.\text{MOE}$ to $\text{0b1010}$, to indicate a Watchpoint exception.

• $\text{DFSR}.\text{CM}$ to indicate whether a cache maintenance instruction caused the exception.
- **DFSR.WnR** to indicate whether the exception was generated on a read instruction or a write instruction.
- **DFAR** to an address that the debugger can use to determine the memory location that triggered the watchpoint. See *Determining the memory location that caused a Watchpoint exception on page G2-9086.*

In addition, if using the:
- Short-descriptor format, the PE sets **DFSR.FS** to the code for a debug exception, 0b00010, and **DFSR.Domain** to an **UNKNOWN** value.
- Long-descriptor format, the PE sets **DFSR.STATUS** to the code for a debug exception, 0b100010.

**Hyp mode**

The PE does all of the following:
- Records information about the exception in the **Hypervisor Syndrome Register, HSR**. See Table G2-19 on page G2-9091.
- Sets **DBGDSCRext.MOE** to 0b1001, to indicate a Watchpoint exception.
- Sets the **HDFAR** to an address that the debugger can use to determine the memory location that triggered the watchpoint. See *Determining the memory location that caused a Watchpoint exception on page G2-9086.*

### Table G2-19 Information recorded in the **HSR**

<table>
<thead>
<tr>
<th>HSR field</th>
<th>Information recorded</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Exception Class, EC</strong></td>
<td>The PE sets this to the code for a Data Abort exception routed to Hyp mode, 0x24.</td>
</tr>
<tr>
<td><strong>Instruction Length, IL</strong></td>
<td>The PE sets this to 1.</td>
</tr>
</tbody>
</table>
| **Instruction Specific Syndrome, ISS** | **ISV[24]** Instruction Syndrome Valid (ISV). The PE sets this to 0.  
**ISS[23:10]** [RES0.  
**ISS[9]** External Abort type (EA). The PE sets this to 0.  
**ISS[8]** Cache Maintenance (CM). The PE sets this to indicate whether a cache maintenance instruction caused the exception.  
**ISS[7]** [RES0.  
**ISS[6]** Write not Read (WnR). The PE sets this to indicate whether the exception was generated on a read instruction or a write instruction.  
**ISS[5:0]** Data Fault Status Code (DFSC). The PE sets this to the code for a debug exception, 0b100010. |

---

**Note**

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions on page G2-9043.*

**Preferred return address**

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

---

**G2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch32 state**

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.
AArch32.StateMatch() tests the values in DBGWCR<n>.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

AArch32.WatchpointMatch() tests the value in DBGWVR<n>.

AArch32.CheckWatchpoint() generates a FaultRecord. A Watchpoint exception is taken if all of the following are true:

- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-9045.
- All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions on page G2-9079.

Note

AArch32.CheckWatchpoint might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The AArch32.Abort() function processes the FaultRecord object returned by AArch32.CheckWatchpoint(), as described in Abort exceptions on page G4-9144. If a Watchpoint exception is taken to AArch32 state, the AArch32.Abort() function generates a Data Abort exception.
**G2.11 Vector Catch exceptions**

Arm deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

--- **Note**

Vector Catch exceptions cannot be generated when the PE is using an AArch64 translation regime.

This section contains the following subsections:
- **About Vector Catch exceptions**
- **Exception vectors that Vector Catch exceptions can be enabled for** on page G2-9095.
- **Generation of Vector Catch exceptions** on page G2-9096.
- **Usage constraints** on page G2-9098.
- **Exception syndrome information and preferred return address for a Vector Catch exception** on page G2-9098.
- **Pseudocode description of Vector Catch exceptions** on page G2-9099.

**G2.11.1 About Vector Catch exceptions**

Whenever the PE takes an exception, execution is forced to an address that is the exception vector for that exception.

Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the address-matching form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the exception-trapping form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The DBGDEVID indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the DBGVCR. This register contains vector catch enable bits. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

--- **Note**

EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the DBGVCR32_EL2. The DBGVCR32_EL2 is architecturally mapped to the DBGVCR.

When Vector Catch exceptions are enabled for an exception vector, this is called an enabled vector catch. The set of exception vectors that Vector Catch exceptions are enabled for is called the enabled vector catch set.

If the form of vector catch implemented is the:

**Address-matching form:**

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.
Exception-trapping form

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

- Address-matching form, the current Security state.
- Exception-trapping form, the Security state that the exception is handled in.

See Generation of Vector Catch exceptions on page G2-9096.

Table G2-20 on page G2-9094 summarizes the differences between the address-matching and exception-trapping forms.

<table>
<thead>
<tr>
<th>Address-matching</th>
<th>Exception-trapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution. This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector. A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.</td>
<td>An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector. This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.</td>
</tr>
<tr>
<td>A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch. Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650 describes this prioritization.</td>
<td>A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it. For this reason, Vector Catch exceptions are outside the scope of the prioritization that Prioritization of Synchronous exceptions taken to AArch64 state on page D1-4650 describes.</td>
</tr>
<tr>
<td>A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.</td>
<td>Vector Catch exceptions must be taken before other exceptions.</td>
</tr>
<tr>
<td>A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.</td>
<td>Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the AArch32 exception handling mode.</td>
</tr>
</tbody>
</table>
| If HCR.TGE is 1, Vector Catch exceptions can be generated for User mode instruction fetches from Non-secure PL1 vectors. | If HCR.TGE is 1, Vector Catch exceptions are never generated in Non-secure state, because:
  - Exceptions are routed away from Non-secure PL1 vectors, to PL2.
  - The architecture does not provide vector catch enable bits for the Hyp exception vectors. |

Depending on the implementation, some vector catch enable bits in the DBGVCR might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See Exception vectors that Vector Catch exceptions can be enabled for on page G2-9095 for the vector catch enable bits that exist for different implementations.

The debug exception enable controls on page G2-9042 describes the enable controls for Vector Catch exceptions.
G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a vector table at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- Local exception vectors.
- Non-secure Local exception vectors.
- Secure Local exception vectors.
- Hyp exception vectors.
- Monitor exception vectors.

Table G2-21 on page G2-9095 shows which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Vector table or tables implemented</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 EL1 EL2 EL3</td>
<td></td>
</tr>
<tr>
<td>32 32 - -</td>
<td>Local exception vectors.</td>
</tr>
<tr>
<td>64 -</td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>32 -</td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Hyp exception vectors.</td>
</tr>
<tr>
<td>- 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>- 32</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Monitor exception vectors.</td>
</tr>
<tr>
<td>64 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td>32 64</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Hyp exception vectors.</td>
</tr>
<tr>
<td>32 32</td>
<td>Secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Non-secure Local exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Hyp exception vectors.</td>
</tr>
<tr>
<td></td>
<td>Monitor exception vectors.</td>
</tr>
</tbody>
</table>

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the DBGVCR:

- Table G2-22 on page G2-9096 shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
The architecture does not provide vector catch enable bits for the Hyp exception vectors.

Table G2-22 Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for

<td>Secure Monitor Call</td>
<td>MVBAR + 0x00000008</td>
</tr>
</tbody>
</table>

Note

There is no vector catch enable bit for Monitor trap exceptions.

G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- **Address-matching form.**
- **Exception-trapping form on page G2-9097.**

**Address-matching form**

The PE compares the virtual address of each instruction in the program flow with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.
• If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

In this case, Table G2-24 on page G2-9097 shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

### Table G2-24 Comparisons made if the implementation includes EL3

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>For exceptions taken to:</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Secure PL1 modes</td>
<td>Non-secure PL1 modes</td>
<td></td>
</tr>
<tr>
<td>AArch64</td>
<td>Secure Local exception vectors</td>
<td>Non-secure Local exception vectors</td>
<td></td>
</tr>
<tr>
<td>AArch32</td>
<td>Secure Local exception vectors and Monitor exception vectors</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

• Whether the instruction passes its Condition code check.
• Whether the instruction is executed as part of exception entry.
• If EL2 is implemented, what HCR. {IMO, FMO, AMO} are set to.
• If EL3 is implemented, what SCR. {IRQ, FIQ, EA} are set to.

### Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

• If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.

• If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that Table G2-25 on page G2-9097 shows. In the table, n/a means not applicable.

### Table G2-25 Subsets that the PE tests within if EL3 is implemented

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>For exceptions taken to:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Monitor mode</td>
</tr>
<tr>
<td>AArch64</td>
<td>n/a</td>
</tr>
<tr>
<td>AArch32</td>
<td>Monitor exception vectors</td>
</tr>
</tbody>
</table>

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.

If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.
G2.11.4 Usage constraints

See the following subsections:

- Usage constraints that apply to both forms of vector catch.
- Usage constraints that apply only to the address-matching form.

Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

Note

The Exception level that debug exceptions are targeting is called the debug target Exception level, EL1. Routing debug exceptions on page G2-9043 describes how EL1 is derived.

Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

- It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.

G2.11.5 Exception syndrome information and preferred return address for a Vector Catch exception

See the following:

- Exception syndrome information for a Vector Catch exception.
- Preferred return address for a Vector Catch exception on page G2-9099.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Vector Catch exception

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.
If the exception is taken to:

**PL1 Abort mode**

The PE sets all of the following:
- **IFS.FS** to the code for a debug exception, 0b00010.
- **DBGDSCR.MOE** to 0b0101, to indicate a Vector Catch exception.
- The IFAR with an UNKNOWN value.

**PL2 Hyp mode**

The PE does all of the following:
- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-26 on page G2-9099.
- Sets DBGDSCR.MOE to 0b0101, to indicate a Vector Catch exception.
- Sets the HIFAR to an unknown value.

---

**Preferred return address for a Vector Catch exception**

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

**G2.11.6 Pseudocode description of Vector Catch exceptions**

The `AArch32.VCRMatch()` pseudocode function checks whether the instruction at address generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The `AArch32.CheckVectorCatch()` pseudocode function uses `AArch32.VCRMatch()` to test whether the instruction generates a Vector Catch exception, and if `AArch32.VCRMatch()` returns TRUE it generates that event.

The `AArch32.Abort()` function processes the FaultRecord object returned by `AArch32.CheckVectorCatch()`, as described in `Abort exceptions on page G4-9144`. If there is a Vector Catch exception, the `AArch32.Abort()` function generates a Prefetch Abort exception.
G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

• The state of the external debug authentication interface.

• Indirect reads of:
  — External debug registers.
  — System registers, including system debug registers.
  — Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example G2-3 Example of synchronization and Breakpoint exception generation

1. Software changes DBGDSCRext.MDBGen from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example G2-4 Example of synchronization and debug exceptions generation

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

--- Note ---

Some register updates are self-synchronizing. Others require an explicit Context synchronization event. For more information, see:

• Synchronization of changes to AArch32 System registers on page G8-9326.
• Accessing PSTATE fields on page G1-8922.
• Synchronization of changes to the external debug registers on page H8-10358.

G2.12.1 State and mode changes without explicit context synchronization events

Most changes to the Exception level, and most changes to the Security state if EL3 is implemented, happen as a result of operations that are an explicit Context synchronization event. This is because taking an exception and returning from an exception are both explicit Context synchronization events, and the Privilege level and Security state can only change as a result of taking or returning from an exception.
However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit *Context synchronization event*. These are:

- AArch32 mode changes caused by MSR and CPS instructions. A mode change might be to a mode at a lower Privilege level.

- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.
Chapter G3
AArch32 Self-hosted Trace

This chapter describes the AArch32 self-hosted trace:

**Introductory information:**
- *About self-hosted trace* on page G3-9104.
- *Trace Sinks* on page G3-9104.
- *Register controls to enable self-hosted trace* on page G3-9104.

**Prohibited regions in trace:**
- *Controls to prohibit trace at Exception levels* on page G3-9105.
- *Self-hosted trace and address translation* on page G3-9105.

**Timestamps and Synchronization:**
- *Self-hosted trace timestamps* on page G3-9106.
- *Synchronization in self-hosted trace* on page G3-9107.
G3.1 About self-hosted trace

A trace unit generates trace data to describe the program flow of the PE.

The trace unit may be an implementation of any of the following:

- In Armv9, the Embedded Trace Extension (ETE). See Chapter D4 The Embedded Trace Extension.
- An IMPLEMENTATION DEFINED trace function.

If an Armv8.4-compliant PE implements an ETM Architecture trace unit that includes the ETM System register interface, FEAT_TRF must be implemented.

If an Armv8.4-compliant PE implements a Trace Unit that is either not an ETM Architecture trace unit or does not implement the ETM System register interface, Arm recommends that FEAT_TRF is implemented, but this is not mandatory. This is not applicable in Armv9.

If an Armv9-compliant PE implements FEAT_ETE, FEAT_TRF must be implemented.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The trace unit and the PE must have the same view of the debug authentication interface. If FEAT_TRF is implemented, ExternalNoninvasiveDebugEnabled() is always TRUE.

G3.1.1 Trace Sinks

The trace unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

If FEAT_TRBE is implemented, the PE includes a Trace Buffer Unit. Trace data is written directly to memory by the Trace Buffer Unit. See Chapter D6 The Trace Buffer Extension.

In Armv8, Arm recommends that a system that includes FEAT_TRF incorporates an ETR, and follows the system architecture described by the CoreSight Base System Architecture (CS-BSA).

G3.1.2 Register controls to enable self-hosted trace

For EL1 using AArch64, see Chapter D3 AArch64 Self-hosted Trace.

If FEAT_TRF is implemented, self-hosted trace is enabled if one of the following is true:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, EL3 is implemented, SDCR.STE == 1, and ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- EDSCR.TFO == 1, EL3 is not implemented, the PE executes in Secure state, and ExternalSecureNoninvasiveDebugEnabled() = FALSE.

The pseudocode function SelfHostedTraceEnabled() shows these rules.

If FEAT_TRF is not implemented, SelfHostedTraceEnabled() returns FALSE.

While SelfHostedTraceEnabled() is FALSE, ExternalNoninvasiveDebugAllowed() controls whether tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the trace unit external debug interface.
G3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited in Secure state when `SDCR.STE == 0`.

G3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled()` == TRUE, `TRFCR, TRFCR_EL1, TRFCR_EL2` and `HTRFCR` control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled()` == FALSE, these registers are ignored.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL0 if one of the following is true:
• The Effective value of `HCR_EL2.TGE == 0` and `TRFCR_EL1.E0TRE == 0`.
• The Effective value of `HCR.TGE == 0` and `TRFCR.E0TRE == 0`.
• The Effective value of `HCR_EL2.TGE == 1` and `TRFCR_EL2.E0HTRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL1 if `TRFCR.E1TRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL2 if `HTRFCR.E2TRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL3 if one of the following is true:
• EL3 is in AArch64 state.
• EL3 is in AArch32 state and `TRFCR.E1TRE == 0`.

The pseudocode `TraceAllowed()` shows the preceding rules.

If `SelfHostedTraceEnabled()` == TRUE, no events are exported to the trace unit when tracing is prohibited.

If `SelfHostedTraceEnabled()` == FALSE, no events are exported to the trace unit when the PE is in Secure state and counting in Secure state is prohibited.

If `FEAT_ETE` is not implemented, when `PMCR_EL0.X==0` or `PMCR.X==0`, no PMU events are exported to the trace unit.

Otherwise, PMU events are exported to the trace unit.

G3.2.2 Self-hosted trace and address translation

A hypervisor can use `HTRFCR.CX` to control visibility of `VTTBR.VMID`.

If `SelfHostedTraceEnabled()` == TRUE, and `HTRFCR.CX == 0`, or if EL2 is not implemented:
• The value of `VTTBR.VMID` is not traced.
• Comparisons with `VTTBR.VMID` do not match and results of comparison are not exposed through the comparators.

The trace unit may either prohibit trace for these values, or may record a `VTTBR.VMID` value of zero in the trace.
G3.3 Self-hosted trace timestamps

For EL1 using AArch64, see Chapter D3 AArch64 Self-hosted Trace.

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While \texttt{SelfHostedTraceEnabled()} == FALSE, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When \texttt{SelfHostedTraceEnabled()} == TRUE, the trace time stamp is one of the following:

- Physical time, which is defined by the physical count value returned by \texttt{PhysicalCountInt()}.
- If \texttt{FEAT_ECV} is implemented and EL2 is executing at AArch64, offset physical time, which is defined as the value of (\texttt{PhysicalCountInt()} - \texttt{CNTPOFF_EL2}). However, the physical offset is treated as zero if \texttt{FEAT_ECV} is disabled.
- Virtual time, which is defined as the value of (\texttt{PhysicalCountInt()} - \texttt{CNTVOFF}). The virtual offset is always \texttt{CNTVOFF}, including when a read of \texttt{CNTVCT} at the current Exception level would treat the virtual offset as zero.

The fields \texttt{TRFCR_EL2.TS}, \texttt{TRFCR.TS} and \texttt{HTRFCR.TS} control which counter is used for self-hosted trace.

The timestamp used for trace is shown in Table G3-1 on page G3-9106.

<table>
<thead>
<tr>
<th>\texttt{SelfHostedTraceEnabled()}</th>

<td>xx</td>
<td>\texttt{PhysicalCountInt()} - \texttt{CNTVOFF} or \texttt{PhysicalCountInt()} - \texttt{CNTVOFF_EL2}</td>
</tr>
<tr>
<td></td>
<td>0b11</td>
<td>xx</td>
<td>\texttt{PhysicalCountInt()}</td>
</tr>
</tbody>
</table>

\textbf{Note}

The value of \texttt{HCR_EL2.E2H} does not affect the counter used for the trace timestamp.
G3.4 Synchronization in self-hosted trace

The trace unit is an indirect observer of the trace control registers.

While `SelfHostedTraceEnabled()` == TRUE, indirect reads of the trace filter control fields, TRFCR.{E1TRE, E0TRE} and HTRFCR.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced, and are subject to the standard requirements for synchronization of System register accesses.

The `TSB CSYNC` operation is used to ensure that a trace operation, due to a trace unit generating trace for an instruction has completed. The `TSB CSYNC` operation may be reordered with respect to other instructions, so must be combined with at least one Context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR or HTRFCR is guaranteed to be observed by the trace unit only after a subsequent Context synchronization event. For more information, see Trace Synchronization Barrier (TSB CSYNC) on page E2-7184.

While `SelfHostedTraceEnabled()` == FALSE, the trace unit might impose stronger synchronization requirements.
Chapter G4
The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- About the memory system architecture on page G4-9110.
- Address space on page G4-9111.
- Mixed-endian support on page G4-9112.
- AArch32 cache and branch predictor support on page G4-9113.
- System register support for IMPLEMENTATION DEFINED memory features on page G4-9138.
- External aborts on page G4-9139.
- Memory barrier instructions on page G4-9141.
- Pseudocode description of general memory System instructions on page G4-9142.
G4.1 About the memory system architecture

The Arm architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system, see Memory hierarchy on page E2-7188.

G4.1.1 Form of the memory system architecture

The A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter G5 The AArch32 Virtual Memory System Architecture describes the AArch32 view of the VMSA.

G4.1.2 Memory attributes

Memory types and attributes on page E2-7198 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table G4-1 on page G4-9110 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Shareability</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device</td>
<td>Outer Shareable</td>
<td>Non-cacheable.</td>
</tr>
<tr>
<td>Normal</td>
<td>One of:</td>
<td>One of:</td>
</tr>
<tr>
<td></td>
<td>• Non-shareable.</td>
<td>• Non-cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Inner Shareable.</td>
<td>• Write-Through Cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

a. Takes additional attributes, see Device memory on page E2-7202.
b. See also Cacheability, cache allocation hints, and cache transient hints on page G4-9116.

For more information on Cacheability and Shareability, see The Cacheability and Shareability memory attributes on page E2-7189, Non-shareable Normal memory on page E2-7200, and Caches and memory hierarchy on page E2-7188.
G4.2 Address space

The architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see About VMSAv8-32 on page G5-9146.

G4.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

(address_of_current_instruction) + (size_of_executed_instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows 0xFFFF FFFF, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes 0xFFFFFFFF and 0x00000000, the bytes that apparently from 0x00000000 onwards come from an UNKNOWN address.

Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes 0xFFFFFFFF and 0x00000000, then the bytes that apparently come from 0x00000000 onwards come from UNKNOWN addresses.
G4.3 Mixed-endian support

Table G4-2 on page G4-9112 shows the endianness of explicit data accesses and translation table walks.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTLR.EE</td>
</tr>
<tr>
<td>EL1</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTLR.EE</td>
</tr>
<tr>
<td>EL2</td>
<td>PSTATE.E</td>
<td>HSCTLR.EE</td>
<td>n/a</td>
</tr>
<tr>
<td>EL3</td>
<td>PSTATE.E</td>
<td>SCTLR(S).EE</td>
<td>n/a</td>
</tr>
</tbody>
</table>

AArch32 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR(S/NS).EE, HSCTLR.EE, and PSTATE.E are RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES0. PSTATE.E is RW when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES1. PSTATE.E is RW when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
  - Each of SCTLR(S/NS).EE, HSCTLR.EE, PSTATE.E, and SPSR.E is RES0.
- All Exception levels support only big-endianness:
  - Each of SCTLR(S/NS).EE, HSCTLR.EE, PSTATE.E, and SPSR.E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

Note

- When using AArch32, Arm deprecates PSTATE.E having a different value from the equivalent System register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.
- If the higher Exception levels are using AArch64, the corresponding registers are:
  - SCTLR_EL1 for SCTLR(NS).
  - SCTLR_EL2 for HSCTLR.
  - SCTLR_EL3 for SCTLR(S).

The BigEndian() function determines whether the current Exception level and Execution state is using big-endian data.

For more information about endianness in the Arm architecture, see Endian support on page E2-7195.
G4.4  AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:

- **General behavior of the caches.**
- **Cache identification** on page G4-9114.
- **Cacheability, cache allocation hints, and cache transient hints** on page G4-9116.
- **Enabling and disabling the caching of memory accesses in AArch32 state** on page G4-9117.
- **Behavior of caches at reset** on page G4-9119.
- **About cache maintenance in AArch32 state** on page G4-9119.
- **AArch32 cache and branch predictor maintenance instructions** on page G4-9123.
- **Execution and data prediction restriction System instructions** on page G4-9134.
- **Cache lockdown** on page G4-9136.
- **System level caches** on page G4-9137.

See also Chapter G5 *The AArch32 Virtual Memory System Architecture*, and in particular *Caches in VMSAv8-32* on page G5-9235.

---

**Note**

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.

- In the instruction mnemonics, MVA is a synonym for VA.

---

G4.4.1  General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.

- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
The AArch32 System Level Memory Model
G4.4 AArch32 cache and branch predictor support

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page G4-9136.

• Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

• It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.

• It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  — The translation regime at the current Exception level.
  — The translation regime at any higher Exception level.

• For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all Requesters in its Shareability domain.

• Any memory location is not guaranteed to remain incoherent with the rest of memory.

• The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR identifies the Cache Write-back Granule.

• The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

Note

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR. {I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

G4.4.2 Cache identification

The cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

• Affect the entire cache, for example ICIALLUIS.
• Operate by VA, for example ICIMVAU.
• Operate by set/way, for example DCISW.

The cache identification registers are:

• A single Cache Type Register, CTR, that defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

Note

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches, see System level caches on page G4-9137.
• A single Cache Level ID Register, CLIDR, that defines:
  — The type of cache that is implemented and can be maintained using the architected cache maintenance
    instructions that operate by set/way or operate on the entire cache at each cache level, up to the
    maximum of seven levels.
  — The Level of Unification Inner Shareable (LoUIS), Level of Coherence (LoC) and the Level of
    Unification (LoU) for the caches. See Terms used in describing the cache maintenance instructions on
    page G4-9120 for a definition of these terms.
  — An optional ICB field to indicate the boundary between the caches used for caching Inner Cacheable
    memory regions and those used only for caching Outer Cacheable regions.

• A single Cache Size Selection Register, CSSELR, that selects the cache level and sort of cache (Instruction,
  Data/Unified/Tag) of the current Cache Size Identification Register.

• For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache
  Size Identification Register, that defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate, and Write-Allocate.
  — The number of sets, associativity, and line length of the cache. See Terms used in describing the cache
    maintenance instructions on page G4-9120 for a definition of these terms.

Note
From Armv8.3, it is possible to have multiple Cache Size Identification Registers. For more details, see
Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache.
   This register also provides the size of the smallest cache lines used for the instruction caches, and for the data
   and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache
   type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data
   or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are
   defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of
   Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   • Write to the Cache Size Selection Register to select the required cache. A cache is identified by its
     level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   • Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2

From Armv8.3, two different formats are available for defining the number of sets and associativity of the currently
selected cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions on
page G4-9120.

When FEAT_CCIDX is implemented:

• There are two Cache Size Identification Registers, CCSIDR and CCSIDR2.
• The length of the CCSIDR.Assoc field is 21 bits. This limits the associativity of the currently selected cache
to 2^{21}.
• The length of the CCSIDR2.NumSets field is 24 bits. This limits the number of sets in the currently selected
  cache to 2^{24}.

This is the 64-bit format of the Cache Size Identification Register.
When FEAT_CCIDX is not implemented:

- There is a single Cache Size Identification Register, CCSIDR.
- The length of the CCSIDR.Assoc field is 10 bits. This limits the associativity of the currently selected cache to $2^{10}$.
- The length of the CCSIDR.NumSets field is 15 bits. This limits the number of sets in the currently selected cache to $2^{15}$.

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

### G4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability applies only to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page E2-7198, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hint is supported the following cache allocation hints can be used:

- **For read accesses:** Read-Allocate, Transient Read-Allocate, or No Read-Allocate.
- **For write accesses:** Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

#### Note

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-32 translation table walks using the Long-descriptor translation table format, the appropriate TCR.\{IRGNn, ORGNn\} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

#### Transient cacheability hint

It is IMPLEMENTATION DEFINED whether a Transient hint is supported for the VMSAv8-32 translation scheme when using the Long-descriptor translation table format. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.
Note
The architecture does not specify what is meant by a relatively short period.

When using the Short-descriptor translation table format, VMSAv8-32 cannot support the Transient hint.

The description of the MAIR0, MAIR1, HMAIR0, and HMAIR1 registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

G4.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note
These Cacheability controls replace the cache enable controls provided in previous versions of the Arm architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

For the Non-secure PL1&0 translation regime

The Non-secure instance of SCTLR holds the EL1 controls that affect cacheability:

- When the value of SCTLR.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR2.CD is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 2 translation tables are Non-cacheable.
- When the value of HCR2.ID is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR.DC is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTLR.C. This applies to translations for both data and instruction accesses.

In addition, when the value of SCTLR.M is 0, indicating that the stage 1 translations are disabled for the translation regime, then if EL2 is using AArch32 and the value of HCR.DC is 0 or if EL2 is using AArch64 and the value of HCR_EL2.DC is 0, then:

- If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
Note

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in Combining the Cacheability attribute on page G5-9214.
- The Non-secure SCTLR.{C, I} and HCR.DC fields have no effect on the Secure PL1&0 and EL2 translation regimes.
- The HCR2.{ID, CD} fields affect only stage 2 of the Non-secure PL1&0 translation regime.
- In Non-secure state, the PL1&0 translation regime can be described as the Non-secure EL1&0 translation regime. This is consistent with the equivalent AArch64 descriptions.
- When FEAT_XS is implemented SCTLR.{C, I} and HCR2.{ID, CD} fields have no effect on the value of the XS attribute.

For the Secure PL1&0 translation regime

The Secure instance of SCTLR holds the controls that determine cacheability:

- When the value of SCTLR.C is 0:
  - All data accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.
  - All accesses to the Secure PL1&0 translation tables are Non-cacheable.
- When the value of SCTLR.I is 0:
  - All instruction accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.

In addition, when the value of SCTLR.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

- The Secure SCTLR.{I, C, M} fields have no effect on the Non-secure PL1&0 and EL2 translation regimes.
- When FEAT_XS is implemented, the SCTLR.{I, C} fields have no effect on the value of the XS attribute.

For the EL2 translation regime

- When the value of HSCTLR.C is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of HSCTLR.I is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of HSCTLR.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of HSCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of HSCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
The effect of the SCTLR.C or HSCTLR.C and HCR2.CD bits is reflected in the result of the address translation instructions in the PAR.

--- Note ---

- The requirements in this section mean the architecturally required effects of SCTLR.I and HSCTLR.I are limited to their effects on caching instruction accesses in unified caches.

- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in MisMatched memory attributes on page E2-7208 must be followed to manage the corresponding loss of coherency.

---

**G4.4.5 Behavior of caches at reset**

The following rules apply to caches at reset:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.

- The Cacheability control fields described in Enabling and disabling the caching of memory accesses in AArch32 state on page G4-9117 reset to values that force all memory locations to be treated as Non-cacheable.

--- Note ---

This applies only to the controls that apply to the Translation regime that is used by the Exception level, PE mode, and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- Arm recommends that whenever an invalidation routine is required, it is based on the cache maintenance instructions.

Similar rules apply to:

- Branch predictor behavior, see Behavior of the branch predictors at reset on page G4-9127.

- TLB behavior, see TLB behavior at reset on page G5-9217.

---

**G4.4.6 About cache maintenance in AArch32 state**

The following sections give general information about cache maintenance:

- Terms used in describing the cache maintenance instructions on page G4-9120.

- Abstraction of the cache hierarchy on page G4-9122.
The following sections describe the AArch32 state cache maintenance instructions:

- AArch32 instruction cache maintenance instructions (IC*) on page G4-9124.
- AArch32 data cache maintenance instructions (DC*) on page G4-9125.

Note
Some descriptions of the cache maintenance instructions refer to the Cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR.\{I, C\} controls.

Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- Terminology for cache maintenance instructions operating by set/way.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page G4-9121.

Note
There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-9154.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level
The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR.

In the Arm architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy on page E2-7188.

Set
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the Arm architecture, sets are numbered from 0.

Way
The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the Arm architecture, ways are numbered from 0.

Note
Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, Arm expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.
Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

Note Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache clean and invalidate instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.

- For instruction operating by VA, two conceptual points are defined:

  Point of Coherency (PoC)

  The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

  Note The presence of system caches can affect the determination of the point of coherency as described in System level caches on page G4-9137.
Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the CLIDR relate to these conceptual points:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see the CLIDR description.

Abstraction of the cache hierarchy

The following subsections describe the abstraction of the cache hierarchy:

- Cache maintenance instructions that operate by VA on page G4-9123.
- Cache maintenance instructions that operate by set/way on page G4-9123.
Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See Terms used in describing the cache maintenance instructions on page G4-9120 for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

AArch32 cache and branch predictor maintenance instructions lists the VA-based maintenance instructions.

The CTR holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

AArch32 cache and branch predictor maintenance instructions lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table G4-3 on page G4-9123 shows the AArch32 System instructions. Instructions that take an argument include Rt in the instruction description.

AArch32 state also provides branch predictor maintenance instructions.

Note

- In Table G4-3 on page G4-9123 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.
- In AArch64 state, branch predictors are always invisible to software, and therefore AArch64 state does not provide any branch predictor maintenance instructions.

Table G4-3 AArch32 System instructions for cache maintenance

<table>
<thead>
<tr>
<th>Register</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICIALLUIS</td>
<td>Invalidate all to Point of Unification, Inner Shareable</td>
</tr>
<tr>
<td>ICIALLU</td>
<td>Invalidate all to Point of Unification</td>

<tr>
<td>ICIMVAU, Rt</td>
<td>Invalidate by virtual address to Point of Unification</td>
</tr>
</tbody>
</table>
A DS8 instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the BPIMVA, BPIALLIS, and BPIALL instructions can execute as NOPs.

The following subsections give more information about these instructions:

- AArch32 instruction cache maintenance instructions (IC*).
- AArch32 data cache maintenance instructions (DC*) on page G4-9125.
- Branch predictors on page G4-9126.
- General requirements for the scope of cache and branch predictor maintenance instructions on page G4-9127.
- Effects of instructions that operate by VA to the Point of Coherency on page G4-9128.
- Effects of instructions that operate by VA but not to the Point of Coherency on page G4-9128.
- Effects of All and set/way maintenance instructions on page G4-9128.
- Effects of virtualization and security on the AArch32 cache maintenance instructions on page G4-9129.
- Boundary conditions for cache maintenance instructions on page G4-9131.
- Ordering of cache and branch predictor maintenance instructions on page G4-9132.
- Performing cache maintenance instructions on page G4-9133.

### AArch32 instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or at EL1.
- For an instruction executed at EL1, the VMID.
That VA to PA translation might fault. However for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case on a Stage 2 fault on a stage 1 translation table walk.

For more information about the possible faults on an instruction that operates by VA, see *Types of MMU faults on page G5-9239*.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the completion requirements for cache and branch predictor maintenance instructions in *Completion and endpoint ordering on page E2-7176*.

See also *Ordering of cache and branch predictor maintenance instructions on page G4-9132*.

### AArch32 data cache maintenance instructions (DC*)

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register. If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see *Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-11574* or the instruction description.

DCISW instructions executed at EL1 perform a clean and invalidate, meaning it performs the same maintenance as a DCCISW instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - EL2 is using AArch32 and the value of HCR.SWIO is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.SWIO is 1.

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from EL1.
- For an instruction executed from EL1, the VMID.

That VA to PA translation might fault. However a data or unified cache maintenance instruction that operates by VA cannot generate a Data Abort exception for a Domain fault, and cannot generate a Data Abort exception for a Permission fault, except for the Permission fault case on a Stage 2 fault on a stage 1 translation table walk.

For more information about the possible faults on an instruction that operates by VA, see *Types of MMU faults on page G5-9239*.

DCIMVAC and DCISW instructions executed at EL1 perform a clean and invalidate, meaning they perform the same maintenance as a DCCIMVAC or DCCISW instruction respectively, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- PL1&0 stage two address translation is enabled, meaning either:
  - EL2 is using AArch32 and the value of HCR.VM is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VM is 1.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also *Ordering of cache and branch predictor maintenance instructions on page G4-9132*.
Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see Specific requirements for branch predictor maintenance instructions.

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as NOPs.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

—  Note  ——

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

—  Note  ——

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also Ordering of cache and branch predictor maintenance instructions on page G4-9132.

Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

• For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.

• For the Non-secure PL1&0 translation regime:
  — When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
  — When stage 2 translations are disabled, enabling or disabling stage 1 translations.
  — Enabling or disabling stage 2 translations.

• Writing new mappings to the translation tables.

• Any change to the TTBR0, TTBR1, or TTBCR registers, unless:
  — For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
  — For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.

• Any change to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

—  Note  ——

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:
• Changing a valid translation to a translation that generates an MMU fault.
• Changing a translation that generates an MMU fault to a valid translation.

Failure to invalidate entries might give CONSTRAINED UNPREDICTABLE results, caused by the execution of old branches. For more information, see Ordering of cache and branch predictor maintenance instructions on page G4-9132.

Note
• There is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
  — Changing the ContextID or VMID.
  — A cache maintenance instruction that is identified as also flushing the branch predictors, see AArch32 cache and branch predictor maintenance instructions on page G4-9123.

Cache maintenance system instructions on page K17-11905 shows the branch predictor maintenance operations in a VMSA implementation.

**Behavior of the branch predictors at reset**

In AArch32 state:
• If branch predictors are not architecturally invisible:
  — The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
  — The branch predictors are disabled at reset.
• An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
• Arm recommends that whenever an invalidation routine is required, it is based on the AArch32 branch predictor maintenance operations.

Similar rules apply:
• To cache behavior, see Behavior of caches at reset on page G4-9119.
• To TLB behavior, see TLB behavior at reset on page G5-9217.

**General requirements for the scope of cache and branch predictor maintenance instructions**

The specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page G4-9113, Behavior of caches at reset on page G4-9119, and Preloading caches on page E2-7191.

This means that as a side-effect of a cache maintenance instruction:
• Any location in the cache might be cleaned.
• Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

Note
Arm recommends that, for best performance, such side-effects are kept to a minimum. Arm strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.
**Effects of instructions that operate by VA to the Point of Coherency**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

**Table G4-4 PEs affected by cache maintenance instructions to the Point of Coherency**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA but not to the Point of Coherency**

The following instruction operate by VA but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, DCCMVAU.
- Invalidate instruction cache line by MVA to Point of Unification, ICIMVAU.
- Invalidate by MVA from branch predictors, BPIMVA.

For these instructions, Table G4-5 on page G4-9128 shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table G4-5 PEs affected by cache maintenance instructions to the Point of Unification**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>

**Note**

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.

**Effects of All and set/way maintenance instructions**

The ICIALLU, BPIALL and Dc* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLU also performs a BPIALL operation.
The ICIALLUIS and BPIALLIS instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLUIS also performs a BPIALLIS operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

--- Note ---

The possible presence of system caches, as described in System level caches on page G4-9137, means architecture does not guarantee that all levels of cache can be maintained using set/way instructions.

**Effects of virtualization and security on the AArch32 cache maintenance instructions**

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table G4-6 on page G4-9129 shows the effects of virtualization and security on these maintenance instructions.

**Table G4-6 Effects of virtualization and security on the AArch32 cache maintenance instructions**

<table>
<thead>
<tr>
<th>Cache maintenance instructions</th>

</table>

- **Invalidate, Clean, or Clean and Invalidate by VA:** DCIMVAC, DCCMVAC, DCCMVACU, DCCIMVAC
  - All lines that hold the PA that, in the current translation regime, are mapped to by the combination of all of:
    - The specified VA.
    - For an instruction executed at EL1, the current ASID if the location is mapped to by a non-global page.
    - For a Non-secure instruction executed at EL1, the current VMID.
    - For a Non-secure instruction executed at EL2 when EL2 is using AArch64 and HCR_EL2.E2H, TGE is not {1,1}, the current VMID.
    - For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR_EL3.EEL2 is 1, the current VMID.
    - For a Secure instruction executed at EL0 when EL3 is using AArch64 and SCR_EL3.EEL2 is 1, and HCR_EL2.E2H, TGE is not {1,1}, the current VMID.

- **Invalidate, Clean, or Clean and Invalidate by set/way:** DCISW, DCCSW, DCCISW
  - For a Non-secure instruction, the line specified by set/way provided that the entry comes from the Non-secure PA space.
  - For a Secure instruction, the line specified by set/way regardless of the PA space that the entry has come from.
### Instruction cache maintenance instructions

Invalidates all lines corresponding to the specified VA\(^b\) in the current translation regime and:
- For an instruction executed at EL1 or EL0, the current ASID.
- For a Non-secure instruction executed at EL1 or EL0, the current VMID\(^a\).
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, the current VMID\(^a\).

For a Secure instruction executed at EL0 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, the current VMID\(^a\).

### Invalidate All: ICIMVAU, ICIMV AUX

Can invalidate any unlocked entry in the instruction cache, and are required to invalidate:
- For a Non-secure instruction executed at EL1, all instruction cache lines containing Non-secure entries associated with the current VMID.
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, all instruction cache lines containing entries associated with the current VMID.
- For a Secure instruction executed at EL0 when EL3 is using AArch64, SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, all instruction cache lines.
- For a Secure instruction executed at EL3 all instruction cache lines.

---

### Branch predictor instructions\(^c\)

Invalidates all lines that, in the current translation regime, are mapped to by the combination of all of:
- The specified VA.
- For an instruction executed at EL1 or EL0, the current ASID.
- For a Non-Secure instruction executed at EL1 or EL0, the current VMID\(^a\).
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, the current VMID\(^a\).
- For a Secure instruction executed at EL0 when EL3 is using AArch64, SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, the current VMID\(^a\).

Invalidates all lines that, in the current translation regime, are mapped to by the combination of all:
- The specified VA.
- For an instruction executed at EL1 or EL0, the current ASID.
- For a Non-Secure instruction executed at EL1 or EL0, the current VMID\(^a\).
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, the current VMID\(^a\).
- For a Secure instruction executed at EL0 when EL3 is using AArch64, SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, the current VMID\(^a\).

Invalidates all lines that, in the current translation regime, are mapped to by the combination of all:
- The specified VA.
- For an instruction executed at EL1 or EL0, the current ASID.
- For a Non-Secure instruction executed at EL1 or EL0, the current VMID\(^a\).
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, the current VMID\(^a\).
- For a Secure instruction executed at EL0 when EL3 is using AArch64, SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, the current VMID\(^a\).

### Invalidate all: BPIMVA, BPI MV A

Can invalidate any unlocked entry in the branch predictor, and are required to invalidate:
- For a Non-secure instruction executed at EL1, all lines containing Non-secure entries associated with the current VMID.
- For a Secure instruction executed at EL1 when EL3 is using AArch64 and SCR\_EL3.EEL2 is 1, all lines containing entries associated with the current VMID.
- For a Secure instruction executed at EL0 when EL3 is using AArch64, SCR\_EL3.EEL2 is 1, and HCR\_EL2.{E2H, TGE} is not \{1,1\}, all lines.
- For a Secure instruction executed at EL3 all lines.

---

\(^a\) Dependencies on the VMID apply even when either EL2 is using AArch32 and the value of HCR.VM is 0 or EL2 is using AArch64 when enabled for the current Security state, and the value of HCR\_EL2.VM is 0. If the PE resets into an Exception level that is using AArch32, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset. However, if the PE resets into an Exception level that is using AArch64, VTTBR\_EL2.VMID resets to a value that is architecturally UNKNOWN, and the VTTBR\_EL2.VMID field must be set to a known value, that might be zero, as part of the PE initialization sequence.
b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:
   □ For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
   □ For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information of types of instruction cache, see Instruction caches on page G5-9235.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in The interaction of cache lockdown with cache maintenance instructions on page G4-9136 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

• The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, EL1 invalidate by set/way instructions executed in at EL1 when HCR_EL2.VM or HCR.VM is 1 and EL2 is enabled can, instead, perform a clean and invalidate by set/way.

• The AArch32 Data cache invalidate instructions DCIMVAC and DCISW perform a cache clean as well as a cache invalidate, meaning DCIMVAC performs the same invalidation as a DCCIMVAC instruction, and DCISW performs the same invalidation as a DCCISW instruction, if both of the following apply:
  — EL2 is using AArch32, the value of HCR.VM is 1, and the instruction is executed at Non-secure EL1.
  — EL2 is using AArch64, the value of HCR_EL2.VM is 1, EL2 is enabled, and the instruction is executed at EL1.

• The AArch32 Data cache invalidate by set/way instruction DCISW performs a cache clean as well as a cache invalidate, meaning it performs the same invalidation as a DCCISW instruction, if either of the following apply:
  — EL2 is using AArch32, the value of HCR.SWIO is 1, and the instruction is executed at Non-secure EL1.
  — EL2 is using AArch64, the value of HCR_EL2.SWIO is 1, EL2 is enabled, and the instruction is executed at EL1.

• TLB and instruction cache invalidate instructions are broadcast across the Inner Shareable domain when either:
  — EL2 is using AArch32, the value of HCR.FB is 1, and execution is at Non-secure EL1.
  — EL2 is using AArch64, the value of HCR_EL2.FWB is 1, EL2 is enabled, and the instruction is executed at EL1.

When EL1 is using AArch32, this applies to the TLBIMVA, TLBIA SID, TLBIMVAA, TLBIMVAL, TLBIMVAAL, and ICIALLU instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example ICIALLU performs the invalidation that would be performed by ICIALLUIS, and BPIALL performs the invalidation that would be performed by BPIALLIS.

For more information about the cache maintenance instructions, see About cache maintenance in AArch32 state on page G4-9119, AArch32 cache and branch predictor maintenance instructions on page G4-9123, and Chapter G5 The AArch32 Virtual Memory System Architecture.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

• Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.
• Any applicable domain control of the address accessed.
• The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

• All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.

All cache and branch predictor instructions that specify an address:

— Execute in program order relative to all cache and branch predictor operations that do not specify an address.
— Execute in program order relative to all cache and branch predictor operations that specify the same address.
— Can execute in any order relative to cache and branch predictor operations that specify a different address.

• Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.

• Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in Ordering and completion of TLB maintenance instructions on page G5-9223 before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.

• A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit memory read and write effects appearing in program order after the DMB.

Also, a DMB instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the DMB are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.

• A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.

• A Context synchronization event is required to guarantee the effects of any branch predictor maintenance operation. This means a Context synchronization event causes the effect of all completed branch predictor maintenance operations appearing in program order before the Context synchronization event to be visible to all instructions after the Context synchronization event. This means that, if a branch instruction appears after an invalidate branch predictor operation and before any Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONSTRAINED UNPREDICTABLE behavior.

• Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit memory read or write effect on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see Definition of the memory model on page E2-7168.

• There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit memory read or write effect on the same PE where the address of the explicit memory read or write effect is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
• There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative
to any explicit memory read or write effect on the same PE. Where the ordering must be restricted, a DMB
instruction must be inserted to enforce ordering.
• Software must execute a Context synchronization event after the completion of an instruction cache
maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any
instruction fetch.

A DSB instruction intended to ensure the completion of cache maintenance instructions or branch predictor
instructions must have an access type of both loads and stores.

See also the completion requirements for cache and branch predictor maintenance instructions in Completion and
endpoint ordering on page E2-7176.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information, see
Instruction caches on page G5-9235.

**Example G4-1 Cache cleaning operations for self-modifying code**

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.

STR Rt, [Rn]
DCCMVAU Rn ; Clean data cache by MVA to point of unification (PoU)
DSB
ICIMVAU Rn ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn ; Invalidate branch predictor by MVA to PoU
DSB ; Ensure completion of the invalidations
ISB ; Synchronize the fetched instruction stream

**Performing cache maintenance instructions**

To ensure all cache lines in a block of address space are maintained through all levels of cache Arm strongly
recommends that software:

• For data or unified cache maintenance, uses the CTR.DMinLine value to determine the loop increment size
for a loop of data cache maintenance by VA instructions.
• For instruction cache maintenance, uses the CTR.IMinLine value to determine the loop increment size for a
loop of instruction cache maintenance by VA instructions.

**Example code for cache maintenance instructions**

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or
more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations
as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of
the cache maintenance instructions.

**Note**

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance
between different PEs, even if those different PEs are each executing the same cache maintenance instructions at
the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line
to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is
not affected by set/way based cache maintenance. Therefore, Arm strongly discourages the use of set/way
instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that
operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if
this is required by the implementation.
The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and Arm advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

System level caches on page G4-9137 refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes the current Cache Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2 on page G4-9115.

```assembly
MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
ANDS R3, R0, #0x07000000
MOV R3, R3, LSR #23 ; Cache level value (naturally aligned)
BEQ Finished
MOV R10, #0
Loop1
ADD R2, R10, R10, LSR #1 ; Work out 3 x cache level
MOV R1, R0, LSR R2 ; bottom 3 bits are the Cache type for this level
AND R1, R1, #7 ; get those 3 bits alone
CMP R1, #2 ; no cache or only instruction cache at this level
BLT Skip
MCR p15, 2, R10, c0, c0, 0 ; write CSSELR from R10
ISB ; ISB to sync the change to the CCSIDR
MRC p15, 1, R1, c0, c0, 0 ; read current CCSIDR to R1
AND R2, R1, #7 ; extract the line length field
ADD R2, R2, #4 ; add 4 for the line length offset (log2 16 bytes)
MOV R4, #0x3FF
ANDS R4, R4, R1, LSR #3 ; R4 is the max number on the way size (right aligned)
CLZ R5, R4 ; R5 is the bit position of the way size increment
MOV R9, R4 ; R9 working copy of the max way size (right aligned)
Loop2
MOV R7, #0x00007FFF
ANDS R7, R7, R1, LSR #13 ; R7 is the max number of the index size (right aligned)
Loop3
ORR R11, R10, R9, LSL R5 ; factor in the way number and cache number into R11
ORR R11, R11, R7, LSL R2 ; factor in the index number
MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
SUBS R7, R7, #1 ; decrement the index
BGE Loop3
SUBS R9, R9, #1 ; decrement the way number
BGE Loop2
Skip
ADD R10, R10, #2 ; increment the cache number
CMP R3, R10 ; ensure completion of previous cache maintenance instruction
DSB
BGT Loop1
Finished
```

Similar approaches can be used for all cache maintenance instructions.

G4.4.8 Execution and data prediction restriction System instructions

When FEAT_SPECRES is implemented, the System instructions for prediction restriction listed in Table G4-7 on page G4-9135 prevent predictions based on information gathered from earlier execution within a particular execution context (CTX), from affecting the later speculative execution within that CTX, to the extent that the speculation execution is observable through side-channels.

G4-9134
The prediction restriction System instructions being used by a particular CTX apply to:

- All control flow prediction resources that predict execution addresses.
- Data value prediction.
- Cache allocation prediction.

For these System instructions, the CTX is defined by:

- The Security state.
- The Exception level.
- When executing at EL1, the VMID.
- When executing at EL0 when using the PL1&0 translation regime, the ASID and VMID.

Note

- The data value prediction applies to all prediction resources that use some form of training to speculate data values as part of an execution.
- The cache allocation applies to all instruction and data caches, and TLB prefetching hardware used by the executing PE that applies to the supplied context.

The context information is passed as a register argument, and is restricted so that:

- Execution of the System instruction at EL0 applies only to the current hardware defined context.
- Execution of the System instruction at EL1 applies only to the current VMID and Security state, and does not apply to EL2 or EL3.
- Execution of the System instruction at EL2 can apply only to the current Security state, and does not apply to EL3.

If the System instruction is specified to apply to Exception levels that are not implemented, or which are higher than the Exception level that the System instruction is executed at, then the System instruction is treated as a \texttt{NOP}.

When the System instruction is complete and synchronized, no predictions of the restricted type for the affected context are influenced by the execution of the program before the System instruction in a manner that can be observed by the use of any side channels.

Note

- Prediction restriction System instructions do not require the invalidation of prediction structures so long as the behavior described for completion is met by an implementation.
- Prediction restriction System instructions are permitted to invalidate more prediction information than is defined by the supplied CTX.

These System instructions are guaranteed to be complete following a \texttt{DSB} that covers both read and write behavior on the same PE that executed the original instruction. A subsequent Context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

In AArch32 state, EL0 access to the System instructions is controlled by \texttt{SCTL.RnRCTX}.

G4.4.9 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DCCSW.
  - Cache invalidate by set/way, DCISW.
  - Cache clean and invalidate by set/way, DCISW.
  - Instruction cache invalidate all, ICIALLU and ICIALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See Data Abort exception on page G1-8975.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DCCMVAC and DCCMVAU.
- Cache invalidate by virtual address, DCIMVAC.
- Cache clean and invalidate by virtual address, DCCIMVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See DFSR or HSR.

In an implementation that includes EL2, if HCR.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.
Note
An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown
An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space.

G4.4.10 System level caches
The Arm Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR, CCSIDR2, and CLIDR, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the Arm architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.
G4.5 System register support for IMPLEMENTATION DEFINED memory features

The VMSA v8-32 defines the following registers for describing IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, TCMTR must be implemented on any implementation where EL1 or above supports AArch32. The format of this register is IMPLEMENTATION DEFINED.
- The System register encoding space with \{\text{coproc}==0b1111, \text{CRn}==c9, \text{CRm}==\{c0-c2, c5-c7\}\} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.
- In a VMSA v8-32 implementation, part of the System register encoding space with \{\text{coproc}==0b1111, \text{CRn}==c10\} is IMPLEMENTATION DEFINED and reserved for TLB functionality, see TLB lockdown on page G5-9218.
- The System register encoding space with \{\text{coproc}==0b1111, \text{CRn}==c11, \text{CRm}==\{c0-c8, c15\}\} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for DMA operations to and from the TCMs.

In addition, the System register encoding space with \{\text{coproc}==0b1111, \text{CRn}==c15\} is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see AArch32 VMSA organization of registers in the (coproc == 0b1111) encoding space on page G7-9304.
G4.6 External aborts

The Arm architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of:
- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page G1-8900.

The RAS Extension provides an expanded taxonomy for describing aborts. When the RAS Extension is not implemented, the Arm architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

VMSAv8-32 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the External abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported. Asynchronous External aborts generate SError interrupt exceptions.

In AArch32 state:
- SError interrupts are taken as asynchronous Data Abort exceptions.
- Synchronous External aborts:
  - On data accesses are taken as synchronous Data Abort exceptions.
  - On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

See also:
- External abort on a translation table walk on page G5-9247.
- Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running. Arm recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:
- Provision for classification of External aborts.
- Parity or ECC error reporting, RAS Extension not implemented on page G4-9140.

The section Exception reporting in a VMSAv8-32 implementation on page G5-9251 describes the reporting of External aborts.

G4.6.1 Provision for classification of External aborts

For an External abort taken to a privileged mode other than Hyp mode, an implementation can use the DFSR.ExT or IFSR.ExT bits to provide more information about the External abort:
- DFSR.ExT provides an IMPLEMENTATION DEFINED classification of External aborts on data accesses.
- IFSR.ExT provides an IMPLEMENTATION DEFINED classification of External aborts on instruction accesses.

For an External abort taken to Hyp mode, the HSR.EA bit, provides an IMPLEMENTATION DEFINED classification of External aborts.

For all aborts other than External aborts these bits return a value of 0.
If the RAS Extension is implemented:

- The HSR.AET field provides information about the state of the PE following an SError interrupt exception taken to Hyp mode.
- The DFSR.AET field provides information about the state of the PE following an asynchronous Data Abort exception.
- The implementation might define error record registers.

For more information on the RAS Extension, see Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

**G4.6.2 Parity or ECC error reporting, RAS Extension not implemented**

The Arm architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Exception reporting in a VMSAv8-32 implementation on page G5-9251. However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
G4.7 Memory barrier instructions

Memory barriers on page E2-7181 describes the memory barrier instructions. This section describes the system level controls of those instructions.

G4.7.1 EL2 control of the Shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports Shareability limitations on the data barrier instructions, the HCR.BSU field can modify the required Shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table G4-8 on page G4-9141 shows the encoding of this field:

Table G4-8 EL2 control of Shareability of barrier instructions executed at EL0 or EL1

<table>
<thead>
<tr>
<th>HCR.BSU</th>
<th>Minimum Shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, Shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1 in Non-secure state, Table G4-9 on page G4-9141 shows how the HCR.BSU is combined with the Shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

Table G4-9 Effect of the HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL1

<table>
<thead>
<tr>
<th>Shareability specified by the DMB or DSB argument</th>
<th>HCR.BSU</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full system</td>
<td>Any</td>
<td>Full system</td>

G4.8 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access.
- Unaligned memory access.
- Exclusives monitors operations.
- Access permission checking on page G4-9143.
- Abort exceptions on page G4-9144.
- Memory barriers on page G4-9144.

G4.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, MemHint_RA, and MemHint_RWA constants.
- Access permissions, defined by the Permissions type.

G4.8.2 Basic memory access

The PhysMemRead() and PhysMemWrite() functions perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page E2-7198, Definition of the memory model on page E2-7168, and Atomicity in the Arm architecture on page E2-7164.

G4.8.3 Aligned memory access

The AArch32.MemSingle[] functions make atomic, little-endian accesses of size bytes.

G4.8.4 Unaligned memory access

See Unaligned data access on page E2-7193 for details of the SCTLR.A and HSCTLR.A controls on the generation of alignment faults. The HSCTLR control applies to Normal memory accesses from Hyp mode, and the SCTLR control applies to Normal memory accesses from all other modes.

The Mem_with_type[] functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to AArch32.MemSingle[]. If that access is not aligned but passes the AArch32.CheckAlignment() checks, each form of the function synthesizes the required access from multiple calls to AArch32.MemSingle[]. It also reverses the byte order if the access is big-endian.

G4.8.5 Exclusives monitors operations

The AArch32.SetExclusiveMonitors() function sets the Exclusives monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by size, at the VA address. The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors and therefore completes successfully.
The `AArch32.ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors, by checking whether the Exclusives monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to `AArch32.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a FullAddress, paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `IsExclusiveLocal()` function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least the size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

### G4.8.6 Access permission checking

The AArch32.S1LDHasPermissionsFault(), AArch32.S1SDHasPermissionsFault(), and AArch32.S2HasPermissionsFault() functions are used by the architecture to perform access permission checking based on attributes derived from the Translation Table descriptors.

The interpretation of access permission is shown in Memory access control on page G5-9192.
G4.8.7 Abort exceptions

The function `AArch32.Abort()` generates a Data Abort exception or a Prefetch Abort exception by calling the `AArch32.TakeDataAbortException()` or `AArch32.TakePrefetchAbortException()` function.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode description of VMSAv8-32 memory system operations on page G5-9278* provides a number of wrappers to generate a `FaultRecord`.

The function `NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

G4.8.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required Shareability domains and required access types used as arguments for `DMB` and `DSB` instructions.

The procedures `DataMemoryBarrier()`, `DataSynchronizationBarrier()`, and `InstructionSynchronizationBarrier()` perform the memory barriers.
Chapter G5
The AArch32 Virtual Memory System Architecture

This chapter describes the A-profile AArch32 Virtual Memory System Architecture (VMSA). It includes the following sections:

• About VMSA v8-32 on page G5-9146.
• The effects of disabling address translation stages on VMSA v8-32 behavior on page G5-9154.
• Translation tables on page G5-9158.
• The VMSA v8-32 Short-descriptor translation table format on page G5-9163.
• The VMSA v8-32 Long-descriptor translation table format on page G5-9172.
• Memory access control on page G5-9192.
• Memory region attributes on page G5-9203.
• Translation Lookaside Buffers (TLBs) on page G5-9216.
• TLB maintenance requirements on page G5-9220.
• Caches in VMSA v8-32 on page G5-9235.
• VMSA v8-32 memory aborts on page G5-9238.
• Exception reporting in a VMSA v8-32 implementation on page G5-9251.
• Address translation instructions on page G5-9271.
• Pseudocode description of VMSA v8-32 memory system operations on page G5-9278.
• About the System registers for VMSA v8-32 on page G5-9281.
• Functional grouping of VMSA v8-32 System registers on page G5-9286.

Note
This chapter must be read with Chapter G4 The AArch32 System Level Memory Model.
G5.1 About VMSAv8-32

This chapter describes the A-profile VMSA for AArch32 state, VMSAv8-32.

This chapter describes the control of the VMSA by Exception levels that are using AArch32. Security state, Exception levels, and AArch32 execution privilege on page G1-8908 summarizes how the AArch32 PE modes map onto the Exception levels.

FEAT_SEL2, if implemented, is not available in AArch32 state and EL2 only executes in Non-secure state.

FEAT_S2FWB, if implemented, is not available in AArch32 state. If EL2 is executing in AArch64 state 2 stage translations might be affected. For more informations see Chapter D8 The AArch64 Virtual Memory System Architecture.

Chapter D8 The AArch64 Virtual Memory System Architecture describes the control of the VMSA by Exception levels that are using AArch64.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a stage of address translation.

In VMSAv8-32, the Memory Management Unit (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

For operation in Secure state
A single stage of address translation, for use when executing at PL1 or EL0. This is the Secure PL1&0 stage 1 address translation stage.

For operation in Non-secure state
  • A single stage of address translation for use when executing at EL2. This is the Non-secure EL2 stage 1 address translation stage.
  • Two stages of address translation for use when executing at PL1 or EL0. These are:
    — The Non-secure PL1&0 stage 1 address translation stage.
    — The Non-secure PL1&0 stage 2 address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

However, if the PE is executing at EL0 using AArch32 when EL1 is using AArch64 then it is using the VMSAv8-64 EL1&0 translation regime, described in Chapter D8 The AArch64 Virtual Memory System Architecture.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called translation tables.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see About address translation for VMSAv8-32 on page G5-9149.

The translation tables define the following properties:

Access to the Secure or Non-secure address map
The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

Memory access permission control
This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:
  • No access.
  • Read-only.
  • Write-only. This is possible only in a translation regime with two stages of translation.
• Read/write.
  For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes
These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

• Both translation table formats support the following Device memory types:
  — Device-nGnRnE
  — Device-nGnRE

• The Long-descriptor translation table format supports, in addition, the following Device memory types:
  — Device-nGRE
  — Device-GRE

  Note
  Armv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the Arm architecture before Armv8:
  • Device-nGnRnE memory is described as Strongly-ordered memory.
  • Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.
For more information, see Memory types and attributes on page E2-7198.

Address translation mappings
An address translation maps an input address to an output address.
A stage 1 translation takes the address of an explicit data access or instruction fetch, a virtual address (VA), as the input address, and translates it to a different output address:

• If only one stage of translation is provided, this output address is the physical address (PA).
• If two stages of address translation are provided, the output address of the stage 1 translation is an intermediate physical address (IPA).

  Note
  In the Armv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.
The possible Security states and privilege levels of memory accesses define a set of translation regimes, where a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. See The VMSAv8-32 translation regimes on page G5-9148.

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see Functional grouping of VMSAv8-32 System registers on page G5-9286.

The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

• The VMSAv8-32 translation regimes on page G5-9148.
• Address types used in a VMSAv8-32 description on page G5-9148.
• Address spaces in VMSAv8-32 on page G5-9149.
• About address translation for VMSAv8-32 on page G5-9149.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in Organization of the remainder of this chapter on page G5-9153.
G5.1.1 The VMSAv8-32 translation regimes

As introduced in Address translation mappings on page G5-9147, a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. Figure G5-1 shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

Translation regimes, for Exception levels that are using AArch32

Secure PL1&0 VA ——— Secure PL1&0 stage 1 ——— PA, Secure or Non-secure

Controlled from Secure PL1 modes†

Non-secure EL2 VA ——— Non-secure EL2 stage 1 ——— PA, Non-secure only

Controlled from Hyp mode†

Non-secure PL1&0 VA ——— Non-secure PL1&0 stage 1 ——— IPA

Controlled from Non-secure PL1 modes†

Non-secure PL1&0 stage 2 ——— PA, Non-secure only

Controlled from Hyp mode†

† Typical control when controlled from an Exception level using AArch32.

Figure G5-1 VMSAv8-32 translation regimes, and associated control

Note

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

Limited use of Privilege level in AArch32 state on page G1-8909 describes the mapping between the PE modes and the Privilege levels (PLs).

Alternative descriptions of the PL1&0 translation regime

The PL1&0 is described in terms of Privilege level because of the way the AArch32 PE modes map onto the Exception levels, as described in Limited use of Privilege level in AArch32 state on page G1-8909. The description of this translation regime in terms of the Exception levels using depends on the current state of the PE, as follows:

• In Non-secure state, PL1 always maps to EL1, and therefore the Non-secure PL1&0 translation regime could be described as the Non-secure EL1&0 translation regime.

• In Secure state:
  — When EL3 is using AArch32, PL1 maps to EL3, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL3&0 translation regime,
  — When EL3 is using AArch64, Secure PL1 maps to Secure EL1, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL1&0 translation regime,

However, these descriptions all refer to the same translation regime, with the same System registers associated with its stage 1 translations. Therefore, the regime is generally referred to as the PL1&0 translation regime.

Note

As Figure G5-1 shows, stage 2 translation is supported only in Non-secure state.

G5.1.2 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.
Note

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

Virtual address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of `0x00000000-0xFFFFFFFF`.

Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

Physical address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G5.1.3 Address spaces in VMSAv8-32

For execution in AArch32 state, the architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

Note

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

G5.1.4 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register (TTBR)* indicates the start of a translation table. Each implemented stage of address translation shown in Figure G5-1 on page G5-9148 requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
• A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

**VMAv8-32 without EL2 or EL3**
- Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by TTBR0 and TTBR1, and controlled by TTBCR.

**VMAv8-32 with EL3 but without EL2**
- Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each Security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of TTBR0 and TTBR1, and controlled by the Secure and Non-secure copies of TTBCR.

**VMAv8-32 with EL2 but without EL3**
- The implementation supports the following stages of address translation:
  - **Non-secure EL2 stage 1 address translation**
    The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.
  - **Non-secure PL1&0 stage 1 address translation**
    Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1, and controlled by the Non-secure instance of TTBCR.
  - **Non-secure PL1&0 stage 2 address translation**
    The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

**VMAv8-32 with EL2 and EL3**
- The implementation supports all of the stages of address translation, as follows:
  - **Secure PL1&0 stage 1 address translation**
    Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of TTBR0 and TTBR1, and controlled by the Secure instance of TTBCR.
  - **Non-secure EL2 stage 1 address translation**
    The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.
  - **Non-secure PL1&0 stage 1 address translation**
    Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1, and controlled by the Non-secure instance of TTBCR.
  - **Non-secure PL1&0 stage 2 address translation**
    The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

Figure G5-2 on page G5-9151 shows the translation regimes and stages in a VMAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:
The term *Typically configured* is used in Figure G5-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G5-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.
- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G5-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:
  - The required output address.
  - The *attributes* and access permissions of the addressed memory.

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

The Arm architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The ASID identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the VMID identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.
Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure PL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure PL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
  - MAIR0, MAIR1, AMAIR0, and AMAIR1.
  - TTBR0, TTBR1, TTBCR, TTBCR2, and CONTEXTIDR.
  - SCTLR.

- The registers associated with the stage 2 translations:
  - VTTBR and VTCR.
  - HSCTLR.

**Note**

Only some fields of SCTLR affect the stage 1 translation, and only some fields of HSCTLR affect the stage 2 translation. However, in each case, changing these fields requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure PL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure PL1&0 translation regime for speculative memory accesses.

If the Statistical Profiling Unit (SPU) is not in use for a lower Exception level when entering an Exception level on completion of a DSB instruction, then no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

If the SPU is in use for a lower Exception level when entering an Exception level on completion of a PSB CSYNC and a subsequent DSB instruction, then no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

**Note**

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
• This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

G5.1.5 Organization of the remainder of this chapter

The remainder of this chapter is organized as follows.

The next part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

• The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-9154.
• Translation tables on page G5-9158.
• Secure and Non-secure address spaces on page G5-9161.
• The VMSAv8-32 Short-descriptor translation table format on page G5-9163.
• The VMSAv8-32 Long-descriptor translation table format on page G5-9172.
• Memory access control on page G5-9192.
• Memory region attributes on page G5-9203.
• Translation Lookaside Buffers (TLBs) on page G5-9216.
• TLB maintenance requirements on page G5-9220.

Caches in VMSAv8-32 on page G5-9235 describes VMSAv8-32-specific cache requirements.

The following sections then describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

• VMSAv8-32 memory aborts on page G5-9238.
• Exception reporting in a VMSAv8-32 implementation on page G5-9251.

Address translation instructions on page G5-9271 then describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the primary encoding spaces, (coproc==0b1110) and (coproc==0b1111) for these registers:

• About the System registers for VMSAv8-32 on page G5-9281.
• Functional grouping of VMSAv8-32 System registers on page G5-9286.

Note

The System registers in the (coproc==0b1110) encoding space provide the following functionality:

• Self-hosted debug. These registers are described in Debug registers on page G8-9831.
• The System register interface to a trace unit These registers are not described in this manual.
• Jazelle registers. These registers are summarized in Legacy feature registers and system instructions on page K17-11908.

Therefore, there is no summary of these registers by functional groups.

Pseudocode description of VMSAv8-32 memory system operations on page G5-9278 then summarizes the pseudocode functions that describe many features of VMSAv8-32 operation.
G5.2 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G5-9146 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- SCTLR.M, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- SCTLR.M, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- HCR.VM controls Non-secure PL1&0 stage 2 address translation.
- HSCTLR.M controls Non-secure EL2 stage 1 address translation.

Note

The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
- Is controlled by the HCR if EL2 is using AArch32.
- Is controlled by the HCR_EL2 if EL2 is using AArch64.

For this reason, links to the HCR link to a table that disambiguates between the AArch32 HCR and the AArch64 HCR_EL2.

- If EL2 is using AArch64, then the equivalent of the Non-secure EL2 translation regime is described in Chapter D8 The AArch64 Virtual Memory System Architecture, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- VMSAv8-32 behavior when stage 1 address translation is disabled.
- VMSAv8-32 behavior when stage 2 address translation is disabled on page G5-9156.
- Behavior of instruction fetches when all associated address translations are disabled on page G5-9156.

Enabling stages of address translation on page G5-9156 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

G5.2.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

Non-secure PL1 and EL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or EL0 mode when HCR.DC is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

When FEAT_XS is implemented and HCR.DC is 1, the XS attribute is set to 0 at stage 1 of the translation. Otherwise, the XS attribute is set to 1 at stage 1 of the translation.

See also Effect of the HCR.DC field on page G5-9155.

All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns Normal memory attribute, with the Cacheability and Shareability attributes determined by the value of:
- The Secure instance of SCTLR.M for the Secure PL1&0 translation regime.
• The Non-secure instance of SCTLR.I for the Non-secure PL1&0 translation regime.
• HSCTLR.I for the Non-secure EL2 translation regime.

In these cases, the meaning of the I field is as follows:

**When I is set to 0**

The stage 1 translation assigns the attributes Outer Shareable,
Non-cacheable.

**When I is set to 1**

The stage 1 translation assigns the attributes Inner Write-Through
Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate
No Write-Allocate Cacheable.

--- **Note** ---

On some implementations, if the SCTLR.TRE field is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when SCTLR.TRE is set to 0 are IMPLEMENTATION DEFINED, see SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers on page G5-9209.

--- **Note** ---

For this stage of translation, no memory access permission checks are performed, and therefore no MMU Permission faults relating to this stage of translation can be generated.

--- **Note** ---

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or EL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also *Behavior of instruction fetches when all associated address translations are disabled* on page G5-9156.

**Effect of the HCR.DC field**

The HCR.DC field determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or EL0 mode with HCR.DC set to 1:

• For all purposes other than reading the value of the SCTLR, the PE behaves as if the value of the SCTLR.M field is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
• For all purposes other than reading the value of the HCR, the PE behaves as if the value of the HCR.VM field is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of HCR.DC might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the HCR.DC value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values* on page K1-11567.

**Effect of disabling translation on maintenance and address translation instructions**

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.
When the Non-secure PL1&0 stage 1 address translation is disabled, any ATS1C** or ATS12NSO** address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR.DC field.

**G5.2.2 VMSAv8-32 behavior when stage 2 address translation is disabled**

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see *Behavior of instruction fetches when all associated address translations are disabled*.

**G5.2.3 Behavior of instruction fetches when all associated address translations are disabled**

The information in this section applies to memory accesses:

- From Secure PL1 and EL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure EL2 stage 1 address translation is disabled
- From Non-secure PL1 and EL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - HCR.DC is set to 0.

In these cases, when execution is in AArch32 state a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same 4KB block of memory, aligned to 4KB, as an instruction which a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset, or is in the 4KB block immediately following such a block.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - If the branch predictor is architecturally invisible, the last synchronization of instruction cache maintenance targeting the address of the branch instruction.
  - If the branch predictor is not architecturally invisible, the last synchronization of branch predictor maintenance targeting the address of the branch instruction.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

--- **Note**

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

**G5.2.4 Enabling stages of address translation**

On powerup or Warm reset, only the SCTLRM field for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other SCTLRM and HSCTLRM fields that are implemented are UNKNOWN after the reset.
This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, SCTLR.M, is banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the SCTLR.M field resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of SCTLR.M is UNKNOWN.

- On an implementation that includes EL2, where EL2 is using AArch32, the HSCTLR.M field, that controls the Non-secure EL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.

- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by SCTLR.M, that resets to 0.

Note

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the System registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, Arm strongly recommends that the input address and the output address are identical in this situation.
G5.3 Translation tables

VMSAv8-32 defines two alternative translation table formats:

Short-descriptor format
It uses 32-bit descriptor entries in the translation tables, and provides:
- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

Long-descriptor format
It uses 64-bit descriptor entries in the translation tables, and provides:
- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

Note
- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its translation granule. This can be 4KB, 16KB, or 64KB. See Translation table descriptor formats on page D8-5123.

In all implementations, of the possible address translations shown in Figure G5-2 on page G5-9151, for stages of address translation that are using AArch32:
- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the TTBCR.EAE field indicates the current translation table format.
- The translation tables for the Non-secure EL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:
- The VMSAv8-32 Short-descriptor translation table format on page G5-9163.
- The VMSAv8-32 Long-descriptor translation table format on page G5-9172.

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:
- Translation table walks for memory accesses using VMSAv8-32 translation regimes on page G5-9159.
- Information returned by a translation table lookup on page G5-9159.
- Determining the translation table base address in the VMSAv8-32 translation regimes on page G5-9160.
- Control of translation table walks on a TLB miss on page G5-9161.
- Access to the Secure or Non-secure PA map on page G5-9161.

See also TLB maintenance requirements on page G5-9220.
G5.3.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G5-9169.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-9187.

Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1 lookup. However, with the Long-descriptor translation table format, the starting-level can be either a level 1 or a level 2 lookup.

For the PL1&0 stage 1 translations, SCTLR.EE determines the endianness of the translation table lookups. SCTLR is banked, and therefore the endianness is determined independently for each Security state.

HSCTLR.EE defines the endianness for the Non-secure EL2 stage 1 and Non-secure PL1&0 stage 2 translations.

Note

Dynamically changing translation table endianness

Because any change to SCTLR.EE or HSCTLR.EE requires synchronization before it is visible to subsequent operations, Arm strongly recommends that:

- SCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by SCTLR.EE.
  - Executing with SCTLR.M set to 0.
- HSCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by HSCTLR.EE.
  - Executing with HSCTLR.M set to 0.

The PA of the base of the starting-level translation table is determined from the appropriate TTBR, see Determining the translation table base address in the VMSAv8-32 translation regimes on page G5-9160.

For more information, see Ordering and completion of TLB maintenance instructions on page G5-9223.

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the Shareability attributes described in the TTBR. These Shareability attributes must be consistent with the Shareability attributes for the translation tables themselves.

G5.3.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required Translation Table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing address map control, access controls, or region attributes. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in Access to the Secure or Non-secure PA map on page G5-9161.

Memory accesses from Non-secure state can only access the Non-secure address map.
Access controls
Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, an MMU fault is generated and there is no memory access.

Memory access control on page G5-9192 describes the properties in this group.

Attributes
Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

Memory region attributes on page G5-9203 describes the properties in this group.

G5.3.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As Figure G5-2 on page G5-9151 shows:

- For a Non-secure EL2 stage 1 translation, the HTTBR holds the required base address. The HTCR is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the VTTBR holds the required base address. The VTCR is the control register for these translations.
- For a PL1&0 stage 1 translation, either TTBR0 or TTBR1 holds the required base address. The TTBCR is the control register for these translations.

The Non-secure copies of TTBR0, TTBR1, and TTBCR, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of TTBR0, TTBR1, and TTBCR, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- TTBR0 can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If TTBR0 is configured to describe the translation of VAs in the lower part of the address map, TTBR1 is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the TTBCR determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G5-9168.
- Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G5-9181.

Example G5-1 shows a typical use of the two sets of translation tables:

Example G5-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

**TTBR0**
Used for process-specific addresses.
- Each process maintains a separate level 1 translation table. On a context switch:
  - TTBR0 is updated to point to the level 1 translation table for the new context.
  - TTBCR is updated if this change changes the size of the translation table.
  - The CONTEXTIDR is updated.
- TTBCR can be programmed so that all translations use TTBR0 in a manner compatible with architecture versions before Armv6.

