J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`.

——— Note ————

Many AArch32 pseudocode functions have not been updated to show the constraints on the Armv7 UNPREDICTABLE behaviors that are described in Appendix K1 Architectural Constraints on UNPREDICTABLE Behaviors. Where AArch32 pseudocode shows something to be UNPREDICTABLE, check Appendix K1 for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- `aarch32/debug` on page J1-11258.
- `aarch32/exceptions` on page J1-11270.
- `aarch32/functions` on page J1-11290.
- `aarch32/translation` on page J1-11320.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- `aarch32/debug/VCRMatch/AArch32.VCRMatch` on page J1-11258.
- `aarch32/debug/pmu/AArch32.CheckForPMUOverflow` on page J1-11262.
- `aarch32/debug/pmu/AArch32.PMUCounterIsHyp` on page J1-11266.
- `aarch32/debug/pmu/AArch32.PMUCycle` on page J1-11266.
- `aarch32/debug/pmu/AArch32.PMUSwIncrement` on page J1-11267.
- `aarch32/debug/taakeexceptiondbg/AArch32.EnterHypModeInDebugState` on page J1-11267.
- `aarch32/debug/taakeexceptiondbg/AArch32.EnterModeInDebugState` on page J1-11267.
- `aarch32/debug/taakeexceptiondbg/AArch32.EnterMonitorModeInDebugState` on page J1-11268.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a FunctionName, without an AArch64 or AArch32 prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example shared/debug/DebugTarget.

The top-level sections of the shared pseudocode hierarchy are:

- shared/debug
- shared/exceptions on page J1-11382.
- shared/functions on page J1-11384.
- shared/trace on page J1-11528.
- shared/translation on page J1-11533.

J1.3.1 shared/debug

This section includes the following pseudocode functions:

- shared/debug/DebugTarget/DebugTarget on page J1-11356.
- shared/debug/DebugTarget/DebugTargetFrom on page J1-11356.
- shared/debug/OSLockStatus/OSLockStatus on page J1-11357.
- shared/debug/SoftwareLockStatus/Component on page J1-11357.
- shared/debug/SoftwareLockStatus/SoftwareLockStatus on page J1-11357.
- shared/debug/authentication/AccessState on page J1-11357.
- shared/debug/authentication/AllowExternalDebugAccess on page J1-11357.
- shared/debug/authentication/AllowExternalPMUAccess on page J1-11358.
- shared/debug/authentication/AllowExternalTraceAccess on page J1-11359.
- shared/debug/authentication/Debug_authentication on page J1-11359.

// Signals the memory system that memory accesses of type HINT to or from the specified address are
// likely in the near future. The memory system may take some action to speed up the memory
// accesses when they do occur, such as pre-loading the specified address into one or more
// caches as indicated by the innermost cache level target (0=L1, 1=L2, etc) and non-temporal hint
// stream. Any or all prefetch hints may be treated as a NOP. A prefetch hint must not cause a
// synchronous abort due to Alignment or Translation faults and the like. Its only effect on
// software-visible state should be on caches and TLBs associated with address, which must be
// accessible by reads, writes or execution, as defined in the translation regime of the current
// Exception level. It is guaranteed not to access Device memory.
// A Prefetch_EXEC hint must not result in an access that could not be performed by a speculative
// instruction fetch, therefore if all associated MMUs are disabled