**TTBR1**
Used for operating system and I/O addresses, that do not change on a context switch.
G5.3.4 Control of translation table walks on a TLB miss

Two fields in the TCR for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two fields are the:

- PD0 and PD1 fields, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 fields, on a PE using the Long-descriptor translation table format.

Note

For the VMSAv8-32 translation regimes, the different field names are because the fields are in different positions in TTBCR, depending on the translation table format.

The effect of these fields is:

{E}PDx == 0  If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current Security state determines whether the memory access is Secure or Non-secure.

{E}PDx == 1  If a TLB miss occurs based on TTBRx, a level 1 Translation fault is returned, and no translation table walk is performed.

G5.3.5 Access to the Secure or Non-secure PA map

As stated in Address spaces in VMSAv8-32 on page G5-9149, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure TTBR0 and TTBR1. In both translation table formats in the Secure translation tables, the NS field in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

NS == 0  Access the Secure PA space.

NS == 1  Access the Non-secure PA space.

Note

In the Non-secure translation tables, the corresponding field is SBZ. Non-secure accesses always access the Non-secure PA space, regardless of the value of this field.

The Long-descriptor translation table format extends this control, adding an NSTable field to the Secure translation tables, as described in Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G5-9180. In the Non-secure translation tables, the corresponding field is SBZ, and Non-secure accesses ignore the value of this field.

The following sections describe the address map controls in the two implementations:

- Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-9168.
- Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-9180.

The following subsection gives more information.

Secure and Non-secure address spaces

EL3 provides two PA spaces, a Secure PA space and a Non-secure PA space.

As described in Access to the Secure or Non-secure PA map, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the registers that control the stage of translation, TTBR0, TTBR1, TTBCR, and TTBCR2 are banked to provide independent Secure and Non-secure instances of the registers, and the Security state of the PE when it performs a memory access whether the Secure or Non-secure instances are used. This means that for stage 1 of the PL1&0 translation regime there are independent Secure and Non-secure translation tables, and translation table walks are made to the PA space corresponding to the Security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.
For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
  - The initial lookup performed must access the Secure address space.
  - If a Table descriptor read from the Secure address space has the NSTable field set to 0, then the next level of lookup is from the Secure address space.
  - If a Table descriptor read from the Secure address space has the NSTable field set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

  For more information, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-9180.

- Otherwise, all memory accesses are to the Secure address space.

--- Note ---

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state, these are:
  - Non-secure EL2 stage 1 translation.
  - Non-secure PL1&0 stage 2 translation.

  These translations can access only the Non-secure address space.

- A system implementation can alias parts of the Secure PA space to the Non-secure PA space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
G5.4 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections** Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of PA must also support Supersections to provide access to the entire PA space.

**Sections** Consist of 1MB blocks of memory.

**Large pages** Consist of 64KB blocks of memory.

**Small pages** Consist of 4KB blocks of memory.

Supersections, Sections, and Large pages map large regions of memory using only a single TLB entry.

--- Note ---

- Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.
- The EL2 translation regime cannot use the Short-descriptor translation table format.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

**Level 1 table**

Holds *level 1 descriptors* that contain the base address and
- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

**Level 2 tables**

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as translation tables.

A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A translation table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits\[1:0\] of the descriptor give the primary indication of the descriptor type.

Figure G5-3 on page G5-9164 gives a general view of address translation when using the Short-descriptor translation table format.
G5.4 The VMSAv8-32 Short-descriptor translation table format

Additional requirements for Short-descriptor format translation tables on page G5-9167 describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in Figure G5-3.

VMSAv8-32 Short-descriptor Translation Table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9167, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-9168 describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G5-9168.
- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G5-9169.

G5.4.1 VMSAv8-32 Short-descriptor Translation Table format descriptors

The following sections describe the formats of the entries in the Short-descriptor Translation Tables:

- Short-descriptor Translation Table level 1 descriptor formats.
- Short-descriptor Translation Table level 2 descriptor formats on page G5-9166.

For more information about level 2 translation tables, see Additional requirements for Short-descriptor format translation tables on page G5-9167.

Note

Information returned by a translation table lookup on page G5-9159 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

Short-descriptor Translation Table level 1 descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G5-4 on page G5-9165 shows the possible level 1 descriptor formats.
Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

0b00, **Invalid entry**

The associated VA is unmapped, and any attempt to access it generates a Translation fault. Bits[31:2] of the descriptor are ignored, see **IGNORED** on page Glossary-11937. This means software can use these bits for its own purposes.

0b01, **Translation table**

The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MByte VA range.

0b10, **Section or Supersection**

The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.

This encoding also defines the PXN field as 0.

0b11, **Section or Supersection, if the implementation supports the PXN attribute**

This encoding is identical to 0b10, except that it defines the PXN field as 1.

**Note**

A VMSAv8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting TTBCR.EAE to 0.

The address information in the level 1 descriptors is:

**Translation table** Bits[31:10] of the descriptor are bits[31:10] of the address of a translation table.

**Section** Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.
Supersection  

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the translation table, Section, or Supersection. Otherwise, the address is the PA of the translation table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9167.

Short-descriptor Translation Table level 2 descriptor formats

Figure G5-5 shows the possible formats of a level 2 descriptor.

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

- **0b00, Invalid entry**
  
The associated VA is unmapped, and attempting to access it generates a Translation fault.

  Bits[31:2] of the descriptor are IGNORED, see IGNORED on page Glossary-11937. This means software can use these bits for its own purposes.

- **0b01, Large page**
  
The descriptor gives the base address and properties of the Large page.

- **0b1x, Small page**
  
The descriptor gives the base address and properties of the Small page.

  In this descriptor format, bit[0] of the descriptor is the XN field.

The address information in the level 2 descriptors is:

- **Large page**  
  Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.

- **Small page**  
  Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the translation table, Section, or Supersection. Otherwise, the address is the PA of the translation table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9167.
Additional requirements for Short-descriptor format translation tables

When using Supersection or Large Page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large Page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- Figure K9-14 on page K9-11727 for the level 1 translation table entry for a Supersection.
- Figure K9-16 on page K9-11729 for the level 2 translation table entry for a Large page.

Considering the case of using Large Page descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these 16 index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

G5.4.2 Memory attributes in the VMSAv8-32 Short-descriptor Translation Table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

TEX[2:0], C, B
Memory region attribute fields, see Memory region attributes on page G5-9203. These fields are not present in a descriptor for a translation table.

XN bit
The Execute-never field, see Access permissions for instruction execution on page G5-9196. This bit is not present in a descriptor for a translation table.

PXN bit
The Privileged execute-never field, see Access permissions for instruction execution on page G5-9196.

When this field is set to 1 in the descriptor for a translation table, it indicates that all memory pages described in the corresponding translation table are Privileged execute-never.

NS bit
Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G5-9168.

This bit is not present in level 2 descriptors. The value of the NS bit in a level 1 descriptor for a translation table applies to all entries in the corresponding level 2 translation table.

Domain
Domain field, see Domains, Short-descriptor format only on page G5-9199.

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0. This bit is not present in level 2 descriptors. The value of the Domain field in the level 1 descriptor for a translation table applies to all entries in the corresponding level 2 translation table.

An IMPLEMENTATION DEFINED bit
This bit is not present in level 2 descriptors.

AP[2], AP[1:0]
Access Permissions bits, see Memory access control on page G5-9192.

AP[0] can be configured as the Access flag, see The Access flag on page G5-9200. These bits are not present in a descriptor for a translation table.

S bit
Shareable bit. Used in determining the Shareability of the addressed region, see Memory region attributes on page G5-9203.

Note
The naming of this bit as the Shareable bit is carried forward from early versions of the Arm architecture. This name is no longer an adequate description of the interpretation of the bit.
This bit is not present in a descriptor for a translation table.

**nG bit**  
The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See Global and process-specific translation table entries on page G5-9216.

This bit is not present in a descriptor for a translation table.

**Bit[18], when bits[1:0] indicate a Section or Supersection descriptor**

- 0  Descriptor is for a Section.
- 1  Descriptor is for a Supersection.

### G5.4.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

*Access to the Secure or Non-secure PA map on page G5-9161* describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 descriptor for a translation table, the NS bit defines the PA map, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 descriptor for a translation table has no effect on the PA map in which that translation table is held. As stated in Secure and Non-secure address spaces on page G5-9161, the PA of that translation table is in:

- The Secure address map if the translation table walk is in Secure state.
- The Non-secure address map if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory maps is 1MB. However, in these memory maps, table entries can define physical memory regions with a granularity of 4KB.

### G5.4.4 Selecting between TTBR0 and TTBR1, VMSA v8-32 Short-descriptor translation table format

As described in Determining the translation table base address in the VMSA v8-32 translation regimes on page G5-9160, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of TTBCR.N indicates the number of most significant bits of the input VA that determine whether TTBR0 or TTBR1 holds the required translation table base address, as follows:

- If N == 0 then use TTBR0. Setting TTBCR.N to zero disables use of a second set of translation tables.
- If N > 0 then:
  - If bits[31:32-N] of the input VA are all zero, then use TTBR0.
  - Otherwise use TTBR1.

Table G5-1 on page G5-9168 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1 translation table addressed by TTBR0.

### Table G5-1 Effect of TTBCR.N on address translation, Short-descriptor format

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table Size</th>
<th>Index range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>TTBR1 not used</td>
<td>16KB</td>
<td>VA[31:20]</td>
</tr>
<tr>
<td>0b001</td>
<td>0x80000000</td>
<td>8KB</td>
<td>VA[30:20]</td>
</tr>
<tr>
<td>0b010</td>
<td>0x40000000</td>
<td>4KB</td>
<td>VA[29:20]</td>
</tr>
<tr>
<td>0b011</td>
<td>0x20000000</td>
<td>2KB</td>
<td>VA[28:20]</td>
</tr>
<tr>
<td>0b100</td>
<td>0x10000000</td>
<td>1KB</td>
<td>VA[27:20]</td>
</tr>
</tbody>
</table>
Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G5-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

In the selected TTBR, bits RGN, S, and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

**G5.4.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format**

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.

Reading a level 1 translation table on page G5-9170 describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the level 1 descriptor.

Reading a level 1 translation table on page G5-9170 shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages on page G5-9170 then shows the complete translation flow for each valid memory access.
**Reading a level 1 translation table**

When performing a fetch based on TTBR0:

- The address bits taken from TTBR0 vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the TTBR0 and VA fields depend on the value of TTBCR.N, as Figure G5-7 shows.

When performing a fetch based on TTBR1, Bits TTBR1[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in Figure G5-7, with N==0.

--- **Note** ---

See *The address and Properties fields shown in the translation flows on page K9-11730* for more information about the *Properties* label used in this and other figures.

---

**Figure G5-7** Accessing level 1 translation table based on TTBR0, Short-descriptor format

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A level 1 descriptor for a Section or Supersection.
- A descriptor for a *translation table*, that points to a level 2 translation table. In this case:
  - A second fetch is performed to retrieve a level 2 descriptor.
  - The descriptor also contains some attributes for the access, see Figure G5-4 on page G5-9165.
- A faulting entry.

**The full translation flow for Sections, Supersections, Small pages and Large pages**

In a translation table walk, only the initial lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The Table descriptor read in the previous lookup.
- The input address.

*Address translation examples using the VMSAv8-32 Short descriptor translation table format on page K9-11726* shows the full translation flow for each of the memory section and page options. As described in *VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9164*, these options are:

- **Supersection**  A 16MB memory region, see *Translation flow for a Supersection on page K9-11726*.
- **Section**  A 1 MB memory region, see *Translation flow for a Section on page K9-11728*. 

---

‡ This field is absent if N is 0

N is the value of TTBCR.N

For details of the *Properties* field, see the register description
Large page  A 64KB memory region, described by the combination of:
  • A level 1 translation table entry that indicates the address of a level 2 translation table.
  • A level 2 descriptor that indicates a Large page.

See Translation flow for a Large page on page K9-11729.

Small page  A 4KB memory region, described by the combination of:
  • A level 1 translation table entry that indicates the address of a level 2 translation table.
  • A level 2 descriptor that indicates a Small page.

See Translation flow for a Small page on page K9-11730.
G5.5 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory Pages, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to blocks of memory, where a block can be 2MB or 1GB.

--- Note ---

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G5-2 on page G5-9151 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure EL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address, then this address is zero-extended to 40 bits.

--- Note ---

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

---

Overview of VMSAv8-32 address translation using Long-descriptor translation tables summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

The following sections then describe the format of the descriptors in the Long-descriptor format translation tables:

- VMSAv8-32 Long-descriptor Translation Table format descriptors on page G5-9173.
- Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176.
- Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-9180.

The following sections then describe this translation table format:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G5-9181.
- VMSAv8-32 Long-descriptor translation table format address lookup levels on page G5-9184.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-9187.
- The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format on page G5-9190.

G5.5.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G5-8 on page G5-9173 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.
G5.5 The VMSAv8-32 Long-descriptor translation table format

Figure G5-8 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G5-9 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

G5.5.2 VMSAv8-32 Long-descriptor Translation Table format descriptors

As described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G5-9184, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at level 1 or level 2 of the address lookup.

In general, a descriptor is one of:
- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor Translation Table descriptor formats:
- VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats on page G5-9174.
- VMSAv8-32 Long-descriptor translation table level 3 descriptor formats on page G5-9175.
Information returned by a translation table lookup on page G5-9159 describes the classification of the non-address fields in the descriptors between address map control, access controls, and region attributes.

VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the Block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

Figure G5-10 shows the Long-descriptor level 1 and level 2 descriptor formats:

![Figure G5-10 VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats](image)

For the level 1 descriptor, n is 30. For the level 2 descriptor, n is 21.

The level 1 descriptor returns the address of the level 2 table.
The level 2 descriptor returns the address of the level 3 table.

See the descriptions of the address fields for more information about bits[47:40] of the Block and Table descriptors.

Descriptor encodings, Long-descriptor level 1 and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- **0, Block**: The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- **1, Table**: The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

**Block descriptor**

Gives the base address and attributes of a block of memory:

- For a level 1 Block descriptor, bits[39:30] are bits[39:30] of the output address that specifies a 1GB block of memory.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G5-9240.
Bits[63:52, 11:2] provide attributes for the target memory block, see Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176. The position and contents of these bits is identical in the level 2 Block descriptor and in the level 3 Page descriptor.

Table descriptor

Bits[39:m] are bits[39:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:

• For a level 1 Table descriptor, this is the address of a level 2 table.
• For a level 2 Table descriptor, this is the address of a level 3 table.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G5-9240.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

VMSAv8-32 Long-descriptor translation table level 3 descriptor formats

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

Figure G5-11 shows the Long-descriptor level 3 descriptor formats.

Figure G5-11 VMSAv8-32 Long-descriptor level 3 descriptor formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page

Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

If bits[47:40] of the descriptor are not zero, then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G5-9240.

Bits[63:52, 11:2] provide attributes for the target memory page, see Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176. The position and contents of these bits are identical in the level 1 Block descriptor and in the level 2 Block descriptor.
If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

**G5.5.3 Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors**

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. *Memory region attributes on page G5-9203* describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see *Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors*

  The hierarchical attributes in the translation tables, APTable, XNTable, and PXNTable, permit subtrees of the translation tables to be used by different agents. Not all operating systems use this functionality, and so FEAT_AA32HPD adds a facility to disable these bits.

  This ability to disable hierarchical attribute bits has no effect on the NSTable bit.

- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G5-9177.*
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G5-9179.*

**Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors**

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

- **NSTable, bit[63]**
  
  For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G5-9180.*

  For memory accesses from Non-secure state, this bit is ignored.

- **APTable, bits[62:61]**
  
  Access permissions limit for subsequent levels of lookup, see *Hierarchical control of access permissions, Long-descriptor format on page G5-9193.*

  APTable[0] is reserved, SBZ, in the Non-secure EL2 stage 1 translation tables.

  From Armv8.2, when FEAT_AA32HPD is implemented, this field can be disabled.

  When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

  - The value of the corresponding APTable field is IGNORED by hardware, allowing the field to be used by software.
  - The behavior of the system is as if the value of the corresponding APTable field is 0, that is to say, the APTable field has an *Effective value* of 0.

- **XNTable, bit[60]**
  
  XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format on page G5-9198.*

  From Armv8.2, when FEAT_AA32HPD is implemented, this field can be disabled.

  When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

  - The value of the corresponding XNTable field is IGNORED by hardware, allowing the field to be used by software.
  - The behavior of the system is as if the value of the corresponding XNTable field is 0, that is to say, the XNTable field has an *Effective value* of 0.

- **PXNTable, bit[59]**
  
  PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format on page G5-9198.*

  This bit is RES0 in the Non-secure EL2 stage 1 translation tables.
From Armv8.2, when FEAT_AA32HPD is implemented, this field can be disabled.

When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is also 1:
- The value of the corresponding PXNTable field is ignored by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0, that is to say, the PXNTable field has an effective value of 0.

Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 1 translation:

- **PBHA**, bits[62:59]
  - Page-based hardware attributes bits.
  - These bits are ignored when FEAT_HPDS2 is not implemented.
  - When FEAT_HPDS2 is implemented, the HTCR and the TTBCR2 registers both contain a control bit for each PBHA bit in the translation tables that they control. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit is 1, hardware can use that PBHA bit for implementation-defined purposes. When the PBHA bit is used for implementation-defined purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for implementation-defined purposes.
  - The control bits for this feature are:
    - For a Non-secure EL2 translation regime:
      - HTCR.HWUnn
        - Controls whether Block or Page descriptor bit[nn] can be used by hardware.
        - These controls apply only when the value of HTCR.HPD is 1.
    - For a PL1&0 translation regime:
      - TTBCR2.HWU1nn
        - For the translation tables indicated by TTBR1, controls whether Block or Page descriptor bit[nn] can be used by hardware.
        - These controls apply only when the value of TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is 1.
      - TTBCR2.HWU0nn
        - For the translation tables indicated by TTBR0, controls whether Block or Page descriptor bit[nn] can be used by hardware.
        - These controls apply only when the value of TTBCR2.HPD0 is 1 and the value of TTBCR.T2E is 1.
Implementation of FEAT_HPDS2 requires the implementation of FEAT_AA32HPD, which provides the Hierarchical permission disables bits. If FEAT_AA32HPD is implemented but FEAT_HPDS2 is not implemented, then the control bits are RAZ/WI but other aspects of FEAT_AA32HPD functionality are implemented. If neither feature is implemented, then:

- The control bits are RAZ/WI.
- The FEAT_AA32HPD identification registers indicate that the functionality is not supported, see FEAT_AA32HPD on page A2-89.
- The TTBCR2 register encoding is treated as unallocated.

**XN, bit[54]**  The Execute-never field, see Access permissions for instruction execution on page G5-9196.

**PXN, bit[53]**  The Privileged execute-never field, see Access permissions for instruction execution on page G5-9196.

This bit is RES0 in the Non-secure EL2 stage 1 translation tables.

**Contiguous, bit[52]**

 Indicates that 16 adjacent translation table entries point to contiguous memory regions, see Contiguous bit on page G5-9211.

**nG, bit[11]**  The not global bit. Determines how the translation is marked in the TLB, see Global and process-specific translation table entries on page G5-9216.

This bit is RES0 in the Non-secure EL2 stage 1 translation tables.

**AF, bit[10]**  The Access flag, see The Access flag on page G5-9200.

**SH, bits[9:8]**  Shareability field, see Memory region attributes on page G5-9203.

**AP[2:1], bits[7:6]**

 Access Permissions bits, see Memory access control on page G5-9192.

--- Note ---

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

---

AP[1] is RES1 in the Non-secure EL2 stage 1 translation tables.

**NS, bit[5]**  Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-9180.

For memory accesses from Non-secure state, this bit is RES0 and is ignored by the PE.

**AttrIndx[2:0], bits[4:2]**

 Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see VMSAv8-32 Long-descriptor format memory region attributes on page G5-9210.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-11937. For more information about these fields, see Other fields in the Long-descriptor translation table format descriptors on page G5-9211.
Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 2 translation:

<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>83 62 60 59 58</td>
<td>11 10 9 8 7 6 5 2</td>
</tr>
<tr>
<td>PBHA†</td>
<td>IGNORED</td>
</tr>
<tr>
<td>Reserved for use by System MMU</td>
<td></td>
</tr>
<tr>
<td>Reserved for software use</td>
<td></td>
</tr>
<tr>
<td>XN[1:0]‡</td>
<td></td>
</tr>
<tr>
<td>Contiguous</td>
<td></td>
</tr>
</tbody>
</table>

† Bit[53] is RES0 if FEAT_XNX is not implemented.
‡ Bits [62:60] are IGNORED and reserved for use by System MMU if FEAT_HPDS2 is not implemented.
Bits [59] is IGNORED if FEAT_HPDS2 is not implemented.

For a stage 2 descriptor, the attributes are:

**PBHA[3:1], bits[62:60]**

Page-based hardware attributes bits.
These bits are IGNORED and reserved for System MMU use when FEAT_HPDS2 is not implemented.

When FEAT_HPDS2 is implemented, VTCR_EL2 has a control bit for each PBHA bit in the EL1&0 stage 2 translation tables:
- When the value of that control bit is 1, hardware can use the corresponding PBHA bit for IMPLEMENTATION DEFINED purposes. When the PBHA bit is used for IMPLEMENTATION DEFINED purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.
- When the value of that control bit is 0, the corresponding PBHA bit is IGNORED and reserved for System MMU use.

**PBHA[0], bit[59]**

Page-based hardware attributes bit.
This bit is IGNORED when FEAT_HPDS2 is not implemented.

When FEAT_HPDS2 is implemented, VTCR_EL2 has a control bit for this bit in the EL1&0 stage 2 translation tables:
- When the value of that control bit is 1, hardware can use this bit for IMPLEMENTATION DEFINED purposes. When the PBHA bit is used for IMPLEMENTATION DEFINED purposes, the value of 0 in the PBHA bit is a safe default setting that gives the same behavior as when the PBHA bit is not used for IMPLEMENTATION DEFINED purposes.
- When the value of that control bit is 0, this bit is IGNORED.

**XN[1:0], bits[54:53]**

The stage 2 Execute-never field, see Access permissions for instruction execution on page G5-9196.
If FEAT_XNX is not implemented, bit[53] is RES0.

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see Contiguous bit on page G5-9211.

**AF, bit[10]**
The Access flag, see The Access flag on page G5-9200.

**SH, bits[9:8]**
Shareability field, see EL2 control of Non-secure memory region attributes on page G5-9212.
S2AP, bits[7:6]
Stage 2 Access Permissions bits, see *Hyp mode control of Non-secure access permissions on page G5-9201.*

--- Note ---
In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. VMSAv8-32 renames the field for greater clarity.

MemAttr, bits[5:2]
Stage 2 memory attributes, see *EL2 control of Non-secure memory region attributes on page G5-9212.*

The definition of *IGNORED* means the architecture guarantees that the PE makes no use of the field, see *IGNORED on page Glossary-11937.* For more information about these fields, see *Other fields in the Long-descriptor translation table format descriptors on page G5-9211.*

### G5.5.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

*Access to the Secure or Non-secure PA map on page G5-9161* describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format.*

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor Format Table descriptors for stage 1 translations, the descriptor includes an NSTable bit, which indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

\[
\text{NSTable} == 0 \quad \text{The defined table address is in the Secure PA map. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.}
\]

\[
\text{NSTable} == 1 \quad \text{The defined table address is in the Non-secure PA map. Because this table is fetched from the Non-secure address map, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:}
\]

\[
\begin{align*}
&\quad \text{• The value of the NS bit in any Block or Page descriptor is ignored. The block or page address refers to Non-secure memory.} \\
&\quad \text{• The value of the NSTable bit in any Table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any Block or Page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.}
\end{align*}
\]

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see *Global and process-specific translation table entries on page G5-9216.*
The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**Note**

- When using the Long-descriptor Format, Table descriptors are defined only for the level 1 and level 2 of lookup.
- Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address map. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

**G5.5.5 Selecting between TTBR0 and TTBR1, VMSA v8-32 Long-descriptor translation table format**

As described in *Determining the translation table base address in the VMSA v8-32 translation regimes* on page G5-9160, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using TTBR0 and using TTBR1. When a PL1&0 stage 1 address translation is enabled, TTBR0 is always used. If TTBR1 is also used then:

- TTBR1 is used for the top part of the input address range.
- TTBR0 is used for the bottom part of the input address range.

The TTBCR.T0SZ and TTBCR.T1SZ size fields control the use of TTBR0 and TTBR1, as Table G5-2 on page G5-9181 shows.

<table>
<thead>
<tr>
<th>TTBCR</th>
<th>Input address range using:</th>
<th>TTBR0</th>
<th>TTBR1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T0SZ</td>
<td>T1SZ</td>
<td>All addresses</td>
</tr>
<tr>
<td>0b000</td>
<td>0b000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$M^a$</td>
<td>0b000</td>
<td>$N^a$</td>
<td>Zero to $(2^{32-M}-1)$</td>
</tr>
<tr>
<td>0b000</td>
<td>$N^a$</td>
<td></td>
<td>Zero to $(2^{32-2(M-N)}-1)$</td>
</tr>
<tr>
<td>$M^a$</td>
<td>$N^a$</td>
<td></td>
<td>Zero to $(2^{32-M}-1)$</td>
</tr>
</tbody>
</table>

a. $M, N$ must be greater than 0. The maximum possible value for each of T0SZ and T1SZ is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is $(2^{32}-1)$.

When address translation is using the Long-descriptor translation table format:

- Figure G5-12 on page G5-9182 shows how, when TTBCR.T1SZ is zero, the value of TTBCR.T0SZ controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.
The AArch32 Virtual Memory System Architecture
G5.5 The VMSAv8-32 Long-descriptor translation table format

Figure G5-12 Control of TTBR boundary, when TTBCR.T1SZ is zero

- Figure G5-13 shows how, when TTBCR.T1SZ is nonzero, the values of TTBCR.T0SZ and TTBCR.T1SZ control the boundaries between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Figure G5-13 Control of TTBR boundaries, when TTBCR.T1SZ is nonzero

- When T0SZ and T1SZ are both nonzero:
  - If both fields are set to 0b001, the boundary between the two regions is 0x80000000. This is identical to having T0SZ set to 0b000 and T1SZ set to 0b011.
  - Otherwise, the TTBR0 and TTBR1 regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the TTBR0 and TTBR1 regions generates a Translation fault.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the TCR_EL1.TnSZ values and the region for which an access generates a Translation fault is wider than shown in Figure G5-13. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. Possible errors in programming the translation table registers on page G5-9183 describes this possibility.

When using the Long-descriptor translation table format:

- The TTBCR contains fields that define memory region attributes for the translation table walk, for each TTBR. These are the SH0, ORGN0, IRGN0, SH1, ORGN1, and IRGN1 bits.
- TTBR0 and TTBR1 each contain an ASID field, and the TTBCR.A1 field selects which ASID to use.
For this translation table format, VMSAv8-32 Long-descriptor translation table format address lookup levels on page G5-9184 summarizes the lookup levels, and Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G5-9187 describes the possible translations.

Possible errors in programming the translation table registers

In all the descriptions in this subsection, the size of the input address supported for a PL1&0 stage 1 translation refers to the size specified by a TTSCR.TxSZ field.

Note

For a PL1&0 stage 1 translation, the input address range can be split so that the lower addresses are translated by TTBR0 and the higher addresses are translated by TTBR1. In this case, each of input address sizes specified by TTSCR.{T0SZ, T1SZ} is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of TTBR0, TTBR1, and TTSCR. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either TTSCR.T0SZ or TTSCR.T1SZ is zero, meaning there is no gap between the address range translated by TTBR0 and the range translated by TTBR1. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. Example G5-2 shows an example of this mis-programming.

- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

Example G5-2 Error in programming the translation table registers

If TTSCR.T0SZ is programmed to 0 and TTSCR.T1SZ is programmed to 7, this means:

- TTBR0 translates addresses in the range 0x00000000-0xFDFFFFFF.
- TTBR1 translates addresses in the range 0xFE000000-0xFFFFFFFF.

The translation table indicated by TTBR0 might be programmed with a block entry for a 1GB region starting at 0xC0000000. This covers the address range 0xC0000000-0xFFFFFFFF, that overlaps the TTBR1 address range. This means this block size is larger than the input address size supported for translations using TTBR0, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address 0xFFFF0000. According to the TTSCR.{T0SZ, T1SZ} values, this must be translated using TTBR1. However, the access matches a TLB entry for the translation, using TTBR0, of the block at 0xC0000000. Hardware is not required to detect that the access to 0xFFFF0000 is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.
  The block might be a block within a contiguous set of blocks.

- Treat such a block as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.
  The block might be a block within a contiguous set of blocks.
Additional constraints apply to programming the VTCR, see Determining the required initial lookup level for stage 2 translations on page G5-9189.

G5.5.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G5-3 on page G5-9184 summarizes the properties of the different levels of address lookup when using this format.

Table G5-3 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables

<table>
<thead>
<tr>
<th>Level</th>
<th>Input address</th>
<th>Output addressa</th>
<th>Number of entries</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Size</td>
<td>Address rangeb</td>
<td>Size</td>
</tr>
<tr>
<td>First</td>
<td>Up to 512GB</td>
<td>Up to Address[38:0]</td>
<td>1GB</td>
</tr>
<tr>
<td>Second</td>
<td>Up to 1GB</td>
<td>Up to Address[29:0]</td>
<td>2MB</td>
</tr>
<tr>
<td>Third</td>
<td>2MB</td>
<td>Address[20:0]</td>
<td>4KB</td>
</tr>
</tbody>
</table>

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.
b. Input address range for the translation table. See Use of concatenated level 1 translation tables on page G5-9185 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range for stage 2 translations at level 1. For stage 1 translations at level 1 the input address range is limited to the VA size of [31:0].

For level 1 and level 2 tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure TTBR0 or TTBR1 holds the translation table base address, and the Secure or Non-secure TTBCR is the control register.
- For a memory access from Hyp mode, HTTBR holds the translation table base address, and HTCR is the control register.

Note

For translations controlled by TTBR0 and TTBR1, if neither TTBR has an input address range larger than 1GB, then translation starts at level 2. Together, TTBR0 and TTBR1 can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G5-3 on page G5-9184 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. Use of concatenated translation tables for the initial stage 2 lookup on page G5-9185 describes how a 40-bit IPA address range is supported. For stage 2 translations:

- VTTBR holds the translation table base address, and VTCR is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.
Use of concatenated translation tables for the initial stage 2 lookup

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

——— Note ————
Stage 2 translations always use the Long-descriptor translation table format.

This use of concatenated translation tables is:
- Required when the stage 2 translation supports a 40-bit input address range, see Use of concatenated level 1 translation tables.
- Supported for a stage 2 translation with an input address range of 31-34 bits, see Use of concatenated level 2 translation tables.

The use of concatenated translation tables requires the software that is defining the translation to:
- Define the concatenated translation tables with the required overall alignment.
- Program VTTBR to hold the address of the first of the concatenated translation tables.
- Program VTCR to indicate the required input address range and initial lookup level.

——— Note ————
The use of concatenated translation tables avoids the overhead of an additional level of translation.

Use of concatenated level 1 translation tables

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated level 1 translation tables, together aligned to 8KB, where:

- The table at the address with PA[12:0]==0b0_0000_0000_0000 defines the translations for input addresses with bit[39]==0.
- The table at the address with PA[12:0]==0b1_0000_0000_0000 defines the translations for input addresses with bit[39]==1.
- The 8KB alignment requirement means that both tables have the same value for PA[39:13].

Use of concatenated level 2 translation tables

A stage 2 translation with an input address range of 31-34 bits can start the translation either:
- With a level 1 lookup, accessing a level 1 translation table with 2-16 entries.
- With a level 2 lookup, accessing a set of concatenated level 2 translation tables.

Table G5-4 on page G5-9186 shows these options, for each of the input address ranges that can use this scheme.

——— Note ————
Because these are stage 2 translations, the input address range is an IPA range.
### Table G5-4 Possible uses of concatenated translation tables for level 2 lookup

See also *Determining the required initial lookup level for stage 2 translations* on page G5-9189.
G5.5.7   Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G5-2 on page G5-9151 shows the possible address translations. If a stage of translation is controlled from an Exception level that is using AArch32, the input and output address constraints and the registers that control the translation are as follows:

**Stage 1 translations**

For all stage 1 translations:
- The input address range is up to 32 bits, as determined by either:
  - TTBCR.T0SZ or TTBCR.T1SZ, for a PL1&0 stage 1 translation.
  - HTCR.T0SZ, for an EL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

**Non-secure PL1&0 stage 1 translation**

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:
- Non-secure TTBR0 or TTBR1 holds the translation table base address.
- Non-secure TTBCR determines which TTBR is used.

**Non-secure EL2 stage 1 translation**

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, HTTBR holds the translation table base address.

**Secure PL1&0 stage 1 translation**

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:
- Secure TTBR0 or TTBR1 holds the translation table base address.
- Secure TTBCR determines which TTBR is used.

**Stage 2 translation**

**Non-secure PL1&0 stage 2 translation**

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:
- The input address range is 40 bits, and VTCR.T0SZ determines the input address size.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- VTTBR holds the translation table base address.
- VTCR specifies the required input address range, and whether the initial lookup is at level 1 or at level 2.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor Format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero, then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G5-9184, and the initial lookup, in which the MMU reads the translation table base address, is at either level 1 or level 2. The following determines the level of the initial lookup:

- For a stage 1 translation, the required input address range. For more information, see Determining the required initial lookup level for stage 1 translations on page G5-9189.
- For a stage 2 translation, the level specified by the VTCR.SL0 field. For more information, see Determining the required initial lookup level for stage 2 translations on page G5-9189.
Note

For a stage 2 translation, the size of the required input address range constrains the VTCR.SL0 value.

Figure G5-14 shows how the descriptor address for the initial lookup for a translation using the Long-descriptor translation table format is determined from the input address and the TTBR value. This figure shows the lookup for a translation that starts with a level 1 lookup, that translates bits[39:30] of the input address, zero extended if necessary.

If bits[47:40] of the TTBR are not zero then the initial lookup will generate an Address size fault, see Address size fault on page G5-9240.

For a translation that starts with a level 1 lookup, as shown in Figure G5-14:

For a stage 1 translation

\( n \) is in the range 4-5 and:

- For a memory access from Hyp mode:
  - HTTBR is the TTBR.
  - \( n = 5 - (HTCR.T0SZ) \).
- For other accesses:
  - The Secure or Non-secure instance of TTBR0 or TTBR1 is the TTBR.
  - \( n = (5 - TTBCR.TxSZ) \), where \( x \) is 0 when using TTBR0, and 1 when using TTBR1.

For a stage 2 translation

\( n \) is in the range 4-13 and:

- VTTBR is the TTBR.
- \( n = 5 - (VTCR.T0SZ) \).
For a translation that starts with a level 2 lookup, the descriptor address is obtained in the same way, except that bits\(((n+17):21)\) of the input address provide bits\(((n-1):3)\) of the descriptor address, where:

**For a stage 1 translation**

\(n\) is in the range 7-12. As *Determining the required initial lookup level for stage 1 translations* shows, for a stage 1 translation to start with a level 2 lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:

- For a memory access from Hyp mode, \(n=14-\text{HTCR.T0SZ}\).
- For other memory accesses, \(n=14-(\text{TTBCR.TxSZ})\), where \(x\) is 0 when using TTBR0, and 1 when using TTBR1.

**For a stage 2 translation**

\(n\) is in the range 7-16. For a stage 2 translation to start with a level 2 lookup, VTCR.SL0 is \(\text{0b00}\), and \(n=14-(\text{VTCR.T0SZ})\).

The following sections describe how the level of the initial lookup is determined:

- *Determining the required initial lookup level for stage 1 translations*.
- *Determining the required initial lookup level for stage 2 translations*.

*Address translation examples using the VMSAv8-32 Long descriptor translation table format* on page K9-11731 shows examples of full translation flows, to an entry for a 4KB memory page, for lookups starting at level 1 and lookups starting at level 2.

**Determining the required initial lookup level for stage 1 translations**

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the initial lookup level. The size of this input address region is \(2^{(32-\text{TxSZ})}\) bytes, and if this size is:

- Less than or equal to \(2^{30}\) bytes, the required start is at level 2, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.
- More than \(2^{30}\) bytes, the required start is at level 1, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the TTBCR:

- Splits the 32-bit VA input address range between TTBR0 and TTBR1, see *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-desciption translation table format* on page G5-9181.
- Holds the input address range sizes for TTBR0 and TTBR1, in the TTBCR.T0SZ and TTBCR.T1SZ fields.

For the EL2 stage 1 translations, HTCR.T0SZ indicates the size of the required input address range. For example, if this field is \(\text{0b000}\), it indicates a 32-bit VA input address range, and translation lookup must start at level 1.

**Determining the required initial lookup level for stage 2 translations**

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

VTCR.SL0 indicates the starting level for the lookup. The permitted SL0 values are:

- \(\text{0b0}\) Stage 2 translation lookup must start at level 2.
- \(\text{0b1}\) Stage 2 translation lookup must start at level 1.

In addition, VTCR.T0SZ must indicate the required input address range. The size of the input address region is \(2^{(32-\text{T0SZ})}\) bytes.
Note

VTCR.T0SZ holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of VTCR must follow the constraints shown in Table G5-5, otherwise any attempt to perform a translation table walk that uses the stage 2 address translation generates a stage 2 level 1 Translation Fault. The table also shows how the VTCR.SL0 and VTCR.T0SZ values determine the VTTBR.BADDR field width.

Note

If VTCR.SL0 is programmed to a reserved value then the constraints shown in Table G5-5 are not met, and a translation table walk that uses stage 2 translation generates a stage 2 level 1 Translation fault.

Table G5-5 Input address range constraints on programming VTCR

<table>
<thead>
<tr>
<th>VTCR.SL0</th>
<th>VTCR.T0SZ</th>
<th>Input address range, R</th>
<th>Initial lookup level</th>
<th>BADDR[39:x] width a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>2 to 7</td>
<td>R ≤ 2^30 bytes</td>
<td>Level 2</td>
<td>[39:12] to [39:7]</td>
</tr>
<tr>
<td>0b00</td>
<td>-2 to 1</td>
<td>2^30 &lt; R ≤ 2^34 bytes</td>
<td>Level 2</td>

<td>-8 to -3</td>
<td>2^34 &lt; R</td>
<td>Level 1</td>
<td>[39:13] to [39:8]</td>
</tr>
</tbody>
</table>

a. The first range corresponds to the first T0SZ value, the second range to the second T0SZ value.

In addition, VTCR.S must be programmed to the value of T0SZ[3], otherwise behavior is CONSTRAINED UNPREDICTABLE with the resulting behavior being that VTCR.T0SZ is treated as an UNKNOWN value.

Note

VTCR.T0SZ being treated as an UNKNOWN value results in a stage 2 level 1 Translation Fault if that UNKNOWN value is not consistent with the programmed value of VTCR.SL0.

CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR on page K1-11581 describes these CONSTRAINED UNPREDICTABLE behaviors.

Where necessary, the initial lookup level provides multiple concatenated translation tables, as described in Use of concatenated level 2 translation tables on page G5-9185. This section also gives more information about the alternatives, shown in Table G5-5, when R is in the range 2^31-2^34.

G5.5.8 The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format

This section gives the algorithm for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithm encodes the descriptions of address translation given earlier in this section. The VMSAv8-32 Long-descriptor format uses a 4KB translation granule.

The description uses the following terms:

BaseAddr

The base address for the level of lookup, as defined by:

- For the initial lookup level, the TTBR.BADDR base address field in the appropriate TTBR, see the description of TnSZ on page G5-9191.
- Otherwise, the translation table address returned by the previous level of lookup.

IA

The supplied IA for this stage of translation.
### The translation table size for this stage of translation:

**For PL1&0 stage 1**
- Either:
  - TTBCR.T0SZ if the translation is using TTBR0.
  - TTBCR.T1SZ if the translation is using TTBR1.

**For PL1&0 stage 2**
- VTCR.T0SZ. The translation uses VTTBR.

**For EL2 stage 1**
- HTCR.T0SZ. The translation uses HTTBR.

### SL0
- VTCR.SL0. Applies to the Non-secure PL1&0 stage 2 translation only.

Table G5-6 on page G5-9191 shows the Translation Table descriptor address, for each level of lookup. The table shows only architecturally-valid programming of the TCR. See also *Possible errors in programming the translation table registers* on page G5-9183.

#### Table G5-6 Translation table entry addresses, VMSAv8-32 using Long-descriptor format

<table>
<thead>
<tr>
<th>Lookup level</th>
<th>Entry address and conditions</th>
<th>Stage 2 translation</th>
<th>General conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>One BaseAddr[39:x]:IA[y:30]:0b000 if 0 ≤ TnSZ ≤ 1 then x = (5 - TnSZ)</td>
<td>BaseAddr[39:x]:IA[y:30]:0b000 if SL0b == 1 then if -8 ≤ T0SZ ≤ 1 then x = (5 - T0SZ)</td>
<td>y = (x + 26)</td>
<td></td>
</tr>
<tr>
<td>Two BaseAddr[39:x]:IA[y:21]:0b000 if 2 ≤ TnSZ ≤ 7 then x = (14 - TnSZ)</td>
<td>BaseAddr[39:x]:IA[y:21]:0b000 if SL0 == 0 then if -2 ≤ T0SZ ≤ 7 then x = (14 - T0SZ) elsif SL0b == 1 then x = 12</td>
<td>y = (x + 17)</td>
<td></td>
</tr>
<tr>
<td>Three BaseAddr[39:12]:IA[20:12]:0b000</td>
<td>BaseAddr[39:12]:IA[20:12]:0b000</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

- This line indicates the range of permitted values for TnSZ, for a lookup that starts at this level, see *Use of concatenated translation tables for the initial stage 2 lookup* on page G5-9185.
- SL0 == 0 if the initial lookup is level 2, SL0 == 1 if the initial lookup is level 1.
- This is the case where this level of lookup is not the initial level of lookup.
G5.6 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. Information returned by a translation table lookup on page G5-9159 describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the Translation Table descriptor. If a translation stage does not permit the access, then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

• About access permissions.
• About the PAN bit on page G5-9195.
• Access permissions for instruction execution on page G5-9196.
• Domains, Short-descriptor format only on page G5-9199.
• The Access flag on page G5-9200.
• Hyp mode control of Non-secure access permissions on page G5-9201.

G5.6.1 About access permissions

The Translation Table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

• System register controls can prevent execution from writable locations, see Preventing execution from writable locations on page G5-9198.

• In Armv8.1, the PSTATE.PAN can affect the access permissions for privileged data accesses, see About the PAN bit on page G5-9195.

Note

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions, as described in Hyp mode control of Non-secure access permissions on page G5-9201. This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a Translation Table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format

This format supports two options for defining the access permissions:

• Three bits, AP[2:0], define the access permissions.
• Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag. SCTLR.AFE selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

Arm deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of SCTLR.AFE is 1, regardless of the value that software has written to this bit.

Note

When use of the Long-descriptor format is enabled, SCTLR.AFE is UNK/SBOP.

The Access flag on page G5-9200 describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see Access permissions for instruction execution on page G5-9196.
An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see *Domains, Short-descriptor format only* on page G5-9199.

--- Note ---

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see *Exception reporting in a VMSAv8-32 implementation* on page G5-9251.

The following sections describe the two access permissions models:

- **AP[2:1] access permissions model**
- **AP[2:0] access permissions control, Short-descriptor format only** on page G5-9194. This section includes some information on access permission control in earlier versions of the Arm VMSA.

### AP[2:1] access permissions model

--- Note ---

Arm recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the simplified access permissions model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the SCTLR.AFE bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (EL0) and System level (PL1) control.
  
  For the Non-secure EL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at EL0.
- Read/write at PL1, no access by software executing at EL0.

Table G5-7 shows this access control model.

<table>
<thead>
<tr>
<th>AP[2], disable write access</th>
<th>AP[1], enable unprivileged access</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0a</td>
<td>Read/write, only at PL1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Read/write, at any privilege level</td>
</tr>
<tr>
<td>1</td>
<td>0a</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Read-only, at any privilege level</td>
</tr>
</tbody>
</table>

a. Not valid for Non-secure EL2 stage 1 translation tables. AP[1] is SBO in these tables.

**Hierarchical control of access permissions, Long-descriptor format**

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in *Hierarchical control of instruction fetching, Long-descriptor format* on page G5-9198.
The AArch32 Virtual Memory System Architecture

G5.6 Memory access control

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table G5-8 on page G5-9194 shows.

However, in an implementation that includes FEAT_AA32HPD, when hierarchical control of data access permissions is disabled for a translation regime, the information in this subsection does not apply. See Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176.

As stated in the table footnote, for the Non-secure EL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01(^a)</td>
<td>Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>11(^a)</td>
<td>Regardless of permissions in subsequent levels of lookup:</td>
</tr>
<tr>
<td></td>
<td>• Write access not permitted, at any Exception level.</td>
</tr>
<tr>
<td></td>
<td>• Read access not permitted at EL0.</td>
</tr>
</tbody>
</table>

\(^a\) Not valid for the Non-secure EL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

---

**Note**

The APTable[1:0] settings are combined with the translation table access permissions in the Translation Tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 Translation Table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**AP[2:0] access permissions control, Short-descriptor format only**

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. Arm deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in AP[2:1] access permissions model on page G5-9193.

Table G5-9 on page G5-9194 shows the full AP[2:0] access permissions model:

<table>
<thead>
<tr>
<th>AP[2]</th>
<th>AP[1:0]</th>
<th>PL1 access</th>
<th>Unprivileged access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00</td>
<td>No access</td>
<td>No access</td>
<td>All accesses generate Permission faults</td>
</tr>
<tr>
<td>01</td>
<td>Read/write</td>
<td>No access</td>
<td>Access only at PL1</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>Read/write</td>
<td>Read-only</td>
<td>Writes at EL0 generate Permission faults</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Read/write</td>
<td>Read/write</td>
<td>Full access</td>
<td></td>
</tr>
</tbody>
</table>
The AArch32 Virtual Memory System Architecture
G5.6 Memory access control

Note

- VMSAv8-32 supports the full set of access permissions shown in Table G5-9 on page G5-9194 only when SCTLR.AFE is set to 0. When SCTLR.AFE is set to 1, the only supported access permissions are those described in AP[2:1] access permissions model on page G5-9193.

G5.6.2 About the PAN bit

When the value of PSTATE.PAN is 1, any privileged data access from PL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in Armv8.0.

A corresponding PAN bit is added to CPSR and SPSR for exception returns, and DSPSR for entry to and exit from Debug state.

A new SPAN bit is added to SCTLR that controls whether the PAN state bit is set on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

CPSR.PAN bit can be written using an MSR instruction at PL1 or higher. Data writes to CPSR.PAN using an MSR instruction at EL0 are ignored. The value that is returned for an MSR instruction of CPSR from EL0 is UNKNOWN. In keeping with all other writes to the CPSR, other than for instruction fetches, the effect of the PAN state bit does not need to be explicitly synchronized.

The PAN state bit has no effect on:
- Data Cache instructions.
- Address translation instructions, other than ATS1CPRP and ATS1CPWP when FEAT_PAN2 is implemented.
- Unprivileged instructions, LDRBT, LDRHT, LDRT, LDRSBT, LDRSHT, STRBT, STRHT, STRT, STRSBT, and STRSHT, unless HCR_EL2.{E2H, TGE} == {1, 0}.
- Instruction accesses.
- Manager domains.

The PAN bit has no effect when the first stage of translation is disabled for the current translation regime or when the first stage of translation for the current translation regime does not describe the permissions for access at EL0.

If access is disabled, then the access will give rise to a stage 1 Permission fault.

On an exception taken from AArch32:
- CPSR.PAN is copied to SPSR_ELx.PAN, when the target Exception level is AArch64.
- CPSR.PAN is copied to SPSR.PAN, when the target Exception level is AArch32.

On an exception return from AArch32 to AArch32, SPSR.PAN is copied to CPSR.PAN.

On entry to Debug state, CPSR.PAN is copied to DSPSR.PAN.
On exit from Debug state, DSPSR.PAN is copied to CPSR.PAN.

The CPSR.PAN bit is not an Execution state bit.

--- Note ---

- In Non-debug state, in AArch32 state, software can use the SETPAN #imm instruction to modify PSTATE.PAN.
- In Debug state, in AArch32 state, a debugger can use the ERET instruction to perform a DRPS operation to modify PSTATE.PAN.

### G5.6.3 Access permissions for instruction execution

Execute-never controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

**XN, Execute-never**

Descriptor bit[54], defined as XN for:

- Stage 1 of any translation regime.
- Stage 2 translations when FEAT_XNX is not implemented.

--- Note ---

XN[1:0], Execute-never, stage 2 only describes the stage 2 control when FEAT_XNX is implemented.

This field applies to execution at any Exception level to which the stage of translation applies. A value of 0 indicates that this control permits execution.

**PXN, Privileged execute-never, stage 1 only**

Descriptor bit[53], used only for stage 1 of any translation regime for which the stage 1 translation can support two VA ranges:

- For stage 1 of a translation regime for which the stage 1 translation supports only a single VA range the stage 1 descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

This field applies only to execution at an Exception level higher than EL0. A value of 0 indicates that this control permits execution.

**XN[1:0], Execute-never, stage 2 only**

Descriptor bits[54:53], defined as XN[1:0] for:

- Stage 2 translations when FEAT_XNX is implemented.

Table G5-10 on page G5-9196 shows the operation of this control.

<table>
<thead>
<tr>
<th>XN[1]</th>
<th>XN[0]</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The stage 2 control permits execution at EL1 and EL0 if read access is permitted</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The stage 2 control does not permit execution at EL1, but permits execution at EL0 if read access is permitted</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The stage 2 control does not permit execution at EL1 or at EL0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The stage 2 control permits execution at EL1 if read access is permitted, but does not permit execution at EL0</td>
</tr>
</tbody>
</table>
For stage 2 translations when FEAT_XNX is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware, and bit[54] is the XN control, see XN, Execute-never on page G5-9196.

Executing an instruction at ELx in a particular Security state generates a Permission fault unless all of the following are true for the instruction address:

- Any stage 1 execute-never control that applies to execution at ELx in the current Security state permits execution.
- If the translation regime that applies to ELx in the current Security state has two stages of translations, the stage 2 execute-never control that applies to execution at ELx permits execution.
- Read access is permitted.

However, if a stage 1 translation is using the Short-descriptor translation table format and the address is in a Managers domain the stage 1 access permissions are not checked, and therefore the access cannot cause a stage 1 Permission fault, see Domains, Short-descriptor format only on page G5-9199.

See also Hyp mode control of Non-secure access permissions on page G5-9201.

In addition, System register controls can enforce execute-never restrictions, regardless of the settings in the translation table XN and PXN fields, see:
- Restriction on Secure instruction fetch on page G5-9199.
- Preventing execution from writable locations on page G5-9198.

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The execute-never controls means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the Translation Table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - The stage 1 execute-never control for the Exception level at which the instruction is executed permits execution.
  - For a translation regime with two stages of address translation, the stage 2 execute-never control that applies to the Exception level at which the instruction is executed permits execution.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.

The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.

Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.

The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as XN. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
• When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN field does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. Behavior of instruction fetches when all associated address translations are disabled on page G5-9156 describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in Hierarchical control of access permissions, Long-descriptor format on page G5-9193.

--- Note ---
Similar hierarchical controls apply to data accesses, see Hierarchical control of access permissions, Long-descriptor format on page G5-9193.

However, in an implementation that includes FEAT-AA32HPD, when hierarchical control of instruction fetching is disabled for a translation regime, the information in this subsection does not apply. See Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-9176.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

• XNTable restricts the XN control:
  — When XNTable is set to 1, the XN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  — When XNTable is set to 0 it has no effect.

• PXNTable restricts the PXN control:
  — When PXNTable is set to 1, the PXN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  — When PXNTable is set to 0 it has no effect.

--- Note ---
The XNTable and PXNTable settings are combined with the XN and PXN fields in the Translation Table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 Translation Table descriptors.

The effect of XNTable or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Preventing execution from writable locations

The architecture provides control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN or PXN, regardless of the value of the XN or PXN field. When the translation stages are controlled by an Exception level that is using AArch32:

• For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.

• For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at EL0 can write to.
• For Non-secure EL2 stage 1 translations, when HSCTRL.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.

________ Note _______
• The SCTLR.WXN controls are intended to be used in systems with very high security requirements.
• Setting a WXN or UWXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, Arm expects WXN and UWXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. A generic sequence to ensure synchronization of a change to these fields, when that change is made without a corresponding change of VMID, is:

Change the WXN or UWXN bit
ISB ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB ; This completes the TLB Invalidation
ISB ; This ensures instruction synchronization

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information, see About access permissions on page G5-9192.

For more information about address translation, see About address translation for VMSAv8-32 on page G5-9149.

Restriction on Secure instruction fetch
EL3 provides a Secure instruction fetch bit, SCR.SIF. When this bit is 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see About access permissions on page G5-9192.

Arm expects SCR.SIF to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

Change the SCR.SIF bit
ISB ; This ensures synchronization of the change
Invalidate entire TLB
DSB ; This completes the TLB Invalidation
ISB ; This ensures instruction synchronization

G5.6.4 Domains, Short-descriptor format only
A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

• Level 1 translation table entries for translation tables and Sections include a domain field.
• Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
• Level 2 translation table entries inherit a domain setting from the parent level 1 Translation Table descriptor.
• Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the DACR defines the permitted access for each domain. The possible settings for each domain are:

No access Any access using the Translation Table descriptor generates a Domain fault.
Clients On an access using the Translation Table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.
Managers

On an access using the Translation Table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See The MMU fault-checking sequence on page G5-9242 for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the Translation Table descriptor.

Note

A single program might:

• Be a Client of some domains.
• Be a Manager of some other domains.
• Have no access to the remaining domains.

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the DACR are ignored.

G5.6.5 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding Translation Table descriptor was set to 0:

• If address translation is using the Short-descriptor translation table format, it must set SCTLR.AFE to 1 to enable use of the Access flag. Setting this bit to 1 redefines the AP[0] bit in the Translation Table descriptors as an Access flag, and limits the access permissions information in the Translation Table descriptors to AP[2:1], as described in AP[2:1] access permissions model on page G5-9193.

• The Long-descriptor format always supports an Access flag bit in the Translation Table descriptors, and address translation using this format behaves as if SCTLR.AFE is set to 1, regardless of the value of that bit.

In Armv8.0, the Access flag is managed by software as described in Software management of the Access flag.

Note

Previous versions of the Arm architecture optionally supported hardware management of the Access flag. Armv8.0 obsolete this option. However, FEAT_HAFDBS provides a new mechanism for hardware management of the Access flag, that is supported only for the VMSAv8-64 translation regimes.

Software management of the Access flag

Armv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a Translation Table descriptor entry for which the value of the Access flag is 0.

Note

When using the Short-descriptor translation table format, Access flag faults are generated only if SCTLR.AFE is set to 1, to enable use of a Translation Table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note

If a system incorporates components that can autonomously update translation table entries that are shared with the Arm PE, then the software must be aware of the possibility that such components can update the access flag autonomously.
In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

G5.6.6 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure EL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the HTTBR and HTCR.
  
  These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:
  - Access permissions for instruction execution on page G5-9196.

  The differences from the Non-secure stage 1 translations are that:
  - The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
  - AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or EL0, and are indicated and controlled by the VTTBR and VTCR.

  The descriptors in the virtualization translation tables define stage 2 access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

  **Note**

  The level 2 access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:
  - The Guest OS, in the stage 1 translation tables.
  - The hypervisor, in the stage 2 translation tables.

  The stage 2 access controls defined from Hyp mode:
  - Affect only the Non-secure stage 1 access permissions settings.
  - Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure EL0 mode.
  - Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

  The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as Table G5-11 on page G5-9201 shows:

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No access permitted</td>
</tr>
<tr>
<td>01</td>
<td>Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>10</td>
<td>Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>11</td>
<td>Read/write. The stage 1 permissions determine the access permissions for the region.</td>
</tr>
</tbody>
</table>

For more information about the S2AP field, see Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G5-9179.
If the stage 2 permissions cause a Permission fault, this is a stage 2 MMU fault. Stage 2 MMU faults are taken to Hyp mode, and reported in the HSR using an EC code of 0x20 or 0x24. For more information, see Use of the HSR on page G5-9265.

——— Note ————
In the HSR, the combination of the EC code and the DFSC or IFSC value in the ISS indicate that the fault is a stage 2 MMU fault.

——— Note ————
The stage 2 permissions include an XN attribute. If this identifies the region as execute-never, execution from the region is not permitted, regardless of the value of the XN or UXN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN field identifies the region as execute-never, this is reported as a stage 2 MMU fault.

——— Note ————
The stage 2 XN attribute:

- Is a single bit if FEAT_XNX is not implemented, see XN, Execute-never on page G5-9196.
- Is a 2-bit field if FEAT_XNX is implemented, see XN[1:0], Execute-never, stage 2 only on page G5-9196.

AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248 describes the abort prioritization if both stages of a translation generate a fault.
Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. Information returned by a translation table lookup describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, Cacheability, and Shareability of the region.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- Overview of memory region attributes for stage 1 translations.
- Short-descriptor format memory region attributes, without TEX remap on page G5-9204.
- Short-descriptor format memory region attributes, with TEX remap on page G5-9207.
- VMSAv8-32 Long-descriptor format memory region attributes on page G5-9210.

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or EL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. EL2 control of Non-secure memory region attributes on page G5-9212 describes these stage 2 assignments.

Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a Translation descriptor divides into:

Memory type and attributes

These are described either:

- Directly, by bits in the Translation Table descriptor.
- Indirectly, by registers referenced by bits in the Table descriptor. This is described as remapping the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the SCTLR.TRE bit:

- **TRE == 0** Remap disabled. The TEX[2:0], C, and B bits in the Translation Table descriptor define the memory region attributes. Short-descriptor format memory region attributes, without TEX remap on page G5-9204 describes this encoding.

--- Note ---

With the Short-descriptor format, remapping is called TEX remap, and the SCTLR.TRE bit is the TEX remap enabled bit.

The description of the TRE == 0 encoding includes information about the encoding in previous versions of the architecture.

- **TRE == 1** Remap enabled. The TEX[0], C, and B bits in the Translation Table descriptor are index bits to the remap registers, that define the memory region attributes:
  - The Primary Region Remap Register, PRRR.
  - The Normal Memory Remap Register, NMRR.

Short-descriptor format memory region attributes, with TEX remap on page G5-9207 describes this encoding scheme.

This scheme reassigns Translation Table descriptor bits TEX[2:1] for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means that when the value of TTBCR.EAE is 1, enabling use of the Long-descriptor translation table format, SCTLR.TRE is **RES1**.

VMSAv8-32 Long-descriptor format memory region attributes on page G5-9210 describes this encoding.
Shareability

In the Short-descriptor translation table format, the S bit in the Translation Table descriptor is used in determining the Shareability of the region. How the S bit is interpreted depends on whether TEX remap is enabled, see:

- **Shareability and the S bit, without TEX remap** on page G5-9206.
- **Determining the Shareability, with TEX remap** on page G5-9208.

In the Long-descriptor translation table format, the SH[1:0] field in the Translation Table descriptor encodes the Shareability of the region, see **Shareability, Long-descriptor format** on page G5-9210.

--- Note ---

Shareability is one of Non-shareable, Inner Shareable, and Outer Shareable. However, when using the Short-descriptor translation table format without TEX remap, VMSAv8-32 does not support any distinction between Inner Shareable and Outer Shareable memory, and a memory region is either Non-shareable or Outer Shareable.

### Stage 1 definition of the XS attribute

When **FEAT_XS** is implemented, all stage 1 memory types defined in the MAIR0, MAIR1, HMAIR0, HMAIR1, PRRR, and NMRR registers, or the TTBCR or HTCR registers, or in the page tables, have the XS attribute set to 1, unless they are Inner Write-Back Cacheable, Outer Write-back Cacheable, which have the XS attribute set to 0. This includes any memory types that are treated as Write-Back Cacheable as a result of **IMPLEMENTATION DEFINED** choices in the architecture.

### G5.7.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when the value of **SCTLR.TRE** is 0.

--- Note ---

- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

--- Table **G5-12** on page G5-9204 shows the C, B, and TEX[2:0] encodings when TEX remap is disabled. In the **Page Shareability** on page G5-9204 column, an entry of S bit indicates that the S bit in the Translation Table descriptor determines the Shareability, see **Shareability and the S bit, without TEX remap** on page G5-9206.

Cacheability attributes, without TEX remap

When the value of TEX[2] is 0, the same Cacheability attribute applies to Inner Cacheable and Outer Cacheable memory regions, and the \{TEX[1:0], C, B\} values identify this attribute, as Table G5-12 on page G5-9204 shows.

When the value of TEX[2] is 1, the memory described by the translation table entry is cacheable, and the rest of the encoding defines the Inner Cacheability and Outer Cacheability attributes:

- TEX[1:0] Define the Outer Cacheability attribute.
- C, B Define the Inner Cacheability attribute.

The translation table entries use the same encoding for the Outer and Inner Cacheability attributes, as Table G5-13 on page G5-9206 shows.

Shareability and the S bit, without TEX remap

The Short-descriptor format translation table entries include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory, or to Normal memory that is Inner Non-cacheable, Outer Non-cacheable.
- For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, determines whether the memory region is Outer Shareable or Non-shareable:
  - $S == 0$: Normal memory region is Non-shareable.
  - $S == 1$: Normal memory region is Outer Shareable.

Without TEX remapping there is no distinction between Inner Shareable and Outer Shareable memory, meaning the S bit determines whether the region is Non-shareable or Outer Shareable.
G5.7.3 Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when the value of SCTLR.TRE is 1. In this configuration:

- The software that defines the translation tables must program the PRRR and NMRR to define seven possible memory region attributes.
- The TEX[0], C, and B bits of the Translation Table descriptors define the memory region attributes, by indexing PRRR and NMRR.
- Hardware makes no use of TEX[2:1], see *The OS managed translation table bits* on page G5-9209.

When TEX remap is enabled:

- For seven of the eight possible combinations of the TEX[0], C and B bits, fields in the PRRR and NMRR define the region attributes, as described in this section.
- The meaning of the eighth combination for the TEX[0], C and B bits is IMPLEMENTATION DEFINED.
- If the TEX[0], C and B bits determine that the region is a Device memory type, or is Normal Inner Non-cacheable, Outer Non-cacheable, then the region is Outer Shareable. Otherwise, the Shareability is determined by the combination of:
  - The S bit from the Translation Table descriptor.
  - The value of the PRRR.NS0 or PRRR.NS1 bit.
  - The value of the appropriate PRRR.NOSn bit, as shown in Table G5-14 on page G5-9207.

For more information, see *Determining the Shareability, with TEX remap* on page G5-9208.

For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, Table G5-14 on page G5-9207 shows which fields of the PRRR and NMRR registers describe the memory region attributes.

<table>

</tbody>
</table>

a. For details of the *Memory type* and *Outer Shareable* encodings see the description of the PRRR. For details of the *Cache attributes* encodings see the description of the NMRR.

b. Applies only if the memory type for the region is mapped as Normal memory.

c. Applies only if both of the following apply:

The memory type for the region is mapped as Normal memory that is not Inner Non-cacheable and Outer Non-cacheable.

The region is not Non-shareable.

See *Determining the Shareability, with TEX remap* on page G5-9208.
As Table G5-14 on page G5-9207 shows, when TEX remap is enabled, for a given set of \{TEX[0], C, B\} bits from a Translation Table descriptor:

1. The primary mapping, to memory type, is given by the PRRR.TRn field as shown in the Memory type column.
2. For any region that the PRRR.TRn maps as Normal memory, NMRR.IRn determines the Inner cacheability attribute, and NMRR.ORn determines the Outer cacheability attribute.
3. For a region that PRRR.TRn maps as Normal memory, if NMRR.{IRn, ORn} do not map the region as Inner Non-cacheable, Outer Non-cacheable, PRRR.{NS0, NS1} and PRRR.NOSn are used to determine the Shareability of the region, see Determining the Shareability, with TEX remap.

The TEX remap registers and the SCTLR.TRE bit are banked between the Secure and Non-secure Security states. For more information, see The effect of EL3 on TEX remap on page G5-9210.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:
- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is CONSTRAINED UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables, see CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:
1. Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or SCTLR.TRE bit.
3. Execute an ISB instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a DSB instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a DSB instruction. This ensures completion of the cache maintenance.
8. Execute an ISB instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in Synchronization of changes to AArch32 System registers on page G8-9326, and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

### Determining the Shareability, with TEX remap

The memory type of a region, as indicated in the Memory type column of Table G5-14 on page G5-9207, provides the first level of control of the Shareability of the region:
- If the memory is any type of Device memory, then the region is Outer Shareable, and any Shareability attributes in the Translation Table descriptor and PRRR for that region are ignored.
  - This applies also to a Normal memory region that the NMRR attributes identify as Inner Non-cacheable and Outer Non-cacheable,
- If using the Short descriptor translation table format then the Shareability of the region is determined using the value of the S bit in the Translation Table descriptor to index one of the PRRR.{NS1, NS0} bits, as described in this section.

Table G5-15 on page G5-9208 shows how the translation table S bit indexes into the PRRR:

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Remapping when S == 0</th>
<th>Remapping when S == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device or Normal Inner Non-cacheable, Outer Non-cacheable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Normal, not Inner Non-cacheable, Outer Non-cacheable</td>
<td>PRRR.NS0</td>
<td>PRRR.NS1</td>
</tr>
</tbody>
</table>
For a Normal memory region that is not Inner Non-cacheable, Outer Non-cacheable, the appropriate bit of the
PRRR indicates whether the region is Non-shareable, as follows:

\[
\text{PRRR.NS} = 0 \quad \text{Non-shareable.}
\]
\[
\text{PRRR.NS} = 1
\]

The appropriate PRRR.NOS field, as shown in Table G5-14 on page G5-9207, indicates
whether the region is Inner Shareable or Outer Shareable:

\[
\text{PRRR.NOS} = 0 \quad \text{Region is Outer Shareable.}
\]
\[
\text{PRRR.NOS} = 1 \quad \text{Region is Inner Shareable.}
\]

Note
This means that TEX remapping can map a translation table entry with \(S = 0\) as shareable memory.

**SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers**

When TEX remap is disabled, because the value of the SCTLR.TRE bit is 0:

- The effect of the PRRR and NMRR registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the PRRR and NMRR registers can differ from the description given earlier
  in this section. One implication of this is that the implementation can provide an IMPLEMENTATION DEFINED
  mechanism to interpret the PRRR.NOS fields.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations.
These registers must not change whether any cache hardware or stages of address translation are enabled. The
mechanism by which the TEX remap registers have an effect when the value of the SCTLR.TRE bit is 0 is
IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED
mechanism has not been invoked:

- If the PL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables,
  the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX
  remap functionality. In other words, memory attribute assignment must comply with the scheme described
  in Short-descriptor format memory region attributes, without TEX remap on page G5-9204.
- If the PL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32
  with address translation disabled must apply, without reference to the TEX remap functionality. See The
effects of disabling address translation stages on VMSAv8-32 behavior on page G5-9154.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when the value
of SCTLR.TRE is 0 include:

- A control bit in the ACTLR, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the PRRR and NMRR registers are changed from their IMPLEMENTATION
  DEFINED reset values.

In addition, if the stage of address translation is disabled and the value of the SCTLR.TRE bit is 1, the
architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply
without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take
effect in the Security state of the registers. See also The effect of EL3 on TEX remap on page G5-9210.

**The OS managed translation table bits**

When TEX remap is enabled, the TEX[2:1] bits in the Translation Table descriptors are available as two bits that
can be managed by the operating system. In VMSAv8-32, as long as the SCTLR.TRE bit is set to 1, the values of
the TEX[2:1] bits are IGNORED by the PE. Software can write any value to these bits in the translation tables.
The effect of EL3 on TEX remap

In an implementation that includes EL3, when EL3 is using AArch32, the TEX remap registers are banked between
the Secure and Non-secure Security states. When EL3 is using AArch32, write accesses to the Secure register for
the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The SCTLR.TRE bit is
banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines
whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the CP15SDISABLE input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see The CP15SDISABLE and CP15SDISABLE2 input signals on page G5-9285.

VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the AttrIndx[2:0] field in a block or
page Translation Table descriptor for a stage 1 translation indicates the 8-bit field, in the appropriate MAIR register,
that specifies the attributes for the corresponding memory region, as follows:

• AttrIndx[2] indicates the MAIR register to be used:
  AttrIndx[2] == 0 Use MAIR0.

• AttrIndx[2:0] indicates the required Attr field, Attrn, where n = AttrIndx[2:0].

Each AttrIndx field defines, for the corresponding memory region:

• The memory type, Normal or a type of Device memory.

• For Normal memory:
  — The Inner cacheability and Outer cacheability attributes, each of which is one of Non-cacheable,
    Write-Through Cacheable, or Write-Back Cacheable.
  — For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and
    Write-Allocate policy hints, each of which is Allocate or No allocate.

For more information about the AttrIndx[2:0] descriptor field, see Attribute fields in VMSAv8-32 Long-descriptor
stage 1 Block and Page descriptors on page G5-9177.

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the SH[1:0] field in a Block or Page Translation
Table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that
region identifies it as Normal memory that is not both Inner Non-cacheable and Outer Non-cacheable. Table G5-16
on page G5-9210 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONstrained UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-11583 for the permitted behavior.</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G5-9215 for constraints on the Shareability attributes of a Normal
memory region that is Inner Non-cacheable, Outer Non-cacheable.
For any type of Device memory, and for Normal Inner Non-cacheable, Outer Non-cacheable memory, the value of the SH[1:0] field of the Translation Table descriptor is ignored.

**Other fields in the Long-descriptor translation table format descriptors**

The following subsections describe the other fields in the Translation Table Block and Page descriptors when a PE is using the Long-descriptor translation table format:

- **Contiguous bit**
- **IGNORED fields.**
- **Field reserved for software use**

**Contiguous bit**

The Long-descriptor Translation Table Format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a contiguous output address range. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, to use this bit for a block of 16 entries in the level 3 translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

**Note**

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

**IGNORED fields**

In the VMSA8-32 translation table long-descriptor format, the following fields are defined as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 and stage 2 Table descriptors, bits[58:52] and bits[11:2].
- In the stage 1 and stage 2 Block and Page descriptors, bit[63] and bits[58:55].
- In the stage 1 and stage 2 Block and Page descriptors in an implementation that does not include FEAT_HPDS2, bits[62:59].

Of these fields:

- In the stage 1 and stage 2 Block and Page descriptors, bits[58:55] are reserved for software use, see Field reserved for software use.

- In the stage 2 Block and Page descriptors:
  - Bit[63] is reserved for use by a System MMU.
  - In an implementation that does not include FEAT_HPDS2, bits[62:59] are reserved for use by a System MMU.

**Field reserved for software use**

The architecture reserves a 4-bit IGNORED field in the Block and Translation Table descriptors, bits[58:55], for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in The OS managed translation table bits on page G5-9209.
Note

The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.

G5.7.5 EL2 control of Non-secure memory region attributes

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure EL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the HTTBR and HTCR. These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in VMSAv8-32 Long-descriptor format memory region attributes on page G5-9210.

- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the VTTBR and VTCR. The descriptors in the virtualization translation tables define level 2 memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

VMSAv8-32 Long-descriptor Translation Table format descriptors on page G5-9173 describes the format of the entries in these tables.

Note

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted Cacheability of a region.
- Increase the required Shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 Translation Table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see Shareability, Long-descriptor format on page G5-9210.

- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as Table G5-17 on page G5-9212 shows:

Table G5-17 Long-descriptor MemAttr[3:2] encoding, stage 2 translation

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device, of type determined by MemAttr[1:0]</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal, Inner cacheability determined by MemAttr[1:0]</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Write-Through Cacheable</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Outer Write-Back Cacheable</td>
<td></td>
</tr>
</tbody>
</table>
The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

— When MemAttr[3:2] == 0b00, indicating a type of Device memory, Table G5-18 shows the encoding of MemAttr[1:0]:

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>

— When MemAttr[3:2] != 0b00, indicating Normal memory, Table G5-19 on page G5-9213 shows the encoding of MemAttr[1:0]:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE, See Reserved values in System and memory-mapped registers and translation table entries on page K1-11583 for the permitted behavior.</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

--- Note ---

The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

• Combining the memory type attribute on page G5-9214.
• Combining the Cacheability attribute on page G5-9214.
• Combining the Shareability attribute on page G5-9215.

--- Note ---

• The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  — MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

• In addition to the attribute combinations described in this section, Access permissions for instruction execution on page G5-9196 describes how the stage 1 and stage 2 execute-never permission fields are combined, so that a region is execute-never if it is defined as execute-never in at least one stage of translation.
Combining the memory type attribute

Table G5-20 shows how the stage 1 and stage 2 memory type assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device-nGnRnE</td>
<td>Any</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td>Device-nGnRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Not Device-nGnRnE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td>Device-nGRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Not (Device-nGnRnE or Device-nGnRE)</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td>Device-GRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Device-nGRE</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td></td>
<td>Device-GRE or Normal</td>
<td>Device-GRE</td>
</tr>
<tr>
<td>Normal</td>
<td>Any type of Device</td>
<td>Device type assigned at stage 2</td>
</tr>
<tr>
<td></td>
<td>Normal</td>
<td>Normal</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G5-9215 for information about the Shareability of:

- A region for which the resultant type is any Device type.
- A region with a resultant type of Normal for which the resultant cacheability, described in Combining the Cacheability attribute, is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to a type of Device memory. If this occurs, then:

- If the value of HCR.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR.PTW is 1, then the memory access generates a stage 2 Permission fault.

Combining the Cacheability attribute

For a Normal memory region, Table G5-21 on page G5-9214 shows how the stage 1 and stage 2 Cacheability assignments are combined. This combination applies, independently, for the Inner Cacheability and Outer Cacheability attributes:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>
<td>Non-cacheable</td>
<td>Non-cacheable</td>
</tr>
</tbody>
</table>
Combining the Shareability attribute

In the following cases, a memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation:

- The resultant memory type attribute, described in Combining the memory type attribute on page G5-9214, is any type of Device memory.
- The resultant memory type attribute is Normal memory, and the resultant Cacheability, described in Combining the Cacheability attribute on page G5-9214, is Inner Non-cacheable Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal that is not Inner Non-cacheable Outer Non-cacheable, Table G5-22 on page G5-9215 shows how the stage 1 and stage 2 shareability assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer Shareable</td>
<td>Any</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Non-shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>

Note: Only Normal memory has a Cacheability attribute.
G5.8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The Arm architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.

- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.

- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.

- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.

- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

Note: A TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- Global and process-specific translation table entries.
- TLB matching on page G5-9217.
- TLB behavior at reset on page G5-9217.
- TLB lockdown on page G5-9218.
- TLB conflict aborts on page G5-9218.

See also TLB maintenance requirements on page G5-9220.

Note: In addition to the functions described in this section, the TLB might cache information from control registers that are described as being "permitted to be cached in a TLB", even when any or all of the stages of translation are disabled. This caching of information gives rise to the maintenance requirements described in General TLB maintenance requirements on page G5-9220.

G5.8.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and EL0 into global and non-global regions, indicated by the nG bit in the Translation Table descriptors:

nG == 0 The translation is global, meaning the region is available for all processes.
nG == 1  The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:
   • TTBR0.ASID or TTBR1.ASID, if using the Long-descriptor translation table format. In this case, TTBCR.A1 selects which ASID is current.
   • CONTEXTIDR.ASID, if using the Short-descriptor translation table format.

Each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

In AArch32 state, the translation regime used for accesses made at EL2 never supports ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information, see Control of Secure or Non-secure memory access, VMSA v8-32 Long-descriptor format on page G5-9180.

G5.8.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in TLB maintenance requirements on page G5-9220 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in Using break-before-make when updating translation table entries on page G5-9221 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:
   • Might generate an exception that is reported using the TLB Conflict fault code, see TLB conflict aborts on page G5-9218.
   • Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. See CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567.

G5.8.3 TLB behavior at reset

The Arm architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore:
   • All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
   • All TLBs are disabled from reset. All stages of address translation that are used from the PE state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information, see Enabling stages of address translation on page G5-9156.
• An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.

Arm recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance instructions described in *The scope of TLB maintenance instructions on page G5-9230.*

Similar rules apply:
• To cache behavior, see *Behavior of caches at reset on page G4-9119.*
• To branch predictor behavior, see *Behavior of the branch predictors at reset on page G4-9127.*

**G5.8.4 TLB lockdown**

The Arm architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

• The architecture does not require TLB lockdown support.
• If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:
• The TLB Type Register, TLBTR, does not define the lockdown scheme in use.
• In AArch32 state, a region of the `{coproc=0b1111, CRn=c10}` encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  — `<Cr>` = `{c0, c1, c4, c8}`.
  — All values of `<opc2>` and `<opc1>`.

An implementation might use some of the `{coproc=0b1111, CRn=c10}` encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:
• Unlock all locked TLB entries.
• Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in a Non-secure PL1 mode or in Non-secure User mode can be routed to either:
• Non-secure Abort mode, using the Non-secure Data Abort exception vector.
• Hyp mode, using the Hyp Trap exception vector.

For more information, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-9016.*

**G5.8.5 TLB conflict aborts**

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort is classified as an MMU fault, see *Types of MMU faults on page G5-9239.* This means:
• A TLB conflict abort on an instruction fetch is reported as a Prefetch Abort exception,
• A TLB conflict abort on a data access is reported as a Data Abort exception,

Fault status codes for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:
• *PL1 fault reporting with the Short-descriptor translation table format on page G5-9256*
• *PL1 fault reporting with the Long-descriptor translation table format on page G5-9258.*
On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

--- Note ---

- An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed.
- A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort not generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see CONSTRANGED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567. The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.
G5.9 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G5-9216 describes the Arm architectural provision for TLBs. Although the Arm architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSaV8-32 TLB maintenance instructions:

- General TLB maintenance requirements.
- Maintenance requirements on changing System register values on page G5-9226.
- Atomicity of register changes on changing virtual machine on page G5-9227.
- Synchronization of changes of ASID and TTBR on page G5-9227.
- The scope of TLB maintenance instructions on page G5-9230.

G5.9.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism to invalidate entries from a TLB. As Translation Lookaside Buffers (TLBs) on page G5-9216 describes, when address translation is enabled translation table entries can be allocated to a TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

Note

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

Note

The effects of certain System register control fields are permitted to be cached in a TLB. For more information, see TLB maintenance on page D8-5197.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information, see Cache maintenance requirement created by changing translation table attributes on page G5-9237.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation. However, a Context synchronization event is required to ensure that instruction fetches are affected by a completed change to translation table entries that, before the change, generated a Translation, Address size, or Access flag fault.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see Using break-before-make when updating translation table entries on page G5-9221.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. Maintenance requirements on changing System register values on page G5-9226 gives more information about this maintenance requirement.

Each of the translation regimes defined in Figure G5-1 on page G5-9148 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or EL0 modes, a change of HCR.VM, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of HCR.VM is visible to software executing in the Non-secure PL1 and EL0 modes.
Any TLB maintenance instruction can affect any other TLB entries that are not locked down.

AArch32 state defines \{coproc==0b1111, Crn==c8\} System instructions for TLB maintenance instructions, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.

--- Note ---

An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

A TLB maintenance instruction that specifies a VA that would generate any MMU fault, including a VA that is not in the range of VAs that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance instructions for use in AArch32 state at EL2, and has some implications for the effect of the other TLB maintenance instructions, see The scope of TLB maintenance instructions on page G5-9230.

In an implementation that includes EL3, the TLB maintenance instructions take account of the current Security state, as part of the address translation required for the TLB maintenance instruction.

Some TLB maintenance instructions are defined as operating only on instruction TLBs, or only on data TLBs. AArch32 state includes these instructions for backwards compatibility. However, more recent TLB maintenance instructions do not support this distinction. From the introduction of Armv7, Arm deprecates any use of Instruction TLB maintenance instructions, or of Data TLB maintenance instructions, and developers must not rely on this distinction being maintained in future revisions of the Arm architecture.

The Arm architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate instructions, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

The scope of TLB maintenance instructions on page G5-9230 describes the TLB maintenance instructions. The following subsections give more information about the general requirements for TLB maintenance:

- Using break-before-make when updating translation table entries.
- The interaction of TLB lockdown with TLB maintenance instructions on page G5-9222.
- Ordering and completion of TLB maintenance instructions on page G5-9223.
- Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page G5-9225.

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, single-copy atomicity properties, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type, including shareability.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entries and the new translation table entry is writable.
- A change to the size of block used by the translation system. This applies both:
  — When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
— When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.

• A change of the output address (OA), if the contents of memory at the new OA do not match the contents of memory at the previous OA.

• Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

Note

Changes to the output address (OA) include changing between Secure and Non-secure output addresses.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

• The effect on locked entry of a TLB invalidate all unlocked entries instruction or a TLB invalidate by VA all ASID instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  — The instructions have no effect on entries that are locked down.
  — The instructions generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the \{coproc==0b1111, CRn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G5-26 on page G5-9256 for the codes used with the Short-descriptor translation table formats, or Table G5-27 on page G5-9258 for the codes used with the Long-descriptor translation table formats.

In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-9016.

This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

• The effect on a locked TLB entry of a TLB invalidate by VA instruction or a TLB invalidate by ASID match instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  — A locked entry is invalidated in the TLB.
  — The instruction has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the instruction as a NOP.
  — The instruction generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the \{coproc==0b1111, CRn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G5-26 on page G5-9256 and Table G5-27 on page G5-9258.
Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required invalidation on entries that are not locked down.

- Implement one of the other specified alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined maintenance instructions. This minimizes the number of customized maintenance operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance instructions on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page G4-9136.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

### Ordering and completion of TLB maintenance instructions

The following rules describe the relations between the memory order model and the TLB maintenance instructions:

- A TLB maintenance instruction executed by a PE, PEe, causes a TLB maintenance operation to be generated on each PE within the shareability domain of PEe that is specified by the instruction.
  - At EL2 or EL3, or at EL1 when the Effective value of HCRX_EL2.FnXS is 0, the associated TLB maintenance operations do not have the nXS qualifier.
  - At EL1, when the Effective value of HCRX_EL2.FnXS is 1, the behavior of the associated TLB maintenance operations is the same as described for the AArch64 TLB maintenance instructions with the nXS qualifier. See Ordering and completion of TLB maintenance instructions on page D8-5213.

- When FEAT_XS is not implemented, all TLB maintenance instructions do not have the nXS qualifier and the Effective value of HCRX_EL2 is 0.

- A TLB maintenance operation generated by a TLB maintenance instruction is finished for a PE when:
  - All memory accesses generated by that PE using in-scope old translation information are complete.
  - All memory accesses RWx generated by that PE are complete.

RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I1 executed by that PE where all of the following apply:

- I1 uses the in-scope old translation information.
- The use of the in-scope old translation information generates a synchronous Data Abort.
- If I1 did not generate an abort from use of the in-scope old translation information, I1 would generate a memory access that RWx would be locally-ordered-before.

In-scope old translation information is any translation information, for addresses that are in the scope of the TLB maintenance instruction, that is not consistent with either:

- The architectural translation information held in the translation tables at the time that the TLB maintenance instruction is executed by PEe.
- Any architecture translation information that is Coherence-after the information held in the translation tables at the time that the TLB maintenance instruction is executed by PEe.
Old translation information of this type might be held in TLBs or other non-coherent caching structures.

A TLB maintenance instruction is complete when the TLB maintenance operations specified by the TLB maintenance instruction are finished for all PEs.

After the TLB maintenance instruction is complete, no new memory accesses using the in-scope old translation information will be architecturally performed by any observer that is affected by the TLB maintenance instruction.

Speculative memory accesses can be performed using those entries if it is impossible for software running on any observer to tell that those memory accesses have been performed.

A TLB maintenance instruction is only guaranteed to be complete after the execution of a DSB instruction.

An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance instructions that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.

An exception causes all completed TLB maintenance instructions, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.

All TLB maintenance instructions are executed in program order relative to each other.

The execution of a Data or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent explicit memory read or write effect instruction after both:
- The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
- Execution of a subsequent Context synchronization event.

The execution of an Instruction or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent instruction fetch after both:
- The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
- Execution of a subsequent Context synchronization event.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance instructions.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:
- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by an explicit memory read or write effect after the execution of both a DSB and an ISB.
  However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory effect that occurs in program order before the write to the translation tables.
- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry] ; write new entry to the translation table
DSB ; ensures visibility of the new entry
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB ; ensure completion of the Invalidate TLB instruction
```
Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID.

Note

The use of ASIDs and VMIDs in VMSAv8-32 is generally similar to their use in VMSAv8-64, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page D8-5194.

For more information about the use of ASIDs in VMSAv8-32 see Global and process-specific translation table entries on page G5-9216.

Common not private translations in VMSAv8-32

In an implementation that includes FEAT_TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of address translation in a particular translation regime. This sharing is enabled by the TTBR.CnP field for the stage of address translation.

When the value of a TTBR.CnP field is 1, translation table entries pointed to by that TTBR are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding TTBR.CnP field has the value 1.
- That TTBR is using the Long-descriptor translation table format.
- If an ASID applies to the stage of translation corresponding to that TTBR then the current ASID value must be the same for all of the PEs that are sharing entries for any translation table entry that is not global or not leaf level.
- If a VMID applies to the stage of translation corresponding to that TTBR then the current VMID value must be the same for all of the PEs that are sharing entries.

Note

In an implementation that includes EL3, the Secure instances of TTBR0 and TTBR1 relate to the Secure PL1&0 translation regime, and the Non-secure instances of TTBR0 and TTBR1 relate to the Non-secure PL1&0 translation regime.

For a translation regime with both stage 1 and stage 2 translations, where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR.CnP bit can be cached in a TLB.

For a given TTBR, if the value of TTBR.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBRs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page G5-9218.
- Otherwise, has a CONSTRAINED UNPREDICTABLE result, as described in CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567.
### G5.9.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB entries associated with a translation regime affected by these control bits must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID, if appropriate depending on the translation regime, that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```plaintext
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the NMRR, PRRR, MAIR0, MAIR1, HMAIR0 or HMAIR1 registers.
- Any change to the SCTLR.AFE bit, see Changing the Access flag enable.
- Any change to any of the SCTLR.{TRE, WXN, UWXN} bits.
- Any change to the Translation table base 0 address in TTBR0.
- Any change to the Translation table base 1 address in TTBR1.
- Any change to HTTBR.BADDR.
- Any change to VTTBR.BADDR.
- Changing TTBCR.EAE, see Changing the current Translation table format on page G5-9227.
- In an implementation that includes EL3, any change to the SCR.SIF bit.
- In an implementation that includes EL2:
  - Any change to the HCR.VM bit.
  - Any change to HCR.PTW bit, see Changing HCR.PTW.
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in TTBR0 or TTBR1.
  - Any change to the N, EAE, PD0 or PD1 fields in TTBCR
- When using the Long-descriptor translation table format:
  - Any change to the EAE, TnSZ, ORGNn, IRGNn, SHn, or EPDn fields in the TTBCR, where \( n \) is 0 or 1.
  - Any change to the TTBCR2.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the HTCR.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the VTCR.

#### Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is CONstrained UNPredictable whether the TLB caches the effect of the SCTLR.AFE bit on translation tables. This means that, after changing the SCTLR.AFE bit software must invalidate the TLB before it relies on the effect of the new value of the SCTLR.AFE bit, otherwise behavior is CONstrained UNPredictable, see CONstrained UNPredictable behaviors due to caching of System register control or data values on page K1-11567.

---

**Note**

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

---

#### Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, HCR.PTW, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR.PTW. Therefore, if the value of HCR.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or EL0 mode. If this is not done, behavior is CONstrained UNPredictable, see CONstrained UNPredictable behaviors due to caching of System register control or data values on page K1-11567.
Changing the current Translation table format

The effect of changing TTBCR.EAE when executing in the translation regime affected by TTBCR.EAE with any stage of address translation for that translation regime enabled is CONSTRAINED UNPREDICTABLE. This means that, when TTBCR.EAE is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567.

G5.9.3 Atomicty of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or EL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
  - PRRR and NMRR, if using the Short-descriptor translation table format.
  - MAIR0 and MAIR1, if using the Long-descriptor translation table format.
  - TTBR0, TTBR1, TTBCR, TTBCR2, DACR, and CONTEXTIDR.
  - The SCTLR.
- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - VTTBR and VTCR.
  - HMAIR0 and HMAIR1.
  - The HSCTLR.

Note
Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Note
By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are in context. Synchronization of changes of ASID and TTBR describes appropriate precautions for such a change.

G5.9.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and TTBR together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
- The use of branch prediction.
When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. Example G5-3, Example G5-4, and Example G5-5 on page G5-9229 describe three possible approaches.

--- Note ---

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

--- Example G5-3 Using a reserved ASID to synchronize ASID and TTBR changes ---

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and TTBR. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given VA is the same in the old and new translation tables.

The maintenance software uses the following sequence, which must be executed from memory marked as global:

```
Change ASID to 0
ISB
Change TTBR
ISB
Change ASID to new value
```

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

--- Example G5-4 Using translation tables containing only global mappings when changing the ASID ---

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, which must be executed from memory marked as global:

```
Change TTBR to the global-only mappings
ISB
Change ASID to new value
ISB
Change TTBR to new value
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.
This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in General TLB maintenance requirements on page G5-9220, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same Shareability and Cacheability attributes, as held in the TTBR0.{ORGN, IRGN} or TTBR1.{ORGN, IRGN} fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

---

**Example G5-5 Disabling non-global mappings when changing the ASID**

In systems where only the translation tables indexed by TTBR0 hold non-global mappings, maintenance software can use the TTBCR.PD0 field to disable use of TTBR0 during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, which must be executed from a memory region with a translation that is accessed using the base address in the TTBR1 register, and is marked as global:

```
Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change TTBR to new value
ISB
Set TTBCR.PD0 = 0
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, TTBCR.A1 holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current TTBR can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- TTBR0 is the only TTBR being used. TTBCR.A1 must be set to 0.
- TTBR0 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 0.
- TTBR1 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

---

**Note**

When using the Long-descriptor translation table format, CONTEXTIDR.ASID has no significance for address translation, and is only an extension of the Context ID value.
The AArch32 Virtual Memory System Architecture

G5.9 TLB maintenance requirements

G5.9.5 The scope of TLB maintenance instructions

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.

- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the level 1 lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at level 2 or level 3 of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.

- In an implementation that includes EL2:
  - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures when these caches are indexed by their input address. The architecture does not restrict having either:

- Translation table entry caching that is indexed by the physical address of the location holding the translation table entry.

- Translation table entry caching that is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry. However, FEAT_nTLBPA allows software discoverability of whether such caches exist, such that if FEAT_nTLBPA is implemented, such caching is not implemented.

If all of the following are true, a TLB maintenance instruction will ensure that any physical address or intermediate physical address indexed cached copies of translation table entries are invalidated for a PE:

- The TLB maintenance instruction applies to that PE with the context information that is relevant to translation table entry caching that is either:
  - Indexed by the physical address of the location holding the translation table entry.
  - Stage 1 translation information that is indexed by the intermediate physical address of the location holding the translation table entry.

- FEAT_nTLBPA is not implemented.

Note

Any TLB caching based on the physical address or intermediate physical address obeys the other rules regarding the caching to TLB entries described in this manner, including restrictions on types of entries that cannot be held in a TLB, and a requirement that entries held in a TLB are distinguished by context information such as translation regime, VMID, and ASID.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
• In an implementation that includes EL2:
  — At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  — At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

Note
For the purpose of TLB maintenance, the term TLB entry denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

For the TLB maintenance instructions:
• If a TLB maintenance instruction is required to apply to stage 1 entries then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.

  Note
  — Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
  — As stated in Global and process-specific translation table entries on page G5-9216, translation table entries from levels of translation other than the final level are treated as being non-global. Arm expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

• If a TLB maintenance instruction is required to apply to stage 2 entries only, then:
  — It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  — It must apply to caching structures that contain information only from stage 2 translation table entries.

• If a TLB maintenance instruction is required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G5-23 on page G5-9232 summarizes the required effect of the AArch32 TLB maintenance instructions, that operate only on TLBs on the PE that executes the instruction. Additional TLB maintenance instructions that:
• Apply across all PEs in the same Inner Shareable domain. Each instruction shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of TLBIALL is TLBIALLIS. See also EL2 forced broadcasting of TLB maintenance instructions on page G5-9234.
• Can apply to separate Instruction or Data TLBs. These instructions are indicated by a footnote to the table. Arm deprecates any use of these instructions.

  Note
  • The architecture permits a TLB invalidation instruction to affect any unlocked entry in the TLB. Table G5-23 on page G5-9232 defines only the entries that each instruction must invalidate.
  • All TLB instructions, including those that operate on a VA match, operate as described regardless of the value of SCTLR.M.
When interpreting the table:

**Related operations**

Each instruction description applies also to any equivalent instruction that either:

- Applies to all PEs in the same Inner Shareable domain.
- Applies only to a data TLB, or only to an instruction TLB.

So, for example, the TLBIALL instruction description applies also to TLBIALLIS, ITLBIALL, and DTLBIALL.

*TLB maintenance system instructions* on page K17-11907 lists all of the TLB maintenance instructions.

**Matches the VA**

Means the VA argument for the instruction must match the VA value in the TLB entry.

**Matches the ASID**

Means the ASID argument for the instruction must match the ASID in use when the TLB entry was assigned.

**Matches the current VMID**

Means the current VMID must match the VMID in use when the TLB entry was assigned.

The dependency on the VMID applies even when the value of HCR.VM is 0, including situations where there is no use of virtualization. However, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset.

**Execution at EL2**

Descriptions of operations at EL2 apply only to implementations that include EL2.

For the definitions of the translation regimes referred to in the table see *About VMSAv8-32* on page G5-9146.

### Table G5-23 Effect of the TLB maintenance instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Executed from</th>
<th>Effect, must invalidate any entry that matches all stated conditions&lt;sup&gt;a&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLBIALL&lt;sup&gt;b&lt;/sup&gt;</td>
<td>Secure PL1</td>
<td>All entries for the Secure PL1&amp;0 translation regime. That is, all entries that were allocated in Secure state.</td>
</tr>
<tr>
<td>Non-secure PL1</td>
<td>Hyp</td>
<td>All entries for stage 1 of the Non-secure PL1&amp;0 translation regime that match the current VMID.</td>
</tr>
</tbody>
</table>
| TLBIMVA<sup>b</sup> | Secure PL1 | Any entry for the Secure PL1&0 translation regime that both:
- Matches the VA argument.
- Matches the ASID argument, or is global. |
| Non-secure PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime to which all of the following apply. The entry:
- Matches the VA argument.
- Matches the ASID argument, or is global.
- Matches the current VMID. |
## Table G5-23 Effect of the TLB maintenance instructions (continued)

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Executed from</th>
<th>Effect, must invalidate any entry that matches all stated conditions&lt;sup&gt;a&lt;/sup&gt;</th>
</tr>
</thead>
</table>
| TLBIASID<sup>b</sup> Secure | PL1 | Any entry for the Secure PL1&0 translation regime that matches the specified ASID and either:  
- Is from a level of lookup above the final level.  
- Is a non-global entry from the final level of lookup. |
| Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that both:  
- Matches the specified ASID and either:  
  - Is from a level of lookup above the final level.  
  - Is a non-global entry from the final level of lookup.  
- Matches the current VMID. |
| TLBIMVAA | Secure | PL1 | Any entry for the Secure PL1&0 translation regime that matches the VA argument. |
| Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that both:  
- Matches the VA argument.  
- Matches the current VMID. |
| TLBIALLNSNH<sup>c</sup> Secure | Monitor | All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID. |
| Non-secure | Hyp | All entries for the Non-secure EL2 translation regime. That is, any entry that was allocated in Non-secure state from Hyp mode. |
| TLBIALLH<sup>c</sup> Secure | Monitor | All entries for the Non-secure EL2 translation regime that matches the VA argument. |
| Non-secure | Hyp | Any entry for stage 1 of the Secure PL1&0 translation regime that is from the last level of the translation table walk and both:  
- Matches the VA argument.  
- Matches the ASID argument, or is global. |
| Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that is from the last level of the translation table walk and to which all of the following apply. The entry:  
- Matches the VA argument.  
- Matches the ASID argument, or is global.  
- Matches the current VMID. |
| TLBIMVAAL Secure | PL1 | Any entry for stage 1 of the Secure PL1&0 translation regime that is from the last level of the translation table walk and matches the VA argument. |
| Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that is from the last level of the translation table walk and both:  
- Matches the VA argument.  
- Matches the current VMID. |
| TLBIMVAH<sup>c</sup> Secure | Monitor | Any entry for the Non-secure EL2 translation regime that matches the VA argument. |
| Non-secure | Hyp | |

<sup>a</sup> Note: Instructions with the prefix "TLBIM" invalidate entries that match all stated conditions, not just those that match ASID.
EL2 forced broadcasting of TLB maintenance instructions

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance instructions that are not broadcast across the Inner Shareable domain are forced to operate across the Inner Shareable domain when executed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA instruction executed in a Non-secure PL1 mode performs the same invalidation as the invalidation performed by a TLBIMVAIS instruction.

TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a VA affecting the EL2 translation regime is broadcast from a PE using AArch32 to a PE using AArch64 using a translation granule size that is different from the AArch32 translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a VA affecting the PL1 translation regime is broadcast from a PE using AArch32 using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE using AArch64 where EL1 for the same ASID, VMID (if applicable), and Security state, is using a translation granule size that is different from the AArch32 translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.
G5.10 Caches in VMSAv8-32

The Arm architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

• Summarizes the architectural requirements for the interaction between caches and memory translation.
• Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

• Data and unified caches.
• Instruction caches.

In addition Cache maintenance requirement created by changing translation table attributes on page G5-9237 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

• AArch32 cache and branch predictor support on page G4-9113. This section describes the Arm cache maintenance instructions.
• Cache maintenance system instructions on page K17-11905. This section summarizes the System register encodings used for these operations when executing in AArch32 state.

G5.10.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access other than as described in Mismatched memory attributes on page E2-7208.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

• Two writes to the same PA occur in program order.
• A read of a PA returns the value of the last successful write to that PA.
• A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.

G5.10.2 Instruction caches

In the Arm architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The Arm architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

• PIPT (Physically-indexed, physically-tagged) instruction caches on page G5-9236.
• VPIPT (VMID-aware PIPT ) instruction caches on page G5-9236.
• VIPT (Virtually-indexed, physically-tagged) instruction caches on page G5-9236.
In AArch32 state, the CTR.L1Ip field identifies the form of the instruction caches.

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT (Physically-indexed, physically-tagged) instruction caches

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in Mismatched memory attributes on page E2-7208.
- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension on page G5-9237.

VPIPT (VMID-aware PIPT) instruction caches

An Armv8.2 implementation can implement VPIPT instruction caches. If it does so then it is described as implementing FEAT_VPIPT.

The CTR.L1Ip field identifies the implemented cache type, meaning it identifies whether FEAT_VPIPT is implemented.

For a VPIPT instruction cache:

- If VMIDs are being used for the current Security state, instruction fetches from EL1 and EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.
- If VMIDs are being used for the current Security state, an instruction cache maintenance instruction executed at EL0 or at EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for PIPT (Physically-indexed, physically-tagged) instruction caches.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension on page G5-9237.

VIPT (Virtually-indexed, physically-tagged) instruction caches

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in Mismatched memory attributes on page E2-7208.

Note

Cache invalidation is the only cache maintenance instruction that can be performed on an instruction cache.

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the VA supplied with the operation. The effect of the invalidation might not be visible to any other VA aliases of that physical memory location.
The only architecturally-guaranteed way to invalidate all aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension.

The IVIPT architecture Extension

Any permitted instruction cache implementation can be described as implementing the IVIPT Extension to the Arm architecture.

The formal definition of the Arm IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

• Instruction cache maintenance is required only after writing new data to a PA that holds an instruction.

Note

Previous versions of the Arm architecture have permitted an instruction cache option that does not implement the Arm IVIPT Extension.

G5.10.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in General TLB maintenance requirements on page G5-9220. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

• Write-Back to Write-Through.
• Write-Back to Non-cacheable.
• Write-Through to Non-cacheable.
• Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the Shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the Shareability attributes to the required new values.
G5.11 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

- **Debug exception**: An exception caused by the debug configuration, see Chapter G2 AArch32 Self-hosted Debug.

- **Alignment fault**: An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see Unaligned data access on page E2-7193 and Alignment faults on page G5-9247.

- **MMU fault**: An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MMU faults on page G5-9239.

- **External abort**: Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called aborts. Chapter G2 AArch32 Self-hosted Debug and Chapter H3 Halting Debug Events describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

An access that causes an abort is said to be aborted, and uses the Fault Address Registers (FARs) and Fault Status Registers (FSRs) or Exception Syndrome Registers (ESRs) to record context information.

The exception generated on a synchronous memory abort:
- **On an instruction fetch is called the Prefetch Abort exception.**
- **On a data access is called the Data Abort exception.**

Note: The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

The Exception level and PE mode that a VMSAv8-32 memory abort is taken to depends on the translation regime and stage that generate the abort. The fault context is dependent on whether:
- **The abort is reported as a Prefetch Abort or as a Data Abort.**
- **The exception is taken from the same or a lower Exception level.**

Note: A memory access from AArch32 state may be subject to one or more VMSAv8-64 translation stages. For example, a Non-secure EL0 access when EL1 is using AArch64 is subject to both stages of the VMSAv8-64 Non-secure EL1&0 translation regime. A memory abort generated on a VMSAv8-64 translation stage is handled as described in Memory aborts on page D8-5180.

For more information, see Routing of aborts taken to AArch32 state on page G1-8948.

External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError interrupt. For more information, see External aborts on page G4-9139.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a type of Data Abort exception.

The following sections describe the abort mechanisms:
- Types of MMU faults on page G5-9239.
- VMSAv8-32 MMU fault terminology on page G5-9241.
- The MMU fault-checking sequence on page G5-9242.
- Alignment faults on page G5-9247.
- External abort on a translation table walk on page G5-9247.
- AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248.
An access that causes an abort is said to be aborted. On an abort, System registers are used to record context information. For more information, see Exception reporting in a VMSAv8-32 implementation on page G5-9251.

G5.11 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in The MMU fault-checking sequence on page G5-9242. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The MMU faults that might be detected during a fault checking sequence are:

- Permission fault.
- Translation fault.
- Address size fault.
- Access flag fault.
- Domain fault, Short-descriptor translation tables only.
- TLB conflict abort.

See also External abort on a translation table walk on page G5-9247.

--- Note ---

- Although the TLB conflict abort is classified as an MMU fault, it is described in the section Translation Lookaside Buffers (TLBs) on page G5-9216.

- In VMSAv8-64 an External abort on a translation table walk is classified as an MMU fault. However, in VMSAv8-32, for consistency with earlier versions of the architecture these aborts are not classified as MMU faults.

---

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See About access permissions on page G5-9192 for information about conditions that cause a Permission fault.

--- Note ---

When using the Short-descriptor translation table format, the Translation Table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in Ordering and completion of TLB maintenance instructions on page G5-9223.

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in Stage 2 fault on a stage 1 translation table walk.

- When FEAT_CMOW is implemented and the Effective value of HCRX_EL2.CMOW is 1, the DCCIMVAC and ICIMVAC cache maintenance instructions can generate a stage 2 Permission fault if they do not have read and write permission at EL1 or EL0. See Permission fault on page D8-5183.
Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a Translation Table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information, see:

- VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9164.
- VMSAv8-32 Long-descriptor Translation Table format descriptors on page G5-9173.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a TTBR, or the TTBR range that it maps onto is disabled. In these cases the fault is reported as a level 1 Translation fault on the translation stage at which the mapping to a region described by a TTBR failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance by VA instruction can generate a Translation fault. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA to the Point of Coherency instruction can generate a Translation fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate a Translation fault.

Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Address size fault is generated if the translation table entries or the TTBR for the stage of translation have nonzero address bits above the most significant bit of the maximum output address size. Because VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this means any case where a translation table entry or the TTBR holds an address for which A[47:40] is nonzero generates an Address size fault.

A data or unified cache maintenance by VA instruction can generate an Address size fault. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate an Address size fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when SCTLR.AFE is set to 1.
  - The Long-descriptor format always supports an Access flag.
• A Translation Table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:
• *VMSAv8-32 Short-descriptor Translation Table format descriptors* on page G5-9164
• *VMSAv8-32 Long-descriptor Translation Table format descriptors* on page G5-9173.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance instruction by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see *The Access flag* on page G5-9200.

### Domain fault, Short-descriptor format translation tables only

When using the Short-descriptor translation table format, a Domain fault can be generated at level 1 or level 2 of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

**Level 1**

When a level 1 descriptor fetch returns a valid Section level 1 descriptor, the domain field of that descriptor is checked against the DACR. A level 1 Domain fault is generated if this check fails.

**Level 2**

When a level 2 descriptor fetch returns a valid level 2 descriptor, the domain field of the level 1 descriptor that required the level 2 fetch is checked against the DACR, and a level 2 Domain fault is generated if this check fails.

For more information, see *Domains, Short-descriptor format only* on page G5-9199.

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in *Ordering and completion of TLB maintenance instructions* on page G5-9223.

Any change to the DACR must be synchronized by a Context synchronization event. For more information, see *Synchronization of changes to AArch32 System registers* on page G8-9326.

### VMSAv8-32 MMU fault terminology

The Armv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. Table G5-24 on page G5-9241 shows the terminology used in this manual for an MMU faults, compared with older Arm documentation. The current terms are the same for faults that occur with the Short descriptor translation table format and with the Long-descriptor format, and also apply to faults in a level 3 lookup when using the Long-descriptor translation table format.

<table>
<thead>
<tr>
<th>Current term</th>
<th>Old term</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1 Translation fault</td>
<td>Section Translation fault</td>
<td></td>
</tr>
<tr>
<td>Level 2 Translation fault</td>
<td>Page Translation fault</td>
<td></td>
</tr>
<tr>
<td>Level 3 Translation fault</td>
<td>Long descriptor translation table format only</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see *Domains, Short-descriptor format only* on page G5-9199.
In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or EL0 mode can generate:

- A stage 1 MMU fault, for example, a stage 1 Translation fault.
- A stage 2 MMU fault, for example, a stage 2 Translation fault.

For more information about Prefetch Abort exceptions and Data Abort exceptions see Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the Translation Table descriptor for the accessed VA. For more information, see Translation tables on page G5-9158 and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.

**Note**

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address map, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

**When using the Short-descriptor format**

- There are one or two levels of lookup.
- Lookup always starts at level 1.
• The final level of lookup checks the Domain field of the descriptor and:
  — Faults if there is no access to the Domain.
  — Checks the access permissions only for Client domains.

**When using the Long-descriptor format**

• There are one, two, or three levels of lookup.
• Lookup starts at either level 1 or level 2.
• Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see *About address translation for VMSAv8-32 on page G5-9149.*

--- **Note**

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in *TLB conflict aborts on page G5-9218.*

*Types of MMU faults on page G5-9239* describes the faults that an MMU fault-checking sequence can report.

*Figure G5-15 on page G5-9244* shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address map, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

--- **Note**

*Figure G5-15 on page G5-9244 and Figure G5-16 on page G5-9245* give an overview of the fault checking performed by the MMU. See *AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248* for the complete set of possible faults and their prioritization.
Figure G5-15 Fetching the descriptor in a VMSAv8-32 translation table walk

Figure G5-16 on page G5-9245 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.
Figure G5-16 VMSAv8-32 fault checking sequence
Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or EL0 mode, any memory access goes through two stages of translation:

- Stage 1, from VA to IPA.
- Stage 2, from IPA to PA.

Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the PA map. However, it actually specifies these addresses in its IPA map. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address map.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous External abort on the memory access.

If SCR.EA is set to 1, a synchronous External abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information, see Use of the HSR on page G5-9265.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the HCR.PTW bit is 1, such an access generates a stage 2 Permission fault.

Note

- On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR.PTW. Therefore, if HCR.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or EL0 mode. For more information, see Changing HCR.PTW on page G5-9226.

A cache maintenance instruction executed at Non-secure PL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.

Note

This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.
The level associated with MMU faults

When an MMU fault is from a stage of translation that is using Long-descriptor translation table format, Table G5-25 shows how the LL bits in the STATUS field of DFSR, IFSR, and HSR encode the lookup level associated with the fault.

Table G5-25 Use of LL bits to encode the lookup level at which the fault occurred

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Level 0 of translation or translation table base register.</td>
</tr>
<tr>
<td>01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>11</td>
<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>

The level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-9250.

G5.11.4 Alignment faults

The Arm memory architecture requires support for strict alignment checking. This checking is controlled by:

- SCTLR.A, for accesses made from any PE mode other than Hyp mode.
- HSCTLR.A, for accesses made from Hyp mode.

In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A or HSCTLR.A.

Unaligned data access on page E2-7193:

- Defines when Alignment faults are generated, for both values of SCTLR.A or HSCTLR.A.
- Describes the possible generation of Alignment faults on accesses to Device memory by AArch32 Load Multiple or Store Multiple instructions when FEAT_LSMAOC is implemented.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

Routing of aborts taken to AArch32 state on page G1-8948 defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information, see AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-9248.

G5.11.5 External abort on a translation table walk

An External abort on a translation table walk can be either synchronous or asynchronous. For more information on External aborts, see External aborts on page G4-9139.
An External abort on a translation table walk is reported:

- If the External abort is synchronous, using:
  - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the External abort is asynchronous, using an SError interrupt, which is taken as an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when PSTATE.A is set to 1, otherwise they are reported using the Data Abort exception.

**Behavior of External aborts on a translation table walk caused by address translation instructions**

The address translation instructions summarized in [Address translation system instructions](#) on page K17-11906 require translation table walks. An External abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see [Handling of faults and aborts during an address translation instruction](#) on page G5-9275.

### G5.11.6 AArch32 state prioritization of synchronous aborts from a single stage of address translation

*Exception prioritization for exceptions taken to AArch32 state* on page G1-8932 describes the prioritization of exceptions taken from an Exception level that is using AArch32. This section gives additional information about the prioritization of MMU faults from VMSAv8-32 translation regimes.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the Arm architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

**Note**

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-32 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch64 list in [MMU fault prioritization from a single address translation stage](#) on page D8-5190.

For a single stage of translation in a VMSAv8-32 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the italic entries show where the faults from the stage 2 translation can occur. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults.
- For synchronous External aborts from translation table walks see also [Synchronous External abort errors from address translation caching structures](#) on page G5-9250.

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring an AArch32 TTBR that is disabled. This includes VTCR.SL0 being inconsistent with VTCR.T0SZ or programmed to a reserved value.
3. Address size fault on an AArch32 TTBR caused by the PA being out of the range implemented.
4. *Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.* This is second stage abort during a first stage translation table walk.
5. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
6. Synchronous External abort on a level 1 lookup level of a translation table walk.
7. Translation fault on a level 1 translation table entry.
8. Address size fault on a level 1 lookup translation table entry caused by the output address being out of the range implemented.
9. Second stage abort on a level 2 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.
10. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.
11. Synchronous External abort on a level 2 lookup level of a translation table walk.
12. Translation fault on a level 2 translation table entry.
13. Address size fault on a level 2 lookup translation table entry caused by the output address being out of the range implemented.
14. Second stage abort on a level 3 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.
15. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.
16. Synchronous External abort on a level 3 lookup level of a translation table walk.
17. Translation fault on a level 3 translation table entry.
18. Address size fault on a level 3 lookup translation table entry caused by the output address being out of the range implemented.
19. Access Flag fault.
20. Alignment fault caused by the memory type.

--- Note ---
Domain faults are possible only when using the VMSAv8-32 Short-descriptor translation table format, see Domain fault, Short-descriptor format translation tables only on page G5-9241.

22. Permission fault.
23. A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.
24. Synchronous parity or ECC error on the memory access.
25. Synchronous External abort on the memory access.

--- Note ---
• The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
• The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

See also The MMU fault-checking sequence on page G5-9242.
Synchronous External abort errors from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, which might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous External abort arising from the caching structure, such as from a parity or ECC error, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.

- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  — The lowest-numbered level that could have given rise to the error.
  — Level 1 if the PE cannot determine any information about the level.
G5.12 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- Reporting exceptions taken to PL1 modes on page G5-9252.
- Fault reporting in PL1 modes on page G5-9255.
- Summary of register updates on faults taken to PL1 modes on page G5-9260.
- Reporting exceptions taken to Hyp mode on page G5-9261.
- Use of the HSR on page G5-9265.
- Summary of register updates on exceptions taken to Hyp mode on page G5-9268.

Note

The registers used for exception reporting also report information about debug exceptions. For more information, see:

- Data Abort exceptions, taken to a PL1 mode on page G5-9253.
- Prefetch Abort exceptions, taken to a PL1 mode on page G5-9255.
- Reporting exceptions taken to Hyp mode on page G5-9261.

G5.12.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
  - On taking an exception to Hyp mode, the Hyp Syndrome Register (HSR), returns syndrome information.
  - On taking an exception to any other mode, a Fault Status Register (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in Fault Address Registers (FARs). For a permitted exception to this requirement see Fault address reporting on synchronous External aborts on page G5-9252.

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.
--- Note ---

- **PE mode for taking exceptions** on page G1-8939 describes how the mode to which an exception is taken is determined.

- **EL2** provides:
  - Specific exception types, that can only be taken from Non-secure PL1 and EL0 modes, and are always taken to Hyp mode.
  - Routing controls that can route some exceptions from Non-secure PL1 and EL0 modes to Hyp mode.

  These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.

---

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- **Reporting exceptions taken to PL1 modes**.
- **Memory fault reporting in Hyp mode** on page G5-9263.

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see **The MMU fault-checking sequence** on page G5-9242 and **AArch32 state prioritization of synchronous aborts from a single stage of address translation** on page G5-9248.

### Fault address reporting on synchronous External aborts

The general architectural requirement is that, on a synchronous abort, the faulting address is recorded in a **Fault Address Register (FAR)**. This requirement is relaxed for the case of a synchronous External abort that is not a synchronous External abort on a translation table walk. In this case only:

- It is IMPLEMENTATION DEFINED whether the faulting address is recorded in a FAR.
- A bit in a fault reporting register, the FnV bit, indicates whether a valid address is recorded.

For exceptions taken to an Exception level that is using AArch32, the details of this reporting depend on whether the exception is taken to:

- A PL1 mode, as described in **Reporting exceptions taken to PL1 modes**.
- Hyp mode, as described in **Reporting exceptions taken to Hyp mode** on page G5-9261.

### G5.12.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- **Registers used for reporting exceptions taken to PL1 modes**.
- **Data Abort exceptions, taken to a PL1 mode** on page G5-9253.
- **Prefetch Abort exceptions, taken to a PL1 mode** on page G5-9255.

**Fault reporting in PL1 modes** on page G5-9255 then describes the fault reporting in these modes, including the encodings used for reporting the faults.

--- Note ---

*Security state, Exception levels, and AArch32 execution privilege* on page G1-8908 describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

---

### Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The **DFSR** holds information about a Data Abort exception.
- The **DFAR** holds the faulting address for some synchronous Data Abort exceptions.
- The **IFSR** holds information about a Prefetch Abort exception.
- The **IFAR** holds the faulting address for some synchronous Prefetch Abort exceptions.
In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see Auxiliary Fault Status Registers.

**Auxiliary Fault Status Registers**

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, ADFSR.
- The Auxiliary Instruction Fault Status Register, AIFSR.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity or ECC errors.

An implementation that does not need to report additional fault information must implement these registers as RES0. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

**Data Abort exceptions, taken to a PL1 mode**

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the value of TTBCR.EAE. For more information about the registers used when reporting the exception, see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G5-9254.
- Otherwise, the DFSR is updated with details of the fault, including the appropriate Fault status code. If the Data Abort exception is synchronous, DFSR.WnR is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, WnR is set to 1, to indicate a fault on a write instruction, and the CM bit is set to 1.

  If the Data Abort is external, then DFSR provides fields for additional classification of the abort, see Provision for classification of External aborts on page G4-9139.

  If the RAS Extension is implemented, and the exception is a virtual SError interrupt exception, the classification reported in DFSR is taken from VDFSR or VSESR_EL2. For more information, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

  See the register description for more information about the returned fault information. See also Data Abort on a Watchpoint exception on page G5-9254.

- Synchronous, the DFAR is updated with the VA that caused the exception, but see Fault address reporting on synchronous External aborts on page G5-952 for a permitted exception to this requirement.
- Asynchronous, the DFAR becomes UNKNOWN.

DFSR.WnR and DFSR.CM are UNKNOWN on an asynchronous Data Abort exception.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure DFSR and DFAR are updated.
**Data Abort on an instruction cache or branch predictor maintenance instruction by VA**

If an instruction cache invalidation by VA or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the DFAR is updated to hold the faulting VA. However, the reporting of the fault depends on the value of TTBCR.EAE:

**TTBCR.EAE == 0**

When the value of TTBCR.EAE is 0, it is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The DFSR indicates an Instruction cache maintenance instruction fault, and the IFSR is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The DFSR indicates the cause of the fault, a Translation fault or Access flag fault. The IFSR is UNKNOWN.

In either case:

- DFSR.WnR is set to 1.
- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.

**TTBCR.EAE == 1**

When the value of TTBCR.EAE is 1:

- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.
- DFSR.STATUS indicates the cause of the fault, a Translation or Access flag fault.
- DFSR.WnR is set to 1.
- The IFSR is UNKNOWN.

**Data Abort on a Watchpoint exception**

On taking a Data Abort exception caused by a watchpoint:

- DFSR.FS is updated to indicate a debug exception.
- DFSR.\{WnR, Domain\} are UNKNOWN.
- DFAR is set to the address that generated the watchpoint

--- Note ---

- \*lr\_ABT indicates the address of the instruction that triggered the watchpoint.

---

A watchpointed address can be any byte-aligned address. The address reported in DFAR might not be the watchpointed address, and:

- For a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
  - The lowest address accessed by the instruction that triggered the watchpoint.
  - The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

--- Note ---

- In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.
- The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

---

- For a watchpoint due to a Data Cache operation, the address is the address passed to the instruction. This might be an address that is above the watchpointed location.
Prefetch Abort exceptions, taken to a PL1 mode

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

• If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
• If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see the following for more information:

• Exception syndrome information and preferred return address for a BKPT instruction on page G2-9052.
• Exception syndrome information and preferred return address for a Breakpoint exception on page G2-9077.
• Exception syndrome information and preferred return address for a Vector Catch exception on page G2-9098.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced sections use the term more generally, to include exception information reported in the IFSR.

On taking a Prefetch Abort exception to a PL1 mode:

• The IFSR is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception.
  See the register description for more information about the returned fault information.
• For a Prefetch Abort exception generated by an instruction fetch, the IFAR is updated with the VA that caused the exception, but see Fault address reporting on synchronous External aborts on page G5-9252 for a permitted exception to this requirement.
• For a Prefetch Abort exception generated by a debug exception, the IFAR is UNKNOWN.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure IFSR and IFAR.

G5.12.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

• PL1 fault reporting with the Short-descriptor translation table format on page G5-9256.
• PL1 fault reporting with the Long-descriptor translation table format on page G5-9258.

Reserved encoding in the IFSR and DFSR encodings tables on page G5-9259 gives some additional information about the encodings for both formats.

Summary of register updates on faults taken to PL1 modes on page G5-9260 shows which registers are updated on each of the reported faults.

Reporting of External aborts taken from Non-secure state to Monitor mode describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

• For a Data Abort exception, the Secure DFSR and DFAR hold information about the abort.
• For a Prefetch Abort exception, the Secure IFSR and IFAR hold information about the abort.
• The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the DFSR and IFSR. However, when SCR.EA is set to 1, to route External aborts to Monitor mode, and an External abort is taken from Non-secure state, this section defines the DFSR and IFSR format.

For an External abort taken from Non-secure state to Monitor mode, the DFSR or IFSR uses the format associated with the Long-descriptor translation table format, as described in PL1 fault reporting with the Long-descriptor translation table format on page G5-9258, if any of the following applies:

• The value of the Secure TTBCR.EAE field is 1.
• The External abort is synchronous and is taken from either:
  — Hyp mode.
  — A Non-secure PL1 or EL0 mode, and the value of the Non-secure TTBCR.EAE field is 1.

Otherwise:

• For a synchronous External abort from a stage 2 translation routed to Monitor mode when the value of the Secure TTBCR.EAE field is 0 it is IMPLEMENTATION DEFINED whether:
  — The format associated with the Long-descriptor translation table format is used, as described in PL1 fault reporting with the Long-descriptor translation table format on page G5-9258.
  — The format associated with the Short-descriptor translation table format is used, as described in PL1 fault reporting with the Short-descriptor translation table format. Arm deprecates using this format. When this format is used, the value of DFSR.FS[1] or IFSR.FS[1] is UNKNOWN when reporting a synchronous External abort, or a synchronous parity or ECC error, on the stage 2 translation.

• In all other cases the DFSR or IFSR uses the format associated with the Short-descriptor translation table format, as described in PL1 fault reporting with the Short-descriptor translation table format.

PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. Table G5-26 on page G5-9256 shows the encoding of that field. Summary of register updates on faults taken to PL1 modes on page G5-9260 shows:

• Whether the corresponding FAR is updated on the fault. That is:
  — For a fault reported in the IFSR, whether the IFAR holds a valid address.
  — For a fault reported in the DFSR, whether the DFAR holds a valid address.
• For faults that update DFSR, whether DFSR.Domain is valid

When reading Table G5-26 on page G5-9256:

• FS values not shown in the table are reserved.
• FS values shown as DFSR only are reserved for the IFSR.

| FS   | Source                              | Notes                      |
|------|-------------------------------------|----------------------------|---|
| 00001| Alignment fault                     | DFSR only. Fault on initial lookup |
| 00100| Fault on instruction cache maintenance | DFSR only                  |
| 01100| Synchronous External abort on translation table walk\(^a,b\) | Level 1                      |
| 01110|                                      | Level 2                      |

\(^a\) Synchronous
\(^b\) External abort on translation table walk

Summary of register updates on faults taken to PL1 modes on page G5-9260 shows:
The level associated with MMU faults on a Short-descriptor translation table lookup

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, Permission fault, or Domain fault, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Supersection, Section, or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-9250.

The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. Summary of register updates on faults taken to PL1 modes on page G5-9260 describes when DFSR Domain is valid.

a. See The level associated with MMU faults on a Short-descriptor translation table lookup.

b. FS[1] is UNKNOWN if the reported error is from a stage 2 translation.

c. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use

d. Including asynchronous External abort on a data access, a translation table walk, or an instruction fetch.
Arm deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the Arm architecture might not support a Domain field in the Short-descriptor translation table format. Arm strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

**PL1 fault reporting with the Long-descriptor translation table format**

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. Table G5-27 on page G5-9258 shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, *Summary of register updates on faults taken to PL1 modes on page G5-9260* shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.

- For a fault taken to the Hyp mode, *Summary of register updates on exceptions taken to Hyp mode on page G5-9268* shows what registers are updated on the fault.

The level associated with MMU faults on a Long-descriptor translation table lookup

For MMU faults, Table G5-28 on page G5-9259 shows how the LL bits in the xFSR.STATUS field encode the lookup level associated with the fault.

Table G5-27 FSR encodings when using the Long-descriptor translation table format (continued)

<td></td>
</tr>
</tbody>
</table>

a. STATUS values not shown in this table are reserved. STATUS values not supported in the IFSR or DFSR are reserved for the register or registers in which they are not supported.
b. See The level associated with MMU faults on a Long-descriptor translation table lookup.
c. Including asynchronous External abort on a data access, a translation table walk, or an instruction fetch.
d. A Domain fault can be reported using the Long-descriptor STATUS encodings only as a result of a fault on an address translation instruction. For more information, see MMU fault on an address translation instruction on page G5-9275.

Reserved encoding in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>

</tr>
<tr>
<td>11</td>
<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-9250.
### G5.12.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, Table G5-29 on page G5-9260 shows the registers affected by each fault. In this table:
- **Yes** indicates that the register is updated.
- **UNK** indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G5-30 on page G5-9261 shows whether DFSR.Domain is valid.

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use.

b. Including asynchronous External abort on a data access, a translation table walk, or an instruction fetch.

G5.12.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.
Note

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- SError interrupt exceptions, IRQ exceptions, and FIQ exceptions, from Non-secure PL1 and EL0 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information, see Asynchronous exception routing controls on page G1-8957.
- When HCR.TGE is set to 1, all exceptions that would be routed to Non-secure PL1 modes. For more information, see Routing exceptions from Non-secure EL0 to EL2 on page G1-8944.
- When HDCR.TDE is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see Routing debug exceptions to EL2 using AArch32 on page G1-8946.
- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode.
- An abort that Routing of aborts taken to AArch32 state on page G1-8948 identifies as taken to Hyp mode.
- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.

Synchronous exceptions taken to Hyp mode provide syndrome information in the HSR.

On an abort exception taken to Hyp mode, the syndrome information in the HSR includes the Fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode.

In addition, for a Debug exception taken to Hyp mode, DBGDSRint.MOE or DBGDSRext.MOE shows what caused the Debug exception. This field is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

For more information, see the following subsections:

- Registers used for reporting exceptions taken to Hyp mode.
- Memory fault reporting in Hyp mode on page G5-9263.
- Use of the HSR on page G5-9265

**Registers used for reporting exceptions taken to Hyp mode**

The following registers are used for reporting exceptions taken to Hyp mode:

- The HSR holds syndrome information for the exception.
- The HDFAR holds the VA associated with a Data Abort exception.
- The HIFAR holds the VA associated with a Prefetch Abort exception.
- The HPFAR holds bits[39:12] of the IPA associated with some aborts on stage 2 address translations.

In addition, if implemented, the optional HADFSR and HAIIFSR can provide additional fault information, see Hyp Auxiliary Fault Syndrome Registers.

**Hyp Auxiliary Fault Syndrome Registers**

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, HADFSR.
- The Hyp Auxiliary Instruction Fault Syndrome Register, HAIIFSR.
An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in Auxiliary Fault Status Registers on page G5-9253. An example use of these registers is to return more information for diagnosing parity or ECC errors.

The architectural requirements for the HADFSR and HAIFSR are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as RES0, but the architecture does not require it to do so.

**Memory fault reporting in Hyp mode**

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the HSR contains the following fault status information:

- The HSR.EC field indicates the type of abort, as Table G5-31 on page G5-9263 shows.
- The HSR.ISS field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in **PL1 fault reporting with the Long-descriptor translation table format on page G5-9258**.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the Syndrome description column of Table G5-31 on page G5-9263, for information about the returned fault information.

<table>
<thead>
<tr>
<th>HSR.EC</th>
<th>Abort</th>
<th>Syndrome description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x20</td>
<td>Prefetch Abort taken from Non-secure PL1 or EL0 mode</td>

<td>Prefetch Abort taken from Hyp mode</td>
<td></td>
</tr>
<tr>
<td>0x24</td>
<td>Data Abort taken from Non-secure PL1 or EL0 mode</td>
<td>ISS encoding for exception from a Data Abort on page G8-9538</td>
</tr>
<tr>
<td>0x25</td>
<td>Data Abort taken from Hyp mode</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Use of the HSR on page G5-9265.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

**Register updates on exception reporting in Hyp mode**

The use of the HSR, and of the other registers listed in Registers used for reporting exceptions taken to Hyp mode on page G5-9262, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the HDFAR holds the associated VA, but see Fault address reporting on synchronous External aborts on page G5-9252 for a permitted exception to this requirement.
- If the fault generates a Prefetch Abort exception, the HIFAR holds the associated VA, but see Fault address reporting on synchronous External aborts on page G5-9252 for a permitted exception to this requirement.
In the following cases, the HPFAR holds the faulting IPA:

— A Translation or Access flag fault on a stage 2 translation.
— A Translation, Access flag, or Permission fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
— A stage 2 Address size fault.

In all other cases, the HPFAR is UNKNOWN.

• On a Data Abort exception that is taken to Hyp mode, the HIFAR is UNKNOWN.

• On a Prefetch Abort exception that is taken to Hyp mode, the HDFAR is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The HPFAR is UNKNOWN.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or EL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the HPFAR holds the IPA that caused the fault. Otherwise, the HPFAR is UNKNOWN.

Abort caused by a synchronous External abort, or synchronous parity or ECC error, and taken to Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault, but see Fault address reporting on synchronous External aborts on page G5-9252 for a permitted exception to this requirement. The HPFAR is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a Watchpoint exception generated in a Non-secure PL1 or EL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

HDFAR is set to the address that generated the watchpoint.

—— Note ———

ELR_hyp indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in HDFAR might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

• The lowest address accessed by the instruction that triggered the watchpoint.
• The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

—— Note ———

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

———

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.
The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also Watchpoint exceptions on page G2-9079.

In all cases, HPFAR is UNKNOWN.

Prefetch Abort caused by a Breakpoint Instruction exception and taken to Hyp mode
This abort is generated if a $BKPT$ instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also Breakpoint Instruction exceptions on page G2-9051.

Prefetch Abort caused by a Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1
When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or EL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a $BKPT$ instruction that is executed in Hyp mode.

Use of the HSR
The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:
• Always provides details of the fault. The DFSR and IFSR are not used.
• Provides more extensive information, for a wider range of exceptions.

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

This section summarizes the general form of the HSR register, to show how it encodes exception syndrome information, see the register description for more information. The register comprises:
• A 6-bit Exception class field, EC, that indicates the cause of the exception.
• An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:
  0 16-bit instruction trapped.
  1 32-bit instruction trapped.
  In other cases the IL field is not valid and is RES1.
• An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one EC.
The format of the HSR depends on the value of the EC field, as follows:

\[ 0b000000 \leq EC \leq 0b001110 \]

The ISS part of the returned value includes the CV and COND fields described in *Encoding of ISS[24:20] when \( 0b000000 \leq EC \leq 0b001110 \).* Figure G5-17 shows the HSR format in this case.

![Figure G5-17 HSR format when the ISS includes CV and COND fields](image1)

EC == \( 0b000000 \) or EC \( 0b001110 \) There are no generic fields within the ISS. Figure G5-18 shows the HSR format in this case.

![Figure G5-18 HSR format when the ISS does not include a COND field](image2)

*Encoding of ISS[24:20] when \( 0b000000 \leq EC \leq 0b001110 \)*

For EC values that are nonzero and less than or equal to \( 0b001100 \), ISS[24:20] provides the Condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

- **CV, ISS[24]** Condition code valid. Possible values of this bit are:
  - 0: The COND field is not valid.
  - 1: The COND field is valid.

- **COND, ISS[23:20]**
  - The Condition code for the trapped instruction. This field is valid only when CV is set to 1.
  - If CV is set to 0, this field is RES0.

The full descriptions of the HSR.ISS formats give more information about the CV field.

---

**Note**

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its Condition code check generates an Undefined Instruction exception, see *Conditional execution of undefined instructions* on page G1-8966.
### HSR exception classes

Table G5-32 on page G5-9267 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. For each EC value, the table references a subsection of the description of the HSR that describes the associated ISS format and gives information about the cause of the exception, for example the configuration required to enable the associated trap.

**G5.12.6 Summary of register updates on exceptions taken to Hyp mode**

For memory system faults that generate exceptions that are taken to Hyp mode, Table G5-33 on page G5-9268 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

Note

For a list of the MMU faults see *Types of MMU faults on page G5-9239.*

Table G5-33 Effect of an exception taken to Hyp mode on the reporting registers

<table>
<thead>
<tr>

Fault reported as Data Abort exception:

| MMU fault* at stage 1.                             | Yes | UNK   | Yes   | UNK   |
| Translation or Access flag MMU fault* at stage 2.  | Yes | UNK   | Yes   | Yes   |
| Otherb MMU fault* at stage 2.                      | Yes | UNK   | Yes   | UNK   |
| Stage 2 MMU fault* on a stage 1 translation.       | Yes | UNK   | Yes   | Yes   |
| Synchronous External abort on translation table walk. | Yes | UNK   | Yes   | UNK   |
Note

Unlike Table G5-29 on page G5-9260, the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see ISS encoding for exception from a Data Abort on page G8-9538.

Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in Table G5-33 on page G5-9268.

Note

All MMU faults are synchronous.

The table uses the following descriptions for MMU faults taken to Hyp mode:

**MMU fault at stage 1**

This is an MMU fault generated on a stage 1 translation performed in the Non-secure EL2 translation regime.

**MMU fault at stage 2**

This is an MMU fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the HPFAR
- Permission faults leave the HPFAR UNKNOWN.

---

Debug exception:

Breakpoint Instruction\(^d\), generates a Prefetch Abort exception. | Yes | UNK | - | UNK |

Debug exception routed to Hyp mode because HDCR.TDE is set to 1. Generates a Hyp Trap exception.

Breakpoint Instruction or Vector Catch | Yes | UNK | - | UNK |

Watchpoint | Yes | - | - | UNK |

---

a. For more information, see Classification of MMU faults taken to Hyp mode
b. MMU fault other than a Translation fault or an Access flag fault.
c. IMPLEMENTATION DEFINED. The FnV bit in the HSR.ISS field indicates whether the register holds a valid address. See Fault address reporting on synchronous External aborts on page G5-9252.
d. All other debug exceptions are not permitted in Hyp mode.
MMU stage 2 fault on a stage 1 translation

This is an MMU fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see "Stage 2 fault on a stage 1 translation table walk" on page G5-9246.

Figure G5-1 on page G5-9148 shows the different translation regimes and associated stages of translation.
G5.13 Address translation instructions

The System register encoding space includes encodings for instructions that either:

- Translate a virtual address (VA) to a physical address (PA).
- Translate a virtual address (VA) to an intermediate physical address (IPA).

Address translation system instructions on page K17-11906 summarizes these instructions.

When using the Short-descriptor translation table format, all translations performed by these instructions take account of TEX remap when this is enabled, see Short-descriptor format memory region attributes, with TEX remap on page G5-9207.

An address translation instruction that executes successfully returns the output address, a PA or an IPA, in the PAR. This is a 64-bit register that can hold addresses of up to 40 bits.

It is IMPLEMENTATION DEFINED whether the address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, Arm recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

The following sections give more information about these instructions:

- Address translation instruction naming and operation summary.
- Encoding and availability of the address translation instructions on page G5-9273.
- Determining the PAR format on page G5-9275.
- Handling of faults and aborts during an address translation instruction on page G5-9275.

G5.13.1 Address translation instruction naming and operation summary

Some older documentation uses the original names for the address translation instructions that were included in the original Armv7 documentation. Table G5-34 on page G5-9271 summarizes the instructions that are available in AArch32 state, and relates the old instruction names to the current names.

### Table G5-34 Naming of address translation instructions

<table>
<thead>
<tr>
<th>Name</th>
<th>Old name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW</td>

</tr>
<tr>
<td>ATS1HR, ATS1HW</td>
<td>Not applicableb</td>
<td>See ATS1H*, Address translation stage 1, Hyp mode on page G5-9273</td>
</tr>
</tbody>
</table>

- a. Instructions are added by FEAT_PAN2 and do not have a previous name.
- b. Instructions are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

For the stage 1 current state and stages 1 and 2 Non-secure state only instructions, the meanings of the final letters of the names are:

- **PR** PL1 mode, read operation.
- **PRP** PL1 mode, read operation, taking account of PSTATE.PAN.
- **PW** PL1 mode, write operation.
- **PWP** PL1 mode, write operation, taking account of PSTATE.PAN.
- **UR** User mode, read operation.
- **UW** User mode, write operation.
Note
User mode can be described as the unprivileged mode. It is the only EL0 mode.

For the stage 1 Hyp mode instructions, the last letter of the instruction name is R for the read operation and W for the write operation.

See also Encoding and availability of the address translation instructions on page G5-9273.

ATS1C**, Address translation stage 1, current security state

Any VMSAv8-32 implementation supports the ATS1C** instructions. They can be executed by any software executing at PL1 or higher, in either Security state.

The ATS1C** instructions are ATS1CPR, ATS1CPW, ATS1CUR, and ATS1CUW and, when FEAT_PAN2 is implemented, ATS1CPRP and ATS1CPWP. These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these instructions return the IPA that is the output address of the stage 1 translation. Figure G5-1 on page G5-9148 shows the different translation regimes.

Note
The Non-secure PL1 and EL0 modes have no visibility of the stage 2 address translations, that can be defined only at EL2, and translate IPAs to be PAs.

See Determining the PAR format on page G5-9275 for the format used when returning the result of these instructions.

ATS12NSO**, Address translation stages 1 and 2, Non-secure state only

A VMSAv8-32 implementation supports the ATS12NSO** instructions only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

• By software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
• If the implementation includes EL3, when EL3 is using AArch32, by software executing in Secure state at PL1.

The ATS12NSO** instructions are ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, and ATS12NSOUW.

In an implementation that includes EL3, when EL3 is using AArch64 and EL1 is using AArch32, any execution of an ATS12NSO** instruction at Secure EL1 is trapped as an exception that is taken to EL3.

In an implementation that does not include EL2, but includes EL3 then these instructions are not UNDEFINED but each instruction behaves in the same way as the equivalent ATS1C** instruction.

If an implementation does not include EL2 and does not include EL3 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see Unallocated System register access instructions on page K1-11565.

Arm deprecates use of these instructions from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these instructions perform the translations made by the Non-secure PL1&0 translation regime.

These instructions always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

• The result of the two stages of address translation for the specified Non-secure input address.
• The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.
From Hyp mode, the ATS1C** and ATS12NSO** instructions both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The ATS1C** instructions return the Non-secure PL1 view of the associated address translation. That is, they return the IPA output address corresponding to the VA input address.
- The ATS12NSO** instructions return the EL2, or Hyp mode, view of the associated address translation. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See Determining the PAR format on page G5-9275 for the format used when returning the result of these instructions.

ATS1H*, Address translation stage 1, Hyp mode

A VMSAv8-32 implementation supports the ATS1H* instructions only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

The ATS1H* instructions are ATS1HR and ATS1HW. In an implementation that includes EL3, these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure PL1 mode other than Monitor mode.

If an implementation does not include EL2 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see Unallocated System register access instructions on page K1-11565.

These instructions perform the translations made by the Non-secure EL2 translation regime. The instruction takes a VA input address and returns a PA output address.

These instructions always return a result in a 64-bit format PAR.

G5.13.2 Encoding and availability of the address translation instructions

Software executing at EL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL1 and EL0.

For information about translations when the stage of address translation is disabled see The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-9154.

Table G5-35 on page G5-9273 shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

Table G5-35 Address translation instructions in AArch32 state

<table>
<thead>
<tr>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All VMSAv8-32 implementations, in all modes, at PL1 or higher, see ATS1C**, Address translation stage 1, current security state on page G5-9272</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The result of an instruction is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an \texttt{MCR} or \texttt{MRC} instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an \texttt{MCRR} or \texttt{MRRC} instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the \texttt{ATS1H*} instructions.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the \texttt{ATS12NSO**} instructions.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see *Unallocated System register access instructions* on page K1-11565.
G5.13.3 Determining the PAR format

The PAR is a 64-bit register that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see Handling of faults and aborts during an address translation instruction.

ATS1C** instructions

Address translations for the current state. From modes other than Hyp mode:

- TTBCR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR format.
- If the implementation includes EL3, the translation performed is for the current security state and, depending on that state:
  - The Secure or Non-secure TTBCR.EAE determines the PAR format.
  - The result is returned to the Secure or Non-secure instance of the PAR

Instructions executed in Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

ATS12NSO** instructions

Address translations for the Non-secure PL1 and EL0 modes. These instructions return a result using the 64-bit PAR format if at least one of the following is true:

- The Non-secure TTBCR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the instruction returns a result using the 32-bit PAR format.

Instructions executed in a Secure PL1 mode return a result to the Secure PAR. Instructions executed in Hyp mode return a result to the Non-secure PAR.

ATS1H* instructions

Address translations from Hyp mode. These instructions always return a result using the 64-bit PAR format.

Instructions executed in Secure Monitor mode return a result to the Secure PAR. Instructions executed in Non-secure Hyp mode return a result to the Non-secure PAR.

G5.13.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an External abort occurs on the required translation table walk.

VMSAv8-32 memory aborts on page G5-9238 describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- MMU fault on an address translation instruction.
- External abort during an address translation instruction on page G5-9276.
- Stage 2 fault on a current state address translation instruction on page G5-9276.

MMU fault on an address translation instruction

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This applies:

- For a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.
• For a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

Using the PAR to report a fault on an address translation instruction gives more information about how these faults are reported.

—— Note ————

• The Domain fault encodings shown in Table G5-27 on page G5-9258 are used only for reporting a fault on an address translation instruction that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  — An ATS1C** instruction executed in Hyp mode.
  — An ATS12NSO** instruction executed when the value of HCR.VM is 1.

These encodings are never used for fault reporting in the DFSR, IFSR, or HSR.

• For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in Stage 2 fault on a current state address translation instruction.

Using the PAR to report a fault on an address translation instruction

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

• The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  — PL1 fault reporting with the Short-descriptor translation table format on page G5-9256.
  — PL1 fault reporting with the Long-descriptor translation table format on page G5-9258.

See also the Note at the start of Determining the PAR format on page G5-9275 about the Domain fault encodings shown in Table G5-27 on page G5-9258.

• A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

External abort during an address translation instruction

As stated in External abort on a translation table walk on page G5-9247, an External abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

Synchronous External abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate External abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

Asynchronous External abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous External abort. No fault address registers are updated.

The PAR is UNKNOWN.

Stage 2 fault on a current state address translation instruction

If the PE is in a Non-secure PL1 mode and executes one of the ATS1C** instructions, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in Stage 2 fault on a stage 1 translation table walk on page G5-9246. When this fault occurs on an ATS1C** address translation instruction:

• A Hyp Trap exception is taken to Hyp mode.
• The **PAR** is **UNKNOWN**.
• The **HSR** indicates that:
  — The fault occurred on a translation table walk.
  — The operation that faulted was a cache maintenance instruction.
• The **HPFAR** holds the IPA that faulted.
• The **HDFAR** holds the VA that the executing software supplied to the address translation instruction.
G5.14 Pseudocode description of VMSAv8-32 memory system operations

This section contains a list of pseudocode functions describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

• Full Physical Address.
• Translation regime.
• Address translation.
• Long-descriptor Translation table walk on page G5-9279.
• Short-descriptor Translation table walk on page G5-9279.
• Memory attribute decoding on page G5-9279.
• Fault detection on page G5-9279.

See also the descriptions of pseudocode for general memory system operations in Pseudocode description of general memory System instructions on page G4-9142.

G5.14.1 Full Physical Address

A complete physical address necessary to identify a location in physical memory is captured by the type FullAddress. This is composed of:

• A bitstring address, which identifies the physical address.
• An enumeration paspace, which identifies the physical address space.

G5.14.2 Translation regime

The architecture specifies translation regimes in terms of Privilege Level (PL). An alternative approach is used in pseudocode where regimes are expressed in terms of ELs instead, mirroring regimes in AArch64. The pseudocode and ARM use a differently named but equivalent set of regimes:

<table>
<thead>
<tr>
<th>Pseudocode Regime</th>
<th>Equivalent ARM regime</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regime_EL10</td>
<td>Secure PL1&amp;0 when EL3 is AArch64 or Non-Secure PL1&amp;0</td>
</tr>
<tr>
<td>Regime_EL30</td>
<td>Secure PL1&amp;0 when EL3 is AArch32</td>
</tr>
<tr>
<td>Regime_EL2</td>
<td>Non-Secure PL2</td>
</tr>
</tbody>
</table>

G5.14.3 Address translation

AArch32.TranslateAddress() acts as the entry point to VMSAv8-32 and performs the required address translation based on the provided parameters and system register configurations. The function returns an AddressDescriptor structure holding valid data for either of the following:

• Target memory address and attributes for a non-faulting translation.
• Fault details holding data to be populated in syndrome registers.

AArch32.FullTranslate() selects the translation regime and performs first and potentially second stage of translation returning the physical address (PA) and attributes of target memory. AArch32.S1TranslateLD() carries out the first stage of translation when stage 1 is not disabled and Long-descriptor format is used, mapping the virtual address (VA) to the intermediate physical address (IPA) and carrying out permission checks. Alternatively AArch32.S1TranslateSD() carries out the first stage of translation using the Short-descriptor format along with Domain checks and TEX memory attribute mapping. Otherwise, AArch32.S1DisabledOutput() assigns the appropriate memory attributes and flat maps the input address to the output address. AArch32.S2Translate() carries out stage 2 translation for Regime_EL10 when enabled, mapping the IPA to the PA. Otherwise, the IPA is the PA.
G5.14.4 Long-descriptor Translation table walk

A separate walk function is dedicated for Stage 1 Long-descriptor format, AArch32.S1WalkLD(), and Stage 2, AArch32.S2Walk(), which supports only Long-descriptor format. Each use walk parameters extracted from related system registers and held in S1TTWParams for stage 1 and S2TTWParams for stage 2. Parameters are collected based on the active translation regime. For instance, stage 1 EL2 translation regime parameters are obtained and returned by the function AArch32.S1TTWParamsEL2(). Given these parameters, a walk initializes a walk state of the type TTWState, holding the base address of the first translation table.

The walk progressively fetches and decodes Translation Table descriptors, updating the walk state to the next base address as it descends through the levels of tables until a Block or Page descriptor is discovered or an invalid descriptor is fetched. Decoding the descriptor for both stage 1 and stage 2 walks is carried out by the function AArch32.DecodeDescriptorTypeLD().

For a non-faulting walk, a valid final walk state is returned, otherwise a faulting walk could report one of the following at a specified level:
- Translation Fault.
- Address Size Fault.
- Access Flag Fault.

G5.14.5 Short-descriptor Translation table walk

Short-Descriptor format is only supported for Regime_EL10 and Regime_EL30 (PL1&0) Stage 1 and a separate walk function is dedicated for that, AArch32.S1WalkSD(). The limited number of parameters are collected in the walk function and would otherwise follow a similar flow to Long-descriptor formats of iteratively updating the walk state. The walk notably collects the domain and Short-descriptor format type which are unique to Short-descriptor formats. The descriptor type is decoded using AArch32.DecodeDescriptorTypeSD().

For a non-faulting walk, a valid final walk state is returned, otherwise a faulting walk could report one of the following at a specified level:
- Translation Fault.
- Address Size Fault.
- Access Flag Fault (when SCTLR.AFE is configured to support Access flags).

G5.14.6 Memory attribute decoding

If a stage of translation is enabled, Fetched Leaf descriptors encode memory attributes assigned to the output of translation. Stage 1 Long-descriptor format memory attributes are decoded by the function S1DecodeMemAttrs(). Likewise, stage 2 memory attributes are decoded by the function S2DecodeMemAttrs() followed by combining stage 1 and stage 2 attributes by the function S2CombineS1MemAttrs(). A separate set of functions are used to assign memory attributes to the output of Short-descriptor format. AArch32.DefaultTEXDecode() is used when TEX remapping is disabled, otherwise AArch32.RemappedTEXDecode() defines output memory attributes.

G5.14.7 Fault detection

As soon as translation is invoked, a reserve FaultRecord accompanies the process, capturing the stage and level of translation as it proceeds. When a fault is detected, it is reflected in the FaultRecord and reported back as the result of translation with the most recent state to be reported already captured within. The following functions detect a certain type of fault, their outputs are all boolean with a TRUE value on detection:

- AArch32.S1LDHasPermissionsFault() and AArch32.S2HasPermissionsFault() detect a permissions fault for stage 1 and stage 2 respectively for Long-descriptor format. AArch32.S1SDHasPermissionsFault() detects a permissions fault for a translation in Short-descriptor format. Note that for atomic instructions introduced by FEAT_LSE, these functions are called twice, once to check for read permissions and another for write allowing the correct failure to be reported.

- AArch32.S1 HasAlignmentFault() and AArch32.S2HasAlignmentFault() detect an alignment fault for stage 1 and stage 2 respectively.
• **AArch32.S2InconsistentSL()** detects a stage 2 translation fault caused by erroneous configuration of the VTCR.SL0 field.

• **AArch32.VAIsOutOfRange()** detects a stage 1 translation fault caused by virtual addresses larger than the address input size configured. Similarly, **AArch64.IPAIsOutOfRange()** detects a stage 2 translation fault caused by the output of stage 1 being larger than the configured input size for stage 2. Both are solely part of Long-descriptor format translation.

--- Note ---

Domain faults are detected inline as part of **AArch32.S1TranslateSD()** since they are a simple equality check.
G5.15 About the System registers for VMSAv8-32

The System registers and System instructions that are accessible in AArch32 state are almost all in the encoding space described in *The AArch32 System register interface* on page G1-8993. This section gives general information about these registers, which comprise:

- Registers in the \( \text{coproc} = 0b1111 \) encoding space, that provide control and status information for the PE in Non-debug state.
- Registers in the \( \text{coproc} = 0b1110 \) encoding space, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

*AArch32 VMSA organization of registers in the \( \text{coproc} = 0b1110 \) encoding space* on page G7-9301 summarizes the registers in the \( \text{coproc} = 0b1110 \) encoding space, and indicates where these registers are described, either in this manual or in other architecture specifications.

*AArch32 VMSA organization of registers in the \( \text{coproc} = 0b1111 \) encoding space* on page G7-9304 summarizes the registers in the \( \text{coproc} = 0b1111 \) encoding space, and indicates where in this manual these registers are described.

**Note**

Many implementations include other interfaces to some System registers, for example a memory-mapped interface to some debug System registers. These are described in the appropriate sections of this manual.

G5.15.1 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some registers in the \( \text{coproc} = 0b1111 \) encoding space.

It contains the following subsections:

- Banked System registers.
- Restricted access System registers on page G5-9282.
- Configurable access System registers on page G5-9282.
- EL2-mode System registers on page G5-9283.
- Common System registers on page G5-9284.
- Access to registers from Monitor mode on page G5-9284.
- *The CP15SDISABLE and CP15SDISABLE2 input signals* on page G5-9285.

**Note**

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

**Banked System registers**

In an implementation that includes EL3 using AArch32, some System registers are banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register.
A Banked System register can contain a mixture of:
- Fields that are banked.
- Fields that are read-only in Non-secure PL1 or EL2 modes but read/write in the Secure state.

The System Control Register SCTLR is an example of a register that contains this mixture of fields.

The Secure copies of the Banked System registers are sometimes referred to as the Secure Banked System registers. The Non-secure copies of the Banked System registers are sometimes referred to as the Non-secure Banked System registers.

**Restricted access System registers**

In an implementation that includes EL3, some System registers are present only in Secure state. These are called Restricted access registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the NSACR, in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at EL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64, then any read of the NSACR from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value 0x00000C00.

- For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:
- SDER is implemented only in Secure state.
- Any read of the NSACR returns the value 0x00000C00.
- All other accesses to Restricted access System registers are UNDEFINED.

**Configurable access System registers**

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.

- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that an RW field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the NSACR control access.

In an AArch32 implementation that includes EL3:
- There are no Configurable access System registers in the (coproc==0b1110) encoding space.
- The only required Configurable access register in the (coproc==0b1111) encoding space is the CPACR.
  - Floating-point Status and Control Register, FPSCR
  - Floating-point Exception register, FPEXC.
  - Floating-point System ID register, FPSID.
  - Media and VFP Feature Register 0, MVFR0.
  - Media and VFP Feature Register 1, MVFR1.
  - Media and VFP Feature Register 2, MVFR2.
EL2-mode System registers

In an implementation that includes EL2, if EL2 can use AArch32, the implementation provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of SCR.NS is 1.

The following subsections describe the EL2-mode registers:

- Hyp mode read/write registers in the (coproc==0b1111) encoding space.
- Hyp mode encodings for shared (coproc==0b1111) System registers.
- Hyp mode (coproc==0b1111) write-only System instructions on page G5-9284.

There are no EL2-mode registers in the (coproc==0b1110) encoding space.

Hyp mode read/write registers in the (coproc==0b1111) encoding space

These registers are implemented only in Non-secure state, and in Non-secure state they are accessible only from Hyp mode.

Except for accesses to CNTVOFF in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from EL3 when SCR.NS is set to 1, see Access to registers from Monitor mode on page G5-9284.
- The following accesses are UNDEFINED:
  - Accesses from Non-secure PL1 modes.
  - Accesses in Secure state when SCR.NS is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to CNTVOFF is as follows:

- Any access from Secure Monitor mode is CONSTRAINED UNPREDICTABLE, regardless of the value of SCR.NS. The CONSTRAINED UNPREDICTABLE behavior is that the access is UNDEFINED, see Unallocated System register access instructions on page K1-11565.
- All other accesses are UNDEFINED.

Note

Except for CNTVOFF, the Hyp mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, CNTVOFF is part of any implementation of the Generic Timer, see The virtual offset register on page G6-9295. This means the behavior of CNTVOFF in an implementation that does not include EL2 is not covered by the general definition of the behavior of the Hyp mode (coproc==0b1111) read/write registers.

Hyp mode encodings for shared (coproc==0b1111) System registers

Some Hyp mode registers share the Secure instance of an existing banked register. In this case, the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when SCR.NS is set to 0.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the DFAR or IFAR encoding with SCR.NS set to 0.
- Using the HDFAR or HIFAR encoding with SCR.NS set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a Context synchronization event is required to ensure the ordering of the accesses.
Hyp mode (coproc==0b1111) write-only System instructions

Architecturally, these encodings are an extension of the banked register encodings described in Banked System registers on page G5-9281, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These instructions can be accessed from Monitor mode regardless of the value of SCR.NS, see Access to registers from Monitor mode.
- Accesses to these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure mode other than Monitor mode.

Accesses to these instructions are UNDEFINED if accessed from a Non-secure PL1 mode.

Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the Common access registers, or simply as the Common registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The ISR.
- All System registers in the (coproc==0b1110) encoding space.

Secure System registers for the (coproc==0b1111) encoding space

The Secure System registers in the (coproc==0b1111) encoding space comprise:

- The Secure copies of the Banked System registers in the (coproc==0b1111) encoding space.
- The Restricted access System registers in the (coproc==0b1111) encoding space.
- The Configurable access System registers in the (coproc==0b1111) encoding space that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure System registers are the System registers other than the Secure System registers.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the SCR.NS bit. In Monitor mode, the SCR.NS bit determines whether, for System registers in the (coproc==0b1111) encoding space, valid uses of the MRC, MCR, MRRC, and MCRR instructions access the Secure Banked System registers or the Non-secure Banked System registers. That is, when:

\[ NS == 0 \]

Common, Restricted access, and Secure Banked System registers are accessed by MRC, MCR, MRRC, and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, the registers listed in Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G5-9283 and Hyp mode encodings for shared (coproc==0b1111) System registers on page G5-9283 are not accessible, and any attempt to access them generates an Undefined Instruction exception.

Note

The operations listed in Hyp mode (coproc==0b1111) write-only System instructions are accessible in Monitor mode regardless of the value of SCR.NS.
System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations performed by these instructions are performed in Secure state.

NS == 1

Common, Restricted access and Non-secure Banked System registers are accessed by MRC, MCR, MRRC, and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, all the registers and operations listed in the subsections of EL2-mode System registers on page G5-9283 are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations by these instructions are performed in Secure state.

The Security state determines whether the Secure or Non-secure banked registers determine the control state.

Note

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, CSSEL R selects the current Cache Size Identification Register, and therefore CSSEL R is used as control state. Therefore, in Monitor mode:

- SCR.NS determines whether the Secure or Non-secure CSSEL R is accessible.
- Because the PE is in Secure state, the Secure CSSEL R selects the current Cache Size Identification Register.

From Armv8.3, it is possible to have multiple Cache Size Identification Registers. For more details, see Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2 on page G4-9115.

The CP15SDisable and CP15SDisable2 input signals

When EL3 is using AArch32, it provides an input signal, CP15SDisable, that disables write access to some of the Secure registers when asserted HIGH. The CP15SDisable signal has no effect on:

- Register accesses from AArch64 state.
- Register accesses from Secure EL1 when EL3 is using AArch64 and EL1 is using AArch32.

Note

When EL3 is using AArch32, the interaction between CP15SDisable and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

On a Warm reset by the external system that resets the PE into EL3 using AArch32, the CP15SDisable input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers that are affected by CP15SDisable results in an Undefined Instruction exception.

The CP15SDisable input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the CP15SDisable input HIGH. However, in an implementation in which the CP15SDisable input can be driven HIGH, changes in the state of CP15SDisable must be reflected as quickly as possible. Any change must occur before completion of an Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to CP15SDisable.

When EL3 is using AArch32, use of CP15SDisable means key Secure features that are accessible only at PL1 can be locked in a known state. This provides an additional level of overall system security. Arm expects control of CP15SDisable to reside in the system, in a block dedicated to security.

When FEAT CP15SDisable2 is implemented and EL3 is using AArch32, EL3 provides a second input signal, CP15SDisable2. CP15SDisable2 has all of the properties of CP15SDisable described above. The difference between CP15SDisable and CP15SDisable2 is only in the set of registers each signal affects.

Information on whether a given register is affected by CP15SDisable, or CP15SDisable2 when it is implemented, can be found in the access pseudocode for that register, as described in Chapter G8 AArch32 System Register Descriptions.
G5.16  Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups. The functional groups of AArch32 registers are:

- Special-purpose registers.
- VMSA-specific registers.
- ID registers.
- Performance monitors registers.
- Activity monitors registers.
- Debug registers.
- The Reliability, Availability, and Serviceability Extension registers.
- Generic timer registers.
- Cache maintenance System instructions.
- Address translation System instructions.
- TLB maintenance System instructions.
- Base system registers.
- Legacy feature registers and System instructions.

For a list of these functional groups and the registers in each group, see Functional index of AArch32 registers and System instructions on page K17-11899.

Chapter G8 AArch32 System Register Descriptions describes each of these registers.

Note

- The functional groups defined in this section mainly consist of the VMSAv8-32 System registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information, see:

- The AArch32 System register interface on page G1-8993 for general information about the access to the AArch32 System registers, including the main register access instructions MRC and MCR.
- About the System registers for VMSAv8-32 on page G5-9281.
- AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space on page G7-9301.
- AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space on page G7-9304.
- About the AArch32 System registers on page G8-9322.

The register descriptions in Chapter G8 AArch32 System Register Descriptions, assume you are familiar with these functional groups, and use conventions and other information from them without any explanation.
Chapter G6
The Generic Timer in AArch32 state

This chapter describes the implementation of the Arm Generic Timer as an extension to an Armv8 AArch32 implementation. It includes an overview of the AArch32 System register interface to an Arm Generic Timer.

It contains the following sections:
• About the Generic Timer in AArch32 state on page G6-9288.
• The AArch32 view of the Generic Timer on page G6-9292.

Chapter D10 The Generic Timer in AArch64 state describes the AArch64 view of the Generic Timer, including additional timers that can be implemented in AArch64 state, and Chapter I2 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
G6.1 About the Generic Timer in AArch32 state

Figure G6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The ARM Generic Interrupt Controller Architecture Specification defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

  — **Note**
  
  The Generic Timer can also provide other components at a system level, but Figure G6-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.

- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure G6-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch32 state. Chapter D10 The Generic Timer in AArch64 state describes access to this component from AArch64 state.

  — **Note**

  The reset requirements of Generic Timer registers are more strict when they are accessed from AArch32 state than when they are accessed from AArch64 state.
A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure G6-1 on page G6-9288.
- Optionally, can provide timer components for use at a system level.

Chapter 12 System Level Implementation of the Generic Timer describes this memory-mapped component.

### G6.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

**The system counter**

This provides a uniform view of system time, see The system counter on page G6-9290. Because this must be implemented at the system level, it is accessed through The system level memory-mapped implementation of the Generic Timer. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

**PE implementations of the Generic Timer**

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter. When FEAT_ECV is implemented, EL2 is using AArch64, and EL2 is implemented and enabled in the current Security state, the CNTPOFF_EL2 register allows offsetting of AArch32 physical timers and counters.
- A virtual counter, that gives access to virtual time. In AArch32 state, the CNTVOFF register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch32 state, the timers that are accessible from AArch32 state are:
  - A Secure PL1 physical timer.
  - A Non-secure EL1 physical timer.
  - A Non-secure EL2 physical timer.
  - An EL1 virtual timer.
  - A Non-secure EL2 virtual timer.
  - A Secure EL2 virtual timer.
  - A Secure EL2 physical timer.

The Non-secure EL2 virtual timer is available when FEAT_VHE is implemented. The Secure EL2 timers are available when FEAT_SEL2 is implemented, but are only accessible in AArch32 state if using EL0, when EL0 is using AArch32, Secure EL2 is using AArch64, and HCR_EL2.{E2H,TGE} == {1, 1}.

**Note**

The Secure PL1 physical timer uses the Secure banked instances of the CNTP_CTL, CNTP_CVAL, and CNTP_TVVAL registers, and the Non-secure EL1 physical timer uses the Non-secure instances of the same registers.

*The AArch32 view of the Generic Timer on page G6-9292 describes these components.*

**The system level memory-mapped implementation of the Generic Timer**

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into frames. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.
Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required
This module controls the system counter. It has two frames:
• A control frame, CNTControlBase.
• A status frame, CNTReadBase.

The memory-mapped timer control module, required
The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:
• Which timers are implemented.
• The features of each implemented timer.
This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional
An implemented memory-mapped timer:
• Must provide a privileged view of the timer, in the CNTBaseN frame.
• Optionally, provides an unprivileged view of the timer in the CNTEL0BaseN frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

Chapter 12 System Level Implementation of the Generic Timer describes these components.

G6.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

Width
From Armv8.0 to Armv8.5 inclusive, at least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.
From Armv8.6, must be 64 bits wide.

Frequency
From Armv8.0 to Armv8.5 inclusive, increments at a fixed frequency, typically in the range 1-50MHz. It can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.
From Armv8.6, increments at a fixed frequency of 1GHz.

Roll-over
Roll-over time of not less than 40 years.

Accuracy
Arm does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
Use of lower-frequency modes must not affect the implemented accuracy.

Start-up
Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:
1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes in architectures from Armv8.0 to Armv8.5, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:
• By 1 at 10MHz.
• By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

From Armv8.6 the counter operates at a higher fixed frequency of 1GHz.
Note

Though each unit of the counter is set to 1ns, this does not require that the counter is incremented every 1ns. A step in the counter might be more than a single bit increment. It is recommended that the count is not incremented at a rate that is less than 50MHz in normal running operation.

The CNTFRQ register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see Initializing and reading the system counter frequency.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

Note

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray-count scheme for timer distribution scheme on page K7-11704 gives more information about this possibility.

Initializing and reading the system counter frequency

The CNTFRQ register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the CNTFRQ register. Only software executing at the highest implemented Exception level can write to CNTFRQ.

Note

The CNTFRQ register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the CNTFRQ register, to determine the current system counter frequency, in the following states and modes:

- Hyp mode.
- Secure PL1 modes and Non-secure EL1 modes.
- When CNTKCTL.{PL0PCTEN, PL0VCTEN} is not {0,0}, Secure and Non-secure EL0 modes.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter I2 System Level Implementation of the Generic Timer.
G6.2 The AArch32 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch32 state:

- The physical counter.
- The virtual counter on page G6-9293.
- Event streams on page G6-9295.
- Timers on page G6-9296.

G6.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The $\text{CNTPCT}$ register holds the current physical counter value. When $\text{FEAT_ECV}$ is implemented and EL2 is executing in AArch64 state, the $\text{CNTPOFF_EL2}$ register holds the optional physical offset that can be applied to EL0 and EL1 whether EL0 and EL1 are using AArch64 state or AArch32 state. For more information, see The physical offset register on page D10-5237.

Reads of $\text{CNTPCT}$ can occur speculatively and out of order relative to other instructions executed on the same PE.

The self-synchronized view of the physical counter

When $\text{FEAT_ECV}$ is implemented, an alternative way to read the physical counter is supported. The $\text{CNTPCTSS}$ register is a non-speculative view of the physical counter, as seen from the Exception level that $\text{CNTPCTSS}$ is read from.

Access to the $\text{CNTPCTSS}$ are subject to the same traps as accesses to the $\text{CNTPCT}$.

Reads of $\text{CNTPCT}$ occur in program order relative to reads of $\text{CNTPCT}$ or $\text{CNTPCTSS}$.

Reads of $\text{CNTPCTSS}$ occur in program order relative to reads of $\text{CNTPCT}$ or $\text{CNTPCTSS}$.

Example G6-1 Ensuring reads of the physical counter occur after signal read from memory

If a read from memory is used to obtain a signal from another agent that indicates that $\text{CNTPCT}$ must be read, an $\text{ISB}$ is used to ensure that the read of $\text{CNTPCT}$ occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]          ; has had the value 1 written to it
  CMP R1, #1
  BNE loop
  ISB ; without this the CNTPCT could be read before the memory location in [R2]
  MRC R1, CNTPCT
```

When $\text{FEAT_ECV}$ is implemented, an access to $\text{CNTPCTSS}$ can be used in place of the $\text{CNTPCT}$ which, because it cannot be accessed speculatively, allows the $\text{ISB}$ to be removed. This means that the following code sequence can be used:

```
loop ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  MRC R1, CNTPCTSS
```

Similarly where a read of the physical counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following code sequences can be used:

```
... ; earlier loads and stores
DSB ; completes earlier loads and stores
ISB ; without this the CNTPCT could be read before the completion of the earlier loads
      ; and stores
  MRC R1, CNTPCT
```
Or, if FEAT_ECV is implemented:

```asm
... ; earlier loads and stores
DSB ; completes earlier loads and stores
MRC R1, CNTPCTSS
```

Neither view of the physical counter ensures that:

- Context changes occurring in program order before the read of the counter have been synchronized.
- Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Where there is a Dependency through registers dependency from the read of the physical counter to a Register effect generated by a read or write, the read or write will be executed after the read of the counter.

**Example G6-2 Ensuring reads of the physical counter occur after previous memory accesses**

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, one of the following sequences should be used:

```asm
DSB
ISB
MRC Rn, CNTPCT{SS} ; either view of the physical counter has the same effect in this example
```

or

```asm
DSB
ISB
CBZ Ra, next
```

```asm
ISB ; this ISB is not needed if the MRC is accessing CNTPCT{SS}
MRC Rn, CNTPCT{SS}
```

To ensure that a memory access occurs only after a read of the counter, then either of the following sequences should be used:

```asm
MRC Rn, CNTPCT{SS} ; either view of the physical counter has the same effect in this example
ISB
LDR Ra, [Rb] ; this load will be executed after the timer has been read
```

or

```asm
MRC Rn, CNTPCT{SS} ; either view of the physical counter has the same effect in this example
EOR Rm, Rn, Rn
LDR Ra, [Rb] ; this load will be executed after the counter has been read
```

**G6.2.2 The virtual counter**

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The CNTVOFF register contains the virtual offset, see The virtual offset register on page G6-9295.

The CNTVCT register holds the current virtual counter value.

Reads of CNTVCT can occur speculatively and out of order relative to other instructions executed on the same PE.
The self-synchronized view of the virtual counter

When FEAT_ECV is implemented, an alternative way to read the virtual counter is supported. The CNTVCTSS register is a non-speculative view of the virtual counter, as seen from the Exception level that CNTVCTSS is read from.

Accesses to the CNTVCTSS are subject to the same traps as accesses to the CNTVCT.

Reads of CNTVCT occur in program order relative to reads of CNTVCT or CNTVCTSS.

Reads of CNTVCTSS occur in program order relative to reads of CNTVCT or CNTVCTSS.

Example G6-3 Ensuring reads of virtual counter occur after signal read from memory

If a read from memory is used to obtain a signal from another agent that indicates that CNTVCT must be read, an ISB is used to ensure that the read of CNTVCT occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2] ; earlier loads and stores
  CMP R1, #1 ; has had the value 1 written to it
  BNE loop
  ISB ; without this the CNTVCT could be read before the memory location in [R2]
  MRC R1, CNTVCT ; and stores
```

When FEAT_ECV is implemented, an access to CNTVCTSS can be used in place of the CNTVCT, which, because it cannot be accessed speculatively, allows the ISB to be removed. This means that the following code sequence can be used:

```
loop ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2] ; earlier loads and stores
  CMP R1, #1 ; has had the value 1 written to it
  BNE loop
  MRC R1, CNTVCTSS
```

Similarly where a read of the virtual counter is required to take place after the completion of all loads and stores appearing in program order before the read of the counter, then the following two sequences can be used:

```
... ; earlier loads and stores
DSB ; completes earlier loads and stores
ISB ; without this the CNTVCT could be read before the completion of the earlier loads
MRC R1, CNTVCT ; and stores
```

Or, if FEAT_ECV is implemented:

```
... ; earlier loads and stores
DSB ; completes earlier loads and stores
MRC R1, CNTVCTSS
```

 Neither view of the virtual counter ensures that:

• Context changes occurring in program order before the read of the counter have been synchronized.

• Accesses to memory appearing in program order after the read of the counter are executed before the counter has been read.

Where there is a Dependency through registers dependency from the read of the virtual counter to a Register effect generated by a read or write, the read or write will be executed after the read of the counter.
Example G6-4 Ensuring reads of virtual counter occur after previous memory accesses

To ensure that all previous memory accesses have completed and all previous context changes have been synchronized before the read of the counter, one of the following sequences should be used:

```
DSB
ISB
MRC Rn, CNTVCT{SS} ; either view of the virtual counter has the same effect in this example
```

or

```
DSB
ISB
CBZ Ra, next
next
ISB ; this ISB is not needed if the MRS is accessing CNTVCT{SS}
MRC Rn, CNTVCT{SS}
```

To ensure that a memory access occurs only after a read of the counter, then either of the following sequences should be used:

```
MRC Rn, CNTVCT{SS} ; either view of the virtual counter has the same effect in this example
ISB
LDR Ra, [Rb] ; this load will be executed after the timer has been read
```

or

```
MRC Rn, CNTVCT{SS} ; either view of the virtual counter has the same effect in this example
EOR Rm, Rn, Rn
LDR Ra, [Rb] ; this load will be executed after the counter has been read
```

The virtual offset register

The virtual counter is a counter that has a virtual offset relative to the physical counter as viewed from EL2 and EL3. This virtual offset is held in the register CNTVOFF. The virtual counter value is the count compared by the EL1 virtual timer.

If EL2 is not implemented and enabled, then the virtual counter uses a fixed virtual offset of zero.

G6.2.3 Event streams

Any implementation of the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in Wait for Event on page D1-4676.

Note

An event stream might be used:
- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

The CNTHCTL.{EVNTEN, EVNTDIR, EVNTI, EVNTIS} fields define an event stream that is generated from the virtual counter.

In all implementations the CNTHCTL.{EVNTEN, EVNTDIR, EVNTI, EVNTIS} fields define an event stream that is generated from the physical counter.

The event stream is configured as follows:
- EVNTI selects the counter bit that triggers the event.
- If FEAT_ECV is not implemented, EVNTI selects between bits[0:15].
- If FEAT_ECV is implemented, EVNTIS selects whether ENVTI selects between bits[0:15] or bits[8:23].
• EVNTDIR selects whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

--- Note ---
If the event stream is configured to produce events from the low order bits of the counter when the counter frequency is very high (for example 1GHz), then the practical update rate of the counter might mean that the event stream is not generated as the low order bit might not change. Software can rely on an event stream rate of at least 1MHz in normal operation.

The pseudocode descriptions of the operation of an event stream are SetEventRegister, TestEventCNTV, and TestEventCNTP.

G6.2.4 Timers

In an implementation of the Generic Timer that includes EL3 the following timers are accessible from AArch32 state, provided the appropriate Exception level can use AArch32:
• A Non-secure EL1 physical timer. A Non-secure EL1 control determines whether this register is accessible from Non-secure EL0.
• A Secure PL1 physical timer. This timer is accessible from EL3 when EL3 is using AArch32.

--- Note ---
When EL3 is using AArch64, the AArch32 EL1 timers are not banked between Secure and Non-secure state.

A Secure PL1 control determines whether this register is accessible from Secure EL0.
• A Non-secure EL2 physical timer, accessible from Non-secure EL2, or EL3 when SCR.NS is set to 1.
• An EL1 virtual timer.
• When FEAT_VHE is implemented, a Non-secure EL2 virtual timer.
• When FEAT_SEL2 is implemented, a Secure EL2 physical timer.
• When FEAT_SEL2 is implemented, a Secure EL2 virtual timer.

--- Note ---
The Secure EL2 timers are accessible in AArch32 state if using EL0, when EL0 is using AArch32 state, Secure EL2 is using AArch64, and HCR_EL2.{E2H,TGE} == {1, 1}.

The output of each implemented timer:
• Provides an output signal to the system.
• If the PE interfaces to a Generic Interrupt Controller (GIC), signals a Private Peripheral Interrupt (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:
• Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
• Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
• Has, in addition, a 32-bit Control register.
In all implementations, the AArch32 System registers for the EL1 (or PL1) physical timer are banked, to provide the Secure and Non-secure implementations of the timer. Table G6-1 on page G6-9297 shows the physical timer registers and Table G6-2 on page G6-9297 show the virtual timer registers.

### Table G6-1 Physical timer registers summary for the Generic Timer

<table>
<thead>
<tr>
<th>Timer register</th>

<td>CNTHV_CTL</td>
<td>CNTHVS_CTL</td>
</tr>
</tbody>
</table>

a. In this column, CV indicates the CompareValue register, and TV indicates the TimerValue register.

b. Only when the implementation includes FEAT_VHE.

c. Only present when the implementation includes FEAT_SEL2.

### Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, CNTHPS_CTL, CNTV_CTL, CNTHV_CTL, or CNTHVS_CTL. For CNTP_CTL, the interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch64 register CNTP_CTL_EL0.

The operation of this view of a timer is:

\[
\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) >= 0)
\]

Where:

- **TimerConditionMet** Is TRUE if the timer condition for this counter is met, and FALSE otherwise.
- **Counter** The physical counter value, that can be read from the CNTPCT register.
- **Offset** For the EL1 physical timer, if ID_AA64MMFR0_EL1.ECV is 0b10, EL2 is using AArch64 and is implemented and enabled in the current Security state, and CNTHCTL_EL2.ECV is 0b1, then the offset value is held in the CNTPOFF_EL2. Otherwise the offset value for the EL1 physical timer is zero.
- **CompareValue** The value of the appropriate CompareValue register, CNTP_CV AL, CNTHP_CV AL, CNTHPS_CV AL, CNTV_CV AL, CNTHV_CV AL, or CNTHVS_CV AL.
In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

--- Note ---

This means that a timer with a CompareValue of, or close to, \(0x\text{FFFFFF_FFFF_FFFF}\) might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Software can observe the counter value by the offset in some situations by reading CNTVCT.

--- Operation of the TimerValue views of the timers ---

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, \(\text{CNTP}_\text{CTL}, \text{CNTHP}_\text{CTL}, \text{CNTHPS}_\text{CTL}, \text{CNTV}_\text{CTL}, \text{CNTHV}_\text{CTL}, \text{or CNTHVS}_\text{CTL}\).

This view of a timer depends on the following behavior of accesses to TimerValue registers:

\begin{align*}
\text{Reads} & \quad \text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset}))[31:0] \\
\text{Writes} & \quad \text{CompareValue} = ((\text{Counter} - \text{Offset})[63:0] + \text{SignExtend}(\text{TimerValue}))[63:0]
\end{align*}

Where the arguments other than \(\text{TimerValue}\) have the definitions used in \textit{Operation of the CompareValue views of the timers} on page G6-9297, and in addition:

\(\text{TimerValue}\) The value of a TimerValue register, \(\text{CNTP}_\text{TV} \_\text{AL}, \text{CNTHP}_\text{TV} \_\text{AL}, \text{CNTHPS}_\text{TV} \_\text{AL}, \text{CNTV}_\text{TV} \_\text{AL}, \text{CNTHV}_\text{TV} \_\text{AL}, \text{or CNTHVS}_\text{TV} \_\text{AL}\).

In this view of a timer, values are signed, in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

--- Note ---

\begin{itemize}
\item \textit{Operation of the CompareValue views of the timers} on page G6-9297 gives a strict definition of \(\text{TimerConditionMet}\). However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from \(0x80000000\), the TimerValue view can be used as giving an effect equivalent to:
\[\text{TimerConditionMet} = (\text{TimerValue} \leq 0)\]

\item Programming TimerValue to a negative number with magnitude greater than \((\text{Counter} - \text{Offset})\) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
\end{itemize}
Chapter G7
AArch32 System Register Encoding

This chapter describes the AArch32 System register encoding space. It contains the following sections:

• The AArch32 System register encoding space on page G7-9300.
• AArch32 VMSA organization of registers in the (coproc==0b1110) encoding space on page G7-9301.
• AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space on page G7-9304.
G7.1 The AArch32 System register encoding space

The T32 and A32 instruction sets include instructions that access the System register encoding space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- The cache, branch predictor, and TLB maintenance instructions, and address translation instructions.

The AArch32 System register interface on page G1-8993 describes the instructions that provide access to these registers and instructions. Chapter G8 AArch32 System Register Descriptions describes these registers and encodings.

When accessing 32-bit registers, or executing these instructions, entries in the encoding space are characterized by the parameter set \{coproc, CRn, opc1, CRm, opc2\}. This encoding space is defined only for the coproc values 0b1110 and 0b1111.

Note

- When accessing 64-bit registers entries in the encoding space are characterized by the parameter set \{coproc, CRn, opc1\}, for the coproc values 0b1110 and 0b1111. A CRn value in this parameter set is equivalent to a CRn value in the parameter set for accessing 32-bit registers.
- Background to the System register interface on page G1-8994 gives more information about this encoding model.

The following describe this encoding space:

- AArch32 VMSA organization of registers in the (coproc==0b1110) encoding space on page G7-9301.
- AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space on page G7-9304.
G7.2 AArch32 VMSA organization of registers in the (coproc==0b1110) encoding space

The System registers in the (coproc==0b1110) encoding space provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are distinct, the descriptions of these registers are distributed, as follows:

- In this manual, Debug registers on page G8-9831 describes the Debug registers.
- The Embedded Trace Macrocell Architecture Specification describes the Trace registers.

This section summarizes the allocation of the System registers in the (coproc==0b1110) encoding space between these different functions, and the register encodings in this space that are reserved.

The 32-bit System register encodings are classified by the \{opc1, CRn, opc2, CRm\} values required to access them using an MCR or an MRC instruction. The 64-bit System register encodings are classified by the \{opc1, CRm\} values required to access them using an MCRR or an MRRC instruction. For the registers in the (coproc==0b1110) encoding space, the opc1 value determines the primary allocation of these registers, as follows:

- **opc1==0** Debug registers.
- **opc1==1** Trace registers.
- **opc1==7** Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

**Other opc1 values**

Reserved.

--- Note ---

Primary allocation of (coproc==0b1110) register function by opc1 value differs from the allocation of (coproc==0b1111) registers, where primary allocation is by CRn value for 32-bit register accesses, or CRn value for 64-bit register accesses.

---

For the Debug and Jazelle registers, Table G7-1 on page G7-9302 defines:

- The \{opc1, CRn, opc2, CRm\} values used for accessing the 32-bit registers using the MRC and MCR instructions.
- The \{opc1, CRm\} values used for accessing the 64-bit register using the MRRC instruction.

Some Debug registers can also be accessed using the LDC and STC instructions. Table G7-1 on page G7-9302 defines the CRn values used for accessing the registers using these instructions.

--- Note ---

The only permitted uses of the LDC and STC instructions are:

- An LDC access to load data from memory to DBGDTRTXint.
- An STC access to store data to memory from DBGDTRRXint.

In the LDC and STC syntax descriptions in this Manual, the required coproc value of p14 and CRn value of c5 are given explicitly.
G7.2.1 Register access instruction arguments, \((\text{coproc}==\text{0b1110})\) registers

Table G7-1 on page G7-9302 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register that can be visible in the System register interface in the \((\text{coproc}==\text{0b1110})\) encoding.

**Table G7-1 Mapping of \((\text{coproc}==\text{0b1110})\) MCR, MRC, and MRRC instruction arguments to System registers**

- a. If EL1 cannot use AArch32, this register is OPTIONAL and deprecated. See the register description for details.
- b. Accesses to not implemented breakpoint and watchpoint register access instructions are UNDEFINED. If EL2 is not implemented or breakpoint \(n\) is not context-aware, DBGBXVR\(<n>\) is unallocated. CRm encodes \(<n>\), the breakpoint or watchpoint number.
- c. Legacy register.

Table G7-2 shows the LDC and STC instruction arguments required for accesses to the Debug registers that can be accessed using these instructions.

Table G7-2 Mapping of LDC and STC instruction arguments to System registers

<table>
<thead>
<tr>
<th>Name</th>
<th>CRn</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGDTRTXint</td>
<td>c5</td>

<td>Debug Data Transfer Register, Receive, Internal View</td>
</tr>
</tbody>
</table>

**Note**

In the instruction syntax descriptions for the LDC and STC instructions, the required coproc and CRn values are given explicitly as coproc==p14, CRn==c5.
G7.3 AArch32 VMSA organization of registers in the (coproc==0b1111) encoding space

For 32-bit accesses to the System registers in the (coproc==0b1111) encoding space, the ordered set of parameters \( \{CRn, opc1, CRm, opc2\} \) determine the register order. Within this ordering, the \( CRn \) value originally provided a functional grouping of these registers. As the number of System registers has increased this ordering has become less appropriate.

This document now:

- Groups the System registers in the (coproc==0b1111) encoding space by functional group, see Functional index of AArch32 registers and System instructions on page K17-11899.
- Describes all of the System registers for the AArch32 VMSA, in Chapter G8 AArch32 System Register Descriptions.
- Gives additional information about the organization of the AArch32 VMSA System registers in the (coproc==0b1111) encoding space, in the remainder of this section.

Note

Not all System registers introduced by architectural extensions are described in Chapter G8 AArch32 System Register Descriptions. For information about the System registers introduced by architectural extensions, see Chapter A2 Armv8-A Architecture Extensions.

This section presents information about the register ordering by \( \{CRn, opc1, CRm, opc2\} \). It contains the following subsections:

- System register summary for (coproc==0b1111) encodings by CRn value on page G7-9305.
- Full list of AArch32 VMSA System registers in the (coproc==0b1111) encoding space on page G7-9307.

Note

The ordered listing of (coproc==0b1111) registers by the \( \{CRn, opc1, CRm, opc2\} \) encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

In addition, the indexes in Appendix K17 Registers Index include all of the System registers.
### G7.3.1 System register summary for (coproc==0b1111) encodings by CRn value

Figure G7-1 summarizes the grouping of the System registers in the (coproc==0b1111) encoding space, for an AArch32 VMSA implementation, by the value of CRn used for a 32-bit access to the register.

#### Note

For the System registers in the (coproc==0b1111) encoding space, Figure G7-1 gives only an overview of the assigned encodings for 32-bit registers for each of the CRn values c0-c15. For more information, see:

- The full list of registers in the (coproc==0b1111) encoding space, in *Full list of AArch32 VMSA System registers in the (coproc==0b1111) encoding space* on page G7-9307, for the definition of the assigned and unassigned encodings for that register.
- The register definitions in *Chapter G8 AArch32 System Register Descriptions* for any dependencies on the implemented Exception levels.

In general, System register accesses using an unallocated set of {CRn, opc1, CRm, opc2} values are UNDEFINED. *Behavior of AArch32 VMSA System registers with (coproc==0b1111, CRn==c0)* on page G7-9306 described the only exceptions to this rule.

The 32-bit System registers with (coproc==0b1111, CRn==c15), and the corresponding 64-bit System registers, are reserved for IMPLEMENTATION DEFINED registers. For more information, see *Reserved encodings in the AArch32 VMSA System register (coproc==0b1111) space* on page G7-9306.

### The HSTR.Tn trap on (coproc==0b1111) System registers

As *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space* on page G1-9024 describes, when the value of HSTR.Tn is 1, Non-secure PL1 accesses to System registers in the (coproc==0b1111) encoding space using a CRn or CRm value that corresponds to the value of Tn are trapped to EL2, even if the encoding is UNDEFINED when the value of HSTR.Tn is 0. This applies:

- For 32 bit register accesses when the value of Rn in the MCR or MRC instruction corresponds to Tn.
- For 64 bit register accesses when the value of Rn in the MCRR or MRRC instruction corresponds to Tn.

If there are matching System register encodings that are accessible from Non-secure EL0 then those accesses are also trapped to EL2 when the value of HSTR.Tn is 1.
Behavior of AArch32 VMSA System registers with \((\text{coproc}==0b1111, \text{CRn}==c0)\)

In the \((\text{coproc}==0b1111)\) encoding space, the 32-bit System registers with \((\text{CRn}==c0)\) provide device and feature identification.

Table G7-3 on page G7-9308 shows all of the architecturally required System registers with \{(\text{coproc}==0b1111, \text{CRn}==c0)\}. The behavior of 32-bit System register encodings in this group that are not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of \(\text{opc1}\), and possibly on the value of \(\text{CRm}\) and \(\text{opc2}\), as follows:

\[
\begin{align*}
\text{opc1} &= 0 & \text{All write accesses to the encodings are UNDEFINED.} \\
& & \text{For read accesses:} \\
& & \quad \text{The following encodings return an UNKNOWN value:} \\
& & \quad \quad \text{CRn}==3, \text{opc2}==\{0, 1, 2\}. \\
& & \quad \quad \text{CRn}==\{4, 6, 7\}, \text{opc2}==\{0, 1\}. \\
& & \quad \quad \text{CRn}==5, \text{opc2}==\{0, 1, 4, 5\}. \\
& & \quad \quad \text{All other encodings are RES0.} \\
\text{opc1} &> 0 & \text{All accesses to the encodings are UNDEFINED.}
\end{align*}
\]

See also \text{Accesses to unallocated encodings in the (\text{coproc}==0b111x) encoding space on page G8-9324.} 

\[\text{Note}\]

Some of these registers were previously described as being part of the CPUID identification scheme, see \text{The CPUID identification scheme on page G8-9323.}

Reserved encodings in the AArch32 VMSA System register \((\text{coproc}==0b1111)\) space

AArch32 state reserves a number of regions in the \((\text{coproc}==0b1111)\) encoding space for IMPLEMENTATION DEFINED System registers. These reservations are defined in terms of the encoding of 32-bit accesses to the System register encoding space. That is, they are defined by the reserved 32-bit \{\text{CRn}, \text{opc1}, \text{CRm}, \text{opc2}\} encodings.

Reserved encodings that do not have an IMPLEMENTATION DEFINED function are UNDEFINED.

The following subsections give more information about these reserved encodings:

\[
\begin{align*}
\text{Reserved 32-bit encodings with } & \{\text{coproc}==0b1111, \text{CRn}==c9\}. \\
& \text{Reserved 32-bit encodings with } \{\text{coproc}==0b1111, \text{CRn}==c10\} \text{ on page G7-9307.} \\
& \text{Reserved 32-bit encodings with } \{\text{coproc}==0b1111, \text{CRn}==c11\} \text{ on page G7-9307.} \\
& \text{Reserved 32-bit encodings with } \{\text{coproc}==0b1111, \text{CRn}==c15\} \text{ on page G7-9307.}
\end{align*}
\]

\text{Reserved 32-bit encodings with } \{\text{coproc}==0b1111, \text{CRn}==c9\}

In the AArch32 encoding space, for 32-bit encodings with \{\text{coproc}==0b1111, \text{CRn}==c9\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

\[
\begin{align*}
\text{Encodings with } & \{\text{coproc}==0b1111, \text{CRn}==c9, \text{opc1}==\{0-7\}, \text{opc2}==\{0-7\}, \text{CRm}==\{c0-c2, c5-c8\}\} \text{ are reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.} \\
\text{Encodings with } & \{\text{coproc}==0b1111, \text{CRn}==c9, \text{opc1}==\{0-7\}, \text{opc2}==\{0-7\}, \text{CRm}==c15\} \text{ are reserved for IMPLEMENTATION DEFINED performance monitors.}
\end{align*}
\]

\[\text{Note}\]

These are distinct from the OPTIONAL Arm Performance Monitors Extension, the registers for which use the encoding space \{\text{coproc}==0b1111, \text{CRn}==c9, \text{opc1}==\{0-7\}, \text{opc2}==\{0-7\}, \text{CRm}==\{c12-c14\}\}.
Reserved 32-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c10 \} \)

In the AArch32 encoding space, for 32-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c10 \} \), the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c10, \text{opc} = \{0-7\}, \text{CRm} = \{c0, c1, c4, c8\} \} \) are reserved for IMPLEMENTATION DEFINED TLB lockdown operations.

Reserved 32-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c11 \} \)

In the AArch32 encoding space, for 32-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c11 \} \), the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c11, \text{opc} = \{0-7\}, \text{CRm} = \{c0-c8, c15\} \} \) are reserved for IMPLEMENTATION DEFINED DMA operations for TCM access.

The remainder of the AArch32 \( \{ \text{coproc} = 0b1111, \text{CRn} = c11 \} \) encoding space is UNDEFINED.

Reserved 32-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c15 \} \)

The AArch32 System register encodings are reserved with \( \{ \text{coproc} = 0b1111, \text{CRn} = c15 \} \) for IMPLEMENTATION DEFINED purposes, and there are no restrictions on the use of these encodings. The documentation of the Arm implementation must describe fully any registers implemented in the \( \{ \text{coproc} = 0b1111, \text{CRn} = c15 \} \) encoding space. Normally, for processor implementations by Arm, this information is included in the Technical Reference Manual for the processor.

Typically, an implementation uses the \( \{ \text{coproc} = 0b1111, \text{CRn} = c15 \} \) encodings to provide test features, and any required configuration options that are not covered by this Manual.

This reservation means that the AArch32 64-bit encodings with \( \{ \text{coproc} = 0b1111, \text{CRn} = c15 \} \) are also reserved for IMPLEMENTATION DEFINED purposes, without any restrictions on the use of these encodings.

### G7.3.2 Full list of AArch32 VMSA System registers in the \( \{ \text{coproc} = 0b1111 \} \) encoding space

Table G7-3 on page G7-9308 shows the System registers in the \( \{ \text{coproc} = 0b1111 \} \) encoding space in the AArch32 VMSA, in the order of the \( \{ \text{CRn}, \text{opc1}, \text{CRm}, \text{opc2} \} \) parameter values used in \text{MCR} or \text{MRC} accesses to the 32-bit registers:

- For \text{MCR} or \text{MRC} accesses to the 32-bit registers, \text{CRn} is the primary identifier of the target System register for the access. This applies, also, to \text{MCR} or \text{MRC} instructions that provide 32-bit accesses to a single word of a 64-bit System register.

- For \text{MCRR} or \text{MRRC} accesses to the 64-bit registers, \text{CRm} is the primary identifier of the target System register for the access. Table G7-3 on page G7-9308 orders the 64-bit registers with the 32-bit registers accessed using the same primary register identifier. For example, the 64-bit encoding of \text{TTBR0}, that is accessed with (\text{CRn} = c2), is listed with the 32-bit registers that are accessed with (\text{CRn} = c2).

</table>
a. **REVIDR** is an optional register. If it is not implemented, the encoding with opc2 set to 2 is an alias of **MIDR**.

b. When **FEAT_CCIDX** is implemented, **CCSIDR2** is implemented.

c. Implemented only as part of EL2 when EL2 is using AArch32. Otherwise, encoding is unallocated and **UNDEFINED**.

d. Implemented only as part of EL3 when EL3 is using AArch32. Otherwise, encoding is unallocated and **UNDEFINED**.

e. GIC System register, see **About the GIC System registers** on page G7-9319. As that subsection describes, each **ICV_** register uses the same encoding as the corresponding **ICC_** register.

f. This register is accessible only in Debug state.

g. RAS Extension System registers, see **The Reliability, Availability, and Serviceability Extension** on page A2-122.

h. When **FEAT_SPECRES** is implemented, the execution and data prediction restriction instructions are implemented, see **Execution and data prediction restriction System instructions** on page G4-9134.

i. For performance reasons, Arm deprecates any use of these memory barrier operations.

j. Reserved for **IMPLEMENTATION DEFINED** branch predictor, cache, and TCM operations, see **Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}** on page G7-9306.

k. Performance Monitors Extension System register, see **Performance Monitors registers** on page G8-9963.

l. Reserved for **IMPLEMENTATION DEFINED** performance monitors, see **Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}** on page G7-9306.

m. Reserved for **IMPLEMENTATION DEFINED** TLB lockdown operations, see **Reserved 32-bit encodings with {coproc==0b1111, CRn==c10}** on page G7-9307.

n. When an implementation is using the Long descriptor translation table format, these encodings access the **MAIR0** and **MAIR1** registers. Otherwise, they use **PRRR** and **NMRR**.

o. Reserved for **IMPLEMENTATION DEFINED** DMA operations for TCM access, see **Reserved 32-bit encodings with {coproc==0b1111, CRn==c11}** on page G7-9307.

p. Only one of **RMR** and **HRMR** is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.

q. Activity Monitors System register, see **Activity Monitors registers** on page G8-10047.

r. Generic Timer System register, see **Generic Timer registers** on page D17-7014.

s. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information, see **The virtual offset register** on page G6-9295.

t. Reserved for **IMPLEMENTATION DEFINED** purposes, see **Reserved 32-bit encodings with {coproc==0b1111, CRn==c15}** on page G7-9307.

### About the GIC System registers

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- **ICC_** GIC physical CPU interface System registers.
- **ICH_** GIC virtual interface control System registers.
- **ICV_** GIC Virtual CPU interface System registers.

**Note**

These registers are in addition to the GIC memory-mapped register groups **GICC_**, **GICD_**, **GICH_**, **GICR_**, **GICV_**, and **GITS_**.

In AArch32, the GIC System registers are all in the (coproc==0b1111) encoding space with (CRn==c12). The **ICV_** registers have the same {CRn, opc1, CRn, op2} encodings as the corresponding **ICC_** registers. For these encodings, GIC register configuration fields determine which register is accessed.
When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

For more information, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).
Chapter G8
AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

- About the AArch32 System registers on page G8-9322.
- General system control registers on page G8-9337.
- Debug registers on page G8-9831.
- Performance Monitors registers on page G8-9963.
- Activity Monitors registers on page G8-10047.
- RAS registers on page G8-10083.
- Generic Timer registers on page G8-10144.
G8.1 About the AArch32 System registers

For general information about the AArch32 System registers, see:

In Chapter G5 The AArch32 Virtual Memory System Architecture:
- About the System registers for VMSAv8-32 on page G5-9281.
- Functional grouping of VMSAv8-32 System registers on page G5-9286.

In Chapter G7 AArch32 System Register Encoding:
- AArch32 VMSA organization of registers in the (coproc == 0b1110) encoding space on page G7-9301.
- AArch32 VMSA organization of registers in the (coproc == 0b1111) encoding space on page G7-9304.

In this chapter:
- Fixed values in the System register descriptions.
- General behavior of System registers.
- Principles of the ID scheme for fields in ID registers on page G8-9332.
- About AArch32 System register accesses on page G8-9334.

The remainder of this chapter describes the AArch32 System registers, in the following sections:
- General system control registers on page G8-9337.
- Debug registers on page G8-9831.
- Performance Monitors registers on page G8-9963.
- Generic Timer registers on page G8-10144.

G8.1.1 Fixed values in the System register descriptions

See Fixed values in AArch32 instruction and System register descriptions on page F1-7235. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

G8.1.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in About the System registers for VMSAv8-32 on page G5-9281, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers:
- Register names.
- Read-only bits in read/write registers on page G8-9323.
- The CPUID identification scheme on page G8-9323.
- IMPLEMENTATION DEFINED performance monitors on page G8-9323.
- UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G8-9323.
- Read-only and write-only register encodings on page G8-9325.
- Reset behavior of AArch32 System registers on page G8-9326.
- Synchronization of changes to AArch32 System registers on page G8-9326.

Unless otherwise indicated, information in the listed sections applies to all AArch32 System registers

See also About AArch32 System register accesses on page G8-9334.

Register names

The Arm architecture guarantees not to define any register name prefixed with IMP_ as part of the standard Arm architecture.
Note

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with IMP_, where appropriate.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group. See Table K17-29 on page K17-11900 for a list of the ID_* registers.

IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional System register encodings in the (coproc==0b1111) encoding space for optional additional IMPLEMENTATION DEFINED performance monitors. Table G8-1 on page G8-9323 shows the allocation of these encodings:

<table>
<thead>
<tr>
<th>CRn</th>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>c9</td>
<td>0-7</td>
<td>c12-c14</td>
<td>0-7</td>
<td>Performance Monitors Extension registers, see Performance monitors registers on page K17-11901</td>
<td>RW or ROa</td>
</tr>
<tr>
<td>c15</td>
<td>0-7</td>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
<td></td>
<td>b</td>
</tr>
</tbody>
</table>

a. The table referenced in the Name on page G8-9323 entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.
b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses

This section defines UNPREDICTABLE and UNDEFINED behaviors for accesses to System registers, including those cases where the Armv8 behavior is CONSTRAINED UNPREDICTABLE.

In AArch32 state the following operations are UNDEFINED:

- All LDC and STC accesses, except for the LDC access to DBGDTRXint and the STC access to DBGDTRXint specified in Table G7-2 on page G7-9303.
- All MCR and MRC operations to the (coproc==0b111x) encoding space, except for those explicitly defined as accessing 64-bit System registers specified in Table G7-1 on page G7-9302 and Table G7-3 on page G7-9308.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field has a CONSTRAINED UNPREDICTABLE effect, see Reserved values in System and memory-mapped registers and translation table entries on page K1-11583.

The following subsections give more information about UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for accesses to the (coproc==0b111x) encoding space:

- Accesses to unallocated encodings in the (coproc==0b111x) encoding space on page G8-9324.
- Additional rules for MCR and MRC accesses to System registers on page G8-9324.
- Effects of EL3 and EL2 on System register accesses on page G8-9324.
**Accesses to unallocated encodings in the \( \text{coproc} = 0b111x \) encoding space**

In Armv8-A, accesses to unallocated register encodings in the \( \text{coproc} = 0b111x \) encoding space are UNDEFINED.

--- **Note** ---

In Armv7, except for 32-bit registers encoded with a \( \text{CRn} \) value of c12, accesses to unallocated 32-bit registers were UNPREDICTABLE. The Armv8 CONSTRAINED UNPREDICTABLE behavior of these accesses is that they are UNDEFINED, see *Unallocated System register access instructions* on page K1-11565.

---

**Additional rules for MCR and MRC accesses to System registers**

The following operations are CONSTRAINED UNPREDICTABLE for all encodings in the \( \text{coproc} = 0b111x \) encoding space:

- All MCR operations from the PC.
- All MRC operations to \( \text{APSR}_{\text{nzcv}} \), except for the \( \text{coproc} = 0b1110 \) MRC operation to \( \text{APSR}_{\text{nzcv}} \) from \( \text{DBGDSCR}_{\text{int}} \).

The CONSTRAINED UNPREDICTABLE behavior of these operations is described in *Using R15 by instruction* on page K1-11563.

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also *Read-only and write-only register encodings* on page G8-9325.

---

**Effects of EL3 and EL2 on System register accesses**

EL2 and EL3 introduce classes of System registers, described in *Classification of System registers* on page G5-9281. Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

--- **Note** ---

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

---

The following register classes restrict access in this way:

**Restricted access System registers**

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the NSACR are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The NSACR is a special case of a Restricted access register and:

- The NSACR is:
  - Read/write accessible from Secure PL1 modes.
  - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the NSACR are UNDEFINED.
For more information, including behavior when EL3 is using AArch64 or is not implemented, see Restricted access System registers on page G5-9282.

Configurable access System registers

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the NSACR permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the NSACR control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the NSACR controls how they behave. The only architecturally-defined register of this type is the CPACR.

For more information, see Configurable access System registers on page G5-9282.

EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

• The Non-secure EL2 mode, Hyp mode.
• Secure Monitor mode when SCR.NS is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see Hyp mode read/write registers in the (coproc == 0b1111) encoding space on page G5-9283 and Hyp mode encodings for shared (coproc == 0b1111) System registers on page G5-9283.

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

• The Non-secure EL2 mode, Hyp mode.
• Secure Monitor mode, regardless of the value of SCR.NS.

Write accesses to these operations are:

• CONSTRAINED UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
• UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see Hyp mode (coproc == 0b1111) write-only System instructions on page G5-9284.

In addition, in any implementation that includes EL3, when EL3 is using AArch32, if write access to a register is disabled by the CP15SDISABLE signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are read-only (RO) or write-only (WO). For example:

• Most identification registers are read-only.
• Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:

• RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L == 0 is UNDEFINED.
• WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L== 1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.
This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.

**Reset behavior of AArch32 System registers**

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch32, see:

- **PE state on reset into AArch32 state on page G1-8986.**
- The appropriate Trace architecture specification, for the Trace System registers.

When the PE resets into an Exception level that is using AArch64, PE state that relates to execution in AArch32 state, including the System register values, is UNKNOWN. The only exception to this is state that applies to execution in both AArch64 state and AArch32 state and that has a defined reset value on the reset into AArch64 state. An example of such PE state is the EDPRSR.SR bit.

For a PE reset into an Exception level that is using AArch32, the architecture defines which AArch32 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and **PE state on reset into AArch32 state on page G1-8986** summarizes these architectural requirements. Otherwise, RW registers reset to an architecturally unknown value.

**Note**

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

**Pseudocode description of resetting System registers**

The `AArch32.ResetControlRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and **PE state on reset into AArch32 state on page G1-8986.**

**Note**

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

**Synchronization of changes to AArch32 System registers**

In this section, this PE means the PE on which accesses are being synchronized.
### Note

See Definitions of direct and indirect reads and writes and their side-effects on page G8-9331 for definitions of the terms direct write, direct read, indirect write, and indirect read.

A direct write to a System register might become visible at any point after the change to the register, but without a Context synchronization event there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- Any System register access that an Arm Architecture Specification or equivalent specification defines as not requiring synchronization.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the memory order model. In this case, if permitted by the memory order model, the instruction that appears in program order before the direct write can be affected by the direct write. For information about the memory order model, see Definition of the memory model on page E2-7168.

These rules mean that an instruction that writes to one of the address translation instructions described in Address translation instructions on page G5-9271 must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the PAR.

### Note

In this case, the direct write to the encoding of the address translation instruction causes an indirect write to the PAR. Without a Context synchronization event after the direct write, there is no guarantee that the indirect write to the PAR is visible.

Conceptually, the explicit synchronization occurs as the first step of any Context synchronization event. This means that if the operation uses the state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

### Note

- This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of changes to the System registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.
- For a synchronous exception, the control state in use at the time the exception is generated determines the exception syndrome information, and this syndrome information is not changed by this synchronization at the start of taking the exception.

Except for the register reads listed in Registers with some architectural guarantee of ordering or observability on page G8-9329, if no Context synchronization event is performed, direct reads of System registers can occur in any order.

Table G8-2 on page G8-9328 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, First and Second refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.

- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

---

**Note**

Such accesses are likely to be given a Device memory attribute, but requiring this is outside the scope of the architecture.

---

- For indirect reads or writes caused by autonomous asynchronous events that are counted, for example events caused by the passage of time, the events are ordered so that:
  - Counts progress monotonically.
  - The events arrive at the PE in finite time and without undue delay.

</tbody>
</table>
a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that Registers with some architectural guarantee of ordering or observability shows as having some guarantee of the visibility of an indirect write, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect. For other information about indirect writes after a direct read or a direct write, see Definitions of direct and indirect reads and writes and their side-effects on page G8-9331

Note

Where a register has more that one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

For information about the additional synchronization requirements for memory-mapped registers, see Synchronization requirements for AArch64 System registers on page D17-5547.

To guarantee the visibility of changes to some registers, additional operations might be required before the Context synchronization event. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

• Accessing a System register refers to a direct read or write of the register.
• Using a System register refers to an indirect read or write of the register.

Registers with some architectural guarantee of ordering or observability

For the registers for which Table G8-3 on page G8-9330 shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which Table G8-3 on page G8-9330 shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

• Observable to direct reads of the register, in finite time, without explicit synchronization.
• Observable to subsequent indirect reads of the register without explicit synchronization.
These two sets of registers are similar, as Table G8-3 on page G8-9330 shows:

</table>

In addition to the requirements shown in Table G8-3 on page G8-9330:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  
  - **OSLAR_EL1.** *OSLAR_EL1* is indirectly read to determine whether the subsequent access is permitted.

    **Note**
    
    *OSLAR_EL1* maps to the AArch32 System register DBGOSLR.

  
  - **EDLR,** if implemented. *EDLR* is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

    **Note**
    
    This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table G8-3 on page G8-9330 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.
For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a Context synchronization event. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state on page H4-10313.

The possibility that direct reads can occur early, in the absence of context synchronization, described in Ordering of reads of System registers on page G8-9334, still applies to the registers listed in Table G8-3 on page G8-9330.

Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

**Direct read**
Is a read of a register, using an MRC, MRRC, or STC instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an indirect write, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

--- Note ---
The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

**Direct write**
Is a write to a register, using an MCR, MCRR, or LDC instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

--- Note ---

As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a PMCNTENCLR.Pr bit is also an indirect write, because if the Pr bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.

- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases. For example, writing 1 to a PMCNTENCLR.Pr bit that is set to 1 also changes the corresponding PMCNTENSET.Pr bit from 1 to 0. This means that the direct write to the PMCNTENCLR defines indirect writes to both itself and to the PMCNTENSET.
**Indirect read** is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether memory accesses are forced to be Non-cacheable.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in *Debug registers on page G8-9831*.
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

**Indirect write** is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of an external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see *Registers with some architectural guarantee of ordering or observability on page G8-9329*.

---

**Note**

Taking an exception is a *Context synchronization event*. Any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in *Exception reporting in a VMSA Arm®-32 implementation on page G5-9251*.

---

**G8.1.3 Principles of the ID scheme for fields in ID registers**

The Arm architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. *AArch32 ID registers to which this scheme applies on page G8-9333* identifies the set of ID registers that are accessible from AArch32 state.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

---

**Note**

- The ID fields described here are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.
- ID fields that do not follow this scheme include the *ID_AA64DFR0_EL1.PMUVer*, *ID_DFR0_EL1.PerfMon*, *ID_DFR0.PerfMon* and *EDDFR.PMUVer* fields, see *Alternative ID scheme used for the Performance Monitors Extension version on page G8-9334*.
- The presence of an ID field for a feature does not imply that the feature is optional.

---

To provide forward compatibility, software can rely on the features of these fields that are described in this section.
The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of \(0x1\) indicates the presence of some instructions, then the value \(0x2\) will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```c
if (value >= number) {
    // do something that relies on the value of the feature
}
```

For ID fields where the value \(0x0\) defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value \(0xF\) indicates that the feature is not implemented.
- The field value \(0x0\) indicates that the feature is implemented.
- Software that depends on the feature can use the test:
  ```c
  if value >= 0 {
      // Software features that depend on the presence of the hardware feature
  }
  ```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a fractional field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example G8-1 shows the use of such a field.

### Example G8-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value \(0x1\) was defined as indicating that item A is present.
- The value \(0x2\) was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value \(0x1\) when A and B only are present. This fractional field is valid only when the original ID field has the value \(0x1\).

This approach means that:

- Software that depends on the test if \((value >= 0x2)\) can rely on features A, B, and C being present,
- Software that depends on the test if \((value >= 0x1)\) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:
  ```c
  if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
      // Software features that depend on A and B only
  }
  ```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

### AArch32 ID registers to which this scheme applies

- The Auxiliary Feature register ID_AFR0.
• The Processor Feature registers ID_PFR0 and ID_PFR1.
• The Debug Feature register ID_DFR0.
• The Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.
• The Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
• The Media and VFP Feature registers MVFR0, MVFR1, and MVFR2.

Note

Principles of the ID scheme for fields in ID registers on page D17-5551 includes information about the AArch64 System registers and the memory-mapped registers to which this scheme applies.

Alternative ID scheme used for the Performance Monitors Extension version

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon, and EDDFR.PMUVer fields, which identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

• The value 0xF indicates that the Arm-architected Performance Monitors Extension is not implemented.
• If the field value is not 0xF the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```c
if (value != 0xF and value >= number) {
    // do something that relies on version 'number' of the feature
}
```

For these fields, Arm deprecates use of the value 0xF in new implementations.

G8.1.4 About AArch32 System register accesses

The following subsections give more information about accesses to the AArch32 System registers:

• Ordering of reads of System registers.
• Accessing 32-bit System registers on page G8-9335.
• Accessing 64-bit System registers on page G8-9336.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

• Any data dependencies between the instructions, as specified in Synchronization of changes to AArch32 System registers on page G8-9326, including read-after-read dependencies, are respected.
• The reads to the register do not occur earlier than the most recent Context synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context synchronization event. For example, where a memory access is used to communicate a read of such a counter, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.
Accessing 32-bit System registers

Software accesses most 32-bit System registers using the generic MCR and MRC System register access instructions, specifying some or all of the parameters \{coproc, CRn, opc1, CRm, opc2\}, where:

- **coproc** Identifies the primary region of the System register encoding space. Takes one of the values:
  - p14 Encoded as 0b1110.
  - p15 Encoded as 0b1111.

- **CRn** Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.
  
  In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and CRn is the most significant identifier for the required register within that group.
  
  In the (coproc==0b1111) encoding space, CRn is the most significant identifier for the required register.

- **opc1** Takes a value in the range 0-7, encoded as its 3-bit binary value.
  
  In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and can take the following values:
  - 0 Debug System registers.
  - 1 Trace System registers.
  - 7 Legacy Jazelle System registers.
  
  In the (coproc==0b1111) encoding space, opc1 can take any value in the range 0-7.

- **CRm** Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.

- **opc2** Takes a value in the range 0-7, encoded as its 3-bit binary value.

  opc2 is optional in the MCR and MRC instruction syntax, and if no value is specified the encoding defaults to 0b000.

- **Rt** A general-purpose register to hold a 32-bit value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

This means an MCR or MRC access to a specific 32-bit System register uses:

- A unique combination of coproc, CRn, opc1, CRm, and opc2, to specify the required System register.
- A general-purpose register, Rt, for the transferred 32-bit value.

See also:

- **MCR** on page F5-7707.
- **MRC** on page F5-7730.

A small number of AArch32 debug System registers are accessed using LDC or STC instructions. In these cases, the register to be accessed is identified in the instruction syntax by the use of p14, c5 where:

- **p14** Identifies that the access is to the (coproc==0b1110) encoding space.
- **c5** Identifies the target debug System register.

See the instruction descriptions:

- **LDC (immediate)** on page F5-7596.
- **LDC (literal)** on page F5-7598.
- **STC** on page F5-7952.

The only uses of LDC and STC permitted in Armv8-A are:

- An LDC access to load data from memory to DBGDTRTXint, see **LDC (immediate)** on page F5-7596 and **LDC (literal)** on page F5-7598.
- An STC access to store data to memory from DBGDTRRXint, see **STC** on page F5-7952.

A small number of AArch32 System registers are accessed using MRS, MSR, VMRS, or VMSR instructions, see the appropriate register and instruction description for more information, see:

- **MRS** on page F5-7734.
- **MSR (immediate)** on page F5-7744.
- **MSR (register)** on page F5-7746.
- **VMRS** on page F6-8565.
Accessing 64-bit System registers

Software accesses a 64-bit System register using the generic MCRR and MRRC System register access instructions, specifying the parameters \( \{ \text{coproc}, \text{Cr}_m, \text{opc1} \} \), where:

- **coproc**
  - Identifies the primary region of the System register encoding space. Takes one of the values:
    - p14 Encoded as \( 0b1110 \).
    - p15 Encoded as \( 0b1111 \).

- **Cr\_m**
  - Takes a value in the range \( c0-c15 \), encoded the corresponding 4-bit binary value, \( 0b0000-0b1111 \).
  - In the \( (\text{coproc}==0b1110) \) encoding space, the opc1 value identifies the System register functional group, and \( \text{Cr}_m \) is the most significant identifier for the required register within that group.
  - In the \( (\text{coproc}==0b1111) \) encoding space, \( \text{Cr}_m \) is the most significant identifier for the required register.

- **opc1**
  - Takes a value in the range 0-15, encoded as its 3-bit binary value.
  - In the \( (\text{coproc}==0b1110) \) encoding space, the opc1 value identifies the System register functional group, and can take the following values:
    - 0 Debug System registers.
    - 1 Trace System registers.
  - In the \( (\text{coproc}==0b1111) \) encoding space, opc1 can take any value in the range 0-15.

- **Rt**
  - A general-purpose register to hold bits[31:0] of the value to transfer to or from the System register.
  - Takes a value in the range \( R0-R14 \), encoded as the corresponding 4-bit binary value, \( 0b0000-0b1111 \).

- **Rt2**
  - A general-purpose register to hold bits[63:32] of the value to transfer to or from the System register.
  - Takes a value in the range \( R0-R14 \), encoded as the corresponding 4-bit binary value, \( 0b0000-0b1111 \).

This means an MCRR or MRRC access to a specific 64-bit System register uses:

- A unique combination of coproc, \( \text{Cr}_m \) and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

This means a PE can access a 64-bit System register using:

- An MCRR instruction to write to a System register, see **MCRR on page F5-7709**.
- An MRRC instruction to read a System register, see **MRRC on page F5-7732**.

When using an MCRR or MRRC instruction the System register access is 64-bit atomic.

Some 64-bit registers also have an MCR and MRC encoding. The MCR and MRC encodings for these registers access the least significant 32 bits of the register. For example, to access the PAR, software can:

- Use the following instructions to access all 64 bits of the register:
  
  ```
  MCRR p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
  MRRC p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
  ```

- Use the following instructions to access the least-significant 32 bits of the register:
  
  ```
  MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt
  MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]
  ```
G8.2 General system control registers

This section lists the System registers in AArch32 state that are not part of one of the other listed groups.
### G8.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR bits [31:0] are architecturally mapped to AArch64 System register ACTLR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ACTLR are UNDEFINED.

Some bits might define global configuration settings, and be common to the Secure and Non-secure instances of the register.

**Attributes**

ACTLR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing ACTLR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC\{c\}\{q\} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}}
\]

    endif
G8.2.2 ACTLR2, Auxiliary Control Register 2

The ACTLR2 characteristics are:

**Purpose**

Provides additional space to the ACTLR register to hold IMPLEMENTATION DEFINED trap functionality for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR2 bits [31:0] are architecturally mapped to AArch64 System register `ACTLR_EL1[63:32]`. This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ACTLR2 are UNDEFINED.

In Armv8.0 and Armv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining `ID_MMFR4.AC2`.

From Armv8.2 this register must be implemented.

**Attributes**

ACTLR2 is a 32-bit register.

**Field descriptions**

### G8.2.5 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

**Configurations**

AArch32 System register AIFSR bits [31:0] are architecturally mapped to AArch64 System register AFSR1_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to AIFSR are UNDEFINED.

**Attributes**

AIFSR is a 32-bit register.

G8.2.6 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

**Configurations**

AArch32 System register AMAIR0 bits [31:0] are architecturally mapped to AArch64 System register AMAIR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to AMAIR0 are UNDEFINED.

**Attributes**

AMAIR0 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR0(S) gives the value for memory accesses from Secure state.
- AMAIR0(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architectured behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**IMPLEMENTATION DEFINED, bits [31:0]**

- IMPLEMENTATION DEFINED.

  The reset behavior of this field is:

  - On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing AMAIR0**

Accesses to this register use the following encodings in the System register encoding space:
**AArch32 System Register Descriptions**

G8.2.7   AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

**Configurations**

AArch32 System register AMAIR1 bits [31:0] are architecturally mapped to AArch64 System register AMAIR_EL1[63:32].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to AMAIR1 are UNDEFINED.

When EL3 is using AArch32, write access to AMAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

AMAIR1 is a 32-bit register.

**Field descriptions**

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR1(S) gives the value for memory accesses from Secure state.
- AMAIR1(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**IMPLEMENTATION DEFINED, bits [31:0]**

G8.2.8 APSR, Application Program Status Register

The APSR characteristics are:

**Purpose**

Hold program status and control information.

--- **Note** ---

Some of the fields in this register are permitted to return the value of the PSTATE field on a read. This is an exception to the general rule that an UNKNOWN field must not return information that cannot be obtained, at the current Privilege level, by an architectured mechanism.

For more information see *The Application Program Status Register, APSR* on page E1-7135.

**Configurations**

This register is present only when AArch32 is supported. Otherwise, direct accesses to APSR are UNDEFINED.

**Attributes**

APSR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>

</tbody>
</table>

**N, bit [31]**

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

**Z, bit [30]**

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

**C, bit [29]**

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

**V, bit [28]**

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

**Q, bit [27]**

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

**Bits [26:23]**

Reserved, RES0.

**PAN, bit [22]**

*When FEAT_PAN is implemented:*

Privileged Access Never. This field is UNKNOWN, but is permitted to return the value of PSTATE.PAN field. On writes, this field is treated as Do-Not-Modify.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [21:20]**

Reserved, RES0.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**Bits [15:10]**

Reserved, RES0.

**E, bit [9]**

Endianness. This field is UNKNOWN, but is permitted to return the value of PSTATE.E field. On writes, this field is treated as Do-Not-Modify.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. This field is UNKNOWN, but is permitted to return the value of PSTATE.A field. On writes, this field is treated as Do-Not-Modify.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. This field is UNKNOWN, but is permitted to return the value of PSTATE.I field. On writes, this field is treated as Do-Not-Modify.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. This field is UNKNOWN, but is permitted to return the value of PSTATE.F field. On writes, this field is treated as Do-Not-Modify.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [5]**

Reserved, RES0.

**M[4:0], bits [4:0]**

Mode. This field is UNKNOWN, but is permitted to return the value of PSTATE.M[4:0] field. On writes, this field is treated as Do-Not-Modify.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
G8.2.9 ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

**Configurations**

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to ATS12NSOPR are UNDEFINED.

**Attributes**

ATS12NSOPR is a 32-bit System instruction.

**Field descriptions**

Bits [31:0]

Input address for translation. The resulting address can be read from the PAR. This System instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

**Executing ATS12NSOPR instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

G8.2.13   ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if reading from the given virtual address.

Configurations

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ATS1CPR are UNDEFINED.

Attributes

ATS1CPR is a 32-bit System instruction.

Field descriptions

Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This System instruction takes a VA as input. If EL2 is implemented and enabled in the current Security state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing ATS1CPR instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

G8.2.21  BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

**Purpose**

Invalidate all entries from branch predictors.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to BPIALL are UNDEFINED.

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

**Attributes**

BPIALL is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing BPIALL instruction**

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a BPIALLIS.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
G8.2.23  **BPIMVA, Branch Predictor Invalidate by VA**

The BPIMVA characteristics are:

**Purpose**

Invalidate virtual address from branch predictors.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to BPIMVA are UNDEFINED.

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

**Attributes**

BPIMVA is a 32-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:0]</th>

elsif PSTATE.EL == EL3 then
   BPIMVA(R[t]);
G8.2.24 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache. When FEAT_CCIDX is implemented, this register is used in conjunction with CCSIDR2.

**Configurations**

AArch32 System register CCSIDR bits [31:0] are architecturally mapped to AArch64 System register CCSIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to CCSIDR are UNDEFINED.

The implementation includes one CCSIDR for each cache that it can access. CSSEL and the Security state select which Cache Size ID Register is accessible.

**Attributes**

CCSIDR is a 32-bit register.

**Field descriptions**

*When FEAT_CCIDX is implemented:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>RES0</strong></td>
</tr>
<tr>
<td>24-23</td>
<td><strong>Associativity</strong></td>
</tr>
<tr>
<td>2-0</td>
<td><strong>LineSize</strong></td>
</tr>
</tbody>
</table>

--- Note ---

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

---

**Bits [31:24]**

Reserved, RES0.

**Associativity, bits [23:3]**

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

**LineSize, bits [2:0]**

(Log2(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1.

--- Note ---

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.
**Otherwise:**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>13</th>
<th>10</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNKNOWN</td>
<td>NumSets</td>
<td>Associativity</td>
<td>LineSize</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

--- **Note** ---

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

---

**Bits [31:28]**

Reserved, UNKNOWN.

**NumSets, bits [27:13]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Associativity, bits [12:3]**

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

**LineSize, bits [2:0]**

(Log₂(Number of bytes in cache line)) - 4. For example:

For a line length of 16 bytes: Log₂(16) = 4, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: Log₂(32) = 5, LineSize entry = 1.

--- **Note** ---

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware-destructive interference size parameter to 256 bytes and the hardware-constructive interference size parameter to 64 bytes.

---

**Accessing CCSIDR**

If CSSEL.R.[Level, InD] is programmed to a cache level that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && ELUsingAArch32(EL2) && HSTR_EL2.T0 == '1' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x03);
    elsif EL2Enabled() && ELUsingAArch32(EL2) && HSTR.T0 == '1' then
        AArch32.TakeHypTrapException(0x03);
    elsif EL2Enabled() && ELUsingAArch32(EL2) && HCR_EL2.TID2 == '1' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x03);

G8.2.26 CFPRCTX, Control Flow Prediction Restriction by Context

The CFPRCTX characteristics are:

Purpose
Control Flow Prediction Restriction by Context applies to all Control Flow Prediction Resources that predict execution based on information gathered within the target execution context or contexts. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

Note
This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

Configurations
This instruction is present only when AArch32 is supported and FEAT_SPECRES is implemented. Otherwise, direct accesses to CFPRCTX are UNDEFINED.

Attributes
CFPRCTX is a 32-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>

<tr>
<td>13</td>
<td>Non-secure state.</td>
</tr>
<tr>
<td>9</td>
<td>ASID</td>
</tr>
<tr>
<td>0</td>
<td>GASID</td>
</tr>
</tbody>
</table>
EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

- **0b00**: EL0.
- **0b01**: EL1.
- **0b10**: EL2.
- **0b11**: EL3.

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

VMID, bits [23:16]

- Only applies when bit[27] is 0 and the target execution context is either:
  - EL1.
  - EL0 when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0) or EL2 is using AArch32 state.

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0 or ELUsingAArch32(EL2)), this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1 and !ELUsingAArch32(EL2)), this field is ignored.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

Bits [15:9]

Reserved, RES0.

GASID, bit [8]

Execution of this instruction applies to all ASIDs or a specified ASID.

- **0b0**: Applies to specified ASID for an EL0 target execution context.
- **0b1**: Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field is treated as 0.

ASID, bits [7:0]

- Only applies for an EL0 target execution context and when bit[8] is 0.
- Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

**Executing CFPRCTX instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

G8.2.27   CLIDR, Cache Level ID Register

The CLIDR characteristics are:

**Purpose**

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Configurations**

AArch32 System register CLIDR bits [31:0] are architecturally mapped to AArch64 System register CLIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to CLIDR are UNDEFINED.

**Attributes**

CLIDR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

</tr>
<tr>
<td>0</td>
<td>Ctype8</td>
</tr>
</tbody>
</table>

**Note**

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.
Note

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

Ctype<\text{n}>, bits [3(n-1)+2:3(n-1)], for \text{n} = 7 to 1

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architectured cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy.

- 0b000: No cache.
- 0b001: Instruction cache only.
- 0b010: Data cache only.
- 0b011: Separate instruction and data caches.
- 0b100: Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architectured cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing CLIDR

Accesses to this register use the following encodings in the System register encoding space:

\[ \text{MRC\{<c>\}{<q>} \text{<coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>{, \{#<opc2}\}}}} \]

G8.2.28 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

Purpose

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configurations

AArch32 System register CONTEXTIDR bits [31:0] are architecturally mapped to AArch64 System register CONTEXTIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to CONTEXTIDR are UNDEFINED.

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

Attributes

CONTEXTIDR is a 32-bit register.

Field descriptions

When TTBCR.EAE == 0:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCID</td>
<td>ASID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

PROCID, bits [31:8]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ASID, bits [7:0]

Address Space Identifier. This field is programmed with the value of the current ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When TTBCR.EAE == 1:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCID</td>
<td></td>
</tr>
</tbody>
</table>

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing CONTEXTIDR**

G8.2.32 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

**Purpose**

Controls access to trace, and to Advanced SIMD and floating-point functionality from EL0, EL1, and EL3.

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

**Configurations**

AArch32 System register CPACR bits [31:0] are architecturally mapped to AArch64 System register CPACR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to CPACR are UNDEFINED.

Bits in the NSACR control Non-secure access to the CPACR fields. See the field descriptions for more information.

--- Note ---

In the register field descriptions, controls are described as applying at specified Privilege levels. This is because, in Secure state, a PL1 control:

- Applies to execution in a Secure EL3 mode when EL3 is using AArch32.
- Applies to execution in a Secure EL1 mode when EL3 is using AArch64.

See Security state, Exception levels, and AArch32 execution privilege on page G1-8908.

**Attributes**

CPACR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASEDIS</td>
<td>Enables PL0 and PL1 execution of Advanced SIMD instructions.</td>
</tr>
<tr>
<td>TRCDIS</td>
<td></td>
</tr>
</tbody>
</table>

**ASEDIS, bit [31]**

Disables PL0 and PL1 execution of Advanced SIMD instructions.

- **0b0**: This control permits execution of Advanced SIMD instructions at PL0 and PL1.
- **0b1**: All instruction encodings that are Advanced SIMD instruction encodings, but are not also floating-point instruction encodings, are UNDEFINED at PL0 and PL1.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field.

If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-7153.

See the description of CPACR.cp10 for a list of other controls that can disable or trap execution of Advanced SIMD instructions in AArch32 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.
G8.2 General system control registers

Bits [30:29]

Reserved, RES0.

TRCDIS, bit [28]
Traps PL0 and PL1 System register accesses to all implemented trace registers to Undefined mode.
0b0 This control has no effect on PL0 and PL1 System register accesses to trace registers.
0b1 PL0 and PL1 System register accesses to all implemented trace registers are trapped to Undefined mode.

If the implementation does not include a trace unit, or does not include a System register interface to the trace unit registers, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

Note
- The ETMv4 architecture and ETE do not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace registers are UNDEFINED.
- The Arm architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:24]

Reserved, RES0.

cp11, bits [23:22]
The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the CPACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

\[
\text{EL3 is implemented} \quad \text{EL3 is using AArch32} \quad \text{!IsCurrentSecurityState(SS_Secure)} \\
\text{NSACR.cp10} = 0 \\
\]

, access to this field is RAZ/WI.

cp10, bits [21:20]
 Defines the access rights for the Advanced SIMD and floating-point functionality. Possible values of the field are:
0b00 PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
0b01 PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
0b10 Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE. See Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-11568.
This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

**Note**

The CPACR has no effect on Advanced SIMD and floating-point accesses from PL2. These can be disabled by the HCPTR_TCP10 field.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

Execution of Advanced SIMD and floating-point instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
  - HCPTR_TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
- For Advanced SIMD instructions only:
  - CPACR.ASEDIS.
  - If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

Bits [19:0]

- Reserved, RES0.

**Accessing CPACR**

Accesses to this register use the following encodings in the System register encoding space:

```

G8.2.33  CPSR, Current Program Status Register

The CPSR characteristics are:

**Purpose**

Holds PE status and control information.

**Configurations**

This register is present only when AArch32 is supported. Otherwise, direct accesses to CPSR are UNDEFINED.

**Attributes**

CPSR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N, bit [31]</td>
<td>Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.</td>
</tr>
<tr>
<td>Z, bit [30]</td>
<td>Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.</td>
</tr>
<tr>
<td>C, bit [29]</td>
<td>Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.</td>
</tr>
<tr>
<td>V, bit [28]</td>
<td>Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.</td>
</tr>
<tr>
<td>Q, bit [27]</td>
<td>Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.</td>
</tr>
<tr>
<td>Bits [26:24]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>SSBS, bit [23]</td>
<td>When FEAT_SSBS is implemented: Speculative Store Bypass Safe. Prohibits speculative loads or stores that might practically allow a cache timing side channel. A cache timing side channel might be exploited where a load or store uses an address that is derived from a register that is being loaded from memory using a load instruction speculatively read from a memory location. If PSTATE.SSBS is enabled, the address derived from the load instruction might be from earlier in the coherence order than the latest store to that memory location with the same virtual address. 0b0 Hardware is not permitted to load or store speculatively in the manner described.</td>
</tr>
</tbody>
</table>
0b1 Hardware is permitted to load or store speculatively in the manner described.
The value of this bit is usually set to the value described by the SCTLR.DSSBS bit on exceptions
to any mode except Hyp mode, and the value described by HSCTRL.DSSBS on exceptions to Hyp
mode.
The reset behavior of this field is:
• On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:
Reserved, RES0.

PAN, bit [22]
When FEAT_PAN is implemented:
Privileged Access Never.
0b0 The translation system is the same as Armv8.0.
0b1 Disables privileged read and write accesses to addresses accessible at EL0.
The value of this bit is usually preserved on taking an exception, except in the following situations:
• When the target of the exception is EL1, and the value of the SCTLR.SPAN bit for the current
  Security state is 0, this bit is set to 1.
• When the target of the exception is EL3, from Secure state, and the value of the Secure
  SCTLR.SPAN is 0, this bit is set to 1.
• When the target of the exception is EL3, from Non-secure state, this bit is set to 0 regardless
  of the value of the Secure SCTLR.SPAN bit.

Otherwise:
Reserved, RES0.

DIT, bit [21]
When FEAT_DIT is implemented:
Data Independent Timing.
0b0 The architecture makes no statement about the timing properties of any instructions.
0b1 The architecture requires that:
• The timing of every load and store instruction is insensitive to the value of the
  data being loaded or stored.
• For certain data processing instructions, the instruction takes a time that is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• For certain data processing instructions, the response of the instruction to
  asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
The data processing instructions affected by this bit are:
• All cryptographic instructions. These instructions are:
  — AESD, AESE, AESIMC, AESMC, SHA1C, SHA1H, SHA1M, SHA1P, SHA1SU0, SHA1SU1, SHA256H,
    SHA256H2, SHA256SU0, and SHA256SU1.
• A subset of the instructions that use the general-purpose register file. For these instructions,
  the effects of CPSR.DIT apply only if they do not use R15 as either their source or destination
  and pass their condition execution check. These instructions are:
  — BFI, BFC, CLZ, CNV, CMP, MLA, MLAS, MLAS, MOV, MUL, NOP, PKHBT, PKHTB, RBIT, REV, REV16,
    REVSH, RRX, SADD16, SADD8, SASX, SBFX, SHADD16, SHADD8, SHASX, SHAESX, SHSUB16, SHSUB8,
    SMLAL**, SMLAW*, SMLSD*, SMLAS*, SMLAS*, SMUL*, SMUL*, SMUAD*, SMUAD*, SSAX, SSUB16, SSUB8,
Bit [20]

Reserved, RES0.

Otherwise:

Reserved, RES0.

A subset of the instructions that use the general-purpose register file. For these instructions, the effects of CPSR.DIT apply only if they do not use R15 as either their source or destination. The effects of CPSR.DIT do not depend on these instructions passing their condition execution check. These instructions are:

- ADC (immediate), ADC (register), ADCS (immediate), ADCS (register), ADD (immediate), ADD (register), ADDS (immediate), ADDS (register), AND (immediate), AND (register), ANDS (immediate), ANDS (register), ASR (immediate), ASR (register), ASRS (immediate), ASRS (register), BIC (immediate), BIC (register), BICS (immediate), BICS (register), EOR (immediate), EOR (register), EORS (immediate), EORS (register), LSL (immediate), LSL (register), LSR (immediate), LSR (register), LSRS (immediate), LSRS (register), MOV (immediate), MOV (register), MOVs (immediate), MOVs (register), MVN (immediate), MVN (register), WNS (immediate), WNS (register), ORR (immediate), ORR (register), ORRS (immediate), ORRS (register), ROR (immediate), ROR (register), RORS (immediate), RORS (register), RSB (immediate), RSB (register), RSBS (immediate), RSBS (register), RSC (immediate), RSC (register), RSCS (immediate), RSCS (register), SBC (immediate), SBC (register), SBCS (immediate), SBCS (register), SUB (immediate), SUB (register), SUBS (immediate), SUBS (register).

If FEAT_CRC32 is implemented, CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW.

A subset of the instructions that use the SIMD&FP register file. For these instructions, the effects of CPSR.DIT apply only if they pass their condition execution check. These instructions are:

- VABA+, VABD+ (integer), VADD (integer), VADDH, VADDL, VADDW, VADD, VAND, VBIC, VBIF, VBIT, VBSL, VCLS, VCLS, VCLZ, VCN, VDUP, VEDO, VEXT, VADDH, VSUB, VMAX (integer), VMIN (integer), VMLA (integer), VMLAL, VMLS (integer), VMLSL, VMOD, VMODL, VMUL (integer and polynomial), VMULL (integer and polynomial), VMVN, VORH, VORR, VPAADDL, VPAADD (integer), VPADDL, VPADDL, VPADDL, VPMAX (integer), VPMIN (integer), VRAADH, VREV+, VRADH, VRHLSL, VRHLSL, VRSRA, VRSUBH, VSLR, VSLL, VSHR, VSLI, VSR, VSB, VSUB (integer), VSUBH, VSBUL, VSUBW, VSWP, VTLB, VTXB, VTRN, VST, VUZP, and VZIP.

Another subset of the instructions that use the SIMD&FP register file. For these instructions, the effects of CPSR.DIT apply only if they pass their condition execution check and apply only when the instructions are operating on integer vector elements. These instructions are:

- VABS, VCEG, VCGT, VCLE, VCLT, VMLA (by scalar), VMUL (by scalar), and VNEG.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.
G8.2 General system control registers

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

Bits [15:10]
Reserved, RES0.

E, bit [9]
Endianness state bit. Controls the load and store endianness for data accesses:

0b0 Little-endian operation
0b1 Big-endian operation.

Instruction fetches ignore this bit.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

The reset behavior of this field is:
• When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

A, bit [8]
SError interrupt mask bit.
0b0 Exception not masked.
0b1 Exception masked.

I, bit [7]
IRQ mask bit.
0b0 Exception not masked.
0b1 Exception masked.

F, bit [6]
FIQ mask bit.
0b0 Exception not masked.
0b1 Exception masked.

Bit [5]
Reserved, RES0.

Bit [4]
Reserved, RES1.

M, bits [3:0]
Current PE mode.
0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0110 Monitor.
0b0111 Abort.

G8.2.34 CPPRCTX, Cache Prefetch Prediction Restriction by Context

The CPPRCTX characteristics are:

**Purpose**

Cache Prefetch Prediction Restriction by Context applies to all Cache Allocation Resources that predict cache allocations based on information gathered within the target execution context or contexts.

The actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control cache prefetch predictions occurring after the instruction is complete and synchronized.

This instruction applies to all:
- Instruction caches.
- Data caches.
- TLB prefetching hardware used by the executing PE that applies to the supplied context or contexts.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

**Note**

This instruction does not require the invalidation of Cache Allocation Resources so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

**Configurations**

This instruction is present only when AArch32 is supported and FEAT_SPECRES is implemented. Otherwise, direct accesses to CPPRCTX are UNDEFINED.

**Attributes**

CPPRCTX is a 32-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>16</th>
<th>15</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>NS</td>
<td>EL</td>
<td>VMID</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**GVMID, bit [27]**

Execution of this instruction applies to all VMIDs or a specified VMID.

- 0b0 Applies to specified VMID for an EL0 or EL1 target execution context.
- 0b1 Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, then this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.
NS, bit [26]

Security State.
- \(0b0\) Secure state.
- \(0b1\) Non-secure state.

If the instruction is executed in Non-secure state, this field is treated as 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.
- \(0b00\) EL0.
- \(0b01\) EL1.
- \(0b10\) EL2.
- \(0b11\) EL3.

If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

VMID, bits [23:16]

Only applies when bit[27] is 0 and the target execution context is either:
- EL1.
- EL0 when \(HCR\_EL2.E2H==0\) or \(HCR\_EL2.TGE==0\) or EL2 is using AArch32 state.

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.
When the instruction is executed at EL0 and \((HCR\_EL2.E2H==0\) or \(HCR\_EL2.TGE==0\) or ELUsingAArch32(EL2)), this field is treated as the current VMID.
When the instruction is executed at EL0 and \((HCR\_EL2.E2H==1\) and \(HCR\_EL2.TGE==1\) and !ELUsingAArch32(EL2)), this field is ignored.
If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

Bits [15:9]

Reserved, RES0.

GASID, bit [8]

Execution of this instruction applies to all ASIDs or a specified ASID.
- \(0b0\) Applies to specified ASID for an EL0 target execution context.
- \(0b1\) Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.
If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [7:0]

Only applies for an EL0 target execution context and when bit[8] is 0.
Otherwise, this field is RES0.
When the instruction is executed at EL0, this field is treated as the current ASID.

Executing CPPRCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:
if PSTATE.EL == EL0 then
    if !ELUsingAArch32(EL1) && !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') && SCTLR_EL1.EnRCTX == '0' then

Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved.

Non-Confidential

G8-9403

ID081822
G8.2.35 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type, which is either instruction cache or data cache.

If FEAT_CCIDX is implemented, CSSELR also selects the current CCSIDR2.

Configurations

AArch32 System register CSSELR bits [31:0] are architecturally mapped to AArch64 System register CSSELR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to CSSELR are UNDEFINED.

Attributes

CSSELR is a 32-bit register.

Field descriptions

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are:

- 0b000: Level 1 cache.
- 0b001: Level 2 cache.
- 0b010: Level 3 cache.
- 0b011: Level 4 cache.
- 0b100: Level 5 cache.
- 0b101: Level 6 cache.
- 0b110: Level 7 cache.

All other values are reserved.

If CSSELR.{Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit. Permitted values are:

- 0b0: Data or unified cache.
- 0b1: Instruction cache.

If CSSELR.{Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing CSSELR

Accesses to this register use the following encodings in the System register encoding space:

<td>28</td>
<td>IDC, bit Data cache clean requirements for instruction to data coherence. The meaning of this bit is: 0b0 Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR.LoC == 0b000 or (CLIDR.LoUIS == 0b000 &amp;&amp; CLIDR.LoUU == 0b000). 0b1 Data cache clean to the Point of Unification is not required for instruction to data coherence.</td>
</tr>
<tr>
<td>27:24</td>
<td>CWG, bits Cache writeback granule. Log2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified. A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either: The architectural maximum of 512 words (2KB) must be assumed. The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers. Values greater than 0b1001 are reserved.</td>
</tr>
</tbody>
</table>
Arm recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches.

**ERG, bits [23:20]**

Exclusives reservation granule. $\log_2$ of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The use of the value 0b0000 is deprecated.

The value 0b0001 and values greater than 0b1001 are reserved.

**DminLine, bits [19:16]**

$\log_2$ of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

**L1Ip, bits [15:14]**

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- 0b00: When FEAT_VPIPT is implemented: VMID aware Physical Index, Physical tag (VPIPT).
- 0b01: ASID-tagged Virtual Index, Virtual Tag (AIVIVT).
- 0b10: Virtual Index, Physical Tag (VIPT).
- 0b11: Physical Index, Physical Tag (PIPT).

From Armv8, the value 0b01 is not permitted.

The value 0b00 is permitted only in an implementation that includes FEAT_VPIPT.

**Bits [13:4]**

Reserved, RES0.

**IminLine, bits [3:0]**

$\log_2$ of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

### Accessing CTR

Accesses to this register use the following encodings in the System register encoding space:

```
MRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}
```

<table>
<thead>
<tr>

G8.2.37 DACR, Domain Access Control Register

The DACR characteristics are:

**Purpose**

Defines the access permission for each of the sixteen memory domains.

**Configurations**

AArch32 System register DACR bits [31:0] are architecturally mapped to AArch64 System register DACR32_EL2[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DACR are UNDEFINED.

This register has no function when TTBCR.EAE is set to 1, to select the Long-descriptor translation table format.

**Attributes**

DACR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>D15</th>
<th>D14</th>
<th>D13</th>

<td>17</td>
<td>16</td>
</tr>
</tbody>
</table>

**D<n>, bits [2n+1:2n], for n = 15 to 0**

Domain n access permission, where n = 0 to 15. Permitted values are:

- **0b00**: No access. Any access to the domain generates a Domain fault.
- **0b01**: Client. Accesses are checked against the permission bits in the translation tables.
- **0b11**: Manager. Accesses are not checked against the permission bits in the translation tables.

The value **0b10** is reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing DACR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>}, \{#\}<opc1>, <Rt>, <CRn>, <CRm>, \{#\}<opc2>\
\]

G8.2.42 DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

Purpose

Clean data or unified cache line by set/way.

Configurations

AArch32 System register DCCSW performs the same function as AArch64 System register DC CSW.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DCCSW are UNDEFINED.

Attributes

DCCSW is a 32-bit System instruction.

Field descriptions

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DCCSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

G8.2.43 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

**Purpose**
Invalid data or unified cache line by virtual address to PoC.

**Configurations**
AArch32 System register DCIMVAC performs the same function as AArch64 System register DCIVAC.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DCIMVAC are UNDEFINED.

**Attributes**
DCIMVAC is a 32-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

**Virtual address to use**

No alignment restrictions apply to this VA.

**Executing DCIMVAC instruction**

It is IMPLEMENTATION DEFINED whether, when this instruction is executed, it can generate a watchpoint. If this instruction can generate a watchpoint this is prioritized in the same way as other watchpoints.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *AArch32 data cache maintenance instructions (DC*) on page G4-9125.

Accesses to this instruction use the following encodings in the System instruction encoding space:

<table>
<thead>
<tr>
<th>MCR{&lt;c&gt;}{&lt;q&gt;} &lt;coproc&gt;, (#)&lt;opc1&gt;, &lt;Rt&gt;, &lt;CRn&gt;, &lt;CRm&gt;{, (#)&lt;opc2&gt;}</th>

        AArch32.TakeHypTrapException(0x03);
    else
        AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_PoC);
    elsif PSTATE.EL == EL2 then
        AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_PoC);
```
elsif PSTATE_EL == EL3 then
  AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_PoC);
G8.2.44 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

**Purpose**

Invalidate data or unified cache line by set/way.

**Configurations**

AArch32 System register DCISW performs the same function as AArch64 System register DCISW.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DCISW are UNDEFINED.

**Attributes**

DCISW is a 32-bit System instruction.

**Field descriptions**

```
+--------+--------+--------+---+--------+
| 31     | 30     | ...   | 1  | 0      |
| SetWay | Level  | RES0   |    | RES0   |
```

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

\[
A = \log_2(\text{ASSOCIATIVITY}), \quad L = \log_2(\text{LINELEN}), \quad B = (L + S), \quad S = \log_2(\text{NSETS}).
\]

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Executing DCISW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Accesses to this instruction use the following encodings in the System instruction encoding space:
MCR{c|q} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}

<table>

  else
    AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_SetWay);
  end-if
elsif PSTATE.EL == EL2 then
  AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_SetWay);
elsif PSTATE.EL == EL3 then
  AArch32.DC(R[t], CacheOp_Invalidate, CacheOpScope_SetWay);
### G8.2.45 DFAR, Data Fault Address Register

The DFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

**Configurations**

AArch32 System register DFAR bits [31:0] are architecturally mapped to AArch64 System register FAR_EL1[31:0].

AArch32 System register DFAR bits [31:0] (DFAR_S) are architecturally mapped to AArch32 System register HDFAR[31:0] when EL2 is implemented, EL3 is implemented and the implementation only supports execution in AArch32 state.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DFAR are UNDEFINED.

**Attributes**

DFAR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>VA of faulting address of synchronous Data Abort exception</th>
</tr>
</thead>
</table>

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing DFAR**

Accesses to this register use the following encodings in the System register encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>
<thead>
<tr>

G8.2.46   DFSR, Data Fault Status Register

The DFSR characteristics are:

**Purpose**

Holds status information about the last data fault.

**Configurations**

AArch32 System register DFSR bits [31:0] are architecturally mapped to AArch64 System register ESR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DFSR are UNDEFINED.

The current translation table format determines which format of the register is used.

**Attributes**

DFSR is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 0:*

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | RES0 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 4 | 3 | 2 | 1 | 0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Bits [31:17]**

Reserved, RES0.

**FnV, bit [16]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0  DFAR is valid.

0b1  DFAR is not valid, and holds an UNKNOWN value.

This field is valid only for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**AET, bits [15:14]**

*When FEAT_RAS is implemented:*

Asynchronous Error Type. When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception. Possible values are:

0b00  Uncontainable (UC).

0b01  Unrecoverable state (UEU).

0b10  Restartable state (UEO).

0b11  Recoverable state (UER).

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other aborts.

In the event of multiple errors taken as a single SError interrupt exception, the overall PE error state is reported.
Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault.

- 0b0: Abort not caused by execution of a cache maintenance instruction.
- 0b1: Abort caused by execution of a cache maintenance instruction, or on an address translation.

On a synchronous Data Abort exception on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction.

- 0b0: Abort caused by a read instruction.
- 0b1: Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==0b1111) encoding space this bit always returns a value of 1.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FS, bits [10, 3:0]

Fault status bits. Possible values of FS[4:0] are:

- 0b00001: Alignment fault.
- 0b00010: Debug exception.
- 0b00011: Access flag fault, level 1.
- 0b00100: Fault on instruction cache maintenance.
- 0b00101: Translation fault, level 1.
- 0b00110: Access flag fault, level 2.
- 0b00111: Translation fault, level 2.
- 0b01000: Synchronous External abort, not on translation table walk.
0b01001  Domain fault, level 1.
0b01011  Domain fault, level 2.
0b01100  Synchronous External abort, on translation table walk, level 1.
0b01101  Permission fault, level 1.
0b01110  Synchronous External abort, on translation table walk, level 2.
0b01111  Permission fault, level 2.
0b10000  TLB conflict abort.
0b10100  IMPLEMENTATION DEFINED fault (Lockdown fault).
0b10101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault).
0b10110  SError interrupt.
0b11000  When FEAT_RAS is not implemented:
          SError interrupt, from a parity or ECC error on memory access.
0b11001  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on memory access, not on translation table walk.
0b11100  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on translation table walk, level 1.
0b11110  When FEAT_RAS is not implemented:
          Synchronous parity or ECC error on translation table walk, level 2.

All other values are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Short-descriptor translation table lookup on page G5-9257.

The FS field is split as follows:
• FS[4] is DFSR[10].
• FS[3:0] is DFSR[3:0].
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:
0b0  Using the Short-descriptor translation table formats.
0b1  Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

Domain, bits [7:4]

The domain of the fault address.

Arm deprecates any use of this field, see The Domain field in the DFSR on page G5-9257.

This field is UNKNOWN for certain faults where the DFSR is updated and reported using the Short-descriptor FSR encodings, see Table G5-30 on page G5-9261.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
**When TTBCR.EAE == 1:**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:17</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**FnV, bit [16]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0   DFAR is valid.
- 0b1   DFAR is not valid, and holds an UNKNOWN value.

This field is valid only for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**AET, bits [15:14]**

*When FEAT_RAS is implemented:*

Asynchronous Error Type. When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception. Possible values are:

- 0b0   Uncontainable (UC).
- 0b1   Unrecoverable state (UEU).
- 0b10  Restartable state (UEO).
- 0b11  Recoverable state (UER).

This field is valid only if the DFSC code is 0b010001. It is RES0 for all other aborts.

In the event of multiple errors taken as a single SError interrupt exception, the overall PE error state is reported.

---- **Note** ----

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

----

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**CM, bit [13]**

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault.

- 0b0   Abort not caused by execution of a cache maintenance instruction.
- 0b1   Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort exception on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.
The reset behavior of this field is:

G8.2.47  DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at EL1, all entries that:
  - Would be required for the EL1&0 translation regime.
  - Match the current VMID, if EL2 is implemented and enabled in the current Security state.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at EL2, and if EL2 is enabled in the current Security state, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DTLBIALL are UNDEFINED.

**Attributes**

DTLBIALL is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing DTLBIALL instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{<c>\}{<q>} \text{ coproc}, \{#\}\text{opc1}, <Rt>, <CRn>, <CRm>{, \{#\}opc2}
\]

G8.2.48 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DTLBIASID are UNDEFINED.

**Attributes**

DTLBIASID is a 32-bit System instruction.

**Field descriptions**

```
       31  8  7  0
          RES0  ASID
```

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this System instruction.

**Executing DTLBIASID instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DTLBIMVA are UNDEFINED.

**Attributes**

DTLBIMVA is a 32-bit System instruction.

G8.2.50   DVPRCTX, Data Value Prediction Restriction by Context

The DVPRCTX characteristics are:

**Purpose**

Data Value Prediction Restriction by Context applies to all Data Value Prediction Resources that predict execution based on information gathered within the target execution context or contexts.

Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSBI that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

___ **Note** ___

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

**Configurations**

This instruction is present only when AArch32 is supported and FEAT SPECRES is implemented. Otherwise, direct accesses to DVPRCTX are UNDEFINED.

**Attributes**

DVPRCTX is a 32-bit System instruction.

**Field descriptions**

```
  | 31  | 28  | 27  | 26  | 25  | 24  | 16  | 15  | 9   | 8   | 7   | 0   |
  +-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----|
  RES0 | NS  | EL  | VMID| RES0| ASID| GASID|
  +-----+-----+-----+-----+-----+-----+-----|
```

**Bits [31:28]**

Reserved, RES0.

**GVMID, bit [27]**

Execution of this instruction applies to all VMIDs or a specified VMID.

0b0  Applies to specified VMID for an EL0 or EL1 target execution context.

0b1  Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

If EL2 is not implemented or not enabled for the target Security state, this field is RES0.

**NS, bit [26]**

Security State.

0b0  Secure state.

0b1  Non-secure state.

If the instruction is executed in Non-secure state, this field has an Effective value of 1.
EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.
0b00 EL0.
0b01 EL1.
0b10 EL2.
0b11 EL3.
If the instruction is executed at an Exception level lower than the specified level, this instruction is treated as a NOP.

VMID, bits [23:16]

Only applies when bit[27] is 0 and the target execution context is either:
• EL1.
• EL0 when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0) or EL2 is using AArch32 state.
Otherwise this field is res0.
When the instruction is executed at EL1, this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0 or ELUsingAArch32(EL2)), this field is treated as the current VMID.
When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1 and !ELUsingAArch32(EL2)), this field is ignored.
If EL2 is not implemented or not enabled for the target Security state, this field is res0.

Bits [15:9]

Reserved, res0.

GASID, bit [8]

Execution of this instruction applies to all ASIDs or a specified ASID.
0b0 Applies to specified ASID for an EL0 target execution context.
0b1 Applies to all ASIDs for an EL0 target execution context.
For target execution contexts other than EL0, this field is res0.
If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [7:0]

Only applies for an EL0 target execution context and when bit[8] is 0.
Otherwise, this field is res0.
When the instruction is executed at EL0, this field is treated as the current ASID.

Executing DVPRCTX instruction

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[\text{MCR}\{<c>\}<q>\ <\text{coproc}, \#<\text{opc1}, <Rt>, <CRn>, <CRm>, \#<\text{opc2})\]

G8.2.51 **ELR_hyp, Exception Link Register (Hyp mode)**

The ELR_hyp characteristics are:

**Purpose**
When taking an exception to Hyp mode, holds the address to return to.

**Configurations**
AArch32 System register ELR_hyp bits [31:0] are architecturally mapped to AArch64 System register ELR_EL2[31:0].
This register is present only when AArch32 is supported. Otherwise, direct accesses to ELR_hyp are UNDEFINED.

**Attributes**
ELR_hyp is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Return address</th>
</tr>
</thead>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing ELR_hyp**
ELR_hyp is accessible only at Hyp mode and Monitor mode.
Accesses to this register use the following encodings in the System register encoding space:

\[ MRS\{<c>\}{<q>} <Rd>, ELR_hyp \]

<table>
<thead>
<tr>
<th>R</th>
<th>M</th>
<th>M1</th>

</table>
G8.2.52  FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

**Purpose**

Identifies whether the Fast Context Switch Extension (FCSE) is implemented.

From Armv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to FCSEIDR are UNDEFINED.

**Attributes**

FCSEIDR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

G8.2.53 FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

**Purpose**

Provides a global enable for the implemented Advanced SIMD and floating-point functionality, and reports floating-point status information.

**Configurations**

AArch32 System register FPEXC bits [31:0] are architecturally mapped to AArch64 System register FPEXC32_EL2[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to FPEXC are **UNDEFINED**.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

**Attributes**

FPEXC is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>EX</th>
<th>EN</th>
<th>VV</th>
<th>RES0</th>
<th>VECITR</th>
<th>RES0</th>
<th>TFV</th>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**EX, bit [31]**

Exception bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Access to this field is **RAZ/WI**.

**EN, bit [30]**

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

0b0 Accesses to the FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are **UNDEFINED** at all Exception levels.

0b1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of Advanced SIMD and floating-point instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
  - HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
For Advanced SIMD instructions only:

- CPACR.ASEDIS.
- If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

### Note

When executing at EL0 using AArch32:

- If EL1 is using AArch64, then the Effective value of FPEXC.EN is 1. This includes when EL2 is using AArch64 and is enabled in the current Security state, HCR_EL2.TGE is 1, and the Effective value of HCR_EL2.RW is 1.
- If EL2 is using AArch64 and is enabled in the current Security state, HCR_EL2.TGE is 1, and the Effective value of HCR_EL2.RW is 0, then it is IMPLEMENTATION DEFINED whether the Effective value of FPEXC.EN is 1 or the value written to FPEXC.EN. However, Arm deprecates using the value of FPEXC.EN to determine behavior.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

### DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr() returning TRUE. This field also indicates whether the FPEXC.TFV field is valid.

The meaning of this bit is:

0b0 The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr(). If FPEXC.TFV is RW then it is invalid and UNKNOWN. If FPEXC.{IDF,IXF,UFF,OFF,DZF,IOF} are RW then they are invalid and UNKNOWN.

0b1 The exception was generated during the execution of an allocated encoding. FPEXC.TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the FPSCR.\{Stride, Len\} fields as RAZ, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### FP2V, bit [28]

FPINST2 instruction valid bit. From Armv8, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES0.

### VV, bit [27]

VECITR valid bit. From Armv8, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES0.
TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} are valid.

0b0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR. {Stride, Len} was non-zero. If FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.

0b1 FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

• When !ImpDefBool("Support trapping of floating-point exceptions"), access to this field is RAZ/WI.

• When ImpDefBool("Implemented FPSCR LEN, STRIDE as RAZ"), access to this field is RAO/WI.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. From Armv8, this field is RES1.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES1.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0b0 Input Denormal exception has not occurred.

0b1 Input Denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

Note

A half-precision floating-point value that is flushed to zero because the value of FPSCR.FZ16 is 1 does not generate an Input Denormal exception.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.
IXF, bit [4]
Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

0b0  Inexact exception has not occurred.
0b1  Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]
Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0b0  Underflow exception has not occurred.
0b1  Underflow exception has occurred.

Underflow trapped exceptions can occur:
• On half-precision data-processing instructions only when FPSCR.FZ16 is 0.
• Otherwise only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]
Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0b0  Overflow exception has not occurred.
0b1  Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]
Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

0b0  Divide by Zero exception has not occurred.
0b1  Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IOE, bit [0]**

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Invalid Operation exception has not occurred.</td>
</tr>
<tr>
<td>0b1</td>
<td>Invalid Operation exception has occurred.</td>
</tr>
</tbody>
</table>

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing FPEXC**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{VMRS}\{<c>}\{<q>\} <Rt>, <\text{spec}\_\text{reg}> \\
\text{reg} \\
0b1000
\]

```c
if PSTATE_EL == EL0 then
    UNDEFINED;

G8.2.54 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

**Purpose**

Provides floating-point system status information and control.

**Configurations**

AArch32 System register FPSCR bits [31:27] are architecturally mapped to AArch64 System register FPSR[31:27].

AArch32 System register FPSCR bit [7] is architecturally mapped to AArch64 System register FPSR[7].

AArch32 System register FPSCR bits [4:0] are architecturally mapped to AArch64 System register FPSR[4:0].

AArch32 System register FPSCR bits [26:15] are architecturally mapped to AArch64 System register FPCR[26:15].

AArch32 System register FPSCR bits [12:8] are architecturally mapped to AArch64 System register FPCR[12:8].

This register is present only when AArch32 is supported. Otherwise, direct accesses to FPSCR are UNDEFINED.

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

**Attributes**

FPSCR is a 32-bit register.

**Field descriptions**

<table>
<thead>

</tr>
</tbody>
</table>

N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero condition flag. This is updated by floating-point comparison operations.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
C, bit [29]

Carry condition flag. This is updated by floating-point comparison operations.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow condition flag. This is updated by floating-point comparison operations.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

AHP, bit [26]

Alternative half-precision control bit:
0b0 IEEE half-precision format selected.
0b1 Alternative half-precision format selected.
This bit is used only for conversions between half-precision floating-point and other floating-point formats.
The data-processing instructions added as part of the FEAT_FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DN, bit [25]

Default NaN mode control bit:
0b0 NaN operands propagate through to the output of a floating-point operation.
0b1 Any operation involving one or more NaNs returns the Default NaN.
The value of this bit controls only scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ, bit [24]

Flush-to-zero mode control bit:
0b0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
0b1 Flush-to-zero mode enabled.
The value of this bit controls only scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.
This bit has no effect on half-precision calculations.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:
0b00 Round to Nearest (RN) mode.
0b01 Round towards Plus Infinity (RP) mode.
0b10 Round towards Minus Infinity (RM) mode.
0b11 Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Stride, bits [21:20]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

Arm strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ16, bit [19]

When FEAT_FP16 is implemented:

Flush-to-zero mode control bit on half-precision data-processing instructions:

0b0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
0b1 Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

Arm strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDE, bit [15]

Input Denormal floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the IDC bit is set to 1.
0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.
When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [14:13]**

Reserved, RES0.

**IXE, bit [12]**

Inexact floating-point exception trap enable.
- 0b0: Untrapped exception handling selected. If the floating-point exception occurs, the IXC bit is set to 1.
- 0b1: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**UFE, bit [11]**

Underflow floating-point exception trap enable.
- 0b0: Untrapped exception handling selected. If the floating-point exception occurs, the UFC bit is set to 1.
- 0b1: Trapped exception handling selected. If the floating-point exception occurs and Flush-to-zero is not enabled, the PE does not update the UFC bit.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**OFE, bit [10]**

Overflow floating-point exception trap enable.
- 0b0: Untrapped exception handling selected. If the floating-point exception occurs, the OFC bit is set to 1.
- 0b1: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DZE, bit [9]**

Divide by Zero floating-point exception trap enable.
- 0b0: Untrapped exception handling selected. If the floating-point exception occurs, the DZC bit is set to 1.
This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI. When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**IOE, bit [8]**

Invalid Operation floating-point exception trap enable.

0b0 Untrapped exception handling selected. If the floating-point exception occurs, the IOC bit is set to 1.

0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI. When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**IDC, bit [7]**

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [6:5]**

Reserved, **RES0**.

**IXC, bit [4]**

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

The criteria for the Inexact floating-point exception to occur are different in Flush-to-zero mode. For more information, see *Flushing denormalized numbers to zero* on page A1-58.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**UFC, bit [3]**

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.
Advanced SIMD instructions set this bit if the Underflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, if FPSCR.UFE is 0 or if Flush-to-zero is enabled.

The criteria for the Underflow floating-point exception to occur are different in Flush-to-zero mode. For more information, see Flushing denormalized numbers to zero on page A1-58.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Divide by Zero floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FPSCR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{VMRS\{<c>\}{<q>} <Rt>, <spec\_reg>}
\]

\[
\begin{array}{l}
\text{if } \text{PSTATE.EL} = \text{EL0} \text{ then} \\
\quad \text{if Halted()} \& \& \text{HaveEL(EL3)} \& \& \text{EDSCR.SDD} = '1' \& \& \text{boolean IMPLEMENTATION_DEFINED "EL3 trap priority when SDD == '1'" \& \& !ELUsingArch32(EL3) \& \& CPTR_EL3.TFP == '1' then} \\
\quad \text{UNDEFINED;}

G8.2.55   FPSID, Floating-Point System ID register

The FPSID characteristics are:

**Purpose**

Provides top-level information about the floating-point implementation.

This register largely duplicates information held in the MIDR. Arm deprecates use of it.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to FPSID are UNDEFINED.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

**Attributes**

FPSID is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>Implementer</td>
</tr>
<tr>
<td>23</td>
<td>SW</td>
</tr>
<tr>
<td>22-16</td>
<td>Subarchitecture</td>
</tr>
<tr>
<td>15-8</td>
<td>PartNum</td>
</tr>
<tr>
<td>7-4</td>
<td>Variant</td>
</tr>
<tr>
<td>3-0</td>
<td>Revision</td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

Implementer codes are the same as those used for the MIDR.

For an implementation by Arm this field is 0x41, the ASCII code for A.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**SW, bit [23]**

Software bit. Defined values are:

0b0  The implementation provides a hardware implementation of the floating-point instructions.

0b1  The implementation supports only software emulation of the floating-point instructions.

In Armv8-A, the only permitted value is 0b0.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**Subarchitecture, bits [22:16]**

Subarchitecture version number. For an implementation by Arm, defined values are:

0b0000000  VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture.

0b0000001  VFPv2 architecture with Common VFP subarchitecture v1.

0b0000010  VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.

0b0000011  VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers. This value can be used only by an implementation that does not support the trap enable bits in the FPSCR.

0b0000100  VFPv3 architecture, or later, with Common VFP subarchitecture v3, and support for trap enable bits in FPSCR. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.
For a subarchitecture designed by Arm the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not Arm, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

In Armv8-A, the permitted values are 0b0000011 and 0b0000100.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**PartNum, bits [15:8]**

Part Number for the floating-point implementation, assigned by the implementer.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**Variant, bits [7:4]**

Variant number. Typically, this field distinguishes between different production variants of a single product.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**Revision, bits [3:0]**

Revision number for the floating-point implementation.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**Accessing FPSID**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{VMRS}\{<c>\}{<q>} \langle Rt \rangle, \langle \text{spec\_reg} \rangle
\]

\[
\begin{array}{c|c}
\text{reg} & 0b0000 \\
\end{array}
\]

G8.2.56  HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

**Purpose**

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

**Configurations**

AArch32 System register HACR bits [31:0] are architecturally mapped to AArch64 System register HACR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HACR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HACR is a 32-bit register.

**Field descriptions**

<table>
<thead>

G8.2.58 HACTLR2, Hyp Auxiliary Control Register 2

The HACTLR2 characteristics are:

**Purpose**

Provides additional space to the HACTLR register to hold IMPLEMENTATION DEFINED trap functionality.

**Configurations**

AArch32 System register HACTLR2 bits [31:0] are architecturally mapped to AArch64 System register ACTLR_EL2[63:32].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HACTLR2 are UNDEFINED.

In Armv8.0 and Armv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining ID_MMFR4.AC2.

From Armv8.2 this register must be implemented.

**Attributes**

HACTLR2 is a 32-bit register.

**Field descriptions**

<table>
<thead>

G8.2.63 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

Purpose

Controls:

• Trapping to Hyp mode of Non-secure access, at EL1 or EL0, to trace, and to Advanced SIMD and floating-point functionality.

• Hyp mode access to trace, and to Advanced SIMD and floating-point functionality.

——— Note ————

Accesses to this functionality:

• From Non-secure modes other than Hyp mode are also affected by settings in the CPACR and NSACR.

• From Hyp mode are also affected by settings in the NSACR.

Exceptions generated by the CPACR and NSACR controls are higher priority than those generated by the HCPTR controls.

Configurations

AArch32 System register HCPTR bits [31:0] are architecturally mapped to AArch64 System register CPTR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HCPTR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HCPTR is a 32-bit register.

Field descriptions

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the CPACR to Hyp mode.

0b0 This control does not cause any instructions to be trapped.

0b1 Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.

——— Note ————

The CPACR is not accessible at EL0.

——— The reset behavior of this field is:

• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.
TAM, bit [30]

*When FEAT_AMUv1 is implemented:*

Trap Activity Monitor access. Traps Non-secure EL1 and EL0 accesses to all Activity Monitor registers to EL2.

- **0b0** Accesses from Non-secure EL1 and EL0 to Activity Monitor registers are not trapped.
- **0b1** Accesses from Non-secure EL1 and EL0 to Activity Monitor registers are trapped to Hyp mode.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

Traps Non-secure System register accesses to all implemented trace registers to Hyp mode.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** Any Non-secure System register access to an implemented trace register is trapped to Hyp mode, unless the access is trapped to EL1 by a CPACR or NSACR control, or the access is from Non-secure EL0 and the definition of the register in the appropriate trace architecture specification indicates that the register is not accessible from EL0. A trapped instruction generates:
  - A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
  - An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

If the implementation does not include a trace unit, or does not include a System register interface to the trace unit registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RES0.
- Is RES1.
- Can be written from Hyp mode, and from Secure Monitor mode when SCR.NS is 1.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

**Note**

- The ETMv4 architecture and ETE do not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace registers are UNDEFINED, and a resulting Undefined Instruction exception is higher priority than a HCPTR.TTA Hyp Trap exception.
- The Arm architecture does not provide traps on trace register accesses through the optional memory-mapped debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
— Otherwise, this field resets to an architecturally UNKNOWN value.

**Bits [19:16]**

Reserved, RES0.

**TASE, bit [15]**

Traps Non-secure execution of Advanced SIMD instructions to Hyp mode when the value of HCPTR.TCP10 is 0.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** When the value of HCPTR.TCP10 is 0, any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:
  - A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
  - An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

When the value of HCPTR.TCP10 is 1, the value of this field is ignored.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, then it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-7153.

The reset behavior of this field is:
- On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

**Bit [14]**

Reserved, RES0.

**Bits [13:12]**

Reserved, RES1.

**TCP11, bit [11]**

When **FEAT_FP** is implemented and **FEAT_AdvSIMD** is implemented:

The value of this field is ignored. If this field is programmed with a different value to the TCP10 bit then this field is UNKNOWN on a direct read of the HCPTR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

The reset behavior of this field is:
- On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:
- Access is RAO/WI if all of the following are true:
  — EL3 is implemented.
  — EL3 is using AArch32.
—   NSACR.cp10 == 0.

**Otherwise:**

Reserved, RES1.

TCP10, bit [10]

**When FEAT_FP is implemented and FEAT_AdvSIMD is implemented:**

Trap Non-secure accesses to Advanced SIMD and floating-point functionality to Hyp mode:

0b0   This control does not cause any instructions to be trapped.

0b1   Any attempted access to Advanced SIMD and floating-point functionality from Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:

•   A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.

•   An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

The Advanced SIMD and floating-point features controlled by these fields are:

•   Execution of any floating-point or Advanced SIMD instruction.

•   Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.

•   Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

The reset behavior of this field is:

•   On a Warm reset:

  —   When the PE resets into EL2 or EL3, this field resets to 0.

  —   Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

•   Access is RAO/WI if all of the following are true:

  —   EL3 is implemented.

  —   EL3 is using AArch32.

  —   NSACR.cp10 == 0.

**Otherwise:**

Reserved, RES1.

**Bits [9:0]**

Reserved, RES1.

**Accessing HCPTR**

Accesses to this register use the following encodings in the System register encoding space:
### MRC{<c>}{<q>} <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>{, (#<opc2>)

G8.2.64  HCR, Hyp Configuration Register

The HCR characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

**Configurations**

AArch32 System register HCR bits [31:0] are architecturally mapped to AArch64 System register HCR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HCR are **UNDEFINED**.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HCR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit [31]</th>

</tbody>
</table>
HCD, bit [29]

When EL3 is not implemented:

HVC instruction disable. Disables Non-secure EL1 and EL2 execution of HVC instructions, when EL2 is enabled in the current Security state.

- **0b0**: HVC instruction execution is enabled at EL2 and EL1.
- **0b1**: HVC instructions are UNDEFINED at EL2 and Non-secure EL1.

The Undefined Instruction exception is taken to the Exception level at which the HVC instruction is executed.

——— Note ————

HVC instructions are always UNDEFINED at EL0.

———

The reset behavior of this field is:

- **On a Warm reset:**
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [28]

Reserved, RES0.

TGE, bit [27]

Trap General Exceptions, from Non-secure EL0.

- **0b0**: This control has no effect on execution at EL0.
- **0b1**: When EL2 is not enabled in the current Security state, this control has no effect on execution at EL0.

When EL2 is enabled in the current Security state, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR.M bit is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR.
- The HCR.{FMO, IMO, AMO} bits are treated as being 1 for all purposes other than returning the result of a direct read of HCR.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.
- Monitor mode execution of an MSR or CPS instruction that changes PSTATE.M to a Non-secure EL1 mode is an illegal change to PSTATE.M. For more information see Illegal changes to PSTATE.M on page G1-8925.

Also, when HCR.TGE is 1:

- If EL3 is using AArch32, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing SCR.NS from 0 to 1 results in SCR.NS remaining as 0.
- The HDCR.{TDRA, TDOSA, TDA, TDE} bits are ignored and treated as being 1 other than for the purpose of a direct read of HDCR.

The reset behavior of this field is:

- **On a Warm reset:**
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.
TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to EL2, when EL2 is enabled in the current Security state.

The registers for which write accesses are trapped are as follows:
SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0'b0 This control does not cause any instructions to be trapped.
0'b1 Non-secure EL1 write accesses to the specified virtual memory control registers are trapped to EL2.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of a TLBI instruction to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
TLBIAALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVALIS, TLBIMVAALIS, ITLBIALL, ITLBIJAVA, ITLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, TBLIALL,
TBLIMVA, TBLIASID, TBLIMVAAL, TBLIMVAAL

0'b0 This control does not cause any instructions to be trapped.
0'b1 Non-secure EL1 accesses to the specified TLB maintenance instructions are trapped to EL2.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps Non-secure EL1 execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
• ICIMVAU, ICIAULLU, ICIAULLUIS, DCCMVAAU.

Note
An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0'b0 This control does not cause any instructions to be trapped.
0'b1 Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.
The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TPC, bit [23]
Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps Non-secure EL1 execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state.
This applies to the following instructions:
• DCIMVAC, DCCIMVAC, DCCMVAC.

Note
An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0 This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TSW, bit [22]
Trap data or unified cache maintenance instructions that operate by Set/Way. Traps Non-secure EL1 execution of those cache maintenance instructions by set/way to EL2, when EL2 is enabled in the current Security state.
This applies to the following instructions:
• DCISW, DCCSW, DCCISW.

Note
An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0 This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TAC, bit [21]
Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2, when EL2 is enabled in the current Security state, from both Execution states.
This applies to the following register accesses:
ACTLR and, if implemented, ACTLR2.

0b0  This control does not cause any instructions to be trapped.

0b1  Non-secure EL1 accesses to the specified registers are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**TIDCP, bit [20]**

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings for IMPLEMENTATION DEFINED System Registers to EL2, when EL2 is enabled in the current Security state.

MCR and MRC instructions accessing the following encodings:

- All coproc==p15, CRn==c9, Opcode1 == {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c10, Opcode1 == {0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c11, Opcode1 == {0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

When HCR.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to EL2. Otherwise, it is UNDEFINED and the PE takes an Undefined Instruction exception to Non-secure Undefined mode.

0b0  This control does not cause any instructions to be trapped.

0b1  Non-secure EL1 accesses to the specified System register encodings for IMPLEMENTATION DEFINED functionality are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**TSC, bit [19]**

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to Hyp mode.

0b0  This control does not cause any instructions to be trapped.

0b1  Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

The Armv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

--- Note ---

- This trap is only implemented if the implementation includes EL3.
- SMC instructions are always UNDEFINED at PL0.
- This bit traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap exceptions and SMC exceptions have different preferred return addresses.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.
TID3, bit [18]
Trap ID group 3. Traps Non-secure EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state as follows:

- VMRS access to MVFR0, MVFR1, and MVFR2, reported using EC syndrome value 0x88, unless access is also trapped by HCPTR which takes priority.
- MRC access to the following registers are reported using EC syndrome value 0x03:
  - ID_PFR0, ID_PFR1, ID_PFR2, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
  - If FEAT_FGT is implemented:
    - ID_MMFR4 and ID_MMFR5 are trapped to EL2.
    - ID_ISAR6 is trapped to EL2.
    - ID_DFR1 is trapped to EL2.
    - This field traps all MRC accesses to registers in the following range that are not already mentioned in this field description: coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.
  - If FEAT_FGT is not implemented:
    - ID_MMFR4 and ID_MMFR5 are trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4 or ID_MMFR5 are trapped.
    - ID_ISAR6 is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_ISAR6 are trapped to EL2.
    - ID_DFR1 is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_DFR1 are trapped to EL2.
    - Otherwise, it is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to registers not already mentioned, with coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.
- 0b0  This control does not cause any instructions to be trapped.
- 0b1  The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to EL2.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TID2, bit [17]
Trap ID group 2. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

- Non-secure EL1 and EL0 reads of the CTR, CCSIDR, CCSIDR2, CLIDR, and CSSELR.
- Non-secure EL1 and EL0 writes to the CSSELR.
- 0b0  This control does not cause any instructions to be trapped.
- 0b1  The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.
TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state:

TCMTR, TLBTR, REVIDR, AIDR.

0b0 This control does not cause any instructions to be trapped.
0b1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to EL2.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TID0, bit [15]

Trap ID group 0. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

• Non-secure EL1 reads of the JIDR and FPSID.
• If the JIDR is RAZ from Non-secure EL0, Non-secure EL0 reads of the JIDR.

Note
• It is IMPLEMENTATION DEFINED whether the JIDR is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then the Undefined Instruction exception takes precedence over this trap.
• The FPSID is not accessible at EL0.
• Writes to the FPSID are ignored, and not trapped by this control.

0b0 This control does not cause any instructions to be trapped.
0b1 The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to EL2.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

TWE, bit [14]

Traps Non-secure EL0 and EL1 execution of WFE instructions to EL2, when EL2 is enabled in the current Security state.

0b0 This control does not cause any instructions to be trapped.
0b1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

Note
Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.
TWI, bit [13]

Traps Non-secure EL0 and EL1 execution of WFI instructions to EL2, when EL2 is enabled in the current Security state.

0b0  This control does not cause any instructions to be trapped.

0b1  Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

DC, bit [12]

Default Cacheability.

0b0  This control has no effect on the Non-secure EL1&0 translation regime.

0b1  In Non-secure state:
  • The SCTLR.M field behaves as 0 for all purposes other than a direct read of the value of the field.
  • The HCR.VM field behaves as 1 for all purposes other than a direct read of the value of the field.
  • The memory type produced by the first stage of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 and EL3 translation regimes.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

0b00  No effect.

0b01  Inner Shareable.

0b10  Outer Shareable.

0b11  Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.
The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**FB, bit [9]**

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

- BPIALL, TLBIALLL, TLBIMVA, TLBIASID, DTLBIALLL, DTLBIMVA, DTLBIASID,
- ITLBIALL, ITLBIIMVA, ITLBIASID, TLBIMVA, ICIALLU, TLBIVAL, TLBIMVAAL.

0b0 This field has no effect on the operation of the specified instructions.

0b1 When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**VA, bit [8]**

Virtual SError interrupt exception.

0b0 This mechanism is not making a virtual SError interrupt pending.

0b1 A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is enabled only when the value of HCR.\{TGE, AMO\} is \{0, 1\}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**VI, bit [7]**

Virtual IRQ exception.

0b0 This mechanism is not making a virtual IRQ pending.

0b1 A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR.\{TGE, IMO\} is \{0, 1\}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**VF, bit [6]**

Virtual FIQ exception.

0b0 This mechanism is not making a virtual FIQ pending.

0b1 A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR.\{TGE, FMO\} is \{0, 1\}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.
The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**AMO, bit [5]**

SError interrupt Mask Override. When this bit is set to 1, it overrides the effect of PSTATE.A, and enables virtual exception signaling by the VA bit.
If the value of HCR.TGE is 0, then virtual SError interrupts are enabled in Non-secure state.
If the value of HCR.TGE is 1, then in Non-secure state the HCR.AMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.
The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**IMO, bit [4]**

IRQ Mask Override. When this bit is set to 1, it overrides the effect of PSTATE.I, and enables virtual exception signaling by the VI bit.
If the value of HCR.TGE is 0, then Virtual IRQ interrupts are enabled in the Non-secure state.
If the value of HCR.TGE is 1, then in Non-secure state the HCR.IMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.
The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**FMO, bit [3]**

FIQ Mask Override. When this bit is set to 1, it overrides the effect of PSTATE.F, and enables virtual exception signaling by the VF bit.
If the value of HCR.TGE is 0, then Virtual FIQ interrupts are enabled in the Non-secure state.
If the value of HCR.TGE is 1, then in Non-secure state the HCR.FMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.
The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**PTW, bit [2]**

Protected Table Walk. In the Non-secure PL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

0b0  The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.

0b1  The memory access generates a stage 2 Permission fault.
This bit is permitted to be cached in a TLB.
The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**SWIO, bit [1]**

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way.

- **0b0** This control has no effect on the operation of data cache invalidate by set/way instructions.
- **0b1** Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When this bit is set to 1, DCISW performs the same invalidation as a DCCISW instruction.

As a result of changes to the behavior of DCISW, this bit is redundant in Armv8. This bit can be implemented as RES1.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**VM, bit [0]**

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime.

- **0b0** Non-secure EL1&0 stage 2 address translation disabled.
- **0b1** Non-secure EL1&0 stage 2 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR.SWIO bit.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

### Accessing HCR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>}\{<coproc>, \{#{opc1}\}, <Rt>, <CRn>, <CRm>\}, \{#{opc2}\}
\]

<table>
<thead>
<tr>

**HCR2, Hyp Configuration Register 2**

The HCR2 characteristics are:

**Purpose**

Provides additional configuration controls for virtualization.

**Configurations**

AArch32 System register HCR2 bits [31:0] are architecturally mapped to AArch64 System register HCR_EL2[63:32].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HCR2 are **UNDEFINED**.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HCR2 is a 32-bit register.

**Bits [31:23]**

Reserved, RES0.

**TTLBIS, bit [22]**

*When FEAT_EVT is implemented:*

Trap TLB maintenance instructions that operate on the Inner Shareable domain. Traps execution of the following TLB maintenance instructions at EL1 to EL2:

- **TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVALIS, TLBIMVAALIS**

  | 0b0 | This control does not cause any instructions to be trapped. |
  | 0b1 | Non-secure EL1 execution of the specified TLB maintenance instructions is trapped to EL2. |

When **FEAT_VHE** and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally **UNKNOWN** value.

**Otherwise:**

Reserved, RES0.

**Bit [21]**

Reserved, RES0.
TOCU, bit [20]

When FEAT_EVT is implemented:

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL1 or EL0 using AArch64, and at EL1 using AArch32, to EL2.

This applies to the following instructions:

- When Non-secure EL0 is using AArch64, IC IVAU, DC CVAU. However, if the value of SCTLR_EL1.UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.
- When EL1 is using AArch64, IC IVAU, IC IALLU, DC CVAU.
- When Non-secure EL1 is using AArch32, ICIMVAU, ICIALLU, DCCMVAU.

--- Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.
- ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure execution of the specified cache maintenance instructions is trapped to EL2.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When FEAT_VHE is implemented, and the value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [19]

Reserved, RES0.

TICAB, bit [18]

When FEAT_EVT is implemented:

Trap ICIALLUIS cache maintenance instructions. Traps execution of those cache maintenance instructions at EL1 to EL2.

This applies to the following instructions:

ICIALLUIS.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.
If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

When FEAT_VHE and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

TID4, bit [17]

*When FEAT_EVT is implemented:*

Trap ID group 4. Traps the following register accesses to EL2:

- EL1 reads of CCSIDR, CCSIDR2, CLIDR, and CSSELR.
- EL1 writes to CSSELR.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified Non-secure EL1 and EL0 accesses to ID group 4 registers are trapped to EL2.

When FEAT_VHE is implemented and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

Bits [16:7]

Reserved, RES0.

MIOCNCE, bit [6]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure PL1&0 translation regime.

0b0 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

0b1 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information, see *Mismatched memory attributes on page E2-7208.*

This field can be implemented as RAZ/WI.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.
TEA, bit [5]

When FEAT_RAS is implemented:

Route synchronous External abort exceptions from EL0 and EL1 to EL2.

0b0  Does not route synchronous External abort exceptions from Non-secure EL0 and EL1 to EL2.

0b1  Route synchronous External abort exceptions from Non-secure EL0 and EL1 to EL2, if not routed to EL3.

The reset behavior of this field is:

• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TERR, bit [4]

When FEAT_RAS is implemented:

Trap Error record accesses from EL1 to EL2. Trap accesses to the following registers from EL1 to EL2:

ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTLR, ERXCTLR2, ERXFR, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS.

When FEAT_RASv1p1 is implemented, ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

0b0  This control does not cause any instructions to be trapped.

0b1  Accesses to the specified registers from EL1 generate a Trap exception to EL2.

The reset behavior of this field is:

• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [3:2]

Reserved, RES0.

ID, bit [1]

Stage 2 Instruction access cacheability disable. For the Non-secure PL1&0 translation regime, when HCR.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

0b0  This control has no effect on stage 2 of the Non-secure PL1&0 translation regime.

0b1  For the Non-secure PL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.
CD, bit [0]

Stage 2 Data access cacheability disable. When HCR.VM==1, this forces all stage 2 translations for
data accesses and translation table walks to Normal memory to be Non-cacheable for the
Non-secure PL1&0 translation regime.

0b0  This control has no effect on stage 2 of the Non-secure PL1&0 translation regime for
data accesses and translation table walks.

0b1  For the Non-secure PL1&0 translation regime, forces all stage 2 translations for data
accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

•  On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to 0.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing HCR2

Accesses to this register use the following encodings in the System register encoding space:

**G8.2.66 HDFAR, Hyp Data Fault Address Register**

The HDFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HDFAR bits [31:0] are architecturally mapped to AArch64 System register FAR_EL2[31:0].

AArch32 System register HDFAR bits [31:0] are architecturally mapped to AArch32 System register DFAR[31:0] (DFAR_S) when EL2 is implemented, EL3 is implemented and the implementation only supports execution in AArch32 state.

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HDFAR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HDFAR is a 32-bit register.

**Field descriptions**

![Field description diagram](image)

**Bits [31:0]**

VA of faulting address of synchronous Data Abort exception taken to Hyp mode.

On a Prefetch Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 or Non-secure EL0 mode makes this register UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing HDFAR**

Accesses to this register use the following encodings in the System register encoding space:

G8.2.68  HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

**Purpose**

Along with HMAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:

- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

**Configurations**

AArch32 System register HMAIR0 bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HMAIR0 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HMAIR0 is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 1:*

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr3</td>
<td>Attr2</td>
<td>Attr1</td>
<td>Attr0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Attr<n>, bits [8n+7:8n], for n = 3 to 0**

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Back Transient.</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient.</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient.</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits \([3:0]\) depends on the value of bits \([7:4]\):

<table>
<thead>
<tr>
<th>Attr(&lt;n&gt;[3:0]</th>
<th>Meaning when Attr(&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr(&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr\(<n\>) fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

When FEAT_XS is implemented, stage 1 Inner Write-Back Cacheable, Outer Write-Back Cacheable memory types have the XS attribute set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNDEFINED value.

**Accessing HMAIR0**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{<c>\}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>, {#}<opc2>\]

<table>
<thead>

HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

**Purpose**

Along with HMAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:
- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

**Configurations**

AArch32 System register HMAIR1 bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL2[63:32].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HMAIR1 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HMAIR1 is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 1:*

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>24</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
<td>Attr6</td>
<td>Attr5</td>
<td>Attr4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 7 to 4

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Back Transient.</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient.</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient.</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

When FEAT_XS is implemented, stage 1 Inner Write-Back Cacheable, Outer Write-Back Cacheable memory types have the XS attribute set to 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing HMAIR1**

Accesses to this register use the following encodings in the System register encoding space:

```
MRC<coproc>, <CRn>, <CRm), <opc1>, <opc2>, <c>, <q>
```

<table>
<thead>

G8.2.70 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

**Purpose**

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

**Configurations**

AArch32 System register HPFAR bits [31:0] are architecturally mapped to AArch64 System register HPFAR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HPFAR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HPFAR is a 32-bit register.

**Field descriptions**

![Field descriptions](image)

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

**FIPA[39:12], bits [31:4]**

Bits [39:12] of the faulting intermediate physical address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [3:0]**

Reserved, RES0.

**Accessing HPFAR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC\{<c><q}\} \{<coproc>, \{#<opc1>, \{<Rt>, \{<CRn>, \{<CRm>, \{#<opc2>\}\}\}\}\}\}
\]

G8.2.71 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

Purpose

If EL2 is the highest implemented Exception level and this register is implemented:
- A write to the register at EL2 can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Configurations

AArch32 System register HRMR bits [31:0] are architecturally mapped to AArch64 System register RMR_EL2[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to HRMR are UNDEFINED.

Only implemented if EL2 is the highest implemented Exception level. In this case:
- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

Attributes

HRMR is a 32-bit register.

Field descriptions

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RR</td>
<td>AA64</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

AA64, bit [0]

When EL2 can use AArch64, determines which Execution state the PE boots into after a Warm reset:
- 0b0 AArch32.
- 0b1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch64 this bit is RAZ/WI.

The reset behavior of this field is:
- When implemented as a RW field, this field resets to 0 on a Cold reset.

Accessing HRMR

Accesses to this register use the following encodings in the System register encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>

G8.2.72 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

**Purpose**

Provides top level control of the system operation in Hyp mode.

**Configurations**

AArch32 System register HSCTLR bits [31:0] are architecturally mapped to AArch64 System register SCTLR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HSCTLR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HSCTLR is a 32-bit register.

**Field descriptions**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| TE | RES1 | RES0 | EE | RES1 | RES0 | RES0 | I  | RES0 | RES0 | RES0 | RES1 | RES1 | RES1 | RES1 | RES1 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 |

**DSSBS, bit [31]**

When FEAT_SSSBS is implemented:

Default PSTATE.SSBS value on Exception Entry. The defined values are:

- 0b0 PSTATE.SSBS is set to 0 on an exception to Hyp mode.
- 0b1 PSTATE.SSBS is set to 1 on an exception to Hyp mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

**Otherwise:**

Reserved, RES0.

**TE, bit [30]**

T32 Exception Enable. This bit controls whether exceptions to EL2 are taken to A32 or T32 state:

- 0b0 Exceptions, including reset, taken to A32 state.
- 0b1 Exceptions, including reset, taken to T32 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

**Bits [29:28]**

Reserved, RES1.

**Bits [27:26]**

Reserved, RES0.
The value of the PSTATE.E bit on entry to Hyp mode, the endianness of stage 1 translation table walks in the EL2 translation regime, and the endianness of stage 2 translation table walks in the PL1&0 translation regime.

- **0b0**: Little-endian. PSTATE.E is cleared to 0 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are little-endian.
- **0b1**: Big-endian. PSTATE.E is set to 1 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception levels higher than EL0, this bit is RES1.

The reset behavior of this field is:
- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

**Bit [24]**
Reserved, RES0.

**Bits [23:22]**
Reserved, RES1.

**Bits [21:20]**
Reserved, RES0.

**WXN, bit [19]**
Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN.

- **0b0**: This control has no effect on memory access permissions.
- **0b1**: Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.

This bit applies only when HSCTLR.M bit is set.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Bit [18]**
Reserved, RES1.

**Bit [17]**
Reserved, RES0.

**Bit [16]**
Reserved, RES1.

**Bits [15:13]**
Reserved, RES0.

**I, bit [12]**
Instruction access Cacheability control, for accesses at EL2:

- **0b0**: All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

0b1
All instruction access to Normal memory from EL2 can be cached at all levels of instruction and unified cache.

If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the PL1&0 translation regime.

The reset behavior of this field is:

• On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

Bit [11]
Reserved, RES1.

Bits [10:9]
Reserved, RES0.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at EL2.

0b0
SETEND instruction execution is enabled at EL2.

0b1
SETEND instructions are UNDEFINED at EL2.

If the implementation does not support mixed-endian operation at EL2, this bit is RES1.

The reset behavior of this field is:

• On a Warm reset, in a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at EL2.

0b0
All IT instruction functionality is enabled at EL2.

0b1
Any attempt at EL2 to execute any of the following is UNDEFINED:

• All encodings of the IT instruction with hw1[3:0]=1000.
• All encodings of the subsequent instruction with the following values for hw1:
  — 11xxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
  — 1011xxxxxxxxxxxx: All instructions in Miscellaneous 16-bit instructions on page F3-7303.
  — 10100xxxxxxxxxxx: ADD Rd, PC, #imm
  — 01001xxxxxxxxxxx: LDR Rd, [PC, #imm]
  — 0100x1xx1111xxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
  — 01001xx1xxx1111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block. It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

• A 16-bit instruction, that can only be followed by another 16-bit instruction.
• The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.
An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information, see Changes to an ITD control by an instruction in an IT block on page E1-7138.

ITD is optional, but if it is implemented in the HSCTLR then it must also be implemented in the SCTLR_EL1, SCTLR_EL2, and SCTLR.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement ITD, access to this field is RAZ/WI.

**Bit [6]**

Reserved, RES0.

**CP15BEN, bit [5]**

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from EL2:

- 0b0  EL2 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
- 0b1  EL2 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the HSCTLR then it must also be implemented in the SCTLR_EL1, SCTLR_EL2, and SCTLR.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement CP15BEN, access to this field is RAO/WI.

**LSMAOE, bit [4]**

*When FEAT_LSMAOC is implemented:*

Load Multiple and Store Multiple Atomicity and Ordering Enable.

- 0b0  For all memory accesses at EL2, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- 0b1  The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL2 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2, this field resets to 1.

*Otherwise:*

Reserved, RES1.

**nTLSMD, bit [3]**

*When FEAT_LSMAOC is implemented:*

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

- 0b0  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
- 0b1  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.
This bit is permitted to be cached in a TLB.
The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2, this field resets to 1.

**Otherwise:**
Reserved, RES1.

**C, bit [2]**

Cacheability control, for data accesses at EL2:
- **0b0** All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.
- **0b1** All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, can be cached at all levels of data and unified cache.

This bit has no effect on the PL1&0 translation regime.
The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:
- **0b0** Alignment fault checking disabled when executing at EL2.
  Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element or data elements being accessed.
- **0b1** Alignment fault checking enabled when executing at EL2.
  All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element or data elements being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.
The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**M, bit [0]**

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:
- **0b0** EL2 stage 1 address translation disabled.
  See the HSCTL.R1 field for the behavior of instruction accesses to Normal memory.
- **0b1** EL2 stage 1 address translation enabled.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2, this field resets to 0.

**Accessing HSCTL.R**

Accesses to this register use the following encodings in the System register encoding space:
```plaintext
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

    HSCTRL = R[t];
```

G8.2.73  HSR, Hyp Syndrome Register

The HSR characteristics are:

**Purpose**

Holds syndrome information for an exception taken to Hyp mode.

**Configurations**

AArch32 System register HSR bits [31:0] are architecturally mapped to AArch64 System register ESR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HSR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HSR is a 32-bit register.

**Field descriptions**

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>EC</td>
<td>IL</td>
<td>ISS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Execution in any Non-secure PE mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

**EC == 0b000000**

Unknown reason.

See ISS encoding for exceptions with an unknown reason.

**EC == 0b000001**

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See ISS encoding for exception from a WFI or WFE instruction.

**EC == 0b000011**

Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.

See ISS encoding for exception from an MCR or MRC access.

**EC == 0b000100**

Trapped MCRR or MRRC access with (coproc==0b1110).

See ISS encoding for exception from an MCRR or MRRC access.

**EC == 0b000101**

Trapped MCR or MRC access with (coproc==0b1110).

See ISS encoding for exception from an MCR or MRC access.
EC == 0b000110
Trapped LDC or STC access.
The only architected uses of these instructions are:
• An STC to write data to memory from DBGDTRRXint.
• An LDC to read data from memory to DBGDTRTXint.
See ISS encoding for exception from an LDC or STC instruction.

EC == 0b000111
Access to Advanced SIMD or floating-point functionality trapped by a HCPTR. {TASE, TCP10} control.
Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.
See ISS encoding for exception from an access to SIMD or floating-point functionality, resulting from HCPTR.

EC == 0b001000
Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.
See ISS encoding for exception from an MCR or MRC access.

EC == 0b001100
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for exception from an MCRR or MRRC access.

EC == 0b001110
Illegal exception return to AArch32 state.
See ISS encoding for exception from an Illegal state or PC alignment fault.

EC == 0b010001
Exception on SVC instruction execution in AArch32 state routed to EL2.
See ISS encoding for exception from HVC or SVC instruction execution.

EC == 0b010010
HVC instruction execution in AArch32 state, when HVC is not disabled.
See ISS encoding for exception from HVC or SVC instruction execution.

EC == 0b010011
Trapped execution of SMC instruction in AArch32 state.
See ISS encoding for exception from SMC instruction execution.

EC == 0b100000
Prefetch Abort from a lower Exception level.
See ISS encoding for exception from a Prefetch Abort.

EC == 0b100001
Prefetch Abort taken without a change in Exception level.
See ISS encoding for exception from a Prefetch Abort.

EC == 0b100010
PC alignment fault exception.
See ISS encoding for exception from an Illegal state or PC alignment fault.

EC == 0b100100
Data Abort exception from a lower Exception level.
See ISS encoding for exception from a Data Abort.

EC == 0b100101
Data Abort exception taken without a change in Exception level.
See ISS encoding for exception from a Data Abort.

All other EC values are reserved by Arm, and:
• Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
• Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction length bit. Indicates the size of the instruction that has been trapped to Hyp mode. When this bit is valid, possible values of this bit are:

0b0 16-bit instruction trapped.
0b1 32-bit instruction trapped.

This field is RES1 and not valid for the following cases:
• When the EC field is 0b000000, indicating an exception with an unknown reason.
• Prefetch Aborts.
• Data Abort exceptions for which the HSR.ISS.ISV field is 0.
• When the EC value is 0b01110, indicating an Illegal state exception.

The IL field is not valid and is UNKNOWN on an exception from a PC alignment fault.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

ISS encoding for exceptions with an unknown reason

<table>
<thead>
<tr>
<th>24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

Bits [24:0]

Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

• The attempted execution of an instruction bit pattern that has no allocated instruction or is not accessible in the current PE mode in the current Security state, including:
  — A read access using a System register encoding pattern that is not allocated for reads or that does not permit reads in the current PE mode and Security state.
  — A write access using a System register encoding pattern that is not allocated for writes or that does not permit writes in the current PE mode and Security state.
  — Instruction encodings that are unallocated.
  — Instruction encodings for instructions not implemented in the implementation.

• In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.

• In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.

• The attempted execution of a short vector floating-point instruction.
• In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.

• An exception generated because of the value of one of the SCTLR.{ITD, SED, CP15BEN} control bits.

• Attempted execution of:
  — An HVC instruction when disabled by HCR.HCD, SCR.HCE, or SCR_EL3.HCE.
  — An SMC instruction when disabled by SCR.SCD or SCR_EL3.SMD.
  — An HLT instruction when disabled by EDSCR.HDE.

• An HVC instruction when disabled by HCR.HCD, SCR.HCE, or SCR_EL3.HCE. An SMC instruction when disabled by SCR.SCD or SCR_EL3.SMD. An HLT instruction when disabled by EDSCR.HDE.

• An exception generated because of the attempted execution of an MSR (Banked register) or MRS (Banked register) instruction that would access a Banked register that is not accessible from the Security state and PE mode at which the instruction was executed.

--- Note ---

An exception is generated only if the CONSTRAINED UNPREDICTABLE behavior of the instruction is that it is UNDEFINED, see MSR (banked register) and MRS (banked register) on page K1-11582.

---

• Attempted execution, in Debug state, of:
  — A DCPS1 instruction in Non-secure state from EL0 when EL2 is using AArch32 and the value of HCR.TGE is 1.
  — A DCPS2 instruction at EL1 or EL0 when EL2 is not implemented, or when EL3 is using AArch32 and the value of SCR.NS is 0, or when EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  — A DCPS3 instruction when EL3 is not implemented, or when the value of EDSCR.SDD is 1.

• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

**Undefined Instruction exception, when the value of HCR.TGE is 1** on page G1-8945 describes the configuration settings for a trap that returns an HSR.EC value of 0b000000.

**ISS encoding for exception from a WFI or WFE instruction**

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>RES0</th>
<th>TI</th>
</tr>
</thead>
</table>

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0b0: The COND field is not valid.
- 0b1: The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

- 0b0 WFI trapped.
- 0b1 WFE trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-9020 describes the configuration settings for this trap.

**ISS encoding for exception from an MCR or MRC access**

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]
The Opc2 value from the issued instruction.
For a trapped VMRS access, holds the value 0b000.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]
The Opc1 value from the issued instruction.
For a trapped VMRS access, holds the value 0b111.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]
The CRn value from the issued instruction.
For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value 0b0000.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction.

```
CV, bit [24]
Condition code valid. Possible values of this bit are:

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]
The Opc1 value from the issued instruction.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [15:14]
Reserved, RES0.

Rt2, bits [13:10]
The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the first general-purpose register used for the transfer.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Direction, bit [0]**

Indicates the direction of the trapped instruction.

- **0b0**: Write to System register space. MCRR instruction.
- **0b1**: Read from System register space. MRRC instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

The following sections describe configuration settings for traps that are reported using EC value **0b001000**:
- Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-9014.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-9029.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Activity Monitors registers on page G1-9021.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page G1-9028.
- General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space on page G1-9024.

The following sections describe configuration settings for traps that are reported using EC value **0b001100**:
- Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-9023.
- Trapping Non-secure System register accesses to Debug ROM registers on page G1-9026.

**ISS encoding for exception from an LDC or STC instruction**

```
   23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
 CV  COND  imm8  RES0  Rn  AM  Offset  Direction
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:
- **0b0**: The COND field is not valid.
- **0b1**: The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**COND, bits [23:20]**

The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
  • If the instruction is conditional, COND is set to the condition code field value from the
    instruction.
  • If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
  • With COND set to 0b1110, the value for unconditional.
  • With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  • CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT
    field to determine the condition, if any, of the T32 instruction.
  • CV is set to 1 and COND is set to the condition code for the condition that applied to the
    instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped
conditional instruction only if the instruction passes its condition code check, these definitions mean
that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110,
or to the value of any condition that applied to the instruction.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]
The immediate value from the issued instruction.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:9]
Reserved, RES0.

Rn, bits [8:5]
The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate
form of the LDC or STC instruction.
When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]
Indicates whether the offset is added or subtracted:
  0b0  Subtract offset.
  0b1  Add offset.
This bit corresponds to the U bit in the instruction encoding.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]
Addressing mode. The permitted values of this field are:
  0b000  Immediate unindexed.
  0b001  Immediate post-indexed.
  0b010  Immediate offset.
  0b011  Immediate pre-indexed.
  0b100  Literal unindexed.
LDC instruction in A32 instruction set only.
For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.

0b110  Literal offset.
LDC instruction only.
For a trapped STC instruction, this encoding is reserved.

The values 0b1101 and 0b1111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRANGED UNPREDICTABLE.

Bit [2] in this subfield indicates the instruction form, immediate or literal.
Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction.
0b0  Write to memory. STC instruction.
0b1  Read from memory. LDC instruction.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Trapping general Non-secure System register accesses to debug registers on page G1-9027 describes the configuration settings for the trap that is reported using EC value 0b000110.

ISS encoding for exception from an access to SIMD or floating-point functionality, resulting from HCPTR

Excludes exceptions that occur because Advanced SIMD and floating-point functionality is not implemented, or because the value of HCR.TGE or HCR_EL2.TGE is 1. These are reported with EC value 0b000000.

CV, bit [24]
Condition code valid. Possible values of this bit are:
0b0  The COND field is not valid.
0b1  The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [19:6]**

Reserved, RES0.

**TA, bit [5]**

Indicates trapped use of Advanced SIMD functionality.
- 0b0 Exception was not caused by trapped use of Advanced SIMD functionality.
- 0b1 Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is not also a floating-point instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

For a list of these instructions, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-7153.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [4]**

Reserved, RES0.

**coproc, bits [3:0]**

When the HSR.TA field returns the value 1, this field returns the value 0b1010. Otherwise, this field is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:
- General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-9021.
- Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-9022.

**ISS encoding for exception from HVC or SVC instruction execution**

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>imm16</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [24:16]**

Reserved, RES0.
imm16, bits [15:0]
The value of the immediate field from the HVC or SVC instruction.
For an HVC instruction, this is the value of the imm16 field of the issued instruction.
For an SVC instruction:
• If the instruction is unconditional, then:
  — For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  — For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
• For the T32 instruction, this field is zero-extended from the imm8 field of the instruction. For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
• If the instruction is conditional, this field is UNKNOWN.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

The HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-8945 describes the configuration settings for the trap reported with EC value 0b010001.

ISS encoding for exception from SMC instruction execution

CV, bit [24]
Condition code valid. Possible values of this bit are:
0b0 The COND field is not valid.
0b1 The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. For more information, see the description of the COND field.
This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
• With COND set to 0b1110, the value for unconditional.
• With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]
Indicates whether the instruction might have failed its condition code check.

- 0b0 The instruction was unconditional, or was conditional and passed its condition code check.
- 0b1 The instruction was conditional, and might have failed its condition code check.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]
Reserved, RES0.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-9017 describes the configuration settings for this trap, for instructions executed in Non-secure EL1.

ISS encoding for exception from a Prefetch Abort

Bits [24:11]
Reserved, RES0.

FnV, bit [10]
FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0 HIFAR is valid.
- 0b1 HIFAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]
External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [8]**

Reserved, RES0.

**S1PTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code. Possible values of this field are:

- 0b000000 Address size fault in translation table base register.
- 0b000001 Address size fault, level 1.
- 0b000010 Address size fault, level 2.
- 0b000011 Address size fault, level 3.
- 0b000100 Translation fault, level 1.
- 0b000101 Translation fault, level 2.
- 0b000110 Translation fault, level 3.
- 0b001001 Access flag fault, level 1.
- 0b001010 Access flag fault, level 2.
- 0b001011 Access flag fault, level 3.
- 0b001101 Permission fault, level 1.
- 0b001110 Permission fault, level 2.
- 0b001111 Permission fault, level 3.
- 0b010000 Synchronous External abort, not on translation table walk.
- 0b010101 Synchronous External abort on translation table walk, level 1.
- 0b010110 Synchronous External abort on translation table walk, level 2.
- 0b010111 Synchronous External abort on translation table walk, level 3.
- 0b011000 When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b011101 When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 1.
- 0b011110 When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 2.
- 0b011111 When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 3.
- 0b100010 Debug exception.
- 0b110000 TLB conflict abort.
All other values are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup* on page G5-9259.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100000:
- *Abort exceptions, when the value of HCR.TGE is 1* on page G1-8945.
- *Routing debug exceptions to EL2 using AArch32* on page G1-8946.

### ISS encoding for exception from an Illegal state or PC alignment fault

**ISV, bit [24]**

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0 No valid instruction syndrome. ISS[23:14] are RES0.
- 0b1 ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults except Data Abort exceptions generated by stage 2 address translations for which all the following apply to the instruction that generated the Data Abort exception:
- The instruction is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
- The instruction is not performing register writeback.
- The instruction is not using the PC as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, as described in Data Aborts in Memory access mode on page H4-10304, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

--- Note ---

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.
ISV is set to 0 on a stage 2 abort on a stage 1 translation table walk.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.
0b00  Byte
0b01  Halfword
0b10  Word
0b11  Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:
0b0  Sign-extension not required.
0b1  Data item must be sign-extended.

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [20]

Reserved, RES0.

SRT, bits [19:16]

Syndrome Register Transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bit [15]
Reserved, RES0.

AR, bit [14]
Acquire/Release. When ISV is 1, the possible values of this bit are:
0b0 Instruction did not have acquire/release semantics.
0b1 Instruction did have acquire/release semantics.
This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [13:12]
Reserved, RES0.

AET, bits [11:10]
When FEAT_RAS is implemented:
AET
Asynchronous Error Type. When DFSC is 0b010001, describes the PE error state after taking the SError interrupt exception.
0b00 Uncontainable (UC).
0b01 Unrecoverable state (UEU).
0b10 Restartable state (UEO).
0b11 Recoverable state (UER).
On a synchronous Data Abort exception, this field is RES0.
In the event of multiple errors taken as a single SError interrupt exception, the overall PE error state is reported.

——— Note ————
Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

——— ————
When FEAT_RAS is not implemented, or when DFSC is not 0b010001:
• Bit[11] is RES0.
• Bit[10] forms the FnV field.

——— Note ————
Armv8.2 requires the implementation of FEAT_RAS.

——— ————
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit[0] of bits [11:10]
FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.
0b0 HDFAR is valid.
0b1 HDFAR is not valid, and holds a \textit{UNKNOWN} value.

When FEAT\_RAS is not implemented, this field is valid only if DFSC is 0b010000. It is RES0 for all other aborts.

When FEAT\_RAS is implemented:

\begin{itemize}
  \item If DFSC is 0b010000, this field is valid.
  \item If DFSC is 0b010001, this bit forms part of the AET field, becoming AET[0].
  \item This field is RES0 for all other aborts.
\end{itemize}

\textbf{Note}

Armv8.2 requires the implementation of FEAT\_RAS.

The reset behavior of this field is:

\begin{itemize}
  \item On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.
\end{itemize}

\textbf{EA, bit [9]}

External Abort type. This bit can provide an \textit{IMPLEMENTATION DEFINED} classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

\begin{itemize}
  \item On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.
\end{itemize}

\textbf{CM, bit [8]}

Cache Maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation instruction. For synchronous faults, the possible values of this bit are:

\begin{itemize}
  \item 0b0 Fault not generated by a cache maintenance or address translation instruction.
  \item 0b1 Fault generated by a cache maintenance or address translation instruction.
\end{itemize}

For an asynchronous Data Abort exception, this bit is 0.

The reset behavior of this field is:

\begin{itemize}
  \item On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.
\end{itemize}

\textbf{S1PTW, bit [7]}

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

\begin{itemize}
  \item 0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
  \item 0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.
\end{itemize}

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

\begin{itemize}
  \item On a Warm reset, this field resets to an architecturally \textit{UNKNOWN} value.
\end{itemize}

\textbf{WnR, bit [6]}

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction.

\begin{itemize}
  \item 0b0 Abort caused by a read instruction.
  \item 0b1 Abort caused by a write instruction.
\end{itemize}

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

On an asynchronous Data Abort exception:

\begin{itemize}
  \item When FEAT\_RAS is not implemented, this bit is \textit{UNKNOWN}.
  \item When FEAT\_RAS is implemented, this bit is RES0.
\end{itemize}
Note

Armv8.2 requires the implementation of FEAT_RAS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

- 0b000000: Address size fault in translation table base register.
- 0b000001: Address size fault, level 1.
- 0b000010: Address size fault, level 2.
- 0b000011: Address size fault, level 3.
- 0b000101: Translation fault, level 1.
- 0b000110: Translation fault, level 2.
- 0b000111: Translation fault, level 3.
- 0b001001: Access flag fault, level 1.
- 0b001010: Access flag fault, level 2.
- 0b001011: Access flag fault, level 3.
- 0b001101: Permission fault, level 1.
- 0b001110: Permission fault, level 2.
- 0b001111: Permission fault, level 3.
- 0b010000: Synchronous External abort, not on translation table walk.
- 0b010001: Asynchronous SError interrupt.
- 0b010101: Synchronous External abort on translation table walk, level 1.
- 0b010110: Synchronous External abort on translation table walk, level 2.
- 0b010111: Synchronous External abort on translation table walk, level 3.
- 0b011000: When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b011001: When FEAT_RAS is not implemented:
  Asynchronous SError interrupt, from a parity or ECC error on memory access.
- 0b011101: When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 1.
- 0b011110: When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 2.
- 0b011111: When FEAT_RAS is not implemented:
  Synchronous parity or ECC error on memory access on translation table walk, level 3.
- 0b100001: Alignment fault.
- 0b100010: Debug exception.
- 0b110000: TLB conflict abort.
- 0b110100: IMPLEMENTATION DEFINED fault (Lockdown).
- 0b110101: IMPLEMENTATION DEFINED fault (Unsupported Exclusive access).

All other values are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G5-9259.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value **0b100100**:

- *Abort exceptions, when the value of HCR.TGE is 1 on page G1-8945.*
- *Routing debug exceptions to EL2 using AArch32 on page G1-8946.*

The following describe cases that can cause a Data Abort exception that is taken to Hyp mode, and reported in the HSR with EC value of **0b100000** or **0b100100**:

- *Hyp mode control of Non-secure access permissions on page G5-9201.*
- *Memory fault reporting in Hyp mode on page G5-9263.*

### Accessing HSR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC} \{<c>\} \{<q>\} \text{<coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm}\{, \{#<opc2}\}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b100</td>
<td>0b0101</td>
<td>0b0010</td>
<td>0b000</td>
</tr>
</tbody>
</table>

\[
\text{MCR} \{<c>\} \{<q>\} \text{<coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm}\{, \{#<opc2}\}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b100</td>
<td>0b0101</td>
<td>0b0010</td>
<td>0b000</td>
</tr>
</tbody>
</table>

\[
\text{if PSTATE.EL == EL0 then}
\begin{align*}
\text{UNDEFINED;}
\end{align*}
\]

\[
\text{elsif PSTATE.EL == EL1 then}
\begin{align*}
\text{if EL2Enabled()} \&\& \text{!ELUsingAAArch32(EL2) \&\& HSTR_EL2.T5 == '1' then}
\text{AArch64.AArch32SystemAccessTrap(EL2, 0x03);}
\text{elsif EL2Enabled()} \&\& \text{ELUsingAAArch32(EL2) \&\& HSTR.T5 == '1' then}
\text{AArch32.TakeHypTrapException(0x03);}
\text{else}
\text{UNDEFINED;}
\end{align*}
\]

\[

\text{UNDEFINED;}
\text{else}
\text{R[t] = HSR;}
\end{align*}
\]
elsif PSTATE.EL == EL2 then
    HSR = R[t];
elsif PSTATE.EL == EL3 then
    if SCR.NS == '0' then
        UNDEFINED;
    else
        HSR = R[t];
    end if;
else
    HSR = R[t];
G8.2.74 HSTR, Hyp System Trap Register

The HSTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to System registers in the coproc == 0b1111 encoding space:

- By the CRn value used to access the register using MCR or MRC instruction.
- By the CRm value used to access the register using MCRR or MRRC instruction.

**Configurations**

AArch32 System register HSTR bits [31:0] are architecturally mapped to AArch64 System register HSTR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HSTR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HSTR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-16, 14-13</td>
<td>T15, T14, T13</td>
</tr>
<tr>
<td>12-8</td>
<td>T9, T8, T7, T6, T5</td>
</tr>
<tr>
<td>7-0</td>
<td>T3, T2, T1, T0</td>
</tr>
</tbody>
</table>

**Bits [31:16, 14, 4]**

Reserved, RES0.

**T<n>, bit [n], for n = 15, 13 to 5, 3 to 0**

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 0b1111 encoding space are trapped to Hyp mode:

- **0b0** This control has no effect on Non-secure EL0 or EL1 accesses to System registers.
- **0b1** Any Non-secure EL1 MCR or MRC access with coproc == 0b1111 and CRn == <n> is trapped to Hyp mode. A Non-secure EL0 MCR or MRC access with these values is trapped to Hyp mode only if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR.T7 is 1, for instructions executed at Non-secure EL1:

- An MCR or MRC instruction with coproc set to 0b1111 and <CRn> set to c7 is trapped to Hyp mode.
- An MCRR or MRRC instruction with coproc set to 0b1111 and <CRm> set to c7 is trapped to Hyp mode.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing HSTR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}\{<q>\} <\text{coproc}, \{#\}<\text{opc1}>, <Rt>, <\text{CRn}>, <\text{CRm}>, \{#\}<\text{opc2}>\]
\]

<table>
<thead>

  else
    HSTR = R[t];
elsif PSTATE.EL == EL3 then
  if SCR.NS == '0' then
    UNDEFINED;
  else
    HSTR = R[t];
G8.2.75 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

**Purpose**

The control register for stage 1 of the EL2 translation regime.

--- Note ---

This stage of translation always uses the Long-descriptor translation table format.

**Configurations**

AArch32 System register HTCR bits [31:0] are architecturally mapped to AArch64 System register TCR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HTCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HTCR is a 32-bit register.

**Field descriptions**

Bit [31]

Reserved, RES1.

**IMPLEMENTATION DEFINED, bit [30]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [29]

Reserved, RES0.

**HWU62, bit [28]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

0b0 Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
**Otherwise:**

Reserved, RES0.

**HWU61, bit [27]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

- **0b0**: Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU60, bit [26]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

- **0b0**: Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HWU59, bit [25]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

- **0b0**: Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
### HPD, bit [24]

*When FEAT_AA32HPD is implemented:*

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the PL2 translation regime.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Hierarchical permissions are enabled.</td>
</tr>
<tr>
<td>01</td>
<td>Hierarchical permissions are disabled.</td>
</tr>
</tbody>
</table>

When disabled, the permissions are treated as if the bits are zero.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN value**.

### Bit [23]

Reserved, RES0.

### Bits [22:14]

Reserved, RES0.

### SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using HTTBR.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Non-shareable.</td>
</tr>
<tr>
<td>010</td>
<td>Outer Shareable.</td>
</tr>
<tr>
<td>011</td>
<td>Inner Shareable.</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN value**.

### ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using HTTBR.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>001</td>
<td>Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>010</td>
<td>Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>011</td>
<td>Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN value**.

### IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using HTTBR.

<table>
<thead>
<tr>
<th>Bit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Normal memory, Inner Non-cacheable.</td>
</tr>
<tr>
<td>001</td>
<td>Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>010</td>
<td>Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
<tr>
<td>011</td>
<td>Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN value**.

### Bits [7:3]

Reserved, RES0.
T0SZ, bits [2:0]

The size offset of the memory region addressed by HTTBR. The region size is 2^(32-T0SZ) bytes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HTCR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>}\ <\text{coproc}, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#\}<\text{opc2}>\]

<table>
<thead>
<tr>
<th>coproc</th>

</tr>
</tbody>
</table>
G8.2.76   HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

**Purpose**

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register HTPIDR bits [31:0] are architecturally mapped to AArch64 System register TPIDR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HTPIDR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

--- Note ---

The PE never updates this register.

**Attributes**

HTPIDR is a 32-bit register.

**Field descriptions**

![Thread ID](image)

**Bits [31:0]**

- Thread ID. Thread identifying information stored by software running at this Exception level.
- The reset behavior of this field is:
  - On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing HTPIDR**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{c\}\{q\} <\text{coproc}\rangle, \langle#\rangle<\text{opc1}\rangle, <\text{Rt}\rangle, <\text{CRn}\rangle, <\text{CRm}\rangle, \langle#\rangle<\text{opc2}\rangle

### G8.2.77 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register HTTBR bits [47:1] are architecturally mapped to AArch64 System register TTBR0_EL2[47:1].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HTTBR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HTTBR is a 64-bit register.

**Field descriptions**

![Field diagram](image)

**Bits [63:48]**

Reserved, RES0.

**BADDR, bits [47:1]**

Translation table base address, bits[47:x]. Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of HTCR.T0SZ as follows:

- If HTCR.T0SZ is 0 or 1, x = 5 - HTCR.T0SZ.
- If HTCR.T0SZ is greater than 1, x = 14 - HTCR.T0SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated. The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
CnP, bit [0]

**When FEAT_TTCNP is implemented:**

Common not Private. This bit indicates whether each entry that is pointed to by HTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

- **0b0** The translation table entries pointed to by HTTBR are permitted to differ from corresponding entries for HTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of HTTBR.CnP on those other PEs.

- **0b1** The translation table entries pointed to by HTTBR are the same as the translation table entries pointed to by HTTBR on every other PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

**Note**

If the value of the HTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those HTTBRs do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are **CONSTRAINED UNPREDICTABLE**, see **CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values** on page K1-11567.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Accessing HTTBR**

Accesses to this register use the following encodings in the System register encoding space:

**MRRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <Rt2>, <CRm>**

<table>
<thead>
<tr>
<th>coproc</th>

### G8.2.78 HVAR, Hyp Vector Base Address Register

The HVAR characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HVAR bits [31:0] are architecturally mapped to AArch64 System register VBAR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HVAR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HVAR is a 32-bit register.

**Field descriptions**

- **Bits [31:5]**
  
  Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

  The reset behavior of this field is:
  
  - On a Warm reset, this field resets to an architecturally UNKNOWN value.

- **Bits [4:0]**

  Reserved, RES0.

**Accessing HVAR**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{<c>\}{<q>} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm}\{, \{#<opc2}>\}
\]

G8.2.79 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

**Purpose**

Invalidate all instruction caches of the PE executing the instruction to the Point of Unification. If branch predictors are architecturally visible, also flush branch predictors.

**Configurations**

AArch32 System register ICIALLU performs the same function as AArch64 System register IC IALLU.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ICIALLU are UNDEFINED.

**Attributes**

ICIALLU is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing ICIALLU instruction**

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a ICIALLUIS.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[ MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>

    AArch32.IC(CacheOpScope_ALLU);
G8.2.80  ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches in the Inner Shareable domain of the PE executing the instruction to the Point of Unification. If branch predictors are architecturally visible, also flush branch predictors.

**Configurations**

AArch32 System register ICIALLUIS performs the same function as AArch64 System register IC IALLUIS.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ICIALLUIS are UNDEFINED.

**Attributes**

ICIALLUIS is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing ICIALLUIS instruction**

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
MCR\{<c>\}{<q>} \text{<coproc>, } \text{(##<opc1>, } \text{<Rt>, } \text{<CRn>, } \text{<CRm>}(, \text{(##<opc2>)}

G8.2.81 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

Purpose

Invalidate instruction cache line by virtual address to PoU.

Configurations

AArch32 System register ICIMVAU performs the same function as AArch64 System register ICIVAU.

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ICIMVAU are UNDEFINED.

Attributes

ICIMVAU is a 32-bit System instruction.

Field descriptions

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>
|     Virtual address to use

Bits [31:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing ICIMVAU instruction

Execution of this instruction might require an address translation from VA to PA, and that translation might fault.

For more information about faults, see Permission fault on page G5-9239.

For more information about data cache maintenance instructions, see AArch32 instruction cache maintenance instructions (IC*) on page G4-9124.

Accesses to this instruction use the following encodings in the System instruction encoding space:

G8.2.82  ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state.

Must be interpreted with the Main ID Register, MIDR.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_AFR0 bits [31:0] are architecturally mapped to AArch64 System register ID_AFR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_AFR0 are UNDEFINED.

**Attributes**

ID_AFR0 is a 32-bit register.

G8.2.83 ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, MIDR.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_DFR0 bits [31:0] are architecturally mapped to AArch64 System register ID_DFR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_DFR0 are UNDEFINED.

**Attributes**

ID_DFR0 is a 32-bit register.

**TraceFilt, bits [31:28]**

Armv8.4 Self-hosted Trace Extension version. Defined values are:

0b0000  Armv8.4 Self-hosted Trace Extension not implemented.
0b0001  Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

**FEAT_TRF** implements the functionality added by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

**PerfMon, bits [27:24]**

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in *Alternative ID scheme used for the Performance Monitors Extension version* on page G8-9334.

Defined values are:

0b0000  Performance Monitors Extension not implemented.
0b0001  Performance Monitors Extension, PMUv1 implemented.
0b0010  Performance Monitors Extension, PMUv2 implemented.
0b0011  Performance Monitors Extension, PMUv3 implemented.
0b0100  PMUv3 for Armv8.1. As 0b0011, and adds support for:

• Extended 16-bit PMEVTPYR<\(n\)>.evtCount field.
• If EL2 is implemented, the HDCR.HPMD control.
0b0101  PMUv3 for Armv8.4. As 0b0100, and adds support for the PMMIR register.
0b0110  PMUv3 for Armv8.5. As 0b0101, and adds support for:

• 64-bit event counters.
• If EL2 is implemented, the HDCR.HCCD control.
• If EL3 is implemented, the SDCR.SCCD control.

0b0111  PMUv3 for Armv8.7. As 0b0110, and adds support for:
  • The PMCR.FZO and, if EL2 is implemented, HPCR.HPMFZO controls.
  • If EL3 is implemented and using AArch64, the MDCR_EL3.{MPMX,MCCD} controls.

0b1000  PMUv3 for Armv8.8. As 0b0111, and:
  • Extends the Common event number space to include 0x0040 to 0x00BF and 0x4040 to 0x40BF.
  • Removes the CONSTRANGED UNPREDICTABLE behaviors if a reserved or unimplemented PMU event number is selected.

0b1111  IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value for new implementations.

All other values are reserved.

FEAT_PMUv3 implements the functionality identified by the value 0b0011.
FEAT_PMUv3p1 implements the functionality identified by the value 0b0100.
FEAT_PMUv3p4 implements the functionality identified by the value 0b0101.
FEAT_PMUv3p5 implements the functionality identified by the value 0b0110.
FEAT_PMUv3p7 implements the functionality identified by the value 0b0111.
FEAT_PMUv3p8 implements the functionality identified by the value 0b1000.

In any Armv8 implementation, the values 0b0001 and 0b0010 are not permitted.
From Armv8.1, if FEAT_PMUv3 is implemented, the value 0b0011 is not permitted.
From Armv8.4, if FEAT_PMUv3 is implemented, the value 0b0100 is not permitted.
From Armv8.5, if FEAT_PMUv3 is implemented, the value 0b0101 is not permitted.
From Armv8.7, if FEAT_PMUv3 is implemented, the value 0b0110 is not permitted.
From Armv8.8, if FEAT_PMUv3 is implemented, the value 0b0111 is not permitted.

Note

PMUv1 and PMUv2 are not permitted in an Armv8 implementation.

MPProfDbg, bits [23:20]
M-profile Debug. Support for memory-mapped debug model for M-profile processors. Defined values are:
  0b0000  Not supported.
  0b0001  Support for M-profile Debug architecture, with memory-mapped access.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

MMapTrc, bits [19:16]
Memory-mapped Trace. Support for memory-mapped trace model. Defined values are:
  0b0000  Not supported.
  0b0001  Support for Arm trace architecture, with memory-mapped access.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.
For more information, see the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064).
CopTrc, bits [15:12]
Support for System registers-based trace model, using registers in the coproc == 0b1110 encoding space. Defined values are:

- 0b0000  Not supported.
- 0b0001  Support for Arm trace architecture, with System registers access.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.
For more information, see the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064).

MMapDbg, bits [11:8]
Memory-mapped Debug. Support for Armv7 memory-mapped debug model for A and R-profile processors. Defined values are:

- 0b0000  Not supported.
- 0b0100  Support for Armv7, v7 Debug architecture, with memory-mapped access.
- 0b0101  Support for Armv7, v7.1 Debug architecture, with memory-mapped access.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.
The optional memory map defined by Armv8 is not compatible with Armv7.

CopSDbg, bits [7:4]
Support for a System registers-based Secure debug model, using registers in the coproc == 0b1110 encoding space, for an A-profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-secure state, this field is RES0. Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]
Debug architecture version. Indicates presence of Armv8 debug architecture. Defined values are:

- 0b0000  Not supported.
- 0b0010  Armv6, v6 Debug architecture, with System registers access.
- 0b0011  Armv6, v6.1 Debug architecture, with System registers access.
- 0b0100  Armv7, v7 Debug architecture, with System registers access.
- 0b0101  Armv7, v7.1 Debug architecture, with System registers access.
- 0b0110  Armv8 debug architecture.
- 0b0111  Armv8 debug architecture with Virtualization Host Extensions.
- 0b1000  Armv8.2 debug architecture, FEAT_Debugv8p2.
- 0b1001  Armv8.4 debug architecture, FEAT_Debugv8p4.
- 0b1010  Armv8.8 debug architecture, FEAT_Debugv8p8.

All other values are reserved.
The values 0b0000, 0b0010, 0b0011, 0b0100, and 0b0101 are not permitted in Armv8.
FEAT_VHE adds the functionality identified by the value 0b0011.
FEAT_Debugv8p2 adds the functionality identified by the value 0b1000.
FEAT_Debugv8p4 adds the functionality identified by the value 0b1001.
FEAT_Debugv8p8 adds the functionality identified by the value 0b1010.
From Armv8.1, when FEAT_VHE is implemented the value 0b0110 is not permitted.
From Armv8.2, the values 0b0110 and 0b0111 are not permitted.
From Armv8.4, the value 0b1000 is not permitted.
From Armv8.8, the value 0b1001 is not permitted.

**Accessing ID_DFR0**

Accesses to this register use the following encodings in the System register encoding space:

\[

ID_DFR1, Debug Feature Register 1

The ID_DFR1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_DFR1 bits [31:0] are architecturally mapped to AArch64 System register ID_DFR1_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_DFR1 are UNDEFINED.

**Note**

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

**Attributes**

ID_DFR1 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>HPMN0</td>
</tr>
<tr>
<td>4</td>
<td>MTPMU</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**HPMN0, bits [7:4]**

Zero PMU event counters for a Guest operating system. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Setting HDCR.HPMN to zero has CONSTRAINED UNPREDICTABLE behavior.</td>
</tr>
<tr>
<td>0b0001</td>
<td>Setting HDCR.HPMN to zero has defined behavior.</td>
</tr>
</tbody>
</table>

All other values are reserved.

If FEAT_PMUv3 is not implemented, FEAT_FGT is not implemented, or EL2 is not implemented, the only permitted value is 0b0000.

FEAT_HPMN0 implements the functionality identified by the value 0b0001.

From Armv8.8, in an implementation that includes FEAT_PMUv3, FEAT_FGT, and EL2, the value 0b0000 is not permitted.

**MTPMU, bits [3:0]**

Multi-threaded PMU extension. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>FEAT_MTPMU not implemented. If FEAT_PMUv3 is implemented, it is IMPLEMENTATION DEFINED whether PMEVTYPER&lt;\n&gt;.MT are read/write or RES0.</td>
</tr>
<tr>
<td>0b0001</td>
<td>FEAT_MTPMU and FEAT_PMUv3 implemented. PMEVTYPER&lt;\n&gt;.MT are read/write. When FEAT_MTPMU is disabled, the Effective values of PMEVTYPER&lt;\n&gt;.MT are 0.</td>
</tr>
<tr>
<td>0b1111</td>
<td>FEAT_MTPMU not implemented. If FEAT_PMUv3 is implemented, PMEVTYPER&lt;\n&gt;.MT are RES0.</td>
</tr>
</tbody>
</table>

All other values are reserved.
FEAT_MTPMU implements the functionality identified by the value 0b0001.
From Armv8.6, in an implementation that includes FEAT_PMUv3, the value 0b0000 is not permitted.
In an implementation that does not include FEAT_PMUv3, the value 0b0001 is not permitted.

Accessing ID_DFR1
Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{<c>\}{<q>\} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>\{, {#}<opc2>\} \]

ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_ISAR0 bits [31:0] are architecturally mapped to AArch64 System register ID_ISAR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_ISAR0 are UNDEFINED.

**Attributes**

ID_ISAR0 is a 32-bit register.

**Field descriptions**

</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**Divide, bits [27:24]**

Indicates the implemented Divide instructions. Defined values are:

0b0000  None implemented.

0b0001  Adds SDIV and UDIV in the T32 instruction set.

0b0010  As for 0b0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0010.

**Debug, bits [23:20]**

Indicates the implemented Debug instructions. Defined values are:

0b0000  None implemented.

0b0001  Adds BKPT.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0001.

**Coproc, bits [19:16]**

Indicates the implemented System register access instructions. Defined values are:

0b0000  None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.

0b0001  Adds generic CDP, LDC, MCR, MRC, and STC.

0b0010  As for 0b0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.

0b0011  As for 0b0010, and adds generic MCRR and MRRC.
0b0100  As for 0b0011, and adds generic MCRR2 and MRRC2.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**CmpBranch, bits [15:12]**
Indicates the implemented combined Compare and Branch instructions in the T32 instruction set.
Defined values are:
0b0000  None implemented.
0b0001  Adds CBNZ and CBZ.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**BitField, bits [11:8]**
Indicates the implemented BitField instructions. Defined values are:
0b0000  None implemented.
0b0001  Adds BFC, BFI, SBFX, and UBFX.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**BitCount, bits [7:4]**
Indicates the implemented Bit Counting instructions. Defined values are:
0b0000  None implemented.
0b0001  Adds CLZ.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**Swap, bits [3:0]**
Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
0b0000  None implemented.
0b0001  Adds SWP and SWPB.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**Accessing ID_ISAR0**
Accesses to this register use the following encodings in the System register encoding space:

```plaintext

</tr>
</tbody>
</table>
• The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.
In Armv8-A, the only permitted value is \texttt{0b0001}.

\textbf{IfThen, bits [19:16]}

Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:

\begin{itemize}
  \item \texttt{0b0000}  None implemented.
  \item \texttt{0b0001}  Adds the IT instructions, and the IT bits in the PSRs.
\end{itemize}

All other values are reserved.
In Armv8-A, the only permitted value is \texttt{0b0001}.

\textbf{Extend, bits [15:12]}

Indicates the implemented Extend instructions. Defined values are:

\begin{itemize}
  \item \texttt{0b0000}  No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
  \item \texttt{0b0001}  Adds the SXTB, SXTH, UXTB, and UXTH instructions.
  \item \texttt{0b0010}  As for \texttt{0b0001}, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.
\end{itemize}

All other values are reserved.
In Armv8-A, the only permitted value is \texttt{0b0010}.

\textbf{Except_AR, bits [11:8]}

Indicates the implemented A and R-profile exception-handling instructions. Defined values are:

\begin{itemize}
  \item \texttt{0b0000}  None implemented.
  \item \texttt{0b0001}  Adds the SRS and RFE instructions, and the A and R-profile forms of the CPS instruction.
\end{itemize}

All other values are reserved.
In Armv8-A, the only permitted value is \texttt{0b0001}.

\textbf{Except, bits [7:4]}

Indicates the implemented exception-handling instructions in the A32 instruction set. Defined values are:

\begin{itemize}
  \item \texttt{0b0000}  Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
  \item \texttt{0b0001}  Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.
\end{itemize}

All other values are reserved.
In Armv8-A, the only permitted value is \texttt{0b0001}.

\textbf{Endian, bits [3:0]}

Indicates the implemented Endian instructions. Defined values are:

\begin{itemize}
  \item \texttt{0b0000}  None implemented.
  \item \texttt{0b0001}  Adds the SETEND instruction, and the E bit in the PSRs.
\end{itemize}

All other values are reserved.
In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0001}.

**Reversal, bits [31:28]**

Indicates the implemented Reversal instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the REV, REV16, and REVSH instructions.
- 0b0010: As for 0b0001, and adds the RBIT instruction.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.

**PSR_AR, bits [27:24]**

Indicates the implemented A and R-profile instructions to manipulate the PSR. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.
The exception return forms of the data-processing instructions are:
- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

**MultU, bits [23:20]**

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the UMULL and UMLAL instructions.
- 0b0010: As for 0b0001, and adds the UMAAL instruction.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.

**MultS, bits [19:16]**
Indicates the implemented advanced signed Multiply instructions. Defined values are:

- **0b0000**: None implemented.
- **0b0001**: Adds the SMULL and SMLAL instructions.
- **0b0010**: As for 0b0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULWT, SMLULB, SMLULT, SMLUTB, SMLWBT, and SMULWT instructions. Also adds the Q bit in the PSRs.
- **0b0011**: As for 0b0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSDX, SMLSLD, SMLSDLX, SMLLA, SMLRAR, SMMLS, SMMLSR, SMMLUL, SMMLULR, SMMUL, SMMULR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0011.

**Mult, bits [15:12]**
Indicates the implemented additional Multiply instructions. Defined values are:

- **0b0000**: No additional instructions implemented. This means only MUL is implemented.
- **0b0001**: Adds the MLA instruction.
- **0b0010**: As for 0b0001, and adds the MLS instruction.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.

**MultiAccessInt, bits [11:8]**
Indicates the support for interruptible multi-access instructions. Defined values are:

- **0b0000**: No support. This means the LDM and STM instructions are not interruptible.
- **0b0001**: LDM and STM instructions are restartable.
- **0b0010**: LDM and STM instructions are continuable.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**MemHint, bits [7:4]**
Indicates the implemented Memory Hint instructions. Defined values are:

- **0b0000**: None implemented.
- **0b0001**: Adds the PLD instruction.
- **0b0010**: Adds the PLD instruction. (0b0001 and 0b0010 have identical effects.)
- **0b0011**: As for 0b0001 (or 0b0010), and adds the PLI instruction.
- **0b0100**: As for 0b0011, and adds the PLDW instruction.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0100.

**LoadStore, bits [3:0]**
Indicates the implemented additional load/store instructions. Defined values are:

- **0b0000**: No additional load/store instructions implemented.
- **0b0001**: Adds the LDRD and STRD instructions.
As for 0b0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0010.

### Accessing ID_ISAR2

Accesses to this register use the following encodings in the System register encoding space:

\[

G8.2.88  ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.
Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5.
For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_ISAR3 bits [31:0] are architecturally mapped to AArch64 System register ID_ISAR3_EL1[31:0].
This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_ISAR3 are UNDEFINED.

**Attributes**

ID_ISAR3 is a 32-bit register.

</tbody>
</table>

**T32EE, bits [31:28]**

Indicates the implemented T32EE instructions. Defined values are:

- 0b0000  None implemented.
- 0b0001  Adds the ENTERX and LEA VEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**TrueNOP, bits [27:24]**

Indicates the implemented true NOP instructions. Defined values are:

- 0b0000  None implemented. This means there are no NOP instructions that do not have any register dependencies.
- 0b0001  Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**T32Copy, bits [23:20]**

Indicates the support for T32 non flag-setting MOV instructions. Defined values are:

- 0b0000  Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.
- 0b0001  Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.
TabBranch, bits [19:16]
Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

0b0000  None implemented.
0b0001  Adds the TBB and TBH instructions.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

SynchPrim, bits [15:12]
Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

0b0000  If SynchPrim_frac == 0b000, no Synchronization Primitives implemented.
0b0001  If SynchPrim_frac == 0b000, adds the LDREX and STREX instructions.
         If SynchPrim_frac == 0b011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.
0b0010  If SynchPrim_frac == 0b000, as for [0b001, 0b011] and also adds the LDREXD and STREXD instructions.
All other combinations of SynchPrim and SynchPrim_frac are reserved.
In Armv8-A, the only permitted value is 0b0010.

SVC, bits [11:8]
Indicates the implemented SVC instructions. Defined values are:

0b0000  Not implemented.
0b0001  Adds the SVC instruction.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

SIMD, bits [7:4]
Indicates the implemented SIMD instructions. Defined values are:

0b0000  None implemented.
0b0001  Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
0b0011  As for 0b0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0011.
The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports Advanced SIMD and floating-point instructions, MVFR0, MVFR1, and MVFR2 give information about the implemented Advanced SIMD instructions.

Saturate, bits [3:0]
Indicates the implemented Saturate instructions. Defined values are:

0b0000  None implemented. This means no non-Advanced SIMD saturate instructions are implemented.
0b0001  Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**Accessing ID_ISAR3**

G8.2.89 **ID_ISAR4, Instruction Set Attribute Register 4**

The ID_ISAR4 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_ISAR4 bits [31:0] are architecturally mapped to AArch64 System register ID_ISAR4_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_ISAR4 are UNDEFINED.

**Attributes**

ID_ISAR4 is a 32-bit register.

**Field descriptions**

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| SWP_frac | PSR_M | Barrier | SMC | | | | | | | | | | | | | | | | | | | | | |
| SynchPrim_frac | | WithShifts | | Writeback |

**SWP_frac, bits [31:28]**

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

- 0b0000: SWP or SWPB instructions not implemented.
- 0b0001: SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other Requesters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if ID_ISAR0.Swap is 0b0000.

In Armv8-A, the only permitted value is 0b0000.

**PSR_M, bits [27:24]**

Indicates the implemented M-profile instructions to modify the PSRs. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the M-profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0000.

**SynchPrim_frac, bits [23:20]**

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- 0b0000: If SynchPrim == 0b0000, no Synchronization Primitives implemented. If SynchPrim == 0b0001, adds the LDREX and STREX instructions. If SynchPrim == 0b0010, also adds the CLREX, LDREXB, LDREXH, STREX, STREXB, STREXH, LDREXD, and STREXD instructions.
- 0b0011: If SynchPrim == 0b0011, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.
All other combinations of SynchPrim and SynchPrim_frc are reserved.  
In Armv8-A, the only permitted value is 0b0000.

**Barrier, bits [19:16]**

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:
- 0b0000: None implemented. Barrier operations are provided only as System instructions in the (coproc==0b1111) encoding space.
- 0b0001: Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**SMC, bits [15:12]**

Indicates the implemented SMC instructions. Defined values are:
- 0b0000: None implemented.
- 0b0001: Adds the SMC instruction.

All other values are reserved.
In Armv8-A, the permitted values are:
- If EL3 is implemented, the only permitted value is 0b0001.
- If neither EL3 nor EL2 is implemented, the only permitted value is 0b0000.

**Writeback, bits [11:8]**

Indicates the support for Writeback addressing modes. Defined values are:
- 0b0000: Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- 0b0001: Adds support for all of the writeback addressing modes.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**WithShifts, bits [7:4]**

Indicates the support for instructions with shifts. Defined values are:
- 0b0000: Nonzero shifts supported only in MOV and shift instructions.
- 0b0001: Adds support for shifts of loads and stores over the range LSL 0-3.
- 0b0011: As for 0b0001, and adds support for other constant shift options, both on load/store and other instructions.
- 0b0100: As for 0b0011, and adds support for register-controlled shift options.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0100.

**Unpriv, bits [3:0]**

Indicates the implemented unprivileged instructions. Defined values are:
- 0b0000: None implemented. No T variant instructions are implemented.
- 0b0001: Adds the LDRBT, LDRT, STRBT, and STRT instructions.
- 0b0010: As for 0b0001, and adds the LDRHT, LDSRBT, LDRSHT, and STRHT instructions.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.
Accessing ID_ISAR4

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC{<c>}{<q>} \coproc, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

\[
\begin{array}{c|c|c|c|c}

    AArch32.TakeHypTrapException(0x03);
  else
    R[t] = ID_ISAR4;
  endif
elsif PSTATE.EL == EL2 then
  R[t] = ID_ISAR4;
elsif PSTATE.EL == EL3 then
  R[t] = ID_ISAR4;
G8.2.90  ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.
Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.
For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-9332.

Configurations

AArch32 System register ID_ISAR5 bits [31:0] are architecturally mapped to AArch64 System register ID_ISAR5_EL1[31:0].
This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_ISAR5 are UNDEFINED.

Attributes

ID_ISAR5 is a 32-bit register.

Field descriptions

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| VCMA | RDM | RES0 | CRC32 | SHA2 | SHA1 | AES | SEVL |

VCMA, bits [31:28]

Indicates AArch32 support for complex number addition and multiplication where numbers are stored in vectors. Defined values are:

0b0000  The VCMLA and VCADD instructions are not implemented in AArch32.
0b0001  The VCMLA and VCADD instructions are implemented in AArch32.
All other values are reserved.
FEAT_FCMA implements the functionality identified by 0b0001.
From Armv8.3, the only permitted value is 0b0001.

RDM, bits [27:24]

Indicates support for the VQRDMLAH and VQRDMLSH instructions in AArch32 state. Defined values are:

0b0000  No VQRDMLAH and VQRDMLSH instructions implemented.
0b0001  VQRDMLAH and VQRDMLSH instructions implemented.
All other values are reserved.
FEAT_RDM implements the functionality identified by the value 0b0001.
From Armv8.1, the only permitted value is 0b0001.

Bits [23:20]

Reserved, RES0.

CRC32, bits [19:16]

Indicates support for the CRC32 instructions in AArch32 state. Defined values are:

0b0000  No CRC32 instructions implemented.
0b0001  CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.
All other values are reserved.
In Armv8.0, the permitted values are 0b0000 and 0b0001.
From Armv8.1, the only permitted value is 0b0001.

**SHA2, bits [15:12]**
Indicates support for the SHA2 instructions in AArch32 state.
- 0b0000  No SHA2 instructions implemented.
- 0b0001  SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

**SHA1, bits [11:8]**
Indicates support for the SHA1 instructions are implemented in AArch32 state. Defined values are:
- 0b0000  No SHA1 instructions implemented.
- 0b0001  SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0010.

**AES, bits [7:4]**
Indicates support for the AES instructions in AArch32 state. Defined values are:
- 0b0000  No AES instructions implemented.
- 0b0001  AESE, AESD, AESMC, and AESIMC implemented.
- 0b0010  As for 0b0001, plus VMULL (polynomial) instructions operating on 64-bit data quantities.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0010.

**SEVL, bits [3:0]**
Indicates support for the SEVL instruction in AArch32 state. Defined values are:
- 0b0000  SEVL is implemented as a NOP.
- 0b0001  SEVL is implemented as Send Event Local.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

**Accessing ID_ISAR5**
Accesses to this register use the following encodings in the System register encoding space:

G8.2.91  ID_ISAR6, Instruction Set Attribute Register 6

The ID_ISAR6 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_ISAR6 bits [31:0] are architecturally mapped to AArch64 System register ID_ISAR6_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_ISAR6 are UNDEFINED.

--- **Note** ---

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

**Attributes**

ID_ISAR6 is a 32-bit register.

**Field descriptions**

</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**I8MM, bits [27:24]**

Indicates support for Advanced SIMD and floating-point Int8 matrix multiplication instructions in AArch32 state. Defined values are:

- 0b0000: Int8 matrix multiplication instructions are not implemented.
- 0b0001: VSMMLA, VSUDOT, VUMMLA, VUSMMLA, and VUSDOT instructions are implemented.

All other values are reserved.

FEAT_AA32I8MM implements the functionality identified by 0b0001.

From Armv8.2, the permitted values are 0b0000 and 0b0001.

**BF16, bits [23:20]**

Indicates support for Advanced SIMD and floating-point BFloat16 instructions in AArch32 state. Defined values are:

- 0b0000: BFloat16 instructions are not implemented.
- 0b0001: VCVT, VCVTB, VCVTT, VDOT, VFMA, VFMA, and VMLA instructions with BFloat16 operand or result types are implemented.

All other values are reserved.

FEAT_AA32BF16 implements the functionality identified by 0b0001.
From Armv8.2, the permitted values are 0b0000 and 0b0001.

**SPECRES, bits [19:16]**
Indicates support for Speculation invalidation instructions in AArch32 state. Defined values are:
- 0b0000  CFPRCTX, DVPRCTX, and CPPRCTX instructions are not implemented.
- 0b0001  CFPRCTX, DVPRCTX, and CPPRCTX instructions are implemented.
All other values are reserved.
From Armv8.5, the only permitted value is 0b0001.

**SB, bits [15:12]**
Indicates support for SB instruction in AArch32 state. Defined values are:
- 0b0000  SB instruction is not implemented.
- 0b0001  SB instruction is implemented.
All other values are reserved.
From Armv8.5, the only permitted value is 0b0001.

**FHM, bits [11:8]**
Indicates support for Advanced SIMD and floating-point VFMAL and VFMSL instructions in AArch32 state. Defined values are:
- 0b0000  VFMAL and VMFSL instructions not implemented.
- 0b0001  VFMAL and VMFSL instructions implemented.
FEAT_FHM implements the functionality identified by the value 0b0001.

**DP, bits [7:4]**
Indicates support for dot product instructions in AArch32 state. Defined values are:
- 0b0000  No dot product instructions implemented.
- 0b0001  VUDOT and VSDOT instructions implemented.
All other values are reserved.
FEAT_DotProd implements the functionality identified by the value 0b0001.

**JSCVT, bits [3:0]**
Indicates support for the Javascript conversion instruction in AArch32 state. Defined values are:
- 0b0000  The VJCVT instruction is not implemented.
- 0b0001  The VJCVT instruction is implemented.
All other values are reserved.
In Armv8.0, the only permitted value is 0b0000.
FEAT_JSCVT implements the functionality identified by 0b0001.
From Armv8.3, if Advanced SIMD or Floating-point is implemented, the only permitted value is 0b0001.
From Armv8.3, if Advanced SIMD or Floating-point is not implemented, the only permitted value is 0b0000.

**Accessing ID_ISAR6**
Accesses to this register use the following encodings in the System register encoding space:
# MRC{<c>}{<q>} <coproc>, {#<opc1>, <Rt>, <CRn>, <CRm>{, {#<opc2>}

\[
\begin{array}{cccccc}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} & \text{opc2} \\
0b1111 & 0b000 & 0b0000 & 0b0010 & 0b111
\end{array}
\]

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && ELUsingAArch32(EL2) && HSTR_EL2.T0 == '1' then

        R[t] = ID_ISAR6;
    \end{if}

G8.2.92  ID_MMFR0, Memory Model Feature Register 0

The ID_MMFR0 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_MMFR0 bits [31:0] are architecturally mapped to AArch64 System register ID_MMFR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_MMFR0 are UNDEFINED.

**Attributes**

ID_MMFR0 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field Description</th>

</tr>
</tbody>
</table>

**InnerShr, bits [31:28]**

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- **0b0000**: Implemented as Non-cacheable.
- **0b0001**: Implemented with hardware coherency support.
- **0b1111**: Shareability ignored.
- All other values are reserved.

In Armv8-A, the permitted values are **0b0000**, **0b0001**, and **0b1111**.

This field is valid only if the implementation supports two levels of shareability, as indicated by ID_MMFR0.ShareLvl having the value **0b0001**.

When ID_MMFR0.ShareLvl is zero, this field is **UNKNOWN**.

**FCSE, bits [27:24]**

Indicates whether the implementation includes the FCSE. Defined values are:

- **0b0000**: Not supported.
- **0b0001**: Support for FCSE.
- All other values are reserved.

In Armv8-A, the only permitted value is **0b0000**.

**AuxReg, bits [23:20]**

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

- **0b0000**: None supported.
- **0b0001**: Support for Auxiliary Control Register only.
- **0b0010**: Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.
- All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.

--- Note ---
Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]
Indicates support for TCMs and associated DMAs. Defined values are:
0b0000  Not supported.
0b0001  Support is IMPLEMENTATION DEFINED.
0b0010  Support for TCM only, Armv6 implementation.
0b0011  Support for TCM and DMA, Armv6 implementation.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

ShareLvl, bits [15:12]
Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:
0b0000  One level of shareability implemented.
0b0001  Two levels of shareability implemented.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

OuterShr, bits [11:8]
Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:
0b0000  Implemented as Non-cacheable.
0b0001  Implemented with hardware coherency support.
0b1111  Shareability ignored.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000, 0b0001, and 0b1111.

PMSA, bits [7:4]
Indicates support for a PMSA. Defined values are:
0b0000  Not supported.
0b0001  Support for IMPLEMENTATION DEFINED PMSA.
0b0010  Support for PMSAv6, with a Cache Type Register implemented.
0b0011  Support for PMSAv7, with support for memory subsections. Armv7-R profile.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

VMSA, bits [3:0]
Indicates support for a VMSA. Defined values are:
0b0000  Not supported.
0b0001  Support for IMPLEMENTATION DEFINED VMSA.
0b0010  Support for VMSAv6, with Cache and TLB Type Registers implemented.
0b0011  Support for VMSAv7, with support for remapping and the Access flag. Armv7-A profile.
0b0100  As for 0b0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
As for 0b0100, and adds support for the Long-descriptor translation table format. All other values are reserved.

In Armv8-A, the only permitted value is 0b0101.

**Accessing ID_MMFR0**

Accesses to this register use the following encodings in the System register encoding space:

BPred, bits [31:28]

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

0b0000  No branch predictor, or no MMU present. Implies a fixed MPU configuration.

0b0001  Branch predictor requires flushing on:
                          • Enabling or disabling a stage of address translation.
                          • Writing new data to instruction locations.
                          • Writing new mappings to the translation tables.
                          • Changes to the TTBR0, TTBR1, or TTBCR registers.
                          • Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.

0b0100  Branch predictor requires flushing on:
                          • Enabling or disabling a stage of address translation.
                          • Writing new data to instruction locations.
                          • Writing new mappings to the translation tables.
                          • Any change to the TTBR0, TTBR1, or TTBCR registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.

0b0111  Branch predictor requires flushing only on writing new data to instruction locations.

0b0100  For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In Armv8-A, the permitted values are 0b0010, 0b0011, or 0b0100. For values other than 0b0000 and 0b0100, the Arm Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.
L1TstCln, bits [27:24]
Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

0b0000  None supported.
0b0001  Supported Level 1 data cache test and clean operations are:
       •  Test and clean data cache.
0b0010  As for 0b0001, and adds:
       •  Test, clean, and invalidate data cache.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1Uni, bits [23:20]
Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

0b0000  None supported.
0b0001  Supported entire Level 1 cache operations are:
       •  Invalidate cache, including branch predictor if appropriate.
       •  Invalidate branch predictor, if appropriate.
0b0010  As for 0b0001, and adds:
       •  Clean cache, using a recursive model that uses the cache dirty status bit.
       •  Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1Hvd, bits [19:16]
Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

0b0000  None supported.
0b0001  Supported entire Level 1 cache operations are:
       •  Invalidate instruction cache, including branch predictor if appropriate.
       •  Invalidate branch predictor, if appropriate.
0b0010  As for 0b0001, and adds:
       •  Invalidate data cache.
       •  Invalidate data cache and instruction cache, including branch predictor if appropriate.
0b0011  As for 0b0010, and adds:
       •  Clean data cache, using a recursive model that uses the cache dirty status bit.
       •  Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1UniSW, bits [15:12]
Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

0b0000  None supported.
0b0001  Supported Level 1 unified cache line maintenance operations by set/way are:
  • Clean cache line by set/way.

0b0010  As for 0b0001, and adds:
  • Clean and invalidate cache line by set/way.

0b0011  As for 0b0010, and adds:
  • Invalidate cache line by set/way.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1HvdSW, bits [11:8]
Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 Harvard cache line maintenance operations by set/way are:
  • Clean data cache line by set/way.
  • Clean and invalidate data cache line by set/way.

0b0010  As for 0b0001, and adds:
  • Invalidate data cache line by set/way.

0b0011  As for 0b0010, and adds:
  • Invalidate instruction cache line by set/way.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1UniVA, bits [7:4]
Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 unified cache line maintenance operations by VA are:
  • Clean cache line by VA.
  • Invalidate cache line by VA.
  • Clean and invalidate cache line by VA.

0b0010  As for 0b0001, and adds:
  • Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

L1HvdVA, bits [3:0]
Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 Harvard cache line maintenance operations by VA are:
  • Clean data cache line by VA.
  • Invalidate data cache line by VA.
  • Clean and invalidate data cache line by VA.
  • Clean instruction cache line by VA.

0b0010  As for 0b0001, and adds:
  • Invalidate branch predictor by VA, if branch predictor is implemented.
All other values are reserved.

In Armv8-A, the only permitted value is 0b0000.

### Accessing ID_MMFR1

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}>, \{#<\text{opc1}>\}, \text{<Rt>}, \text{<CRn>}, \text{<CRm>}, \{#<\text{opc2}>\}

    R[t] = ID_MMFR1;
```
G8.2.94 ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_MMFR2 bits [31:0] are architecturally mapped to AArch64 System register ID_MMFR2_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_MMFR2 are UNDEFINED.

**Attributes**

ID_MMFR2 is a 32-bit register.

**Field descriptions**

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| HWAccFlg | WFIStall | MemBarr | UniTLB | HvdTLB | L1HvdRng | L1HvdBG | L1HvdFG |

**HWAccFlg, bits [31:28]**

Hardware Access Flag. In earlier versions of the Arm Architecture, this field indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Defined values are:

- **0b0000** Not supported.
- **0b0001** Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

In Armv8-A, the only permitted value is **0b0000**.

**WFIStall, bits [27:24]**

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

- **0b0000** Not supported.
- **0b0001** Support for WFI stalling.

All other values are reserved.

In Armv8-A, the permitted values are **0b0000** and **0b0001**.

**MemBarr, bits [23:20]**

Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc == 1111) encoding space. Defined values are:

- **0b0000** None supported.
- **0b0001** Supported memory barrier System instructions are:
  - Data Synchronization Barrier (DSB).
- **0b0010** As for 0b0001, and adds:
  - Instruction Synchronization Barrier (ISB).
  - Data Memory Barrier (DMB).

All other values are reserved.
In Armv8-A, the only permitted value is 0b0010.
Arm deprecates the use of these operations. ID_ISAR4.Barrier_instrs indicates the level of support for the preferred barrier instructions.

**UniTLB, bits [19:16]**

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

- **0b0000** Not supported.
- **0b0001** Supported unified TLB maintenance operations are:
  - Invalidate all entries in the TLB.
  - Invalidate TLB entry by VA.
- **0b0010** As for 0b0001, and adds:
  - Invalidate TLB entries by ASID match.
- **0b0011** As for 0b0010, and adds:
  - Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation
- **0b0100** As for 0b0011, and adds:
  - Invalidate Hyp mode unified TLB entry by VA.
  - Invalidate entire Non-secure PL1&0 unified TLB.
  - Invalidate entire Hyp mode unified TLB.
- **0b0101** As for 0b0100, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL,TLBIMVALH.
- **0b0110** As for 0b0101, and adds the following operations: TLBIIIPAS2IS, TLBIIIPAS2LIS, TLBIIIPAS2, TLBIIIPAS2L.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0110.

**HvdTLB, bits [15:12]**

If the value of ID_MMFR2.UniTLB is not 0b0000, then the meaning of this field is IMPLEMENTATION DEFINED. Arm deprecates the use of this field by software.

**L1HvdRng, bits [11:8]**

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

- **0b0000** Not supported.
- **0b0001** Supported Level 1 Harvard cache maintenance range operations are:
  - Invalidate data cache range by VA.
  - Invalidate instruction cache range by VA.
  - Clean data cache range by VA.
  - Clean and invalidate data cache range by VA.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0000.

**L1HvdBG, bits [7:4]**

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:

- **0b0000** Not supported.
Supported Level 1 Harvard cache background fetch operations are:
- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**L1HvdFG, bits [3:0]**
Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:
- 0b0000 Not supported.
- 0b0001 Supported Level 1 Harvard cache foreground fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

**Accessing ID_MMFR2**
Accesses to this register use the following encodings in the System register encoding space:

$$MRC{<c>}{<q>}{<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}}$$

elsif PSTATE.EL == EL3 then
  R[t] = ID_MMFR2;
G8.2.95  ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-9332.

**Configurations**

AArch32 System register ID_MMFR3 bits [31:0] are architecturally mapped to AArch64 System register ID_MMFR3_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_MMFR3 are UNDEFINED.

**Attributes**

ID_MMFR3 is a 32-bit register.

**Field descriptions**

### Supersec, bits [31:28]

Supersections. On a VMSA implementation, indicates whether Supersections are supported.

Defined values are:

- **0b0000**  Supersections supported.
- **0b1111**  Supersections not supported.

All other values are reserved.

In Armv8-A, the permitted values are **0b0000** and **0b1111**.

### CMemSz, bits [27:24]

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

- **0b0000**  4GB, corresponding to a 32-bit physical address range.
- **0b0001**  64GB, corresponding to a 36-bit physical address range.
- **0b0010**  1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

In Armv8-A, the permitted values are **0b0000**, **0b0001**, and **0b0010**.

### CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the Point of Unification. Defined values are:

- **0b0000**  Updates to the translation tables require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.
- **0b0001**  Updates to the translation tables do not require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

In Armv8-A, the only permitted value is **0b0001**.
PAN, bits [19:16]

Privileged Access Never. Indicates support for the PAN bit in CPSR, SPSR, and DSPSR in AArch32 state. Defined values are:

- 0b0000  PAN not supported.
- 0b0001  PAN supported.
- 0b0010  PAN supported and ATS1CPRP and ATS1CPWP instructions supported.

All other values are reserved.

FEAT_PAN implements the functionality identified by the value 0b0001.

FEAT_PAN2 implements the functionality added by the value 0b0010.

In Armv8.1, the value 0b0000 is not permitted.

From Armv8.2, the only permitted value is 0b0010.

MaintBest, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:

- 0b0000  Cache, TLB, and branch predictor operations only affect local structures.
- 0b0001  Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0b0010  Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0010.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:

- 0b0000  None supported.
- 0b0001  Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- 0b0010  As for 0b0001, and adds:
  - Invalidate branch predictors by VA.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0010.

CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:

- 0b0000  None supported.
- 0b0001  Supported hierarchical cache maintenance instructions by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0001.

In a unified cache implementation, the data cache maintenance operations apply to the unified caches.
CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

0b0000  None supported.
0b0001  Supported hierarchical cache maintenance operations by VA are:
    • Invalidate data cache by VA.
    • Clean data cache by VA.
    • Clean and invalidate data cache by VA.
    • Invalidate instruction cache by VA.
    • Invalidate all instruction cache entries.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0001.
In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

Accessing ID_MMFR3

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} \ <coproc>, \{#\}<opc1>, \ <Rt>, \ <CRn>, \ <CRm>\{, \{#\}<opc2>\}
\]

G8.2.96  ID_MMFR4, Memory Model Feature Register 4

The ID_MMFR4 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_MMFR4 bits [31:0] are architecturally mapped to AArch64 System register ID_MMFR4_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_MMFR4 are UNDEFINED.

**Attributes**

ID_MMFR4 is a 32-bit register.

**Field descriptions**

| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| EVT | CCIDX | LSM | HPDS | CnP | XNX | AC2 | SpecSEI |

**EVT, bits [31:28]**

Enhanced Virtualization Traps. If EL2 is implemented, indicates support for the HCR2.{TTLBIS, TOCU, TICAB, TID4} traps. Defined values are:

- **0b0000**: HCR2.{TTLBIS, TOCU, TICAB, TID4} traps are not supported.
- **0b0001**: HCR2.{TOCU, TICAB, TID4} traps are supported. HCR2.TTLBIS trap is not supported.
- **0b0010**: HCR2.{TTLBIS, TOCU, TICAB, TID4} traps are supported.

All other values are reserved.

**FEAT_EVT** implements the functionality identified by the values **0b0001** and **0b0010**.

If EL2 is not implemented supporting AArch32, the only permitted value is **0b0000**.

In Armv8.2, the permitted values are **0b0000**, **0b0001**, and **0b0010**.

From Armv8.5, the permitted values are:

- **0b0000** when EL2 is not implemented or does not support AArch32.
- **0b0010** when EL2 is implemented and supports AArch32.

**CCIDX, bits [27:24]**

Support for use of the revised CCSIDR format and the presence of the CCSIDR2 is indicated. Defined values are:

- **0b0000**: 32-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is not implemented.
- **0b0001**: 64-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is implemented.

All other values are reserved.

**FEAT_CCIDX** implements the functionality identified by **0b0001**.

From Armv8.3, the permitted values are **0b0000** and **0b0001**.
LSM, bits [23:20]
Indicates support for LSMAOE and nTLSMD bits in HSCTLR and SCTLR. Defined values are:

- **0b0000**: LSMAOE and nTLSMD bits not supported.
- **0b0001**: LSMAOE and nTLSMD bits supported.

All other values are reserved.

**FEAT_LSMAOC** implements the functionality identified by the value **0b0001**.

From Armv8.2, the permitted values are **0b0000** and **0b0001**.

HPDS, bits [19:16]
Hierarchical permission disables bits in translation tables. Defined values are:

- **0b0000**: Disabling of hierarchical controls not supported.
- **0b0001**: Supports disabling of hierarchical controls using the TTBCR2.HPD0, TTBCR2.HPD1, and HTCR.HPD bits.
- **0b0100**: As for value **0b0001**, and adds possible hardware allocation of bits[62:59] of the Translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

**FEAT_AA32HPD** implements the functionality identified by the value **0b0001**.

**FEAT_HPDS2** implements the functionality added by the value **0b0100**.

--- **Note**

The value **0b0000** implies that the encoding for TTBCR2 is UNDEFINED.

---

CnP, bits [15:12]
Common not Private translations. Defined values are:

- **0b0000**: Common not Private translations not supported.
- **0b0001**: Common not Private translations supported.

All other values are reserved.

**FEAT_TTCNP** implements the functionality identified by the value **0b0001**.

From Armv8.2, the only permitted value is **0b0001**.

XNX, bits [11:8]
Support for execute-never control distinction by Exception level at stage 2. Defined values are:

- **0b0000**: Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
- **0b0001**: Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.

**FEAT_XNX** implements the functionality identified by the value **0b0001**.

When **FEAT_XNX** is implemented:

- If all of the following conditions are true, it is IMPLEMENTATION DEFINED whether the value of ID_MMFR4.XNX is **0b0000** or **0b0001**:
  - **ID_AA64MMFR1_EL1.XNX == 1**.
  - EL2 cannot use AArch32.
  - EL1 can use AArch32.
- If EL2 can use AArch32 then the only permitted value is **0b0001**.
AC2, bits [7:4]

Indicates the extension of the ACTLR and HACTLR registers using ACTLR2 and HACTLR2.
Defined values are:

0b0000  ACTLR2 and HACTLR2 are not implemented.
0b0001  ACTLR2 and HACTLR2 are implemented.

All other values are reserved.
In Armv8.0, the permitted values are 0b0000 and 0b0001.
From Armv8.2, the only permitted value is 0b0001.

SpecSEI, bits [3:0]

When FEAT_RAS is implemented:

- Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches.

  0b0000  The PE never generates an SError interrupt due to an External abort on a speculative read.

  0b0001  The PE might generate an SError interrupt due to an External abort on a speculative read.

All other values are reserved.

Otherwise:

- Reserved, RES0.

Accessing ID_MMFR4

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC} \text{<c>}{<q}> \text{<coproc>, (#}<opc1>, <Rt>, <CRn>, <CRm>{, (#}<opc2>}

### G8.2.97 ID_MMFR5, Memory Model Feature Register 5

The ID_MMFR5 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_MMFR5 bits [31:0] are architecturally mapped to AArch64 System register ID_MMFR5_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_MMFR5 are UNDEFINED.

**Attributes**

ID_MMFR5 is a 32-bit register.

**Field descriptions**

<table>

<td>ETS</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**nTLBPA, bits [7:4]**

Indicates support for intermediate caching of translation table walks. Defined values are:

- 0b0000: The intermediate caching of translation table walks might include non-coherent physical translation caches.
- 0b0001: The intermediate caching of translation table walks does not include non-coherent physical translation caches.

Non-coherent physical translation caches are non-coherent caches of previous valid translation table entries since the last completed relevant TLBI applicable to the PE, where either:

- The caching is indexed by the physical address of the location holding the translation table entry.
- The caching is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry.

All other values are reserved.

**ETS, bits [3:0]**

Indicates support for Enhanced Translation Synchronization. Defined values are:

- 0b0000: Enhanced Translation Synchronization is not supported.
- 0b0001: Enhanced Translation Synchronization is supported.

All other values are reserved.

From Armv8.0, the permitted values are 0b0000 and 0b0001.
From Armv8.7, the only permitted value is 0b0001.

**Accessing ID_MMFR5**

Accesses to this register use the following encodings in the System register encoding space:

G8.2.98  ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

**Purpose**

Gives top-level information about the instruction sets and other features supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_PFR0 bits [31:0] are architecturally mapped to AArch64 System register ID_PFR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_PFR0 are UNDEFINED.

**Attributes**

ID_PFR0 is a 32-bit register.

**Field descriptions**

**RAS, bits [31:28]**

RAS Extension version. Defined values are:

- 0b0000  No RAS Extension.
- 0b0001  RAS Extension implemented.
- 0b0010  FEAT_RASv1p1 implemented. As 0b0001, and adds support for additional ERXMISC<m> System registers.

Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS and support for the optional RAS Timestamp Extension.

All other values are reserved.

FEAT_RAS implements the functionality identified by the value 0b0001.

FEAT_RASv1p1 implements the functionality identified by the value 0b0010.

In Armv8.0 and Armv8.1, the permitted values are 0b0000 and 0b0001.

In Armv8.2, the only permitted value is 0b0001.

From Armv8.4, if FEAT_DoubleFault is implemented, the only permitted value is 0b0010.

From Armv8.4, when FEAT_DoubleFault is not implemented, and ERRIDR.NUM is 0, the permitted values are IMPLEMENTATION DEFINED 0b0001 or 0b010.

**Note**

When the value of this field is 0b0001, ID_PFR2.RAS_frac indicates whether FEAT_RASv1p1 is implemented.

**DIT, bits [27:24]**

Data Independent Timing. Defined values are:

- 0b0000  AArch32 does not guarantee constant execution time of any instructions.
AArch32 provides the PSTATE.DIT mechanism to guarantee constant execution time of certain instructions.

All other values are reserved.

FEAT_DIT implements the functionality identified by the value 0b0001.

From Armv8.4, the only permitted value is 0b0001.

**AMU, bits [23:20]**

Indicates support for Activity Monitors Extension. Defined values are:

- 0b0000: Activity Monitors Extension is not implemented.
- 0b0001: FEAT_AMUv1 is implemented.
- 0b0010: FEAT_AMUv1p1 is implemented. As 0b0001 and adds support for virtualization of the activity monitor event counters.

All other values are reserved.

FEAT_AMUv1 implements the functionality identified by the value 0b0001.

FEAT_AMUv1p1 implements the functionality identified by the value 0b0010.

In Armv8.0, the only permitted value is 0b0000.

In Armv8.4, the permitted values are 0b0000 and 0b0001.

From Armv8.6, the permitted values are 0b0000, 0b0001, and 0b0010.

**CSV2, bits [19:16]**

Speculative use of out of context branch targets. Defined values are:

- 0b0000: The implementation does not disclose whether FEAT_CSV2 is implemented.
- 0b0001: FEAT_CSV2 is implemented, but FEAT_CSV2_1p1 is not implemented.
- 0b0010: FEAT_CSV2_1p1 is implemented.

All other values are reserved.

FEAT_CSV2 implements the functionality identified by the value 0b0001.

FEAT_CSV2_1p1 implements the functionality identified by the value 0b0010.

From Armv8.5, the permitted values are 0b0001 and 0b0010.

**State3, bits [15:12]**

T32EE instruction set support. Defined values are:

- 0b0000: Not implemented.
- 0b0001: T32EE instruction set implemented.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0000.

**State2, bits [11:8]**

Jazelle extension support. Defined values are:

- 0b0000: Not implemented.
- 0b0001: Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.
- 0b0010: Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0001.

**State1, bits [7:4]**

T32 instruction set support. Defined values are:

- 0b0000: T32 instruction set not implemented.
0b0001  T32 encodings before the introduction of Thumb-2 technology implemented:
  • All instructions are 16-bit.
  • A BL or BLX is a pair of 16-bit instructions.
  • 32-bit instructions other than BL and BLX cannot be encoded.

0b0011  T32 encodings after the introduction of Thumb-2 technology implemented, for all
  16-bit and 32-bit T32 basic instructions.

All other values are reserved.
In Armv8-A, the only permitted value is 0b0011.

State0, bits [3:0]
A32 instruction set support. Defined values are:
0b0000  A32 instruction set not implemented.
0b0001  A32 instruction set implemented.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0001.

Accessing ID_PFR0
Accesses to this register use the following encodings in the System register encoding space:

ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

**Purpose**

Gives information about the AArch32 programmers' model.

Must be interpreted with ID_PFR0.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register ID_PFR1 bits [31:0] are architecturally mapped to AArch64 System register ID_PFR1_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_PFR1 are UNDEFINED.

**Attributes**

ID_PFR1 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>20</th>
<th>19</th>

<td>GenTimer</td>
<td>MPrgMod</td>
<td>Security</td>
<td>ProgMod</td>
<td>GIC</td>
<td>Virt_frac</td>
<td>Virtualization</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**GIC, bits [31:28]**

System register GIC CPU interface. Defined values are:

- 0b0000  GIC CPU interface system registers not implemented.
- 0b0001  System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
- 0b0011  System register interface to version 4.1 of the GIC CPU interface is supported.

All other values are reserved.

**Virt_frac, bits [27:24]**

Virtualization fractional field. When the Virtualization field is 0b0000, determines the support for Virtualization Extensions. Defined values are:

- 0b0000  No Virtualization Extensions are implemented.
- 0b0001  The following Virtualization Extensions are implemented:
  - The SCR.SIF bit, if EL3 is implemented.
  - The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
  - The MSR (banked register) and MRS (banked register) instructions.
  - The ERET instruction.

All other values are reserved.

In Armv8-A, the permitted values are:

- 0b0000 when EL2 is implemented.
- 0b0001 when EL2 is not implemented.

This field is valid only when the value of ID_PFR1.Virtualization is 0, otherwise it holds the value 0b0000.
Note
The ID_ISAR registers do not identify whether the instructions added by the Virtualization Extensions are implemented.

Sec_frac, bits [23:20]
Security fractional field. When the Security field is 0b0000, determines the support for Security Extensions. Defined values are:

- 0b0000: No Security Extensions are implemented.
- 0b0001: The following Security Extensions are implemented:
  - The VBAR register.
  - The TTBCR.PD0 and TTBCR.PD1 bits.
- 0b0010: As for 0b0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In Armv8-A, the permitted values are:
- 0b0000 when EL3 is implemented.
- 0b0001 or 0b0010 when EL3 is not implemented.

This field is valid only when the value of ID_PFR1.Security is 0, otherwise it holds the value 0b0000.

GenTimer, bits [19:16]
Generic Timer support. Defined values are:

- 0b0000: Generic Timer is not implemented.
- 0b0001: Generic Timer is implemented.
- 0b0010: Generic Timer is implemented, and also includes support for CNTHCTL.EVTNIS and CNTKCTL.EVTNIS fields, and CNTPCTSS and CNTVCTSS counter views.

All other values are reserved.

FEAT_ECV implements the functionality identified by the value 0b0010.

In Armv8.0, the only permitted value is 0b0001.

From Armv8.6, the only permitted value is 0b0010.

Virtualization, bits [15:12]
Virtualization support. Defined values are:

- 0b0000: EL2, Hyp mode, and the HVC instruction not implemented.
- 0b0001: EL2, Hyp mode, the HVC instruction, and all the features described by Virt_fracli == 0b0001 implemented.

All other values are reserved.

In Armv8-A, the permitted values are:
- 0b0000 when EL2 is not implemented.
- 0b0001 when EL2 is implemented.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0b0001.

Note
The ID_ISARs do not identify whether the HVC instruction is implemented.
MProgMod, bits [11:8]

M-profile programmers' model support. Defined values are:

- 0b0000: Not supported.
- 0b0010: Support for two-stack programmers' model.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0000.

Security, bits [7:4]

Security support. Defined values are:

- 0b0000: EL3, Monitor mode, and the SMC instruction not implemented.
- 0b0001: EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0b0001 implemented.
- 0b0010: As for 0b0001, and adds the ability to set the NSACR.RFR bit. Not permitted in Armv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In Armv8-A, the permitted values are:

- 0b0000 when EL3 is not implemented.
- 0b0001 when EL3 is implemented.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0b0001.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

- 0b0000: Not supported.
- 0b0001: Supported.

All other values are reserved.

In Armv8-A, the only permitted value is 0b0001.

Accessing ID_PFR1

Accesses to this register use the following encodings in the System register encoding space:

<table>
<thead>

G8.2.100  ID_PFR2, Processor Feature Register 2

The ID_PFR2 characteristics are:

Purpose

Gives information about the AArch32 programmers' model.
Must be interpreted with ID_PFR0 and ID_PFR1.
For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-9332.

Configurations

AArch32 System register ID_PFR2 bits [31:0] are architecturally mapped to AArch64 System register ID_PFR2_EL1[31:0].
This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ID_PFR2 are UNDEFINED.

Attributes

ID_PFR2 is a 32-bit register.

Field descriptions

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>

<td>RAS_frac</td>
<td>SSBS</td>
<td>CSV3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:12]

Reserved, RES0.

RAS_frac, bits [11:8]

RAS Extension fractional field.
0b0000  If ID_PFR0.RAS == 0b0001, RAS Extension implemented.
0b0001  If ID_PFR0.RAS == 0b0001, as 0b0000 and adds support for additional ERXMISC<m> System registers.

Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS and support for the optional RAS Timestamp Extension.
All other values are reserved.

This field is valid only if ID_PFR0.RAS == 0b0001.

SSBS, bits [7:4]

Speculative Store Bypassing controls in AArch64 state. Defined values are:
0b0000  AArch32 provides no mechanism to control the use of Speculative Store Bypassing.
0b0001  AArch32 provides the PSTATE.SSBS mechanism to mark regions that are Speculative Store Bypass Safe.

In Armv8.0, the permitted values are 0b0000 and 0b0001.
From Armv8.5, the only permitted value is 0b0001.

All other values are reserved.
CSV3, bits [3:0]
Speculative use of faulting data. Defined values are:

0b0000  This PE does not disclose whether data loaded under speculation with a permission or domain fault can be used to form an address or generate condition codes or SVE predicate values to be used by other instructions in the speculative sequence.

0b0001  Data loaded under speculation with a permission or domain fault cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence. The execution timing of any other instructions in the speculative sequence is not a function of the data loaded under speculation.

All other values are reserved.
FEAT_CSV3 implements the functionality identified by the value 0b0001.
In Armv8.0, the permitted values are 0b0000 and 0b0001.
From Armv8.5, the only permitted value is 0b0001.
If FEAT_E0PD is implemented, FEAT_CSV3 must be implemented.

Accessing ID_PFR2

G8.2.101 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

**Purpose**
Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

**Configurations**
- **AArch32 System register IFAR bits [31:0]** are architecturally mapped to AArch64 System register FAR_EL1[63:32].
- **AArch32 System register IFAR bits [31:0]** (IFAR_S) are architecturally mapped to AArch32 System register HIFAR[31:0] when EL2 is implemented, EL3 is implemented and the implementation only supports execution in AArch32 state.
- **AArch32 System register IFAR bits [31:0]** (IFAR_S) are architecturally mapped to AArch64 System register FAR_EL2[63:32] when EL2 is implemented.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to IFAR are **UNDEFINED**.

**Attributes**
IFAR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA of faulting address of synchronous Prefetch Abort exception</td>
</tr>
</tbody>
</table>

Bits [31:0]
VA of faulting address of synchronous Prefetch Abort exception.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Accessing IFAR**

Accesses to this register use the following encodings in the System register encoding space:

`MRC<c>{q}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}`

<table>
<thead>

G8.2.102 IFSR, Instruction Fault Status Register

The IFSR characteristics are:

Purpose

Holds status information about the last instruction fault.

Configurations

AArch32 System register IFSR bits [31:0] are architecturally mapped to AArch64 System register IFSR32_EL2[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to IFSR are UNDEFINED.

The current translation table format determines which format of the register is used.

Attributes

IFSR is a 32-bit register.

Field descriptions

When TTBCR.EAE == 0:

<table>
<thead>

</tbody>
</table>

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0  IFAR is valid.
0b1  IFAR is not valid, and holds an UNKNOWN value.

This field is valid only for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [15:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bit [11]

Reserved, RES0.

FS, bits [10, 3:0]

- **0b00001**: PC alignment fault.
- **0b00010**: Debug exception.
- **0b00011**: Access flag fault, level 1.
- **0b00101**: Translation fault, level 1.
- **0b00110**: Access flag fault, level 2.
- **0b00111**: Translation fault, level 2.
- **0b01000**: Synchronous External abort, not on translation table walk.
- **0b01001**: Domain fault, level 1.
- **0b01011**: Domain fault, level 2.
- **0b01100**: Synchronous External abort, on translation table walk, level 1.
- **0b01101**: Permission fault, level 1.
- **0b01110**: Synchronous External abort, on translation table walk, level 2.
- **0b01111**: Permission fault, level 2.
- **0b10000**: TLB conflict abort.
- **0b10010**: IMPLEMENTATION DEFINED fault (Lockdown fault).
- **0b11001**: When FEAT_RAS is not implemented:
  - Synchronous parity or ECC error on memory access, not on translation table walk.
- **0b11100**: When FEAT_RAS is not implemented:
  - Synchronous parity or ECC error on translation table walk, level 1.
- **0b11110**: When FEAT_RAS is not implemented:
  - Synchronous parity or ECC error on translation table walk, level 2.

All other values are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Short-descriptor translation table lookup on page G5-9257*.

The FS field is split as follows:

- **FS[4]** is IFSR[10].
- **FS[3:0]** is IFSR[3:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- **0b0**: Using the Short-descriptor translation table formats.
- **0b1**: Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.
When TTBCR.EAE == 1:

Bits [31:17]
Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 IFAR is valid.

0b1 IFAR is not valid, and holds an UNKNOWN value.

This field is valid only for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

The reset behavior of this field is:

G8.2.103  ISR, Interrupt Status Register

The ISR characteristics are:

**Purpose**

Shows the pending status of the IRQ, FIQ, or SError.

When executing at EL2, EL3, or Secure EL1, when \( \text{SCR\_EL3.EEL2} = \overline{0b0} \), this shows the pending status of the physical interrupts.

When executing at Non-secure EL1, or at Secure EL1, when \( \text{SCR\_EL3.EEL2} = \overline{0b01} \):
- If the \( \text{HCR.\{IMO,FMO,AMO\}} \) bit has a value of 1, the corresponding ISR.\{I,F,A\} bit shows the pending status of the virtual IRQ, FIQ, or SError.
- If the \( \text{HCR.\{IMO,FMO,AMO\}} \) bit has a value of 0, the corresponding ISR.\{I,F,A\} bit shows the pending status of the physical IRQ, FIQ, or SError.

**Configurations**

AArch32 System register ISR bits [31:0] are architecturally mapped to AArch64 System register ISR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ISR are UNDEFINED.

**Attributes**

ISR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>

G8.2.104  ITLBIALL, Instruction TLB Invalidate All

The ITLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at EL1, all entries that:
  - Would be required for the EL1&0 translation regime.
  - Match the current VMID, if EL2 is implemented and enabled in the current Security state.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at EL2, and if EL2 is enabled in the current Security state, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ITLBIALL are UNDEFINED.

**Attributes**

ITLBIALL is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing ITLBIALL instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[ \text{MCR}\{<c>\}{<q>} <\text{coproc}>, {#}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>{, {#}<\text{opc2}>} \]

**G8.2.105 ITLBIASID, Instruction TLB Invalidate by ASID match**

The ITLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ITLBIASID are undefined.

**Attributes**

ITLBIASID is a 32-bit System instruction.

**Field descriptions**

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this System instruction.

**Executing ITLBIASID instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:
MCR{<c>}{<q>} <coproc>, (#)opc1, <Rt>, <CRn>, <CRm>{, (#)opc2}

<table>

    R[t]);

ITLBIMVA, Instruction TLB Invalidate by VA

The ITLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to ITLBIMVA are UNDEFINED.

**Attributes**

ITLBIMVA is a 32-bit System instruction.

**Field descriptions**

G8.2.110  MAIR0, Memory Attribute Indirection Register 0

The MAIR0 characteristics are:

**Purpose**

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIndx[2] indicates the MAIR register to be used:
- When AttrIndx[2] is 0, MAIR0 is used.
- When AttrIndx[2] is 1, MAIR1 is used.

**Configurations**

AArch32 System register MAIR0 bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL1[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register MAIR0 bits [31:0] are architecturally mapped to AArch32 System register PRRR[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register MAIR0 bits [31:0] (MAIR0_NS) are architecturally mapped to AArch32 System register PRRR[31:0] (PRRR_NS) when EL3 is using AArch32.

AArch32 System register MAIR0 bits [31:0] (MAIR0_S) are architecturally mapped to AArch32 System register PRRR[31:0] (PRRR_S) when EL3 is using AArch32.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MAIR0 are UNDEFINED.

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:
- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

When EL3 is using AArch32, write access to MAIR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

MAIR0 is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 1:*

<table>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Attr<n>, bits [8n+7:8n], for n = 3 to 0**

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.
Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b0</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01RW, RW not 0b0</td>
<td>Normal memory, Outer Write-Back Transient.</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient.</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient.</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b0</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b0</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b0</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b0</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

When `FEAT_XS` is implemented, stage 1 Inner Write-Back Cacheable, Outer Write-Back Cacheable memory types have the XS attribute set to 0.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally `UNKNOWN` value.
Accessing MAIR0

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{<c>\}{<q>} \{coproc\}, \{\#\}<opc1>, <Rt>, <CRn>, <CRm>{, \{\#\}<opc2>}\]

G8.2.111 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

**Purpose**

Along with MAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIndx[2] indicates the MAIR register to be used:

- When AttrIndx[2] is 0, MAIR0 is used.
- When AttrIndx[2] is 1, MAIR1 is used.

**Configurations**

AArch32 System register MAIR1 bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL1[63:32] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register MAIR1 bits [31:0] are architecturally mapped to AArch32 System register NMRR[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register MAIR1 bits [31:0] (MAIR1_NS) are architecturally mapped to AArch32 System register NMRR[31:0] (NMRR_NS) when EL3 is using AArch32.

AArch32 System register MAIR1 bits [31:0] (MAIR1_S) are architecturally mapped to AArch32 System register NMRR[31:0] (NMRR_S) when EL3 is using AArch32.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MAIR1 are UNDEFINED.

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

When EL3 is using AArch32, write access to MAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

MAIR1 is a 32-bit register.

**Field descriptions**

G8.2.112  MIDR, Main ID Register

The MIDR characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

AArch32 System register MIDR bits [31:0] are architecturally mapped to AArch64 System register MIDR_EL1[31:0].

AArch32 System register MIDR bits [31:0] are architecturally mapped to External register MIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MIDR are UNDEFINED.

Some fields of the MIDR are IMPLEMENTATION DEFINED. For more information about the values of these fields for a particular Armv8 implementation, and any implementation-specific significance of these values, see the product documentation.

**Attributes**

MIDR is a 32-bit register.

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

- **0x00**  Reserved for software use.
- **0x41**  Arm Limited.
- **0x42**  Broadcom Corporation.
- **0x43**  Cavium Inc.
- **0x44**  Digital Equipment Corporation.
- **0x46**  Fujitsu Ltd.
- **0x49**  Infineon Technologies AG.
- **0x40**  Motorola or Freescale Semiconductor Inc.
- **0x4E**  NVIDIA Corporation.
- **0x50**  Applied Micro Circuits Corporation.
- **0x51**  Qualcomm Inc.
- **0x56**  Marvell International Ltd.
- **0x69**  Intel Corporation.
- **0xC0**  Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.
Variant, bits [23:20]

Variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Architecture, bits [19:16]

Architecture version. Defined values are:
- 0b0001 Armv4.
- 0b0010 Armv4T.
- 0b0011 Armv5 (obsolete).
- 0b0100 Armv5T.
- 0b0101 Armv5TE.
- 0b0110 Armv5TEJ.
- 0b0111 Armv6.
- 0b1111 Architectural features are individually identified in the ID_* registers.

All other values are reserved.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

PartNum, bits [15:4]

Primary Part Number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Revision, bits [3:0]

Revision number for the device.

This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Accessing MIDR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>{, \{#<opc2>\}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>

<td>0b0000</td>
<td>0b000</td>
</tr>
</tbody>
</table>
elsif EL2Enabled() && ELUsingAArch32(EL2) then
    R[t] = VPIDR;
elsif PSTATE.EL == EL2 then
    R[t] = MIDR;
elsif PSTATE.EL == EL3 then
    R[t] = MIDR;
else
    R[t] = MIDR;
G8.2.113 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

**Purpose**

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Configurations**

AArch32 System register MPIDR bits [31:0] are architecturally mapped to AArch64 System register MPIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MPIDR are UNDEFINED.

In a uniprocessor system, Arm recommends that each Aff<n> field of this register returns a value of 0.

**Attributes**

MPIDR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>

<tr>
<td>Aff2</td>
<td>bits [23:16]</td>
</tr>
<tr>
<td>Aff1</td>
<td></td>
</tr>
<tr>
<td>Aff0</td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the Armv7 Multiprocessing Extensions.

- 0b0: This implementation does not include the Armv7 Multiprocessing Extensions functionality.
- 0b1: This implementation includes the Armv7 Multiprocessing Extensions functionality.

Access to this field is RAO/WI.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

- 0b0: Processor is part of a multiprocessor system.
- 0b1: Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels.

- 0b0: Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
- 0b1: Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

**Aff2, bits [23:16]**

Affinity level 2. See the description of Aff0 for more information.
Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

Aff0, bits [7:0]

Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR.\{Aff2, Aff1, Aff0\} or MPIDR.EL1.\{Aff3, Aff2, Aff1, Aff0\} set of fields of each PE must be unique within the system as a whole.

Accessing MPIDR

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{<c>\{<q>\} \langle coproc\rangle, \langle#opc1\rangle, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle\{, \langle#opc2\rangle\} \]

<table>

G8.2.114   MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, holds the vector base address for any exception that is taken to Monitor mode.

Secure software must program the MVBAR with the required initial value as part of the PE boot sequence.

**Configurations**

This register is present only when EL3 is capable of using AArch32. Otherwise, direct accesses to MVBAR are UNDEFINED.

It is IMPLEMENTATION DEFINED whether MVBAR[0] has a fixed value and ignored writes, or takes the last value written to it.

On a Warm reset into EL3 using AArch32, the reset value of MVBAR is an IMPLEMENTATION DEFINED choice between the following:

- MVBAR[31:5] = an IMPLEMENTATION DEFINED value, which might be UNKNOWN, MVBAR[4:1] = RES0, and MVBAR[0] = 0.
- MVBAR[31:1] = an IMPLEMENTATION DEFINED value that is bits[31:1] of the AArch32 reset address, and MVBAR[0] = 1.

**Attributes**

MVBAR is a 32-bit register.

**Field descriptions**

*When programmed with a vector base address:*

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Vector Base Address</td>
</tr>
<tr>
<td>4-0</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

**Reserved, bits [4:0]**

Reserved, see Configurations.

**Accessing MVBAR**

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{<c>\}{<q>\} \langle\{#\}\langle opc1\rangle, <Rt>, <CRn>, <CRm\rangle, \{#\}\langle opc2\rangle\rangle \]

G8.2.115   MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR1 and MVFR2.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-9332.

**Configurations**

AArch32 System register MVFR0 bits [31:0] are architecturally mapped to AArch64 System register MVFR0_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MVFR0 are UNDEFINED.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR0 is a 32-bit register.

**Field descriptions**

</tbody>
</table>

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

- **0b0000**: Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.
- **0b0001**: All rounding modes supported.

All other values are reserved.

In Armv8-A, the permitted values are **0b0000** and **0b0001**.

**FPShVec, bits [27:24]**

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

- **0b0000**: Short vectors not supported.
- **0b0001**: Short vector operation supported.

All other values are reserved.

In Armv8-A, the only permitted value is **0b0000**.

**FPSqrt, bits [23:20]**

Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

- **0b0000**: Not supported in hardware.
- **0b0001**: Supported.

All other values are reserved.
In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0001}.
The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPDivide**, bits [19:16]

Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:
- \texttt{0b0000} Not supported in hardware.
- \texttt{0b0001} Supported.
All other values are reserved.

In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0001}.
The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPTrap**, bits [15:12]

Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:
- \texttt{0b0000} Not supported.
- \texttt{0b0001} Supported.
All other values are reserved.

A value of \texttt{0b0001} indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

**FPDP**, bits [11:8]

Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:
- \texttt{0b0000} Not supported in hardware.
- \texttt{0b0001} Supported, VFPv2.
- \texttt{0b0010} Supported, VFPv3, VFPv4, or Armv8. VFPv3 and Armv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.
All other values are reserved.

In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0010}.

A value of \texttt{0b0001} or \texttt{0b0010} indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:
- VSQRT.F64 is only available if the Square root field is \texttt{0b0001}.
- VDIV.F64 is only available if the Divide field is \texttt{0b0001}.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

**FPSP**, bits [7:4]

Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:
- \texttt{0b0000} Not supported in hardware.
- \texttt{0b0001} Supported, VFPv2.
- \texttt{0b0010} Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.
All other values are reserved.
In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0010}.

A value of \texttt{0b0001} or \texttt{0b0010} indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is \texttt{0b0001}.
- VDIV.F32 is only available if the Divide field is \texttt{0b0001}.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

\textbf{SIMDReg, bits [3:0]}

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- \texttt{0b0000} The implementation has no Advanced SIMD and floating-point support.
- \texttt{0b0001} The implementation includes floating-point support with 16 x 64-bit registers.
- \texttt{0b0010} The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In Armv8-A, the permitted values are \texttt{0b0000} and \texttt{0b0010}.

\textbf{Accessing MVFR0}

Accesses to this register use the following encodings in the System register encoding space:

\texttt{VMRS<\texttt{c}>>\texttt{q}>>\texttt{Rt},<\texttt{spec_reg}>}

\begin{align*}
\text{reg} & \quad \text{0b}0111 \\
\end{align*}

G8.2.116  MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR2.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register MVFR1 bits [31:0] are architecturally mapped to AArch64 System register MVFR1_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MVFR1 are UNDEFINED.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR1 is a 32-bit register.

**SIMDFMAC, bits [31:28]**

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

- **0b0000**  Not implemented.
- **0b0001**  Implemented.

All other values are reserved.

In Armv8-A, the permitted values are **0b0000** and **0b0001**.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

**FPHP, bits [27:24]**

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- **0b0000**  Not supported.
- **0b0001**  Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- **0b0010**  As for **0b0001**, and adds instructions for conversion between double-precision and half-precision.
- **0b0011**  As for **0b0010**, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In Armv8-A, the permitted values are:

- 0b0000 in an implementation without floating-point support.
- 0b0010 in an implementation with floating-point support that does not include the FEAT_FP16 extension.
• 0b0011 in an implementation with floating-point support that includes the FEAT_FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the SIMDHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

0b0000  Not supported.
0b0001  SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision.
0b0010  As for 0b0001, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In Armv8-A, the permitted values are:

• 0b0000 in an implementation without SIMD floating-point support.
• 0b0001 in an implementation with SIMD floating-point support that does not include the FEAT_FP16 extension.
• 0b0010 in an implementation with SIMD floating-point support that includes the FEAT_FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the FPHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

SIMDSP, bits [19:16]

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:

0b0000  Not implemented.
0b0001  Implemented. This value is permitted only if the SIMDInt field is 0b0001.

All other values are reserved.

In Armv8-A, the permitted values are 0b0000 and 0b0001.

SIMDInt, bits [15:12]

Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:

0b0000  Not implemented.
0b0001  Implemented.

All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

SIMDLS, bits [11:8]
Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:
0b0000 Not implemented.
0b0001 Implemented.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

FPDNaN, bits [7:4]
Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:
0b0000 Not implemented, or hardware supports only the Default NaN mode.
0b0001 Hardware supports propagation of NaN values.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

FPFtZ, bits [3:0]
Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:
0b0000 Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
0b0001 Hardware supports full denormalized number arithmetic.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.

Accessing MVFR1

**G8.2.117 MVFR2, Media and VFP Feature Register 2**

The MVFR2 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-9332.

**Configurations**

AArch32 System register MVFR2 bits [31:0] are architecturally mapped to AArch64 System register MVFR2_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to MVFR2 are UNDEFINED.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR2 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>FPMisc</td>
<td>SIMDMisc</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**FPMisc, bits [7:4]**

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

- **0b0000**: Not implemented, or no support for miscellaneous features.
- **0b0001**: Support for Floating-point selection.
- **0b0010**: As 0b0001, and Floating-point Conversion to Integer with Directed Rounding modes.
- **0b0011**: As 0b0010, and Floating-point Round to Integer Floating-point.
- **0b0100**: As 0b0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

In Armv8-A, the permitted values are 0b0000 and 0b0100.

**SIMDMisc, bits [3:0]**

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

- **0b0000**: Not implemented, or no support for miscellaneous features.
- **0b0001**: Floating-point Conversion to Integer with Directed Rounding modes.
- **0b0010**: As 0b0001, and Floating-point Round to Integer Floating-point.
- **0b0011**: As 0b0010, and Floating-point MaxNum and MinNum.

All other values are reserved.

In Armv8-A, the permitted values are 0b0000 and 0b0011.
Accessing MVFR2

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{VMRS}(<c>){q} <Rt>, <\text{spec\_reg}>
\]

\[
\begin{align*}
\text{reg} &= 0b0101
\end{align*}
\]
G8.2.118   NMRR, Normal Memory Remap Register

The NMRR characteristics are:

**Purpose**

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the PRRR.

Used in conjunction with the PRRR.

**Configurations**

AArch32 System register NMRR bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL1[63:32] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register NMRR bits [31:0] are architecturally mapped to AArch32 System register MAIR1[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register NMRR bits [31:0] (NMRR_S) are architecturally mapped to AArch32 System register MAIR1[31:0] (MAIR1_S) when EL3 is using AArch32.

AArch32 System register NMRR bits [31:0] (NMRR_NS) are architecturally mapped to AArch32 System register MAIR1[31:0] (MAIR1_NS) when EL3 is using AArch32.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to NMRR are UNDEFINED.

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

**Attributes**

NMRR is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 0:*

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| OR7 | OR6 | OR5 | OR4 | OR3 | OR2 | OR1 | OR0 | IR7 | IR6 | IR5 | IR4 | IR3 | IR2 | IR1 | IR0 |

**OR<n>**, bits [2n+17:2n+16], for n = 7 to 0

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated.

- 0b00  Region is Non-cacheable.
- 0b01  Region is Write-Back, Write-Allocate.
- 0b10  Region is Write-Through, no Write-Allocate.
- 0b11  Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is IMPLEMENTATION DEFINED.

When FEAT_XS is implemented, stage 1 Outer Write-Back Cacheable memory types have the XS attribute set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IR\textless{}n\textgreater{}, bits \texttt{[2n+1:2n]}, for \(n = 7\) to 0

Inner Cacheable property mapping for memory attributes \(n\), if the region is mapped as Normal memory by the PRRR.TR\textless{}n\textgreater{} entry. \(n\) is the value of the TEX[0], C, and B bits concatenated.

\begin{itemize}
  \item \texttt{0b00} Region is Non-cacheable.
  \item \texttt{0b01} Region is Write-Back, Write-Allocate.
  \item \texttt{0b10} Region is Write-Through, no Write-Allocate.
  \item \texttt{0b11} Region is Write-Back, no Write-Allocate.
\end{itemize}

The meaning of the field with \(n = 6\) is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is IMPLEMENTATION DEFINED.

When \texttt{FEAT\_XS} is implemented, stage 1 Inner Write-Back Cacheable memory types have the XS attribute set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing NMRR

Accesses to this register use the following encodings in the System register encoding space:

\[ \text{MRC}\{<c>\}\{<q>\} <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>{{\{, \{#\}<opc2}\}} } \]

G8.2.119 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the Non-secure access permissions to Trace, Advanced SIMD and floating-point functionality. Also includes IMPLEMENTATION DEFINED bits that can define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to NSACR are UNDEFINED.

--- Note ---

In AArch64 state, the NSACR controls are replaced by controls in CPTR_EL3.

**Attributes**

NSACR is a 32-bit register.

**Field descriptions**

If EL3 is implemented and is using AArch64 then:

- Any read of the NSACR from Non-secure EL2 or Non-secure EL1 returns a value of 0x00000C00.
- Any read or write to NSACR from Secure EL1 is trapped as an exception to EL3.

If EL3 is not implemented, then any read of the NSACR from EL2 or EL1 returns a value of 0x00000C00.

**Bits [31:21]**

Reserved, RES0.

**NSTRCDIS, bit [20]**

Disables Non-secure System register accesses to all implemented trace registers.

- **0**: This control has no effect on:
  - System register access to implemented trace registers.
  - The behavior of CPACR.TRCDIS and HCPR.TTA.

- **1**: Non-secure System register accesses to all implemented trace registers are disabled, meaning:
  - CPACR.TRCDIS behaves as RAO/WI in Non-secure state, regardless of its actual value.
  - HCPR.TTA behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the CPACR.TRCDIS field:

- If CPACR.TRCDIS is RAZ/WI, this field is RAZ/WI.
- If CPACR.TRCDIS is RW, this field is RW.
Note

- The ETMv4 architecture and ETE do not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace registers are UNDEFINED.
- The Arm architecture does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

Bit [19]
Reserved, RES0.

IMPLEMENTATION DEFINED, bits [18:16]
IMPLEMENTATION DEFINED.

NSASEDIS, bit [15]

Disables Non-secure access to the Advanced SIMD functionality.

0b0 This control has no effect on:
- Non-secure access to Advanced SIMD functionality.
- The behavior of CPACR.ASEDIS and HCPTR.TASE.

0b1 Non-secure access to the Advanced SIMD functionality is disabled, meaning:
- CPACR.ASEDIS behaves as RAO/WI in Non-secure state, regardless of its actual value.
- HCPTR.TASE behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the CPACR.ASEDIS field:
- If CPACR.ASEDIS is RES0, this field is RES0. If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.
- If CPACR.ASEDIS is RAZ/WI, this field is RAZ/WI.
- If CPACR.ASEDIS is RW, this field is RW.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

Bits [14:12]
Reserved, RES0.

cp11, bit [11]
The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the NSACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.
**cp10, bit [10]**

Enable Non-secure access to the Advanced SIMD and floating-point features. Possible values of the fields are:

- **0b0**: Advanced SIMD and floating-point features can be accessed only from Secure state. Any attempt to access this functionality from Non-secure state is **UNDEFINED**. When the PE is in Non-secure state:
  - The CPACR.{cp11, cp10} fields ignore writes and read as 0b00, access denied.
  - The HCPTR.{TCP11, TCP10} fields behave as RAO/WI, regardless of their actual values.

- **0b1**: Advanced SIMD and floating-point features can be accessed from both Security states. If Non-secure access to the Advanced SIMD and floating-point functionality is enabled, the CPACR must be checked to determine the level of access that is permitted.

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is **RES0**.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL3, this field resets to an architecturally **UNKNOWN** value.

**Bits [9:0]**

Reserved, **RES0**.

**Accessing NSACR**

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{<c>\}{<q>} <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>\{, \{#\}<opc2>\} \]

G8.2.120 PAR, Physical Address Register

The PAR characteristics are:

**Purpose**

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

**Configurations**

AArch32 System register PAR bits [63:0] are architecturally mapped to AArch64 System register PAR_EL1[63:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to PAR are UNDEFINED.

PAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits[31:0] and do not modify bits[63:32].

The Configurations section specifies the cases where each PAR format is used.

PAR is accessed as a 32-bit value:

- When the PE is not in Hyp mode and is using the Short-descriptor translation table format.
- When the PE is in Hyp mode and executes an ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, or ATS12NSOUW instruction and the value of HCR.VM is 0 and the value of TTBCR.EAE is 0.

In these cases, PAR[63:32] is RES0.

Otherwise, the PAR is accessed as a 64-bit value, if any of the following is true:

- When using the Long-descriptor translation table format.
- If the stage 1 address translation is disabled and TTBCR.EAE is set to 1.
- In an implementation that includes EL2, for the result of an ATS1Cxx instruction performed from Hyp mode.

For PL1&0 stage 1 translations, TTBCR.EAE selects the translation table format.

**Attributes**

PAR is a 64-bit register.

**Field descriptions**

*When the instruction returned a 32-bit value to the PAR, PAR.F==0:*

```
  63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8
  7  6  5  4  3  2  1  0
    RES0
      12   11  10  9  8  7  6  5  4  3  2  1  0
      PA   NS  SH  SS  F
    LPAE  NOS  Outer[1:0] Inner[2:0] IMPLEMENTATION DEFINED
```

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.
On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the Translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the Translation table descriptors. This applies to the NOS, SH, Inner, and Outer fields.
- See the NS bit description for constraints on the value it returns.

**Bits [63:32]**

Reserved, RES0.

**PA, bits [31:12]**

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits [31:12].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

- 0b0 Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NOS, bit [10]**

Not Outer Shareable. When the returned value of PAR.SH is 1, indicates the Shareability attribute for the physical memory region:

- 0b0 Memory region is Outer Shareable.
- 0b1 Memory region is Inner Shareable.

When the returned value of PAR.SH is 0 the value returned to this field is UNKNOWN.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bit [8]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
SH, bit [7]
Shareability. Indicates whether the physical memory region is Non-shareable:

0b0  Memory is Non-shareable.
0b1  Memory is shareable, and PAR.NOS indicates whether the region is Outer Shareable or Inner Shareable.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

Inner[2:0], bits [6:4]
Inner cacheability attribute for the region. Permitted values are:

0b000  Non-cacheable.
0b001  Device-nGnRnE.
0b011  Device-nGnRE.
0b101  Write-Back, Write-Allocate.
0b110  Write-Through.
0b111  Write-Back, no Write-Allocate.

The values 0b10 and 0b100 are reserved.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

Outer[1:0], bits [3:2]
Outer cacheability attribute for the region. Permitted values are:

0b00  Non-cacheable.
0b01  Write-Back, Write-Allocate.
0b10  Write-Through, no Write-Allocate.
0b11  Write-Back, no Write-Allocate.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
* On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [1]
Supersection. Used to indicate if the result is a Supersection:

0b0  Result is not a Supersection. PAR[31:12] contains OA[31:12].
0b1  Result is a Supersection, and:
    * PAR[15:12] contains 0b0000.

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**F, bit [0]**
Indicates whether the instruction performed a successful address translation.
- 0b0 Address translation completed successfully.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*When the instruction returned a 32-bit value to the PAR, PAR.F==1:*

```
  63       32
   RES0    RES0
  24       15
 IMPLEMENTATION DEFINED  RES0
  12       5
   RES0     FS[4:0]
  10       0
   LPAE FS[5]
```

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**Bits [63:32]**
Reserved, RES0.

**IMPLEMENTATION DEFINED, bits [31:16]**
IMPLEMENTATION DEFINED.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [15:12]**
Reserved, RES0.

**LPAE, bit [11]**
When updating the PAR with the result of the translation operation, this bit is set as follows:
- 0b0 Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [10:7]**
Reserved, RES0.

**FS[5], bit [6]**
Fault status bits, External abort type. Provides an IMPLEMENTATION DEFINED classification of an External abort. Values are as in the DFSR.ExT field when using the Short-descriptor translation table format.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
FS[4:0], bits [5:1]

Fault status bits. Values are as in the DFSR.FS field when using the Short-descriptor translation table format.

- 0b00001  Alignment fault.
- 0b00011  Access flag fault, level 1.
- 0b00100  Fault on instruction cache maintenance.
- 0b00101  Translation fault, level 1.
- 0b00110  Access flag fault, level 2.
- 0b00111  Translation fault, level 2.
- 0b01001  Domain fault, level 1.
- 0b01011  Domain fault, level 2.
- 0b01100  Synchronous External abort, on translation table walk, level 1.
- 0b01101  Permission fault, level 1.
- 0b01110  Synchronous External abort, on translation table walk, level 2.
- 0b01111  Permission fault, level 2.
- 0b10000  TLB conflict abort.
- 0b11001  When FEAT_RAS is not implemented: Synchronous parity or ECC error on memory access, not on translation table walk.
- 0b11100  When FEAT_RAS is not implemented: Synchronous parity or ECC error on translation table walk, level 1.
- 0b11110  When FEAT_RAS is not implemented: Synchronous parity or ECC error on translation table walk, level 2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an UNKNOWN value.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 0b1  Address translation aborted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When the instruction returned a 64-bit value to the PAR, PAR.F==0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the Translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the Translation table descriptors. This applies to the ATTR and SH fields.
• See the NS bit description for constraints on the value it returns.

**ATTR, bits [63:56]**

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR0 and MAIR1.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [55:40]**

Reserved, RES0.

**PA, bits [39:12]**

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[39:12].

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:
0b1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bit [10]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SH, bits [8:7]**

Shareability attribute, for the returned output address. Permitted values are:

0b00 Non-shareable.
0b10 Outer Shareable.
0b11 Inner Shareable.

The value 0b01 is reserved.

**Note**

This field returns the value 0b10 for:
• Any type of Device memory.
• Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [6:1]**
Reserved, RES0.

**F, bit [0]**
Indicates whether the instruction performed a successful address translation.

0b0 Address translation completed successfully.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

*When the instruction returned a 64-bit value to the PAR, PAR.F==1:*

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**IMPLEMENTATION DEFINED, bits [63:56]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bits [55:52]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bits [51:48]**

IMPLEMENTATION DEFINED.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [47:12]**
Reserved, RES0.
LPAE, bit [11]

When updating the PAR with the result of the translation operation, this bit is set as follows:

0b1  Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [10]

Reserved, RES0.

FSTAGE, bit [9]

Indicates the translation stage at which the translation aborted:

0b0  Translation aborted because of a fault in the stage 1 translation.
0b1  Translation aborted because of a fault in the stage 2 translation.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S2WLK, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status field. Values are as in the DFSR.STATUS and IFSR.STATUS fields when using the Long-descriptor translation table format.

0b000000  Address size fault in translation table base register.
0b000001  Address size fault, level 1.
0b000010  Address size fault, level 2.
0b000011  Address size fault, level 3.
0b000101  Translation fault, level 1.
0b000110  Translation fault, level 2.
0b000111  Translation fault, level 3.
0b001001  Access flag fault, level 1.
0b001010  Access flag fault, level 2.
0b001011  Access flag fault, level 3.
0b001101  Permission fault, level 1.
0b001110  Permission fault, level 2.
0b001111  Permission fault, level 3.
0b010101  Synchronous External abort on translation table walk, level 1.
0b010110  Synchronous External abort on translation table walk, level 2.
0b010111  Synchronous External abort on translation table walk, level 3.
0b011101  When FEAT_RAS is not implemented:
    Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011110  When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk, level 2.

0b01111

When FEAT_RAS is not implemented:
Synchronous parity or ECC error on memory access on translation table walk, level 3.

0b11000

TLB conflict abort.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

0b1

Address translation aborted.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PAR

Accesses to this register use the following encodings in the System register encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.2.121 PRRR, Primary Region Remap Register

The PRRR characteristics are:

**Purpose**

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

**Configurations**

AArch32 System register PRRR bits [31:0] are architecturally mapped to AArch64 System register MAIR_EL1[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register PRRR bits [31:0] are architecturally mapped to AArch32 System register MAIR0[31:0] when EL3 is not implemented or EL3 is using AArch64.

AArch32 System register PRRR bits [31:0] (PRRR_S) are architecturally mapped to AArch32 System register MAIR0[31:0] (MAIR0_S) when EL3 is using AArch64.

AArch32 System register PRRR bits [31:0] (PRRR_NS) are architecturally mapped to AArch32 System register MAIR0[31:0] (MAIR0_NS) when EL3 is using AArch32.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to PRRR are UNDEFINED.

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

**Attributes**

PRRR is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 0:*

NOS<n>, bit [n+24], for n = 7 to 0

Not Outer Shareable. NOS<n> is the Outer Shareable property for memory attributes n, if the region is mapped as Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, and the appropriate PRRR. {NS0, NS1} field identifies the region as shareable. n is the value of the concatenation of the {TEX[0], C, B} bits from the Translation table descriptor. The possible values of each NOS<n> field other than NOS6 are:

- 0b0 Memory region is Outer Shareable.
- 0b1 Memory region is Inner Shareable.

The value of this bit is ignored if the region is:

- Device memory
- Normal memory that is at least one of:
  - Inner Non-cacheable, Outer Non-cacheable.
  - Identified by the appropriate PRRR. {NS0, NS1} field as Non-shareable.

The meaning of the NOS6 field is IMPLEMENTATION DEFINED.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:20]
Reserved, RES0.

NS1, bit [19]
Mapping of S = 1 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
• Is not Inner Non-cacheable, Outer Non-cacheable.
• Has the S bit in the Translation table descriptor set to 1.
0b0 Region is Non-shareable.
0b1 Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

NS0, bit [18]
Mapping of S = 0 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
• Is not Inner Non-cacheable, Outer Non-cacheable.
• Has the S bit in the Translation table descriptor set to 0.
0b0 Region is Non-shareable.
0b1 Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DS1, bit [17]
Mapping of S = 1 attribute for Device memory. From Armv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

DS0, bit [16]
Mapping of S = 0 attribute for Device memory. From Armv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

TR<n>, bits [2n+1:2n], for n = 7 to 0
TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the concatenation of the {TEX[0], C, B} bits from the Translation table descriptor. The possible values for each field other than TR6 are:
0b00 Device-nGnRnE memory
0b01 Device-nGnRE memory
0b10 Normal memory
The value 0b11 is reserved. The effect of programming a field to 0b11 is CONSTRAINED UNPREDICTABLE.
The meaning of the TR6 field is IMPLEMENTATION DEFINED.
When FEAT_XS is implemented, stage 1 Inner Write-Back Cacheable, Outer Write-Back Cacheable memory types have the XS attribute set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

Non-Confidential

ARM DDI 0487I.a
ID081822
G8.2.122   REVIDR, Revision ID Register

The REVIDR characteristics are:

Purpose

Provides implementation-specific minor revision information.

Configurations

AArch32 System register REVIDR bits [31:0] are architecturally mapped to AArch64 System register REVIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to REVIDR are UNDEFINED.

If REVIDR has the same value as MIDR, then its contents have no significance.

Attributes

REVIDR is a 32-bit register.

Field descriptions

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>IMPLEMENTATION DEFINED</th>
</tr>
</thead>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing REVIDR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC} \{<c>\}\{<q>\} \langle\text{coproc}\rangle, \{\#\}<\text{opc1}>, \langle\text{Rt}\rangle, \langle\text{CRn}\rangle, \langle\text{CRm}\rangle, \{\#\}<\text{opc2}> \\
\]

\[
\begin{array}{c c c c c}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} & \text{opc2} \\
0b1111 & 0b0000 & 0b0000 & 0b0000 & 0b1110 \\
\end{array}
\]

if PSTATE_EL == EL0 then
  UNDEFINED;
elsif PSTATE_EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && HSTR_EL2.T0 == '1' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x03);
  elsif EL2Enabled() && ELUsingAArch32(EL2) && HSTR.T0 == '1' then
    AArch32.TakeHypTrapException(0x03);
  else
    R[t] = REVIDR;
  endif
elsif PSTATE_EL == EL2 then
  R[t] = REVIDR;
elsif PSTATE_EL == EL3 then
  R[t] = REVIDR;
**G8.2.123  RMR, Reset Management Register**

The RMR characteristics are:

**Purpose**

If EL1 or EL3 is the highest implemented Exception level and this register is implemented:
- A write to the register at the highest implemented Exception level can request a Warm reset.
- If the highest implemented Exception level can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch32 System register RMR bits [31:0] are architecturally mapped to AArch64 System register RMR_EL1[31:0] when the highest implemented Exception level is EL1.

AArch32 System register RMR bits [31:0] are architecturally mapped to AArch64 System register RMR_EL3[31:0] when EL3 is implemented.

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to RMR are UNDEFINED.

Only implemented if EL1 or EL3 is the highest implemented Exception level. In this case:
- If the highest implemented Exception level can use AArch32 and AArch64 then this register must be implemented.
- If the highest implemented Exception level cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

**Attributes**

RMR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>

\text{UNDEFINED;}
\text{elsif CP15SDISABLE2 == HIGH then} \\
\text{UNDEFINED;}
\text{else} \\
\text{RMR = R[t];}
\]
**G8.2.124   RVBAR, Reset Vector Base Address Register**

The RVBAR characteristics are:

**Purpose**
If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

**Configurations**
This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to RVBAR are UNDEFINED.

This register is only implemented if the highest Exception level implemented is capable of using AArch32, and is not EL3.

**Attributes**
RVBAR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>

G8.2.125 SCR, Secure Configuration Register

The SCR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the configuration of the current Security state. It specifies:

- The Security state, either Secure or Non-secure.
- What mode the PE branches to if anIRQ, FIQ, or External abort occurs.
- Whether the PSTATE.F or PSTATE.A bits can be modified when SCR.NS==1.

**Configurations**

This register is present only when EL3 is capable of using AArch32. Otherwise, direct accesses to SCR are UNDEFINED.

**Attributes**

SCR is a 32-bit register.

</tbody>
</table>

**TERR, bit [15]**

*When FEAT_RAS is implemented:*

Trap Error record accesses. Generate a Monitor Trap exception on accesses to the following registers from modes other than Monitor mode:

ERRIDR, ERXADDR, ERXADDR2, ERXCTRLR, ERXCTRLR2, ERXFR, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS. When FEAT_RASv1p1 is implemented, ERXMISC4, ERXMISC5, ERXMISC6, ERXMISC7.

- 0b0 This control does not cause any instructions to be trapped.
- 0b1 Accesses to the specified registers from modes other than Monitor mode generate a Monitor Trap exception.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

**Bit [14]**

Reserved, RES0.

**TWE, bit [13]**

Traps WFE instructions to Monitor mode.

- 0b0 This control does not cause any instructions to be trapped.
Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWE or HCR.TWE.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

**TWI, bit [12]**
Traps WFI instructions to Monitor mode.
- **0b0** This control does not cause any instructions to be trapped.
- **0b1** Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWI or HCR.TWI.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

**Bits [11:10]**
Reserved, RES0.

**SIF, bit [9]**
Secure instruction fetch. When the PE is in Secure state, this bit disables instruction execution from Non-secure memory.
- **0b0** Secure state instruction execution from Non-secure memory is permitted.
- **0b1** Secure state instruction execution from Non-secure memory is not permitted.

This bit is permitted to be cached in a TLB.
The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.
HCE, bit [8]
Hypervisor Call instruction enable. If EL2 is implemented, enables execution of HVC instructions at Non-secure EL1 and EL2.

0b0 HVC instructions are:
• UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken from PL1 to PL1.
• UNPREDICTABLE at EL2. Behavior is one of the following:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

0b1 HVC instructions are enabled at Non-secure EL1 and EL2.

Note
HVC instructions are always UNDEFINED at EL0 and in Secure state.

If EL2 is not implemented, this bit is RES0 and HVC is UNDEFINED.
The reset behavior of this field is:
• On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

SCD, bit [7]
Secure Monitor Call disable. Disables SMC instructions.

0b0 SMC instructions are enabled.

0b1 In Non-secure state, SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
In Secure state, behavior is one of the following:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

Note
SMC instructions are always UNDEFINED at PL0.
The reset behavior of this field is:
• On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

nET, bit [6]
Not Early Termination. This bit disables early termination.

0b0 Early termination permitted. Execution time of data operations can depend on the data values.

0b1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

On implementations that do not support early termination or do not support disabling early termination, this bit is RES0.
The reset behavior of this field is:
• On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.
AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether PSTATE.A masks an External abort taken from Non-secure state.

0b0  External aborts taken from Non-secure state are not masked by PSTATE.A, and are taken to EL3.

0b1  External aborts taken from Secure state are masked by PSTATE.A.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

The reset behavior of this field is:
•  On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

FW, bit [4]

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether PSTATE.F masks an FIQ interrupt taken from Non-secure state.

0b0  An FIQ taken from Non-secure state is not masked by PSTATE.F, and is taken to EL3.

0b1  An FIQ taken from Secure state is masked by PSTATE.F.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

The reset behavior of this field is:
•  On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

EA, bit [3]

External Abort handler. This bit controls which mode takes External aborts and SError interrupt exceptions.

0b0  External aborts taken to Abort mode.

0b1  External aborts taken to Monitor mode.

The reset behavior of this field is:
•  On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions.

0b0  FIQs taken to FIQ mode.

0b1  FIQs taken to Monitor mode.

The reset behavior of this field is:
•  On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions.

0b0  IRQs taken to IRQ mode.

0b1  IRQs taken to Monitor mode.

The reset behavior of this field is:
•  On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

NS, bit [0]

Non-secure bit. Except when the PE is in Monitor mode, this bit determines the Security state of the PE.

0b0  PE is in Secure state.

0b1  PE is in Non-secure state.
If the HCR.TGE bit is set, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing the SCR.NS bit from 0 to 1 results in the SCR.NS bit remaining as 0.

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL3, this field resets to 0.

**Accessing SCR**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{<c}\{<q}\{ coproc, \{#opc1\}, \{Rt\}, \{CRn\}, \{CRm\}\{, \{#opc2\}\}
\]

<table>
<thead>
<tr>

</table>
G8.2.126  SCTLVR, System Control Register

The SCTLVR characteristics are:

Purpose

Provides the top level control of the system, including its memory system.

Configurations

AArch32 System register SCTLVR bits [31:0] are architecturally mapped to AArch64 System register SCTLVR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to SCTLVR are UNDEFINED.

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Attributes

SCTLVR is a 32-bit register.

Field descriptions

DSSBS, bit [31]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on Exception Entry. The defined values are:

0b0  PSTATE.SSBS is set to 0 on an exception to any mode in this security state except Hyp mode

0b1  PSTATE.SSBS is set to 1 on an exception to any mode in this security state except Hyp mode

----- Note -----

When EL3 is implemented and is using AArch32, this bit is banked between the two Security states.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions to an Exception level that is executing at PL1 are taken to A32 or T32 state:

0b0  Exceptions, including reset, taken to A32 state.
0b1  Exceptions, including reset, taken to T32 state.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

AFE, bit [29]
Access Flag Enable. When using the Short-descriptor translation table format for the PL1&0
translation regime, this bit enables use of the AP[0] bit in the translation descriptors as the Access
flag, and restricts access permissions in the translation descriptors to the simplified model.

0b0  In the Translation table descriptors, AP[0] is an access permissions bit. The full range
of access permissions is supported. No Access flag is implemented.
0b1  In the Translation table descriptors, AP[0] is the Access flag. Only the simplified model
for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to
1, regardless of the value of this bit.
The AFE bit is permitted to be cached in a TLB.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to 0.

TRE, bit [28]
TEX remap enable. This bit enables remapping of the TEX[2:1] bits in the PL1&0 translation
regime for use as two translation table bits that can be managed by the operating system. Enabling
this remapping also changes the scheme used to describe the memory region attributes in the
VMSA.

0b0  TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory
region attributes.
0b1  TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating
system. The TEX[0], C, and B bits are used to describe the memory region attributes,
with the MMU remap registers.

When the value of TTBCR.EAE is 1, this bit is RES1.
The TRE bit is permitted to be cached in a TLB.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to 0.

Bits [27:26]
Reserved, RES0.

EE, bit [25]
The value of the PSTATE.E bit on branch to an exception vector or coming out of reset, and the
endianness of stage 1 translation table walks in the PL1&0 translation regime.

0b0  Little-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset.
Stage 1 translation table walks in the PL1&0 translation regime are little-endian.
0b1  Big-endian. PSTATE.E is set to 1 on taking an exception or coming out of reset. Stage
1 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support for data accesses at Exception levels
higher than EL0, this bit is RES0.
If an implementation does not provide Little-endian support for data accesses at Exception levels
higher than EL0, this bit is RES1.
The reset behavior of this field is:
  •  On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]
Reserved, RES0.
SPAN, bit [23]

*When FEAT_PAN is implemented:*

Set Privileged Access Never, on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

- **0b0** PSTATE.PAN is set to 1 in the following situations:
  - In Non-secure state, on taking an exception to EL1.
  - In Secure state, when EL3 is using AArch64, on taking an exception to EL1.
  - In Secure state, when EL3 is using AArch32, on taking an exception to EL3.
- **0b1** The value of PSTATE.PAN is left unchanged on taking an exception to EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, RES1.

Bit [22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies PL1 XN (Execute-never). This bit can force all memory regions that are writable at PL0 to be treated as XN for accesses from software executing at PL1.

- **0b0** This control has no effect on memory access permissions.
- **0b1** Any region that is writable at PL0 forced to XN for accesses from software executing at PL1.

The UWXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the PL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN.

- **0b0** This control has no effect on memory access permissions.
- **0b1** Any region that is writable in the PL1&0 translation regime is forced to XN for accesses from software executing at PL1 or PL0.

This bit applies only when SCTLR.M bit is set.

The WXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to Undefined mode.

- **0b0** Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- **0b1** This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.
Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to Undefined mode.

0b0 Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1 This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:
- On a Warm reset, this field resets to 1.

Bits [15:14]

Reserved, RES0.

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors for exceptions taken to a PE mode other than Monitor mode or Hyp mode:

0b0 Normal exception vectors. Base address is held in VBAR.

0b1 High exception vectors (Hivecs), base address 0xFFFF0000. This base address cannot be remapped.

The reset behavior of this field is:
- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

I, bit [12]

Instruction access Cacheability control, for accesses at EL1 and EL0:

0b0 All instruction access to Normal memory from PL1 and PL0 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

0b1 All instruction access to Normal memory from PL1 and PL0 can be cached at all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.
Instruction accesses to Normal memory from EL1 and EL0 are Cacheable regardless of the value of the 
SCTLR.I bit if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

Bit [11]
Reserved, RES1.

EnRCTX, bit [10]

When FEAT_SPECRES is implemented:
Enable EL0 access to the AArch32 CFPRCTX, DVPRCTX, and CPPRCTX instructions.

- 0b0 EL0 access to these instructions is disabled, and these instructions are trapped to EL1.
- 0b1 EL0 access to these instructions is enabled.

Note
When EL3 is implemented and is using AArch32, this bit is banked between the two Security states.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [9]
Reserved, RES0.

SED, bit [8]
SETEND instruction disable. Disables SETEND instructions at PL0 and PL1.

- 0b0 SETEND instruction execution is enabled at PL0 and PL1.
- 0b1 SETEND instructions are UNDEFINED at PL0 and PL1.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

ITD, bit [7]
IT Disable. Disables some uses of IT instructions at PL1 and PL0.

- 0b0 All IT instruction functionality is enabled at PL1 and PL0.
- 0b1 Any attempt at PL1 or PL0 to execute any of the following is UNDEFINED:
  - All encodings of the IT instruction with hw1[3:0]=1000.
  - All encodings of the subsequent instruction with the following values for hw1:
    - 11xxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
    - 1011xxxxxxxxxx: All instructions in Miscellaneous 16-bit instructions on page F3-7303.
    - 10100xxxxxxxxxxx: ADD Rd, PC, #imm
    - 01001xxxxxxxxxxx: LDR Rd, [PC, #imm]
    - 01001xxxxxxxxxxx: ADD Rd, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
— 010001xx1xxxx111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

• A 16-bit instruction, that can only be followed by another 16-bit instruction.
• The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONstrained UNpredictable. For more information see Changes to an ITD control by an instruction in an IT block on page E1-7138.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1, SCTLR_EL2, and HSCTLR.

The reset behavior of this field is:

• On a Warm reset, this field resets to 0.

When an implementation does not implement ITD, access to this field is RAZ/WI.

UNK, bit [6]

 Writes to this bit are IGNORED. Reads of this bit return an UNKNOWN value.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from PL1 and PL0:

0b0 PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.

0b1 PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1, SCTLR_EL2, and HSCTLR.

The reset behavior of this field is:

• On a Warm reset, this field resets to 1.

When an implementation does not implement CP15BEN, access to this field is RAO/WI.

LSMAOE, bit [4]

When FEAT_LSMAOC is implemented:

Load Multiple and Store Multiple Atomicity and Ordering Enable.

0b0 For all memory accesses at EL1 or EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.

0b1 The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

• On a Warm reset, this field resets to 1.
nTLSMD, bit [3]

When FEAT_LSMAOC is implemented:

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

0b0  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.

0b1  All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

• On a Warm reset, this field resets to 1.

Otherwise:

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL1 and EL0:

0b0  All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.

0b1  All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, can be cached at all levels of data and unified cache.

The PE ignores SCTLR.C for Non-secure state and data accesses to Normal memory from EL1 and EL0 are Cacheable if either:

• EL2 is using AArch32 and the value of HCR.DC is 1.
• EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

The reset behavior of this field is:

• On a Warm reset, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at PL1 and PL0:

0b0  Alignment fault checking disabled when executing at PL1 or PL0. Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1  Alignment fault checking enabled when executing at PL1 or PL0. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

The reset behavior of this field is:

• On a Warm reset, this field resets to 0.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0b0  EL1 and EL0 stage 1 address translation disabled. See the SCTLR.I field for the behavior of instruction accesses to Normal memory.
0b1 EL1 and EL0 stage 1 address translation enabled.

In the Non-secure state the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of the field if either:

- EL2 is using AArch32 and the value of HCR.{DC, TGE} is not {0, 0}.
- EL2 is using AArch64 and the value of HCR_EL2.{DC, TGE} is not {0, 0}.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

### Accessing SCTLR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}>, {#}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>\{, {#}<\text{opc2}>\}
\]

<table>
<thead>

</table>
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to the current mode, and copied to PSTATE.IT on executing an exception return operation in the current mode.

SPSR.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR[26:25].
- IT[7:2] is SPSR[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to the current mode, and copied to PSTATE.SSBS on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to the current mode, and copied to PSTATE.PAN on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to the current mode, and copied to PSTATE.DIT on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to the current mode, and copied to PSTATE.IL on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to the current mode, and copied to PSTATE.GE on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to the current mode, and copied to PSTATE.E on executing an exception return operation in the current mode.

If the implementation does not support big-endian operation, SPSR.E is RES0. If the implementation does not support little-endian operation, SPSR.E is RES1. On executing an exception return operation in the current mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR.E is RES1.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to the current mode, and copied to PSTATE.A on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to the current mode, and copied to PSTATE.I on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to the current mode, and copied to PSTATE.F on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to the current mode, and copied to PSTATE.T on executing an exception return operation in the current mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to the current mode, and copied to PSTATE.M[4:0] on executing an exception return operation in the current mode.

- 0b10000: User.
- 0b10001: FIQ.
- 0b10010: IRQ.
- 0b10011: Supervisor.
- 0b10110: Monitor.
- 0b10111: Abort.
- 0b11010: Hyp.
0b11011  Undefined.
0b11111  System.

Other values are reserved. If SPSR.M[4:0] has a Reserved value, or a value for an unimplemented
Exception level, executing an exception return operation in the current mode is an illegal return
event, as described in Illegal return events from AArch32 state on page G1-8952.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.
G8.2.128 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Abort mode.

**Configurations**

AArch32 System register SPSR_abt bits [31:0] are architecturally mapped to AArch64 System register SPSR_abt[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_abt are UNDEFINED.

**Attributes**

SPSR_abt is a 32-bit register.

**Field descriptions**

</table>
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Abort mode, and copied to PSTATE.IT on executing an exception return operation in Abort mode.

SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_abt[26:25].
- IT[7:2] is SPSR_abt[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

*When FEAT_SSBS is implemented:*
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Abort mode, and copied to PSTATE.SSBS on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

PAN, bit [22]

*When FEAT_PAN is implemented:*
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode, and copied to PSTATE.PAN on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

DIT, bit [21]

*When FEAT_DIT is implemented:*
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode, and copied to PSTATE.DIT on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and copied to PSTATE.IL on executing an exception return operation in Abort mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode, and copied to PSTATE.GE on executing an exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to PSTATE.E on executing an exception return operation in Abort mode.

If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an exception return operation in Abort mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and copied to PSTATE.A on executing an exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied to PSTATE.I on executing an exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied to PSTATE.F on executing an exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and copied to PSTATE.T on executing an exception return operation in Abort mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Abort mode.

<table>

</tbody>
</table>
0b11111 System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Abort mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-8952.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_abt

SPSR_abt is accessible in all modes other than User mode and Abort mode.

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRS}\{c\}\{q\} \; <Rd>, \; \text{SPSR\_abt}
\]

\[
\begin{array}{ccc}
\text{R} & \text{M} & \text{M1} \\
0b1 & 0b1 & 0b100 \\
\end{array}
\]

\[
\text{MSR}\{c\}\{q\} \; \text{SPSR\_abt}, \; <Rn>
\]

\[
\begin{array}{ccc}
\text{R} & \text{M} & \text{M1} \\
0b1 & 0b1 & 0b100 \\
\end{array}
\]
G8.2.129  SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to FIQ mode.

**Configurations**

AArch32 System register SPSR_fiq bits [31:0] are architecturally mapped to AArch64 System register SPSR_fiq[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_fiq are UNDEFINED.

**Attributes**

SPSR_fiq is a 32-bit register.

**Field descriptions**

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to FIQ mode, and copied to PSTATE.N on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to FIQ mode, and copied to PSTATE.Z on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to FIQ mode, and copied to PSTATE.C on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to FIQ mode, and copied to PSTATE.V on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to FIQ mode, and copied to PSTATE.Q on executing an exception return operation in FIQ mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to FIQ mode, and copied to PSTATE.IT on executing an exception return operation in FIQ mode.

SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR_fiq[26:25].
- IT[7:2] is SPSR_fiq[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to FIQ mode, and copied to PSTATE.SSBS on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to FIQ mode, and copied to PSTATE.PAN on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to FIQ mode, and copied to PSTATE.DIT on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to FIQ mode, and copied to PSTATE.IL on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to FIQ mode, and copied to PSTATE.GE on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to FIQ mode, and copied to PSTATE.E on executing an exception return operation in FIQ mode.

If the implementation does not support big-endian operation, SPSR_fiq.E is RES0. If the implementation does not support little-endian operation, SPSR_fiq.E is RES1. On executing an exception return operation in FIQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_fiq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_fiq.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to FIQ mode, and copied to PSTATE.A on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to FIQ mode, and copied to PSTATE.I on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to FIQ mode, and copied to PSTATE.F on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to FIQ mode, and copied to PSTATE.T on executing an exception return operation in FIQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to FIQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in FIQ mode.

SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Hyp mode.

**Configurations**

AArch32 System register SPSR_hyp bits [31:0] are architecturally mapped to AArch64 System register SPSR_EL2[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_hyp are UNDEFINED.

**Attributes**

SPSR_hyp is a 32-bit register.

**Field descriptions**

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Hyp mode, and copied to PSTATE.N on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Hyp mode, and copied to PSTATE.Z on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Hyp mode, and copied to PSTATE.C on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Hyp mode, and copied to PSTATE.V on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Hyp mode, and copied to PSTATE.Q on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Hyp mode, and copied to PSTATE.IT on executing an exception return operation in Hyp mode.

SPSR_hyp.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_hyp[26:25].
- IT[7:2] is SPSR_hyp[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Hyp mode, and copied to PSTATE.SSBS on executing an exception return operation in Hyp mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Hyp mode, and copied to PSTATE.PAN on executing an exception return operation in Hyp mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Hyp mode, and copied to PSTATE.DIT on executing an exception return operation in Hyp mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Hyp mode, and copied to PSTATE.IL on executing an exception return operation in Hyp mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Hyp mode, and copied to PSTATE.GE on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to Hyp mode, and copied to PSTATE.E on executing an exception return operation in Hyp mode.
If the implementation does not support big-endian operation, SPSR_hyp.E is RES0. If the implementation does not support little-endian operation, SPSR_hyp.E is RES1. On executing an exception return operation in Hyp mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_hyp.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_hyp.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Hyp mode, and copied to PSTATE.A on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Hyp mode, and copied to PSTATE.I on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Hyp mode, and copied to PSTATE.F on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Hyp mode, and copied to PSTATE.T on executing an exception return operation in Hyp mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Hyp mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Hyp mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11010 Hyp.
0b11011  Undefined.
0b11111  System.

Other values are reserved. If SPSR_hyp.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Hyp mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-8952*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing SPSR_hyp

SPSR_hyp is accessible only in Monitor mode.

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRS}\{c\}\{q\} \text{ } \text{SPSR}_\text{hyp}
\]

<table>
<thead>
<tr>
<th>R</th>
<th>M</th>
<th>M1</th>

<td>0b1</td>
<td>0b1110</td>
</tr>
</tbody>
</table>
G8.2.131  SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Configurations

AArch32 System register SPSR_irq bits [31:0] are architecturally mapped to AArch64 System register SPSR_irq[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_irq are UNDEFINED.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to IRQ mode, and copied to PSTATE.N on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to IRQ mode, and copied to PSTATE.Z on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to IRQ mode, and copied to PSTATE.C on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to IRQ mode, and copied to PSTATE.V on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to IRQ mode, and copied to PSTATE.Q on executing an exception return operation in IRQ mode.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to IRQ mode, and copied to PSTATE.IT on executing an exception return operation in IRQ mode.

SPSR_irq.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR_irq[26:25].
- IT[7:2] is SPSR_irq[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to IRQ mode, and copied to PSTATE.SSBS on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to IRQ mode, and copied to PSTATE.PAN on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to IRQ mode, and copied to PSTATE.DIT on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to IRQ mode, and copied to PSTATE.IL on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to IRQ mode, and copied to PSTATE.GE on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to IRQ mode, and copied to PSTATE.E on executing an exception return operation in IRQ mode.

If the implementation does not support big-endian operation, SPSR_irq.E is RES0. If the implementation does not support little-endian operation, SPSR_irq.E is RES1. On executing an exception return operation in IRQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_irq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_irq.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to IRQ mode, and copied to PSTATE.A on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to IRQ mode, and copied to PSTATE.I on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to IRQ mode, and copied to PSTATE.F on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to IRQ mode, and copied to PSTATE.T on executing an exception return operation in IRQ mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to IRQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in IRQ mode.
0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b1111 System.

Other values are reserved. If SPSR_irq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in IRQ mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-8952.*

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SPSR_irq**

SPSR_irq is accessible in all modes other than User mode and IRQ mode.

Accesses to this register use the following encodings in the System register encoding space:

\[ MRS{<c>}{<q>} <Rd>, SPSR_irq \]

<table>
<thead>
<tr>

</table>
G8.2.132  SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Monitor mode.

**Configurations**

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_mon are UNDEFINED.

**Attributes**

SPSR_mon is a 32-bit register.

**Field descriptions**

| 29  | C     | Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Monitor mode, and copied to PSTATE.C on executing an exception return operation in Monitor mode. The reset behavior of this field is:  
| 28  | V     | Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Monitor mode, and copied to PSTATE.V on executing an exception return operation in Monitor mode. The reset behavior of this field is:  
| 27  | Q     | Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Monitor mode, and copied to PSTATE.Q on executing an exception return operation in Monitor mode. The reset behavior of this field is:  

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
IT, bits \([15:10, 26:25]\)

If-Then. Set to the value of PSTATE.IT on taking an exception to Monitor mode, and copied to PSTATE.IT on executing an exception return operation in Monitor mode.

SPSR_mon.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR_mon[26:25].
- IT[7:2] is SPSR_mon[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the \(\{J, T\}\) bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When \textit{FEAT SSBS is implemented}:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Monitor mode, and copied to PSTATE.SSBS on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When \textit{FEAT PAN is implemented}:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Monitor mode, and copied to PSTATE.PAN on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When \textit{FEAT DIT is implemented}:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Monitor mode, and copied to PSTATE.DIT on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Monitor mode, and copied to PSTATE.IL on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Monitor mode, and copied to PSTATE.GE on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to Monitor mode, and copied to PSTATE.E on executing an exception return operation in Monitor mode.

If the implementation does not support big-endian operation, SPSR_mon.E is RES0. If the implementation does not support little-endian operation, SPSR_mon.E is RES1. On executing an exception return operation in Monitor mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_mon.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_mon.E is RES1.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Monitor mode, and copied to PSTATE.A on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Monitor mode, and copied to PSTATE.I on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Monitor mode, and copied to PSTATE.F on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Monitor mode, and copied to PSTATE.T on executing an exception return operation in Monitor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Monitor mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Monitor mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10110 Monitor.
0b10111 Abort.
0b11010  Hyp.
0b11011  Undefined.
0b11111  System.

Other values are reserved. If SPSR_mon.M[4:0] has a Reserved value, or a value for an
unimplemented Exception level, executing an exception return operation in Monitor mode is an
illegal return event, as described in Illegal return events from AArch32 state on page G1-8952.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_mon

SPSR_mon is only accessible in EL3 modes other than Monitor mode.

Accesses to this register use the following encodings in the System register encoding space:

\[

### G8.2.133 SPSR_svc, Saved Program Status Register (Supervisor mode)

The SPSR_svc characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Supervisor mode.

**Configurations**

AArch32 System register SPSR_svc bits [31:0] are architecturally mapped to AArch64 System register `SPSR_EL1[31:0]`.

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_svc are UNDEFINED.

**Attributes**

SPSR_svc is a 32-bit register.

**Field descriptions**

- **N**, bit [31]
  - Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Supervisor mode, and copied to PSTATE.N on executing an exception return operation in Supervisor mode.
  - The reset behavior of this field is:
    - On a Warm reset, this field resets to an architecturally UNKNOWN value.

- **Z**, bit [30]
  - Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Supervisor mode, and copied to PSTATE.Z on executing an exception return operation in Supervisor mode.
  - The reset behavior of this field is:
    - On a Warm reset, this field resets to an architecturally UNKNOWN value.

- **C**, bit [29]
  - Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Supervisor mode, and copied to PSTATE.C on executing an exception return operation in Supervisor mode.
  - The reset behavior of this field is:
    - On a Warm reset, this field resets to an architecturally UNKNOWN value.

- **V**, bit [28]
  - Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Supervisor mode, and copied to PSTATE.V on executing an exception return operation in Supervisor mode.
  - The reset behavior of this field is:
    - On a Warm reset, this field resets to an architecturally UNKNOWN value.

- **Q**, bit [27]
  - Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Supervisor mode, and copied to PSTATE.Q on executing an exception return operation in Supervisor mode.
  - The reset behavior of this field is:
    - On a Warm reset, this field resets to an architecturally UNKNOWN value.
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Supervisor mode, and copied to PSTATE.IT on executing an exception return operation in Supervisor mode.

SPSR_svc.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:
- IT[1:0] is SPSR_svc[26:25].
- IT[7:2] is SPSR_svc[15:10].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When \textit{FEAT_SSBS is implemented}:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Supervisor mode, and copied to PSTATE.SSBS on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When \textit{FEAT_PAN is implemented}:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Supervisor mode, and copied to PSTATE.PAN on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When \textit{FEAT_DIT is implemented}:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Supervisor mode, and copied to PSTATE.DIT on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Supervisor mode, and copied to PSTATE.IL on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Supervisor mode, and copied to PSTATE.GE on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to Supervisor mode, and copied to PSTATE.E on executing an exception return operation in Supervisor mode.

If the implementation does not support big-endian operation, SPSR_svc.E is RES0. If the implementation does not support little-endian operation, SPSR_svc.E is RES1. On executing an exception return operation in Supervisor mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_svc.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_svc.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Supervisor mode, and copied to PSTATE.A on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Supervisor mode, and copied to PSTATE.I on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Supervisor mode, and copied to PSTATE.F on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Supervisor mode, and copied to PSTATE.T on executing an exception return operation in Supervisor mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Supervisor mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Supervisor mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b1111 System.

Other values are reserved. If SPSR_svc.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Supervisor mode is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-8952.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SPSR_svc**

SPSR_svc is accessible in all modes other than User mode and Supervisor mode.

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRS\{<c>\}{<q>}} <Rd>, \text{SPSR\_svc} \\
\text{MSR\{<c>\}{<q>}} \text{SPSR\_svc}, <Rn>
\]

G8.2.134  SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Undefined mode.

**Configurations**

AArch32 System register SPSR_und bits [31:0] are architecturally mapped to AArch64 System register SPSR_und[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to SPSR_und are UNDEFINED.

**Attributes**

SPSR_und is a 32-bit register.

**Field descriptions**

<tr>
<td></td>
<td></td>
<td>• On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>
IT, bits [15:10, 26:25]

If-Then. Set to the value of PSTATE.IT on taking an exception to Undefined mode, and copied to PSTATE.IT on executing an exception return operation in Undefined mode.

SPSR_und.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

- IT[1:0] is SPSR_und[26:25].
- IT[7:2] is SPSR_und[15:10].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

SSBS, bit [23]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Undefined mode, and copied to PSTATE.SSBS on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Undefined mode, and copied to PSTATE.PAN on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Undefined mode, and copied to PSTATE.DIT on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Undefined mode, and copied to PSTATE.IL on executing an exception return operation in Undefined mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.
GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Undefined mode, and copied to PSTATE.GE on executing an exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to Undefined mode, and copied to PSTATE.E on executing an exception return operation in Undefined mode.

If the implementation does not support big-endian operation, SPSR_und.E is RES0. If the implementation does not support little-endian operation, SPSR_und.E is RES1. On executing an exception return operation in Undefined mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_und.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_und.E is RES1.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Undefined mode, and copied to PSTATE.A on executing an exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Undefined mode, and copied to PSTATE.I on executing an exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Undefined mode, and copied to PSTATE.F on executing an exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Undefined mode, and copied to PSTATE.T on executing an exception return operation in Undefined mode.

The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Undefined mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Undefined mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.
Other values are reserved. If SPSR_und.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Undefined mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-8952.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing SPSR Und**

SPSR_und is accessible in all modes other than User mode and Undefined mode.

Accesses to this register use the following encodings in the System register encoding space:

\[ \text{MRS}<c>{<q}> <Rd>, \text{SPSR}_{\text{und}} \]

\[
\begin{array}{c|c|c}
\text{R} & \text{M} & \text{M1} \\
0b1 & 0b1 & 0b0110 \\
\end{array}
\]

\[ \text{MSR}<c>{<q}> \text{SPSR}_{\text{und}}, <Rn> \]

\[
\begin{array}{c|c|c}
\text{R} & \text{M} & \text{M1} \\
0b1 & 0b1 & 0b0110 \\
\end{array}
\]
TCMTR, TCM Type Register

The TCMTR characteristics are:

**Purpose**

Provides information about the implementation of the TCM.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TCMTR are UNDEFINED.

If EL1 or above can use AArch32 then this register must be implemented.

**Attributes**

TCMTR is a 32-bit register.

**Field descriptions**

G8.2.136 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at EL1, all entries that:
  - Would be required for the EL1&0 translation regime.
  - Match the current VMID, if EL2 is implemented and enabled in the current Security state.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at EL2, and if EL2 is enabled in the current Security state, the stage 1 or stage 2 translation table entries that would be required for the PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TLBIALL are UNDEFINED.

**Attributes**

TLBIALL is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing TLBIALL instruction**

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[ MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>

  endif
G8.2.137 TLBIALLH, TLB Invalidate All, Hyp mode

The TLBIALLH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are
from any level of the translation table walk that would be required for the Non-secure EL2
translation regime.

The invalidation only applies to the PE that executes this System instruction.

Configurations

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses
to TLBIALLH are UNDEFINED.

Attributes

TLBIALLH is a 32-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

Executing TLBIALLH instruction

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is
CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction executes as if it had been executed in Monitor mode.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{c\}\{q\} \ <\text{coproc}, \ {#}<\text{opc1}, <\text{Rt}, <\text{CRn}, <\text{CRm}, {#}<\text{opc2}\}
\]

\]
G8.2.138  TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to TLBIALLHIS are **UNDEFINED**.

**Attributes**

TLBIALLHIS is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by `<Rt>` is ignored.

**Executing TLBIALLHIS instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is **CONSTRAINED UNPREDICTABLE**, and one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this instruction use the following encodings in the System instruction encoding space:

G8.2.140 TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to TLBIALLNSNH are UNDEFINED.

**Attributes**

TLBIALLNSNH is a 32-bit System instruction.

**Field descriptions**

This instruction has no applicable fields.

The value in the register specified by <Rt> is ignored.

**Executing TLBIALLNSNH instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this instruction use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{<c>\}{<q>}\{\#}\text{<opc1>}, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \{\#\text{<opc2>}}
\]

```
G8.2.141 TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

**Purpose**
If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.
The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**
This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to TLBIALLNSNHIS are UNDEFINED.

**Attributes**
TLBIALLNSNHIS is a 32-bit System instruction.

**Field descriptions**
This instruction has no applicable fields.
The value in the register specified by <Rt> is ignored.

**Executing TLBIALLNSNHIS instruction**
If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this instruction use the following encodings in the System instruction encoding space:

**G8.2.142 TLBIASID, TLB Invalidate by ASID match**

The TLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TLBIASID are **UNDEFINED**.

**Attributes**

TLBIASID is a 32-bit System instruction.

**Field descriptions**

G8.2.144 TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:
- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to TLBIIPAS2 are UNDEFINED.

---

**Note**

This System instruction is not implemented in architecture versions before Armv8.

---

**Attributes**

TLBIIPAS2 is a 32-bit System instruction.

G8.2.148 TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TLBIMVA are UNDEFINED.

**Attributes**

TLBIMVA is a 32-bit System instruction.

**Field descriptions**

<table>

G8.2.153 TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to TLBIMVAH are UNDEFINED.

**Attributes**

TLBIMVAH is a 32-bit System instruction.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA, bits [31:12]</td>
<td>Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.</td>
</tr>
<tr>
<td>Bits [11:0]</td>

</tr>
</tbody>
</table>

**Executing TLBIMVAH instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```

G8.2.155 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

This instruction is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TLBIMVAIS are UNDEFINED.

**Attributes**

TLBIMVAIS is a 32-bit System instruction.

G8.2.160   TLBTR, TLB Type Register

The TLBTR characteristics are:

**Purpose**

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TLBTR are UNDEFINED.

**Attributes**

TLBTR is a 32-bit register.

**Field descriptions**

<table>

G8.2.161 TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register TPIDRPRW bits [31:0] are architecturally mapped to AArch64 System register TPIDR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TPIDRPRW are UNDEFINED.

Note

The PE never updates this register.

Attributes

TPIDRPRW is a 32-bit register.

G8.2.164 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

**Purpose**

The control register for stage 1 of the PL1&0 translation regime. Its controls include:

- Where the VA range is split between addresses translated using TTBR0 and addresses translated using TTBR1.
- The translation table format used by this stage of translation.

From Armv8.2, when the value of TTBCR.{EAE, T2E} is \{1, 1\}, TTBCR is used with TTBCR2.

**Configurations**

AArch32 System register TTBCR bits [31:0] are architecturally mapped to AArch64 System register TCR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TTBCR are UNDEFINED.

The current translation table format determines which format of the register is used.

Some RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 then:

- The EAE bit resets to 0 in both the Secure and the Non-secure instances of the register.
- Other reset values apply only to the Secure instance of the register.

**Attributes**

TTBCR is a 32-bit register.

**Field descriptions**

*When TTBCR.EAE == 0:*

![Field diagram]

**EAE, bit [31]**

Extended Address Enable.

0b0 Use the VMSAv8-32 translation system with the Short-descriptor translation table format.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

**Bits [30:6]**

Reserved, RES0.

**PD1, bit [5]**

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1.

0b0 Perform translation table walks using TTBR1.

0b1 A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.
The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

**PD0, bit [4]**

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0.

0b0  Perform translation table walks using TTBR0.
0b1  A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

**Bit [3]**

Reserved, RES0.

**N, bits [2:0]**

Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:
• Whether TTBR0 or TTBR1 is used as the base address for translation table walks.
• The size of the translation table pointed to by TTBR0.

N can take any value from 0 to 7, that is, from 0b000 to 0b111.
When N has its reset value of 0, the translation table base is compatible with Armv5 and Armv6.
The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

*When TTBCR.EAE == 1:*

**EAE, bit [31]**

Extended Address Enable.

0b1  Use the VMSAv8-32 translation system with the Long-descriptor translation table format.

The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

**IMPLEMENTATION DEFINED, bit [30]**

IMPLEMENTATION DEFINED.
The reset behavior of this field is:
• On a Warm reset, this field resets to 0.

**SH1, bits [29:28]**

Shareability attribute for memory associated with translation table walks using TTBR1.

0b00  Non-shareable.
0b10  Outer Shareable.
0b11  Inner Shareable.
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**ORGN1, bits [27:26]**

Outer cacheability attribute for memory associated with translation table walks using TTBR1.
- 0b00 Normal memory, Outer Non-cacheable.
- 0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**IRGN1, bits [25:24]**

Inner cacheability attribute for memory associated with translation table walks using TTBR1.
- 0b00 Normal memory, Inner Non-cacheable.
- 0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**EPD1, bit [23]**

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1.
- 0b0 Perform translation table walks using TTBR1.
- 0b1 A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**A1, bit [22]**

Selects whether TTBR0 or TTBR1 defines the ASID.
- 0b0 TTBR0.ASID defines the ASID.
- 0b1 TTBR1.ASID defines the ASID.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**Bits [21:19]**

Reserved, RES0.

**T1SZ, bits [18:16]**

See *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G5-9181 for how TTBCR.T1SZ, T0SZ determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.
Bits [15:14]
Reserved, RES0.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0.
- 0b00  Non-shareable
- 0b10  Outer Shareable
- 0b11  Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0.
- 0b00  Normal memory, Outer Non-cacheable.
- 0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0.
- 0b00  Normal memory, Inner Non-cacheable.
- 0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

EPD0, bit [7]
Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0.
- 0b0  Perform translation table walks using TTBR0.
- 0b1  A TLB miss on an address that is translated using TTBR0 generates a Translation fault.

No translation table walk is performed.

The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

T2E, bit [6]

When FEAT_AA32HPD is implemented:
TTBCR2 Enable.
- 0b0  TTBCR2 is disabled. The contents of TTBCR2 are treated as 0 for all purposes other than reading or writing the register.
- 0b1  TTBCR2 is enabled.

If TTBCR.EAE==0, then the behavior is as if the bit is 0.
Otherwise:

Reserved, RES0.

Bits [5:3]

Reserved, RES0.

**T0SZ, bits [2:0]**

See Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G5-9181 for how TTBCR, {T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

**Accessing TTBCR**

Accesses to this register use the following encodings in the System register encoding space:

\[ MRC\{c\}\{q\} <coproc>, \{\#<opc1>, <Rt>, <CRn>, <CRm>\}, \{\#<opc2}\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>

G8.2.165 TTBCR2, Translation Table Base Control Register 2

The TTBCR2 characteristics are:

**Purpose**

The second control register for stage 1 of the PL1&0 translation regime.

If FEAT_AA32HPD is not implemented then this register is not implemented and its encoding is UNDEFINED. Otherwise:

- When the value of TTBCR.{EAE, T2E} is not \{1, 1\} the contents of TTBCR2 are treated as zero for all purposes other than reading or writing the register.
- When the value of TTBCR.{EAE, T2E} is \{1, 1\} TTBCR2 is used with TTBCR.

**Configurations**

AArch32 System register TTBCR2 bits [31:0] are architecturally mapped to AArch64 System register TCR_EL1[63:32].

This register is present only when EL1 is capable of using AArch32 and FEAT_AA32HPD is implemented. Otherwise, direct accesses to TTBCR2 are UNDEFINED.

**Attributes**

TTBCR2 is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:19]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>18</td>
<td>HWU162, bit [18]</td>
</tr>
</tbody>
</table>

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1.

- For translations using TTBR1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- For translations using TTBR1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.
HWU161, bit [17]

When **FEAT_HPDS2** is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0  For translations using TTBR1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  For translations using TTBR1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU160, bit [16]

When **FEAT_HPDS2** is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0  For translations using TTBR1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  For translations using TTBR1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU159, bit [15]

When **FEAT_HPDS2** is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0  For translations using TTBR1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  For translations using TTBR1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HWU062, bit [14]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0.

0b0 For translations using TTBR0, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [13]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0.

0b0 For translations using TTBR0, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU060, bit [12]

When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0.

0b0 For translations using TTBR0, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HWU059, bit [11]  
When FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0.

0b0  For translations using TTBR0, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1  For translations using TTBR0, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [10]  
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR1.

0b0  Hierarchical permissions are enabled.
0b1  Hierarchical permissions are disabled if TTBCR.T2E == 1.

When disabled, the permissions are treated as if the bits are 0.

The Effective value of this field is 0 if the value of TTBCR.T2E is 0.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

HPD0, bit [9]  
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR0.

0b0  Hierarchical permissions are enabled.
0b1  Hierarchical permissions are disabled if TTBCR.T2E == 1.

When disabled, the permissions are treated as if the bits are 0.

The Effective value of this field is 0 if the value of TTBCR.T2E is 0.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:0]  
Reserved, RES0.

Accessing TTBCR2

G8.2.166   TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the PL1&0 translation regime, and other information for this translation regime.

Configurations

AArch32 System register TTBR0 bits [63:0] are architecturally mapped to AArch64 System register TTBR0_EL1[63:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TTBR0 are UNDEFINED.

TTBR0 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32]. TTBCR.EAE determines which TTBR0 format is used:

• TTBCR.EAE == 0b0: 32-bit format is used. TTBR0[63:32] are ignored.
• TTBCR.EAE == 0b1: 64-bit format is used.

When EL3 is using AArch32, write access to TTBR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

Attributes

TTBR0 is a 64-bit register.

Field descriptions

When TTBCR.EAE == 0:

Bits [63:32]

Reserved, RES0.

TTB0, bits [31:7]

Translation table base address, bits[31:x], where x is 14-(TTBCR.N). Register bits [x-1:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Register bits [x-1:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
IRGN, bits [0, 6]

Inner region bits. Bits [0,6] of this register together indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- **0b00**: Normal memory, Inner Non-cacheable.
- **0b01**: Normal memory, Inner Write-Back Write-Allocate Cacheable.
- **0b10**: Normal memory, Inner Write-Through Cacheable.
- **0b11**: Normal memory, Inner Write-Back no Write-Allocate Cacheable.

--- Note ---

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

The IRGN field is split as follows:

- **IRGN[0]** is TTBR0[6].
- **IRGN[1]** is TTBR0[0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR0.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

- **0b0**: Memory is Outer Shareable.
- **0b1**: Memory is Inner Shareable.

This bit is ignored when the value of TTBR0.S is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- **0b00**: Normal memory, Outer Non-cacheable.
- **0b01**: Normal memory, Outer Write-Back Write-Allocate Cacheable.
- **0b10**: Normal memory, Outer Write-Through Cacheable.
- **0b11**: Normal memory, Outer Write-Back no Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Shareable:

- **0b0**: Memory is Non-shareable.
Memory is Shareable. The TTBR0.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

*When TTBCR.EAE == 1:*

Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]

Translation table base address, bits[47:x]. Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T0SZ as follows:

- If TTBCR.T0SZ is 0 or 1, x = 5 - TTBCR.T0SZ.
- If TTBCR.T0SZ is greater than 1, x = 14 - TTBCR.T0SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CnP, bit [0]

*When FEAT_TTCNP is implemented:*

Common not Private. When TTBCR.EAE == 1, this bit indicates whether each entry that is pointed to by TTBR0 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1.

0b0

The translation table entries pointed to by this instance of TTBR0, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR0 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0.CnP on those other PEs.
- The value of TTBCR.EAE on those other PEs.
- The value of the current ASID or, for the Non-secure instance of TTBR0, the value of the current VMID.
The translation table entries pointed to by this instance of TTBR0 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1 for this instance of TTBR0 and all of the following apply:

- The translation table entries are pointed to by this instance of TTBR0.
- The value of the applicable TTBCR.EAE field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of TTBR0, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

**Note**

If the value of the TTBR0.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values](#) on page K1-11567.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing TTBR0

Accesses to this register use the following encodings in the System register encoding space:

$$MRC{<c>}{<q>}{<coproc>}, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}$$

G8.2.167   TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the PL1&0 translation regime, and other information for this translation regime.

Configurations

AArch32 System register TTBR1 bits [63:0] are architecturally mapped to AArch64 System register TTBR1_EL1[63:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to TTBR1 are UNDEFINED.

TTBR1 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

TTBCR.EAE determines which TTBR1 format is used:

• TTBCR.EAE == 0b0: 32-bit format is used. TTBR1[63:32] are ignored.
• TTBCR.EAE == 0b1: 64-bit format is used.

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

Attributes

TTBR1 is a 64-bit register.

Field descriptions

When TTBCR.EAE == 0:

Bits [63:32]

Reserved, RES0.

TTB1, bits [31:7]

Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

• Register bits [13:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
• The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.
IRGN, bits [6, 0]

Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Cacheable.
- 0b11: Normal memory, Inner Write-Back no Write-Allocate Cacheable.

Note

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for Armv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

The IRGN field is split as follows:
- IRGN[1] is TTBR1[6].
- IRGN[0] is TTBR1[0].

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR1.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

- 0b0: Memory is Outer Shareable.
- 0b1: Memory is Inner Shareable.

This bit is ignored when the value of TTBR1.S is 0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Cacheable.
- 0b11: Normal memory, Outer Write-Back no Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is RES0.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Shareable:

- 0b0: Memory is Non-shareable.
Memory is Shareable. The TTBR1.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

*When TTBCR.EAE == 1:*

### Bits [63:56]

Reserved, RES0.

### ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

### BADDR, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are **CONSTRAINED UNPREDICTABLE**, and must be one of the following:
- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T1SZ as follows:
- If TTBCR.T1SZ is 0 or 1, x = 5 - TTBCR.T1SZ.
- If TTBCR.T1SZ is greater than 1, x = 14 - TTBCR.T1SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

### CnP, bit [0]

*When FEAT_TTCNP is implemented:*

Common not Private. When TTBCR.EAE ==1, this bit indicates whether each entry that is pointed to by TTBR1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1.

0b0 The translation table entries pointed to by this instance of TTBR1, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR1 for other PEs in the Inner Shareable domain. This is not affected by:
- The value of TTBR1.CnP on those other PEs.
- The value of TTBCR.EAE on those other PEs.
- The value of the current ASID or, for the Non-secure instance of TTBR1, the value of the current VMID.
The translation table entries pointed to by this instance of TTBR1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1 for this instance of TTBR1 and all of the following apply:

- The translation table entries are pointed to by this instance of TTBR1.
- The value of the applicable TTBCR.EAE field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of TTBR1, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

**Note**

If the value of the TTBR1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONstrained UNPREDICTABLE, see [CONstrained UNPREDICTABLE behaviors due to caching of System register control or data values](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing TTBR1

Accesses to this register use the following encodings in the System register encoding space:

      TTBR1_NS = R[t2]:R[t];
  endif
G8.2.168 VBAR, Vector Base Address Register

The VBAR characteristics are:

**Purpose**

When high exception vectors are not selected, holds the vector base address for exceptions that are not taken to Monitor mode or to Hyp mode.

Software must program VBAR(NS) with the required initial value as part of the PE boot sequence.

**Configurations**

AArch32 System register VBAR bits [31:0] are architecturally mapped to AArch64 System register VBAR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to VBAR are UNDEFINED.

**Attributes**

VBAR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:5]</th>
<th>Vector Base Address</th>
<th>RES0</th>
</tr>
</thead>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

**Bits [4:0]**

Reserved, RES0.

**Accessing VBAR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>}, \text{(#}<opc1>, <Rt>, <CRn>, <CRm>, \text{(#}<opc2>)}
\]

<table>

G8.2.169 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

**Purpose**

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

**Configurations**

AArch32 System register VMPIDR bits [31:0] are architecturally mapped to AArch64 System register VMPIDR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to VMPIDR are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MPIDR.

**Attributes**

VMPIDR is a 32-bit register.

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the Armv7 Multiprocessing Extensions.

0b0 This implementation does not include the Armv7 Multiprocessing Extensions functionality.

0b1 This implementation includes the Armv7 Multiprocessing Extensions functionality.

Access to this field is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

0b0 Processor is part of a multiprocessor system.

0b1 Processor is part of a uniprocessor system.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MPIDR.U.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels.

0b0 Performance of PEs at the lowest affinity level is largely independent.

0b1 Performance of PEs at the lowest affinity level is very interdependent.
The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MPIDR.MT.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Aff2, bits [23:16]**

Affinity level 2. See the description of Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff2.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Aff1, bits [15:8]**

Affinity level 1. See the description of Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff1.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Aff0, bits [7:0]**

Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR.{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Accessing VMPIDR**

Accesses to this register use the following encodings in the System register encoding space:

```assembly
MRC{<c}<{q}> <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>), (#<opc2>)
```

<table>

G8.2.170 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

**Purpose**

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

**Configurations**

AArch32 System register VPIDR bits [31:0] are architecturally mapped to AArch64 System register VPIDR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to VPIDR are UNDEFINED.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MIDR.

**Attributes**

VPIDR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Variant</td>
<td></td>
<td></td>
<td></td>
<td>PartNum</td>
<td></td>
<td>Revision</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

Assigned codes include the following:

- **0x00** Reserved for software use.
- **0x41** Arm Limited.
- **0x42** Broadcom Corporation.
- **0x43** Cavium Inc.
- **0x44** Digital Equipment Corporation.
- **0x46** Fujitsu Ltd.
- **0x49** Infineon Technologies AG.
- **0x40** Motorola or Freescale Semiconductor Inc.
- **0x4E** NVIDIA Corporation.
- **0x50** Applied Micro Circuits Corporation.
- **0x51** Qualcomm Inc.
- **0x56** Marvell International Ltd.
- **0x69** Intel Corporation.
- **0xC0** Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MIDR.Implementer.
  - Otherwise, this field resets to an architecturally UNKNOWN value.
Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MIDR.Variant.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Architecture, bits [19:16]

Architecture version. Defined values are:

- 0b0001  Armv4.
- 0b0010  Armv4T.
- 0b0011  Armv5 (obsolete).
- 0b0100  Armv5T.
- 0b0101  Armv5TE.
- 0b0110  Armv5TEJ.
- 0b0111  Armv6.
- 0b1111  Architectural features are individually identified in the ID_* registers.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MIDR.Architecture.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MIDR.PartNum.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to the value in MIDR.Revision.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing VPIDR

G8.2.171 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

**Purpose**

The control register for stage 2 of the Non-secure PL1&0 translation regime.

--- Note ---

This stage of translation always uses the Long-descriptor translation table format.

**Configurations**

AArch32 System register VTCR bits [31:0] are architecturally mapped to AArch64 System register VTCR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to VTCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

VTCR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES1.</td>
</tr>
<tr>
<td>30-29</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**HWU62, bit [28]**

*When FEAT_HPDS2 is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table Block or Page entry.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Bit[62] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
<tr>
<td>1</td>
<td>Bit[62] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.</td>
</tr>
</tbody>
</table>

The reset behavior of this field is:

* On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
HWU61, bit [27]

When `FEAT_HPDS2` is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table Block or Page entry.

0b0  Bit[61] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[61] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU60, bit [26]

When `FEAT_HPDS2` is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table Block or Page entry.

0b0  Bit[60] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[60] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU59, bit [25]

When `FEAT_HPDS2` is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table Block or Page entry.

0b0  Bit[59] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1  Bit[59] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [24:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using VTTBR.

0b00  Non-shareable.

0b10  Outer Shareable.

0b11  Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**ORGN0, bits [11:10]**
Outer cacheability attribute for memory associated with translation table walks using VTTBR.
- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IRGN0, bits [9:8]**
Inner cacheability attribute for memory associated with translation table walks using VTTBR.
- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SL0, bits [7:6]**
Starting level for translation table walks using VTTBR.
- 0b00: Start at level 2
- 0b01: Start at level 1

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of T0SZ, then a stage 2 level 1 Translation fault is generated.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [5]**
Reserved, RES0.

**S, bit [4]**
Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the stage 2 T0SZ value is treated as an UNKNOWN value.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**T0SZ, bits [3:0]**
The size offset of the memory region addressed by VTTBR. The region size is $2^{(32-\text{T0SZ})}$ bytes.
This field holds a four-bit signed integer value, meaning it supports values from -8 to 7.

--- Note ---

This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

---

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 1 Translation fault is generated.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally \textsc{unknown} value.

### Accessing VTCR

Accesses to this register use the following encodings in the System register encoding space:

\begin{verbatim}
MRC\{<c>\}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
\end{verbatim}

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b100</td>
<td>0b0010</td>
<td>0b0001</td>
<td>0b010</td>
</tr>
</tbody>
</table>

\begin{verbatim}
MCR\{<c>\}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
\end{verbatim}

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b100</td>
<td>0b0010</td>
<td>0b0001</td>
<td>0b010</td>
</tr>

    \text{UNDEFINED};
else
  \text{VTCR = R[t]};
G8.2.172 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Non-secure PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register VTTBR bits [63:0] are architecturally mapped to AArch64 System register VTTBR_EL2[63:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to VTTBR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

VTTBR is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-56</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>55-48</td>
<td>VMID</td>
</tr>
<tr>
<td>47-32</td>
<td>BADDR</td>
</tr>
<tr>
<td>31-1</td>
<td>BADDR</td>
</tr>
<tr>
<td>0</td>
<td>CnP</td>
</tr>
</tbody>
</table>

**Bits [63:56]**

Reserved, RES0.

**VMID, bits [55:48]**

The VMID for the translation table.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, bits[47:x]. Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of VTCR.SL0 and VTCR.T0SZ as follows:

- If VTCR.SL0 is @b00, meaning that lookup starts at level 2, then x is 14 - VTCR.T0SZ.
- If VTCR.SL0 is @b01, meaning that lookup starts at level 1, then x is 5 - VTCR.T0SZ.
- If VTCR.SL0 is either @b10 or @b11 then a stage 2 level 1 Translation fault is generated.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.
The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

**CnP, bit [0]**

**When FEAT_TTCNP is implemented:**

Common not Private. This bit indicates whether each entry that is pointed to by VTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1.

- 0b0: The translation table entries pointed to by VTTBR are permitted to differ from the entries for VTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.
- 0b1: The translation table entries pointed to by VTTBR are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1 and the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

---

**Note**

If the value of the VTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBRs do not point to the same translation table entries when the VMID value is the same as the current VMID, then the results of translations are CONSTRAINED UNPREDICTABLE, see **CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values** on page K1-11567.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Accessing VTTBR**

Accesses to this register use the following encodings in the System register encoding space:

```
MRRC(<c>){<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

<table>

G8.3 Debug registers

This section lists the Debug System registers in AArch32 state, in alphabetic order.
### G8.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Configurations**

AArch32 System register DBGAUTHSTATUS bits [31:0] are architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1[31:0].

AArch32 System register DBGAUTHSTATUS bits [31:0] are architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGAUTHSTATUS are UNDEFINED.

This register is required in all implementations.

**Attributes**

DBGAUTHSTATUS is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-8</td>
<td>SNID</td>
</tr>
<tr>
<td>7-6</td>
<td>SID</td>
</tr>
<tr>
<td>5-4</td>
<td>NSID</td>
</tr>
<tr>
<td>3</td>
<td>NSNID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SNID, bits [7:6]**

*When FEAT_Debugv8p4 is implemented:*

Secure Non-Invasive Debug.

This field has the same value as DBGAUTHSTATUS.SID.

*Otherwise:*

Secure Non-Invasive Debug.

- **0b00** Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 1.
- **0b10** Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- **0b11** Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

**SID, bits [5:4]**

Secure Invasive Debug.

- **0b00** Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.
- **0b10** Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- **0b11** Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.
NSID, bits [3:2]

*When FEAT_Debugv8p4 is implemented:*

- **0b00**: Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 0.
- **0b11**: Implemented and enabled. EL3 is implemented or the Effective value of SCR.NS is 1.

All other values are reserved.

*Otherwise:*

- **0b00**: Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 0.
- **0b10**: Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- **0b11**: Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

- **0b00**: Not implemented. EL3 is not implemented or the Effective value of SCR_EL3.NS is 0.
- **0b10**: Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- **0b11**: Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

**Accessing DBGAUTHSTATUS**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC\{<c>\}{<q> \ coproc, \ (#<opc1>, \ <Rt>, \ <CRn>, \ <CRm>{, \ (#<opc2>))
}

  R[t] = DBGAUTHSTATUS;
G8.3.2 **DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15**

The DBGBCR<n> characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

**Configurations**

AArch32 System register DBGBCR<n> bits [31:0] are architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].

AArch32 System register DBGBCR<n> bits [31:0] are architecturally mapped to External register DBGBCR<n>_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGBCR<n> are UNDEFINED.

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**

DBGBCR<n> is a 32-bit register.

**Field descriptions**

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- **0b0000**: Unlinked instruction address match. DBGBVR<n> is the address of an instruction.
- **0b0001**: As 0b0000, but linked to a Context matching breakpoint.
- **0b0010**: Unlinked Context ID match. When FEAT_VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBCR<n>.ContextID must match the CONTEXTIDR_EL2 value. Otherwise, DBGBCR<n>.ContextID must match the CONTEXTIDR value.
- **0b0011**: As 0b0010 with linking enabled.
- **0b0100**: Unlinked instruction address mismatch. DBGBVR<n> is the address of an instruction to be stepped.
- **0b0101**: As 0b0100, but linked to a Context matching breakpoint.
- **0b0110**: Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>.ContextID is a Context ID compared against CONTEXTIDR.
- **0b0111**: As 0b0110 with linking enabled.
- **0b1000**: Unlinked VMID match. DBGBXVR<n>.VMID is a VMID compared against VTTBR.VMID.
- **0b1001**: As 0b1000 with linking enabled.
### LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<\text-prev>.E is 0.

The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

### SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint \text-prev is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields.

For more information, see *Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063* and *Reserved DBGBCR<\text-prev>.\{SSC, HMC, PMC\} values on page G2-9075*.

The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

### HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint \text-prev is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063*.

The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

### Bits [12:9]

Reserved, RES0.

### BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state.

The permitted values depend on the breakpoint type.
For Address match breakpoints, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see Reserved DBGCR<n>.BAS values on page G2-9075.

For more information on using the BAS field in Address Match breakpoints, see Using the BAS field in Address Match breakpoints on page G2-9067.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see Reserved DBGCR<n>.BAS values on page G2-9075.

For more information on using the BAS field in address mismatch breakpoints, see Using the BAS field in Address Match breakpoints on page G2-9067.

For Context matching breakpoints, this field is RES1 and ignored.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [4:3]**

Reserved, RES0.

**PMC, bits [2:1]**

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGCR<n>.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-9063.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E, bit [0]**

Enable breakpoint DBGBVR<n>. Possible values are:

- 0b0 Breakpoint disabled.
- 0b1 Breakpoint enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.
Accessing DBGBCR<n>

Accesses to this register use the following encodings in the System register encoding space:

\[

G8.3.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGCR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

**Configurations**

AArch32 System register DBGBVR<n> bits [31:0] are architecturally mapped to AArch64 System register DBGBVR<n>_EL1[31:0].

AArch32 System register DBGBVR<n> bits [31:0] are architecturally mapped to External register DBGBVR<n>_EL1[31:0].

**Note**

Writes to DBGBVR<n> do not modify DBGBVR<n>_EL1[63:32].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGBVR<n> are UNDEFINED.

How this register is interpreted depends on the value of DBGCR<n>.BT.

- When DBGCR<n>.BT is 0b00x, this register holds a virtual address.
- When DBGCR<n>.BT is 0bxx1x, this register holds a Context ID.

For other values of DBGCR<n>.BT, this register is RES0.

Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGIDR.CTX_CMPs field.

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**

DBGBVR<n> is a 32-bit register.

**Field descriptions**

*When DBGCR<n>.BT == 0b000x:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA[31:2]</td>
<td></td>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

VA[31:2], bits [31:2]

Bits[31:2] of the address value for comparison.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.
When DBGBCR<\textit{n}>,\textit{BT} == 0b001\textit{x}:

ContextID, bits [31:0]
Context ID value for comparison.
The value is compared against CONTEXTIDR_EL2 when all of the following are true:
- FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented.
- HCR_EL2.{E2H, TGE} is \{1,1\}.
- The PE is executing at EL0.
- EL2 is using AArch64 and is enabled in the current Security state.
Otherwise, the value is compared against CONTEXTIDR.
The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<\textit{n}>,\textit{BT} == 0b101\textit{x} and EL2 is implemented:

ContextID, bits [31:0]
Context ID value for comparison against CONTEXTIDR.
The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<\textit{n}>,\textit{BT} == 0bx11x, EL2 is implemented and (FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented):

ContextID, bits [31:0]
Context ID value for comparison against CONTEXTIDR.
The reset behavior of this field is:
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBVR<\textit{n}>

G8.3.4 DBGBXVR\(<n>\), Debug Breakpoint Extended Value Registers, \(n = 0 - 15\)

The DBGBXVR\(<n>\) characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR\(<n>\) and a value register DBGBVR\(<n>\), where EL2 is implemented and breakpoint \(n\) supports Context matching.

**Configurations**

- AArch32 System register DBGBXVR\(<n>\) bits [31:0] are architecturally mapped to AArch64 System register DBGBVR\(<n>\)_EL1[63:32].
- AArch32 System register DBGBXVR\(<n>\) bits [31:0] are architecturally mapped to External register DBGBVR\(<n>\)_EL1[63:32].

--- Note ---

Writes to DBGBXVR\(<n>\) do not modify DBGBVR\(<n>\)_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGBXVR\(<n>\) are UNDEFINED.

How this register is interpreted depends on the value of DBGBCR\(<n>\).BT.

- When DBGBCR\(<n>\).BT is 0b10xx, this register holds a VMID.
- When DBGBCR\(<n>\).BT is 0b11xx, this register holds a Context ID.

For other values of DBGBCR\(<n>\).BT, this register is RES0.

Accesses to this register are UNDEFINED in any of the following cases:

- Breakpoint \(n\) is not implemented.
- Breakpoint \(n\) does not support Context matching.
- EL2 is not implemented.

For more information, see the description of the DBGDIDR.CTX_CMPs field.

**Attributes**

DBGBXVR\(<n>\) is a 32-bit register.

**Field descriptions**

*When DBGBCR\(<n>\).BT == 0b10xx and EL2 is implemented:*

![](image)

- **Bits [31:16]**
  - Reserved, RES0.
- **VMID[15:8]**, bits [15:8]
  - *When FEAT_VMID16 is implemented and VTCR_EL2.VS == 1:*
    - Extension to VMID[7:0]. For more information, see VMID[7:0].
  - The reset behavior of this field is:
    - On a Cold reset, this field resets to an architecturally UNKNOWN value.
  - *Otherwise:*
    - Reserved, RES0.
VMID[7:0], bits [7:0]

VMID value for comparison. The VMID is 8 bits when any of the following are true:

- EL2 is using AArch32.
- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>.BT == 0b11xx and EL2 is implemented:

ContextID2, bits [31:0]

When FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing DBGBXVR<n>

G8.3.5 DBGCLAIMCLR, Debug CLAIM Tag Clear register

The DBGCLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

---

CLAIM tags are used in conjunction with the DBGCLAIMSET register.

**Configurations**

AArch32 System register DBGCLAIMCLR bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

AArch32 System register DBGCLAIMCLR bits [31:0] are architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGCLAIMCLR are UNDEFINED.

An implementation must include eight CLAIM tag bits.

**Attributes**

DBGCLAIMCLR is a 32-bit register.

**Field descriptions**

![Field Descriptions Diagram]

**Bits [31:8]**

Reserved, RAZ/WI.

**CLAIM, bits [7:0]**

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

The reset behavior of this field is:

- On a Cold reset, this field resets to 0.

**Accessing DBGCLAIMCLR**

Accesses to this register use the following encodings in the System register encoding space:
MRC{<c>}{<q>} <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>{, (#<opc2>}

G8.3.6 DBGCLAIMSET, Debug CLAIM Tag Set register

The DBGCLAIMSET characteristics are:

**Purpose**

- Used by software to set the CLAIM tag bits to 1.
- The architecture does not define any functionality for the CLAIM tag bits.

--- **Note** ---

 CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR register.

**Configurations**

- AArch32 System register DBGCLAIMSET bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].
- AArch32 System register DBGCLAIMSET bits [31:0] are architecturally mapped to External register DBGCLAIMSET_EL1[31:0].
- This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGCLAIMSET are UNDEFINED.
- An implementation must include eight CLAIM tag bits.

**Attributes**

- DBGCLAIMSET is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>8-7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/WI</td>
<td>CLAIM</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

- Reserved, RAZ/WI.

**CLAIM, bits [7:0]**

- Set CLAIM tag bits.
- This field is RAO.
- Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.
- Writing 0 to one of these bits has no effect.
- The reset behavior of this field is:
  - On a Cold reset, this field resets to 0.

**Accessing DBGCLAIMSET**

Accesses to this register use the following encodings in the System register encoding space:
MRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>, (#)<opc2>}

<table>
<thead>

G8.3.8   DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

**Purpose**

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGDEVID are UNDEFINED.

This register is required in all implementations.

**Attributes**

DBGDEVID is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDMask</td>

<td>DoubleLock</td>
<td>VirtExtns</td>
<td>WPAddrMask</td>
<td>BPAddrMask</td>
<td>VectorCatch</td>
<td>PCSample</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**CIDMask, bits [31:28]**

Indicates the level of support for the Context ID matching breakpoint masking capability. Defined values are:

- 0b0000  Context ID masking is not implemented.
- 0b0001  Context ID masking is implemented.

All other values are reserved. The value of this for Armv8 is 0b0000.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

- 0b0000  None supported.
- 0b0001  Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

**DoubleLock, bits [23:20]**

OS Double Lock implemented. Defined values are:

- 0b0000  OS Double Lock is not implemented. DBGOSDLR is RAZ/WI.
- 0b0001  OS Double Lock is implemented. DBGOSDLR is RW.

FEAT_DoubleLock implements the functionality identified by the value 0b0001.

All other values are reserved.

**VirtExtns, bits [19:16]**

Indicates whether EL2 is implemented. Defined values are:

- 0b0000  EL2 is not implemented.
- 0b0001  EL2 is implemented.

All other values are reserved.
VectorCatch, bits [15:12]

Defines the form of Vector Catch exception implemented. Defined values are:

- 0b0000  Address matching Vector Catch exception implemented.
- 0b0001  Exception matching Vector Catch exception implemented.

All other values are reserved.

BPAddrMask, bits [11:8]

Indicates the level of support for the instruction address matching breakpoint masking capability. Defined values are:

- 0b0000  Breakpoint address masking might be implemented. If not implemented, DBGBCR<n>[28:24] is RAZ/WI.
- 0b0001  Breakpoint address masking is implemented.
- 0b1111  Breakpoint address masking is not implemented. DBGBCR<n>[28:24] is RES0.

All other values are reserved. The value of this for Armv8 is 0b1111.

WPAddrMask, bits [7:4]

Indicates the level of support for the data address matching watchpoint masking capability. Defined values are:

- 0b0000  Watchpoint address masking might be implemented. If not implemented, DBGWCR<n>.MASK (Address mask) is RAZ/WI.
- 0b0001  Watchpoint address masking is implemented.
- 0b1111  Watchpoint address masking is not implemented. DBGWCR<n>.MASK (Address mask) is RES0.

All other values are reserved. The value of this for Armv8 is 0b0001.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers. Defined values are:

- 0b0000  PC Sample-based Profiling Extension is not implemented in the external debug registers space.
- 0b0010  Only EDPCSР and EDCIDSР are implemented. This option is only permitted if EL3 and EL2 are not implemented.
- 0b0011  EDPCSР, EDCIDSР, and EDVIDSR are implemented.

All other values are reserved.

When FEAT_PCSRv8p2 is implemented, the only permitted value is 0b0000.

--- Note ---

FEAT_PCSRv8p2 implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Accessing DBGDEVID

Accesses to this register use the following encodings in the System register encoding space:

G8.3.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

Configurations

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGDEVID1 are UNDEFINED.

This register is required in all implementations.

Attributes

DBGDEVID1 is a 32-bit register.

Field descriptions

Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in Armv8 are:

- 0b0000: EDPCSR is not implemented.
- 0b0010: EDPCSR implemented. Samples have no offset applied and do not sample the instruction set state in AArch32 state.

When FEAT_PCSRv8p2 is implemented, the only permitted value is 0b0000.

Note

FEAT_PCSRv8p2 implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Accessing DBGDEVID1

Accesses to this register use the following encodings in the System register encoding space:

G8.3.11  **DBGDIDR, Debug ID Register**

The DBGDIDR characteristics are:

**Purpose**
Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

**Configurations**
This register is present only when AArch32 is supported. Otherwise, direct accesses to DBGDIDR are UNDEFINED.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

**Attributes**
DBGDIDR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Permitted values</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRPs, bits</td>
<td>The number of watchpoints implemented, minus 1.</td>
<td>from 0b0001 to 0b1111</td>
</tr>
<tr>
<td>BRPs, bits</td>
<td>The number of breakpoints implemented, minus 1.</td>
<td>from 0b0001 to 0b1111</td>
</tr>
<tr>
<td>CTX_CMPs, bits</td>
<td>The number of breakpoints that can be used for Context matching, minus 1.</td>
<td>from 0b0000 to 0b1111</td>
</tr>
<tr>
<td>Version, bits</td>
<td>Debug architecture version. Indicates presence of Armv8 debug architecture. Defined values are:</td>
<td>0b0000 Not supported, 0b0001 Armv6, v6 Debug architecture, with System registers access, 0b0010 Armv6, v6.1 Debug architecture, with System registers access</td>
</tr>
</tbody>
</table>

**WRPs, bits [31:28]**
The number of watchpoints implemented, minus 1.

**BRPs, bits [27:24]**
The number of breakpoints implemented, minus 1.

**CTX_CMPs, bits [23:20]**
The number of breakpoints that can be used for Context matching, minus 1.

**Version, bits [19:16]**
Debug architecture version. Indicates presence of Armv8 debug architecture. Defined values are:
0b0011  Armv7, v7 Debug architecture, with only baseline System registers.
0b0100  Armv7, v7 Debug architecture, with all System registers implemented.
0b0101  Armv7, v7.1 Debug architecture, with System registers access.
0b0110  Armv8 debug architecture.
0b0111  Armv8 debug architecture with Virtualization Host Extensions.
0b1000  Armv8.2 debug architecture, FEAT_Debugv8p2.
0b1001  Armv8.4 debug architecture, FEAT_Debugv8p4.
0b1010  Armv8.8 debug architecture, FEAT_Debugv8p8.

All other values are reserved.
The values 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101 are not permitted in Armv8.

FEAT_VHE adds the functionality identified by the value 0b0111.
FEAT_Debugv8p2 adds the functionality identified by the value 0b1000.
FEAT_Debugv8p4 adds the functionality identified by the value 0b1001.
FEAT_Debugv8p8 adds the functionality identified by the value 0b1010.

From Armv8.1, when FEAT_VHE is implemented the value 0b0110 is not permitted.
From Armv8.2, the values 0b0110 and 0b0111 are not permitted.
From Armv8.4, the value 0b1000 is not permitted.
From Armv8.8, the value 0b1001 is not permitted.

Bit [15]
Reserved, RES1.

nSUHD_imp, bit [14]
Previously indicated that Secure User Halting Debug is not implemented.
The value of this bit must match the value of the SE_imp bit.

Bit [13]
Reserved, RES0.

SE_imp, bit [12]
EL3 implemented. The meanings of the values of this bit are:
0b0   EL3 not implemented.
0b1   EL3 implemented.
The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]
Reserved, RES0.

Accessing DBGDIDR
Arm deprecates any access to this register from EL0.
Accesses to this register use the following encodings in the System register encoding space:
if Halted() && ConstrantUnpredictableBool(UNPREDICTABLE_IGNORETRAPINDEBUG) then
    \( R[t] = \text{DBGIDR} \);

G8.3.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. Armv8 deprecates any use of this register.

**Configurations**

AArch32 System register DBGDRAR bits [63:0] are architecturally mapped to AArch64 System register MDRAR_EL1[63:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to DBGDRAR are UNDEFINED.

DBGDRAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

If EL3 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

**Attributes**

DBGDRAR is a 64-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-48</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>47-12</td>
<td>ROMADD[47:12]</td>
</tr>
<tr>
<td>11-2</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>1-0</td>
<td>Valid</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**ROMADD[47:12], bits [47:12]**

Bits[47:12] of the ROM table physical address.

If the physical address size in bits (PAsize) is less than 48 then the register bits corresponding to ROMADD[47:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

Arm strongly recommends that bits ROMADD[(PAsize-1):32] are zero in any system where the implementation only supports execution in AArch32 state.

In an implementation that includes EL3, ROMADD is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

If DBGDRAR.Valid == 0b00, then this field is UNKNOWN.

**Bits [11:2]**

Reserved, RES0.

**Valid, bits [1:0]**

This field indicates whether the ROM Table address is valid.

0b00  ROM Table address is not valid. Software must ignore ROMADD.

0b11  ROM Table address is valid.

Other values are reserved.
Arm recommends implementations set this field to zero.

**Accessing DBGDRAR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{\langle c\rangle,\langle q\rangle\} \langle \text{coproc}, \{\langle #\rangle\langle opc1\rangle, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \{\langle #\rangle\langle opc2\rangle\} \}
\]

<table>
<thead>

G8.3.14  DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

**Purpose**

Main control register for the debug implementation.

**Configurations**

AArch32 System register DBGDSCRext bits [31:0] are architecturally mapped to AArch64 System register MDSCR_EL1[31:0].

AArch32 System register DBGDSCRext bit [15] is architecturally mapped to AArch32 System register DBGDSCRint[15].

AArch32 System register DBGDSCRext bit [12] is architecturally mapped to AArch32 System register DBGDSCRint[12].

AArch32 System register DBGDSCRext bits [5:2] are architecturally mapped to AArch32 System register DBGDSCRint[5:2].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGDSCRext are UNDEFINED.

This register is required in all implementations.

**Attributes**

DBGDSCRext is a 32-bit register.

**Field descriptions**

**TFO, bit [31]**

*When FEAT_TRF is implemented:*

Trace Filter override. Used for save/restore of EDSR_TFO.

When the OS Lock is unlocked, DBGOSLR.OSLK == 0, software must treat this bit as UNK/SBZP.

When the OS Lock is locked, DBGOSLR.OSLK == 1, this bit holds the value of EDSR_TFO.

Reads and writes of this bit are indirect accesses to EDSR_TFO.

Accessing this field has the following behavior:

- When DBGOSLR.OSLK == 1, access to this field is RW.
- When DBGOSLR.OSLK == 0, access to this field is RO.

*Otherwise:*

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. Used for save/restore of EDSR_RXfull.

When DBGOSLR.OSLK == 0, software must treat this bit as UNK/SBZP.
When `DBGOSLSR.OSLK == 1`, this bit holds the value of `EDSCR.RXfull`. Reads and writes of this bit are indirect accesses to `EDSCR.RXfull`.

Arm deprecates use of this bit other than for save/restore. Use `DBGDSCRint` to access the DTRRX full status.

The reset behavior of this field is:
- The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
- When `DBGOSLSR.OSLK == 1`, access to this field is RW.
- When `DBGOSLSR.OSLK == 0`, access to this field is RO.

**TXfull, bit [29]**

DTRTX full. Used for save/restore of `EDSCR.TXfull`.

When `DBGOSLSR.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `DBGOSLSR.OSLK == 1`, this bit holds the value of `EDSCR.TXfull`. Reads and writes of this bit are indirect accesses to `EDSCR.TXfull`.

Arm deprecates use of this bit other than for save/restore. Use `DBGDSCRint` to access the DTRTX full status.

The reset behavior of this field is:
- The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
- When `DBGOSLSR.OSLK == 1`, access to this field is RW.
- When `DBGOSLSR.OSLK == 0`, access to this field is RO.

**Bit [28]**

Reserved, RES0.

**RXO, bit [27]**

Used for save/restore of `EDSCR.RXO`.

When `DBGOSLSR.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `DBGOSLSR.OSLK == 1`, this bit holds the value of `EDSCR.RXO`. Reads and writes of this bit are indirect accesses to `EDSCR.RXO`.

When `DBGOSLSR.OSLK == 1`, if bits [27,6] of the value written to `DBGDSCRext` are \{1,0\}, that is, the RXO bit is 1 and the ERR bit is 0, the PE sets `EDSCR.{RXO,ERR}` to UNK/SBZP values.

The reset behavior of this field is:
- The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
- When `DBGOSLSR.OSLK == 1`, access to this field is RW.
- When `DBGOSLSR.OSLK == 0`, access to this field is RO.

**TXU, bit [26]**

Used for save/restore of `EDSCR.TXU`.

When `DBGOSLSR.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `DBGOSLSR.OSLK == 1`, this bit holds the value of `EDSCR.TXU`. Reads and writes of this bit are indirect accesses to `EDSCR.TXU`.

When `DBGOSLSR.OSLK == 1`, if bits [26,6] of the value written to `DBGDSCRext` are \{1,0\}, that is, the TXU bit is 1 and the ERR bit is 0, the PE sets `EDSCR.{TXU,ERR}` to UNK/SBZP values.

The reset behavior of this field is:
- The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:
- When `DBGOSLSR.OSLK == 1`, access to this field is RW.
• When DBGOSLSR.OSLK == 0, access to this field is RO.

**Bits [25:24]**

Reserved, RES0.

**INTdis, bits [23:22]**

Used for save/restore of EDSCR.INTdis.

When DBGOSLSR.OSLK == 0, this field is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1, this field holds the value of EDSCR.INTdis. Reads and writes of this field are indirect accesses to EDSCR.INTdis.

The reset behavior of this field is:

• The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:

• When DBGOSLSR.OSLK == 1, access to this field is RW.

• When DBGOSLSR.OSLK == 0, access to this field is RO.

**TDA, bit [21]**

Used for save/restore of EDSCR.TDA.

When DBGOSLSR.OSLK == 0, software must treat this bit as UNK/SBZP.

When DBGOSLSR.OSLK == 1, this bit holds the value of EDSCR.TDA. Reads and writes of this bit are indirect accesses to EDSCR.TDA.

The reset behavior of this field is:

• The architected behavior of this field determines the value it returns after a reset.

Accessing this field has the following behavior:

• When DBGOSLSR.OSLK == 1, access to this field is RW.

• When DBGOSLSR.OSLK == 0, access to this field is RO.

**Bit [20]**

Reserved, RES0.

**SC2, bit [19]**

*When FEAT_PCSRv8 is implemented, FEAT_VHE is implemented and FEAT_PCSRv8p2 is not implemented:*

Used for save/restore of EDSCR.SC2.

When DBGOSLSR.OSLK == 0, software must treat this bit as UNK/SBZP.

When DBGOSLSR.OSLK == 1, this bit holds the value of EDSCR.SC2. Reads and writes of this bit are indirect accesses to EDSCR.SC2.

Accessing this field has the following behavior:

• When DBGOSLSR.OSLK == 1, access to this field is RW.

• When DBGOSLSR.OSLK == 0, access to this field is RO.

**Otherwise:**

Reserved, RES0.

**NS, bit [18]**

Non-secure status.

Arm deprecates use of this field.

0b0 Secure state.

0b1 Non-secure state.

Access to this field is RO.
SPNIDis, bit [17]

When EL3 is implemented:

Secure privileged profiling disabled status bit.

0b0  Profiling allowed in Secure privileged modes.
0b1  Profiling prohibited in Secure privileged modes.

This field reads as 0 if any of the following applies, and reads as 1 otherwise:

- FEAT_Debugv8p2 is not implemented and ExternalSecureNoninvasiveDebugEnabled() returns TRUE.
- EL3 is using AArch32 and the value of SDCR.SPME is 1.
- EL3 is using AArch64 and the value of MDCR_EL3.SPME is 1.

Arm deprecates use of this field.

Access to this field is RO.

Otherwise:

Reserved, RES0.

SPIDis, bit [16]

When EL3 is implemented:

Secure privileged AArch32 invasive self-hosted debug disabled status bit. The value of this bit depends on the value of SDCR.SPD and the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled().

0b0  Self-hosted debug enabled in Secure privileged AArch32 modes.
0b1  Self-hosted debug disabled in Secure privileged AArch32 modes.

This bit reads as 1 if any of the following is true and reads as 0 otherwise:

- EL3 is using AArch32 and SDCR.SPD has the value 0b10.
- EL3 is using AArch64 and MDCR_EL3.SPD32 has the value 0b10.
- EL3 is using AArch32, SDCR.SPD has the value 0b00, and AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled() returns FALSE.
- EL3 is using AArch64, MDCR_EL3.SPD32 has the value 0b00, and AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled() returns FALSE.

Arm deprecates use of this field.

Access to this field is RO.

Otherwise:

Reserved, RES0.

MDBGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

0b0  Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
0b1  Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to 0.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When DBGOSLSR.OSLK == 0, software must treat this bit as UNK/SBZP.

When DBGOSLSR.OSLK == 1, this bit holds the value of EDSCR.HDE. Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The reset behavior of this field is:

- The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When DBGOSLSR.OSLK == 1, access to this field is RW.
- When DBGOSLSR.OSLK == 0, access to this field is RO.

**Bit [13]**
Reserved, RES0.

**UDCCdis, bit [12]**
Traps EL0 accesses to the DCC registers to Undefined mode.
- 0b0: This control does not cause any instructions to be trapped.
- 0b1: EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTTRXint, DBGDIDR, DBGDSAR, and DBGDRAR are trapped to Undefined mode.

**Note**
All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRRXint and DBGDTTRXint, and MRRR accesses to DBGDSAR and DBGDRAR.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTTRXint are ignored in Debug state.
The reset behavior of this field is:
- On a Warm reset, this field resets to 0.

**Bits [11:7]**
Reserved, RES0.

**ERR, bit [6]**
Used for save/restore of EDSR.ERR.
When DBGOSLSR.OSLK == 0, software must treat this bit as UNK/SBZP.
When DBGOSLSR.OSLK == 1, this bit holds the value of EDSR.ERR. Reads and writes of this bit are indirect accesses to EDSR.ERR.
The reset behavior of this field is:
- The architected behavior of this field determines the value it returns after a reset.
Accessing this field has the following behavior:
- When DBGOSLSR.OSLK == 1, access to this field is RW.
- When DBGOSLSR.OSLK == 0, access to this field is RO.

**MOE, bits [5:2]**
Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:
- 0b0001: Breakpoint.
- 0b0011: Software breakpoint (BKPT) instruction.
- 0b0101: Vector catch.
- 0b0100: Watchpoint.
The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [1:0]**
Reserved, RES0.

**Accessing DBGDSCRext**
Individual fields within this register might have restricted accessibility when the OS Lock is unlocked, DBGOSLSR.OSLK == 0. See the field descriptions for more detail.
Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} \{#<opc1>\}, <Rt>, <CRn>, <CRm>\{, \{#<opc2>\}\}
\]

### G8.3.15  DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

**Purpose**

Main control register for the debug implementation. This is an internal, read-only view.

**Configurations**

AArch32 System register DBGDSCRint bits [30:29] are architecturally mapped to AArch64 System register MDCCSR_EL0[30:29].

AArch32 System register DBGDSCRint bit [15] is architecturally mapped to AArch64 System register MDSCR_EL1[15].

AArch32 System register DBGDSCRint bit [12] is architecturally mapped to AArch64 System register MDSCR_EL1[12].

AArch32 System register DBGDSCRint bits [5:2] are architecturally mapped to AArch64 System register MDSCR_EL1[5:2].

AArch32 System register DBGDSCRint bit [15] is architecturally mapped to AArch32 System register DBGDSCRext[15].

AArch32 System register DBGDSCRint bit [12] is architecturally mapped to AArch32 System register DBGDSCRext[12].

This register is present only when AArch32 is supported. Otherwise, direct accesses to DBGDSCRint are UNDEFINED.

This register is required in all implementations.

DBGDSCRint. {NS, SPNIdis, SPIdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext. {NS, SPNIdis, SPIdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

**Attributes**

DBGDSCRint is a 32-bit register.

NS, bit [18]
Non-secure status.
Read-only view of the equivalent bit in the DBGDSCRext. Arm deprecates use of this field.

SPNIDdis, bit [17]
Secure privileged non-invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. Arm deprecates use of this field.

SPIDdis, bit [16]
Secure privileged invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. Arm deprecates use of this field.

MDBGen, bit [15]
Monitor debug events enable.
Read-only view of the equivalent bit in the DBGDSCRext.

Bits [14:13]
Reserved, RES0.

UDCCdis, bit [12]
User mode access to Debug Communications Channel disable.
Read-only view of the equivalent bit in the DBGDSCRext. Arm deprecates use of this field.

Bits [11:6]
Reserved, RES0.

MOE, bits [5:2]
Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0b0001 Breakpoint
- 0b0011 Software breakpoint (BKPT) instruction
- 0b0101 Vector catch
- 0b1010 Watchpoint

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [1:0]
Reserved, RES0.

**Accessing DBGDSCRint**

When <Rt> is APSR_nzcv, encoded as R15, then instead of reading the entire register, the access copies DBGDSCRint[31:28] into the PSTATE NZCV flags.

Accesses to this register use the following encodings in the System register encoding space:
MRC<coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>, (#<opc2>)

<table>

G8.3.16 DBGDTRRXext, Debug OS Lock Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

**Purpose**

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel.

**Configurations**

AArch32 System register DBGDTRRXext bits [31:0] are architecturally mapped to AArch64 System register OSDTRRX_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGDTRRXext are UNDEFINED.

**Attributes**

DBGDTRRXext is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Update DTRRX without side-effect.</td>
</tr>
<tr>
<td></td>
<td>Writes to this register update the value in DTRRX and do not change RXfull.</td>
</tr>
<tr>
<td></td>
<td>Reads of this register return the last value written to DTRRX and do not change RXfull.</td>
</tr>
<tr>
<td></td>
<td>For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.</td>
</tr>
<tr>
<td></td>
<td>The reset behavior of this field is:</td>
</tr>
<tr>
<td></td>
<td>• On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing DBGDTRRXext**

Arm deprecates reads and writes of DBGDTRRXext through the System register interface when the OS Lock is unlocked, DBGOSLSR.OSLK == 0.

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC{<c>}{<q>}{<coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>{, (#<opc2>)}
\]

<table>
<thead>
<tr>

G8.3.17  DBGDTRRXint, Debug Data Transfer Register, Receive

The DBGDTRRXint characteristics are:

**Purpose**

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

**Configurations**

AArch32 System register DBGDTRRXint bits [31:0] are architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

AArch32 System register DBGDTRRXint bits [31:0] are architecturally mapped to External register DBGDTRRX_EL0[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to DBGDTRRXint are UNDEFINED.

**Attributes**

DBGDTRRXint is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Update DTRRX</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Update DTRRX.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing DBGDTRRXint**

Data can be stored to memory from this register using STC.

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{c\}\{q\} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>, \{#<opc2>\}
\]

if Halted() then

G8.3.18   DBGDTRTXext, Debug OS Lock Data Transfer Register, Transmit

The DBGDTRTXext characteristics are:

Purpose

Used for save/restore of DBGDTRTXint. It is a component of the Debug Communication Channel.

Configurations

AArch32 System register DBGDTRTXext bits [31:0] are architecturally mapped to AArch64 System register OSDTRTX_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGDTRTXext are UNDEFINED.

Attributes

DBGDTRTXext is a 32-bit register.

Field descriptions

Bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTXext

Arm deprecates reads and writes of DBGDTRTXext through the System register interface when the OS Lock is unlocked, DBGOSLSR.OSLK == 0.

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{c\}\{q\} <\text{coproc}, \ (#)\langle opc1\rangle, <Rt>, <\text{CRn}>, <\text{CRm}\rangle\{, \ (#)\langle opc2\rangle\}
\]

<table>

G8.3.19  DBGDTRTXint, Debug Data Transfer Register, Transmit

The DBGDTRTXint characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configurations

AArch32 System register DBGDTRTXint bits [31:0] are architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

AArch32 System register DBGDTRTXint bits [31:0] are architecturally mapped to External register DBGDTRTX_EL0[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to DBGDTRTXint are UNDEFINED.

Attributes

DBGDTRTXint is a 32-bit register.

Field descriptions

Bits [31:0]

Return DTRTX.

Writes to this register:

- If TXfull is set to 1, set DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTXint

Data can be loaded from memory into this register using LDC (immediate) and LDC (literal).

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MCR\{<c>\}{<q}> <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}}
\]

G8.3.21  DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

**Purpose**

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

**Configurations**

AArch32 System register DBGOSECCR bits [31:0] are architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

AArch32 System register DBGOSECCR bits [31:0] are architecturally mapped to External register EDECCR[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGOSECCR are UNDEFINED.

If DBGOSLSR.OSLK == 0 then DBGOSECCR returns an UNKNOWN value on reads and ignores writes.

**Attributes**

DBGOSECCR is a 32-bit register.

**Field descriptions**

When DBGOSLSR.OSLK == 1:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDECCR</td>
<td>Bits [31:0] Used for save/restore to EDECCR over powerdown. Reads or writes to this field are indirect accesses to EDECCR.</td>
</tr>
</tbody>
</table>

**Accessing DBGOSECCR**

Accesses to this register use the following encodings in the System register encoding space:

\[
MRC\{<c>\}{<q>} \{<opc1>, \{#\}<opc2>, <Rt>, <CRn>, <CRm}\{, \{#\}<opc2>\}
\]

<table>

### G8.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

**Purpose**

Provides status information for the OS Lock.

**Configurations**

AArch32 System register DBGOSLSR bits [31:0] are architecturally mapped to AArch64 System register OSLSR_EL1[31:0].  

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGOSLSR are UNDEFINED.  

The OS Lock status is also visible in the external debug interface through EDPRSR.

**Attributes**

DBGOSLSR is a 32-bit register.

**Field descriptions**

- **Bits [31:4]**
  - Reserved, RES0.
- **OSLM, bits [3, 0]**
  - OS Lock model implemented. Identifies the form of OS save and restore mechanism implemented.
    - 0b00: OS Lock not implemented.
    - 0b10: OS Lock implemented.
  - All other values are reserved. In an Armv8 implementation the value 0b00 is not permitted.  
  - The OSLM field is split as follows:
    - OSLM[1] is DBGOSLSR[3].
    - OSLM[0] is DBGOSLSR[0].
- **nTT, bit [2]**
  - Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.
- **OSLK, bit [1]**
  - OS Lock Status.
    - 0b0: OS Lock unlocked.
    - 0b1: OS Lock locked.
  - The OS Lock is locked and unlocked by writing to the OS Lock Access Register.
  - The reset behavior of this field is:
    - On a Cold reset, this field resets to 1.

### Accessing DBGOSLSR

Accesses to this register use the following encodings in the System register encoding space:
if PSTATE_EL == EL0 then
  UNDEFINED;

  R[t] = DBGOSLSR;
G8.3.24  DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

**Purpose**

Controls behavior of the PE on powerdown request.

**Configurations**

AArch32 System register DBGPRCR bits [31:0] are architecturally mapped to AArch64 System register DBGPRCR_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGPRCR are UNDEFINED.

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

**Attributes**

DBGPRCR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>CORENPDRQ, bit [0]</td>
</tr>
</tbody>
</table>

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

0b0  If the system responds to a powerdown request, it powers down Core power domain.

0b1  If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see Core power domain power states on page H6-10336.

--- Note ---

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is set to an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.
Otherwise:

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

0b0 If the system responds to a powerdown request, it powers down Core power domain.

0b1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPSCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see Core power domain power states on page H6-10336.

——— Note ———

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, this field resets to the value in EDPSCR.COREPURQ.

Accessing DBGPRCR

Accesses to this register use the following encodings in the System register encoding space:

### G8.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

**Purpose**

Controls Vector Catch debug events.

**Configurations**

AArch32 System register DBGVCR bits [31:0] are architecturally mapped to AArch64 System register DBGVCR32_EL2[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGVCR are **UNDEFINED**.

This register is required in all implementations.

**Attributes**

DBGVCR is a 32-bit register.

**Field descriptions**

*When EL3 is implemented and EL3 is using AArch32:*

<table>
<thead>
<tr>

</table>
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**NSS, bit [26]**
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is **0x08**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**NSU, bit [25]**
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is **0x04**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [24:16]**
Reserved, **RES0**.

**MF, bit [15]**
FIQ vector catch enable in Monitor mode.
The exception vector offset is **0x1C**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**MI, bit [14]**
IRQ vector catch enable in Monitor mode.
The exception vector offset is **0x18**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bit [13]**
Reserved, **RES0**.

**MD, bit [12]**
Data Abort exception vector catch enable in Monitor mode.
The exception vector offset is **0x10**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**MP, bit [11]**
Prefetch Abort vector catch enable in Monitor mode.
The exception vector offset is **0x0C**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**MS, bit [10]**
Secure Monitor Call (SMC) vector catch enable in Monitor mode.
The exception vector offset is **0x08**.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Bits [9:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]

IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort exception vector catch enable in Secure state.
The exception vector offset is 0x10.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.
When EL3 is implemented and EL3 is using AArch64:

<table>
<thead>

SP, bit [3]
Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]
Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
The reset behavior of this field is:
• On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]
Reserved, RES0.

When EL3 is not implemented:
Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.
The exception vector offset is 0x1C.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [6]

IRQ vector catch enable.
The exception vector offset is 0x18.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort exception vector catch enable.
The exception vector offset is 0x10.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

P, bit [3]

Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [2]

Supervisor Call (SVC) vector catch enable.
The exception vector offset 0x08.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [1]

Undefined Instruction vector catch enable.
The exception vector offset 0x04.
The reset behavior of this field is:
  • On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

G8.3.26    DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>.

**Configurations**

AArch32 System register DBGWCR<n> bits [31:0] are architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

AArch32 System register DBGWCR<n> bits [31:0] are architecturally mapped to External register DBGWCR<n>_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGWCR<n> are UNDEFINED.

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**

DBGWCR<n> is a 32-bit register.

**Field descriptions**

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- 0b00000  No mask.
- 0b00001  Reserved.
- 0b00010  Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b000011 masking 3 address bits (0x00000007 mask for address) to 0b11111111 masking 31 address bits (0x7FFFFFFF mask for address).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [23:21]**

Reserved, RES0.
WT, bit [20]

Watchpoint type. Possible values are:

0b0  Unlinked data address match.
0b1  Linked data address match.

The reset behavior of this field is:

• On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

The reset behavior of this field is:

• On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-9081, and Reserved DBGWCR<n>.{SSC, HMC, PAC} values on page G2-9088.

The reset behavior of this field is:

• On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-9081.

The reset behavior of this field is:

• On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0bxxxxxxx1</td>
<td>Match byte at DBGWVR&lt;n&gt;</td>
</tr>
<tr>
<td>0bxxxxxx1x</td>
<td>Match byte at DBGWVR&lt;n&gt;+1</td>
</tr>
<tr>
<td>0bxxxxx1xx</td>
<td>Match byte at DBGWVR&lt;n&gt;+2</td>
</tr>
<tr>
<td>0bxxxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<n> addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;n&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0bxxx1xxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+4</td>
</tr>
</tbody>
</table>

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<\text{n}>.BAS values on page G2-9089.

The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:
0b01  Match instructions that load from a watchpointed address.
0b10  Match instructions that store to a watchpointed address.
0b11  Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint \( \text{n} \) is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-9081.

The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint \( \text{n} \). Possible values are:
0b0  Watchpoint disabled.
0b1  Watchpoint enabled.

The reset behavior of this field is:
• On a Cold reset, this field resets to an architecturally UNKNOWN value.

### Accessing DBGWCR<\text{n}>

Accesses to this register use the following encodings in the System register encoding space:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;\text{n}&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0bxx1xxxx</td>

G8.3.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

**Purpose**

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RES0.

**Configurations**

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGWFAR are UNDEFINED.

**Attributes**

DBGWFAR is a 32-bit register.

**Field descriptions**

Bits [31:0]  
Reserved, RES0.

**Accessing DBGWFAR**

Accesses to this register use the following encodings in the System register encoding space:

G8.3.28  **DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15**

The DBGWVR<n> characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>.

**Configurations**

AArch32 System register DBGWVR<n> bits [31:0] are architecturally mapped to AArch64 System register DBGWVR<n>_EL1[31:0].

AArch32 System register DBGWVR<n> bits [31:0] are architecturally mapped to External register DBGWVR<n>_EL1[31:0].

This register is present only when EL1 is capable of using AArch32. Otherwise, direct accesses to DBGWVR<n> are UNDEFINED.

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

**Attributes**

DBGWVR<n> is a 32-bit register.

**Field descriptions**

<table>
<thead>

### G8.3.29 DLR, Debug Link Register

The DLR characteristics are:

**Purpose**

In Debug state, holds the address to restart from.

**Configurations**

AArch32 System register DLR bits [31:0] are architecturally mapped to AArch64 System register `DLR_EL0[31:0]`.

This register is present only when AArch32 is supported. Otherwise, direct accesses to DLR are UNDEFINED.

**Attributes**

DLR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Restart address</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Restart address.

**Accessing DLR**

Accesses to this register use the following encodings in the System register encoding space:

**MRC\{<c>\}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2}>**

<table>

</table>

if !Halted() then
  UNDEFINED;
else
  DLR = R[t];
G8.3.30  **DSPSR, Debug Saved Program Status Register**

The DSPSR characteristics are:

**Purpose**

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

**Configurations**

AArch32 System register DSPSR bits [31:0] are architecturally mapped to AArch64 System register DSPSR_EL0[31:0].

This register is present only when AArch32 is supported. Otherwise, direct accesses to DSPSR are UNDEFINED.

**Attributes**

DSPSR is a 32-bit register.

**Field descriptions**

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
```

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

The reset behavior of this field is:
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Q, bit [27]**

Overflow or saturation flag. Set to the value of PSTATE.Q on entering Debug state, and copied to PSTATE.Q on exiting Debug state.
The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IT, bits [15:10, 26:25]**

If-Then. Set to the value of PSTATE.IT on entering Debug state, and copied to PSTATE.IT on exiting Debug state.

DSPSR.IT must contain a value that is valid for the instruction being returned to.

The IT field is split as follows:

• IT[1:0] is DSPSR[26:25].
• IT[7:2] is DSPSR[15:10].

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DIT, bit [24]**

*When FEAT_DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**SSBS, bit [23]**

*When FEAT_SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**PAN, bit [22]**

*When FEAT_PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**SS, bit [21]**

Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.

The reset behavior of this field is:

• On a Warm reset, this field resets to an architecturally UNKNOWN value.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on entering Debug state, and copied to PSTATE.GE on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on entering Debug state, and copied to PSTATE.E on exiting Debug state.

If the implementation does not support big-endian operation, DSPSR.E is RES0. If the implementation does not support little-endian operation, DSPSR.E is RES1. On exiting Debug state, if the implementation does not support big-endian operation at the Exception level being returned to, DSPSR.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, DSPSR.E is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on entering Debug state, and copied to PSTATE.T on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on entering Debug state, and copied to PSTATE.M[4:0] on exiting Debug state.

- 0b10000 User
- 0b10001 FIQ
- 0b10010 IRQ
- 0b10011 Supervisor
- 0b10110 Monitor
Other values are reserved. If DSPSR.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-8952.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

### Accessing DSPSR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} \text{ <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>{, (#<opc2>}}
\]

```

    \( \text{DSPSR} = R[t]; \)
**G8.3.31 HDCR, Hyp Debug Control Register**

The HDCR characteristics are:

**Purpose**

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

**Configurations**

AArch32 System register HDCR bits [31:0] are architecturally mapped to AArch64 System register MDCR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32. Otherwise, direct accesses to HDCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3, and other than for a direct read of the register, the PE behaves as if HDCR.HPMN \(=\) PMCR.N.

**Attributes**

HDCR is a 32-bit register.

**Field descriptions**

Bits [31:30]

Reserved, RES0.

HPMFZO, bit [29]

*When FEAT_PMUv3p7 is implemented:*

Hyp Performance Monitors Freeze-on-overflow. Stop event counters on overflow.

0b0  Do not freeze on overflow.

0b1  Event counters do not count when PMOVSR[(PMCR.N-1):HDCR.HPMN] is nonzero.

If HDCR.HPMN is less than PMCR.N, this field affects the operation of event counters in the range [HDCR.HPMN .. (PMCR.N-1)].

This field does not affect the operation of other event counters and PMCCNTR.

The operation of this field applies even when EL2 is disabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

MTPME, bit [28]

*When FEAT_MTPMU is implemented and EL3 is not implemented:*

Multi-threaded PMU Enable. Enables use of the PMEVTYPE\(<n>\).MT bits.

0b0  FEAT_MTPMU is disabled. The Effective value of PMEVTYPE\(<n>\).MT is zero.

0b1  PMEVTYPE\(<n>\).MT bits not affected by this bit.
If FEAT_MTPMU is disabled for any other PE in the system that has the same level 1 Affinity as the PE, it is IMPLEMENTATION DEFINED whether the PE behaves as if this bit is 0b0.

The reset behavior of this field is:

- **On a Cold reset:**
  - When the PE resets into EL2 or EL3, this field resets to 1.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**TDCC, bit [27]**

When FEAT_FGT is implemented:

Trap DCC. Traps use of the Debug Comms Channel at EL1 and EL0 to EL2.

0b0  This control does not cause any register accesses to be trapped.

0b1  If EL2 is implemented and enabled in the current Security state, accesses to the DCC registers at EL1 and EL0 generate a Hyp Trap exception, unless the access also generates a higher priority exception.

Traps on the DCC data transfer registers are ignored when the PE is in Debug state.

The DCC registers trapped by this control are:

- DBGDTRRXext, DBGDTRRXtext, DBGDSRCRint, DBGDCCINT, and, when the PE is in Non-debug state, DBGDTRRXint and DBGDTRTXint.

The traps are reported with EC syndrome value:

- 0x05 for trapped MRC and MCR accesses with coproc == 0b1110.
- 0x06 for trapped LDC to DBGDTRRXint and STC from DBGDTRRXint.

When the PE is in Debug state, HDCR.TDCC does not trap any accesses to:

- DBGDTRRXint and DBGDTRTXint.

The reset behavior of this field is:

- **On a Warm reset:**
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**HLP, bit [26]**

When FEAT_PMUv3p5 is implemented:

Hypervisor Long event counter enable. Determines when unsigned overflow is recorded by an event counter overflow bit.

0b0  Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<ν>[31:0].

0b1  Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<ν>[63:0].

If the highest implemented Exception level is using AArch32, it is IMPLEMENTATION DEFINED whether this bit is read/write or RAZ/WI.

If HDCR.HPMN is less than PMCR.N, this bit affects the operation of event counters in the range [HDCR.HPMN..(PMCR.N-1)].

This field does not affect the operation of other event counters.

The operation of this field applies even when EL2 is disabled in the current Security state.
--- Note ---

The reset behavior of this field is:
- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [25:24]**
Reserved, RES0.

**HCCD, bit [23]**

*When FEAT_PMUv3p5 is implemented:*

Hypervisor Cycle Counter Disable. Prohibits PMCCNTR from counting at EL2.

- 0b0 Cycle counting by PMCCNTR is not affected by this mechanism.
- 0b1 Cycle counting by PMCCNTR is prohibited at EL2.

This field does not affect the CPU_CYCLES event or any other event that counts cycles.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [22:20]**
Reserved, RES0.

**TTRF, bit [19]**

*When FEAT_TRF is implemented:*

Traps use of the Trace Filter Control registers at EL1 to EL2.

- 0b0 Accesses to TRFCR at EL1 are not affected by this control bit.
- 0b1 Accesses to TRFCR at EL1 generate a Hyp Trap exception.

The reset behavior of this field is:
- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bit [18]**
Reserved, RES0.

**HPMD, bit [17]**

*When FEAT_PMUv3p1 is implemented and FEAT_Debugv8p2 is implemented:*

Guest Performance Monitors Disable. Controls event counting by some event counters at EL2.

- 0b0 Event counting and PMCCNTR are not affected by this mechanism.
Event counting by some event counters is prohibited in Hyp mode. If PMCR.DP is 1, PMCCNTR is disabled in Hyp mode. Otherwise, PMCCNTR is not affected by this mechanism.

If HDCR.HPMN is not 0, this field affects the operation of event counters in the range \([0..(HDCR.HPMN-1)]\).

This field does not affect the operation of other event counters.

If PMCR.DP is 1, this field affects PMCCNTR.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**When FEAT_PMUv3p1 is implemented:**

Guest Performance Monitors Disable. Controls event counting by some event counters at EL2.

- Event counting and PMCCNTR are not affected by this mechanism.
- If ExternalSecureNoninvasiveDebugEnabled() is FALSE, event counting by some event counters is prohibited in Hyp mode, and if PMCR.DP is 1, PMCCNTR is disabled in Hyp mode.
- If ExternalSecureNoninvasiveDebugEnabled() is TRUE, this field does not affect the event counters and does not affect PMCCNTR.

Otherwise:

- If HDCR.HPMN is not 0, this field affects the operation of event counters in the range \([0..(HDCR.HPMN-1)]\).
- This field does not affect the operation of other event counters.
- If PMCR.DP is 1, this field affects PMCCNTR.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

**Bits [16:12]**

Reserved, RES0.

**TDRA, bit [11]**

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode.

- This control does not cause any instructions to be trapped.
- Non-secure EL0 and EL1 System register accesses to the DBGDRAR or DBGDSAR are trapped to Hyp mode, unless it is trapped by DBGDSCR.ext.UDCCdis.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.
TDOSA, bit [10]

When FEAT_DoubleLock is implemented:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to DBGOSDLR are trapped.

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers in the (copro==0b1110) encoding space that are not trapped by either of the following:

- HDCR.TDRA.
- HDCR.TDOSA.

0b0  This control does not cause any instructions to be trapped.
Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by HDCR.TDRA and HDCR.TDOSA, are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**TDE, bit [8]**

Trap Debug exceptions. Controls routing of Debug exceptions, and defines the debug target Exception level, EL_D:

- The debug target Exception level is EL1.
- If EL2 is enabled for the current Effective value of SCR.NS, the debug target Exception level is EL2, otherwise the debug target Exception level is EL1.

The HDCR.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

For more information, see Routing debug exceptions on page G2-9043.

When HCR.TGE == 1, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

**HPME, bit [7]**

*When FEAT_PMUv3 is implemented:*

[HDCR.HPMN.\((N-1)\)] event counters enable.

- Event counters in the range [HDCR.HPMN.\((PMCR.N-1)\)] are disabled.
- Event counters in the range [HDCR.HPMN.\((PMCR.N-1)\)] are enabled by PMCNTENSET.

If HDCR.HPMN is less than PMCR.N, this field affects the operation of event counters in the range [HDCR.HPMN.\((PMCR.N-1)\)].

This field does not affect the operation of other event counters.

The operation of this field applies even when EL2 is disabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**TPM, bit [6]**

*When FEAT_PMUv3 is implemented:*

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

- This control does not cause any instructions to be trapped.

---

G8-9940 Copyright © 2013-2022 Arm Limited or its affiliates. All rights reserved. ARM DDI 0487I.a Non-Confidential
Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

--- Note ---
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TPMCR, bit [5]
When FEAT_PMUv3 is implemented:
Trap PMCR accesses. Traps Non-secure EL0 and EL1 accesses to the PMCR to Hyp mode.

0b0	This control does not cause any instructions to be trapped.

0b1	Non-secure EL0 and EL1 accesses to the PMCR are trapped to Hyp mode, unless it is trapped by PMUSERENR.EN.

--- Note ---
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HPMN, bits [4:0]
When FEAT_PMUv3 is implemented:
Defines the number of event counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If HPMN is not 0 and is less than PMCR.N, HPMN divides the event counters into a first range [0..(HPMN-1)], and a second range [HPMN..(PMCR.N-1)].

If FEAT_HPMN0 is implemented and this field is 0, all event counters are in the second range and none are in the first range.

If HPMN is equal to PMCR.N, all event counters are in the first range, and none are in the second range.

For an event counter <n> in the first range:

- The counter is accessible from EL1, EL2, EL3.
- The counter is accessible from EL0 if permitted by PMUSERENR.
- If FEAT_PMUv3p5 is implemented, PMCR.LP determines whether the counter overflows at PMEVCNTR<n>[31:0] or PMEVCNTR<n>[63:0].
- PMCR.E and PMCNTENSET[n] enable the operation of event counter n.

For an event counter <n> in the second range:

- The counter is accessible from EL2 and EL3.
• If EL2 is disabled in the current Security state, the event counter is also accessible from EL1, and from EL0 if permitted by PMUSERENR.
• If FEAT_PMUV3p5 is implemented, HDCR.HLP determines whether the counter overflows at PMEVCTR<n>[31:0] or PMEVCTR<n>[63:0].
• HDCR.HPME and PMCNTENSET[n] enable the operation of event counter n.

If HPMN is larger than PMCR.N, or if FEAT_HPMN0 is not implemented and HPMN is 0, the following CONSTRAINED UNPREDICTABLE behaviors apply:
• The value returned by a direct read of HDCR.HPMN is UNKNOWN.
• Either:
  — An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than or equal to PMCR.N.
  — All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

The reset behavior of this field is:
• On a Warm reset:
  — When the PE resets into EL2 or EL3, this field resets to the value in PMCR.N.
  — Otherwise, this field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing HDCR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} \text{ <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2}>}
\]

### G8.3.32 HTRFCR, Hyp Trace Filter Control Register

The HTRFCR characteristics are:

#### Purpose

Provides EL2 controls for Trace.

#### Configurations

AArch32 System register HTRFCR bits [31:0] are architecturally mapped to AArch64 System register TRFCR_EL2[31:0].

This register is present only when EL2 is capable of using AArch32 and FEAT_TRF is implemented. Otherwise, direct accesses to HTRFCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from Monitor mode when SCR.NS == 1.

#### Attributes

HTRFCR is a 32-bit register.

#### Field descriptions

Bit [2]

Reserved, RES0.

E2TRE, bit [1]

EL2 Trace Enable.

0b0  Tracing is prohibited at EL2.

0b1  Tracing is allowed at EL2.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

E0HTRE, bit [0]

EL0 Trace Enable.

0b0  Tracing is prohibited at EL0 when HCR.TGE == 1.

0b1  Tracing is allowed at EL0 when HCR.TGE == 1.

This field is ignored if any of the following are true:

- The PE is in Secure state.
- SelfHostedTraceEnabled() == FALSE.
- HCR.TGE == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the PE resets into EL2 or EL3, this field resets to 0.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing HTRFCR

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{<c>\}{<q>} \langle\text{coproc}\rangle, \{\#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{\#\}<\text{opc2}> \]

G8.3.33 PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

**Purpose**

Describes Performance Monitors parameters specific to the implementation to software.

**Configurations**

This register is present only when EL1 is capable of using AArch32 and FEAT_PMUv3p4 is implemented. Otherwise, direct accesses to PMMIR are UNDEFINED.

**Attributes**

PMMIR is a 32-bit register.

**Field descriptions**

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>0b1110</td>
<td>12 bits.</td>
<td></td>
</tr>
</tbody>
</table>

All other values are reserved.

If FEAT_PMUv3_TH is not implemented, this field is zero.

Otherwise, the largest value that can be written to PMEVTYPER<\(n\)>_EL0.TH is \(2^{(\text{PMMIR.THWIDTH}) - 1}\).

**Note**

PMEVTYPER<\(n\)>_EL0.TH cannot be accessed through PMEVTYPER<\(n\)>.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.
**BUS_WIDTH, bits [19:16]**

Bus width. Indicates the number of bytes each BUS_ACCESS event relates to. Encoded as \( \log_2(\text{number of bytes}) \), plus one.

- 0b0000  The information is not available.
- 0b0011  Four bytes.
- 0b0100  8 bytes.
- 0b0101  16 bytes.
- 0b0110  32 bytes.
- 0b0111  64 bytes.
- 0b1000  128 bytes.
- 0b1001  256 bytes.
- 0b1010  512 bytes.
- 0b1011  1024 bytes.
- 0b1100  2048 bytes.

All other values are reserved.

Each transfer is up to this number of bytes. An access might be smaller than the bus width.

When this field is nonzero, each access counted by BUS_ACCESS is at most BUS_WIDTH bytes. An implementation might treat a wide bus as multiple narrower buses, such that a wide access on the bus increments the BUS_ACCESS counter by more than one.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**BUS_SLOTS, bits [15:8]**

Bus count. The largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle.

When this field is nonzero, the largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle is BUS_SLOTS.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**SLOTS, bits [7:0]**

Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL SLOT event is not implemented, this field might read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

**Accessing PMMIR**

Accesses to this register use the following encodings in the System register encoding space:

\[
\text{MRC}\{\langle c\rangle\}\{\langle q\rangle\} \langle \text{coproc}\rangle, \langle\#\langle \text{opc1}\rangle\rangle, \langle \text{Rt}\rangle, \langle \text{CRn}\rangle, \langle \text{CRm}\rangle, \langle\#\langle \text{opc2}\rangle\rangle
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b000</td>
<td>0b1001</td>
<td>0b1110</td>
<td>0b110</td>
</tr>
</tbody>
</table>
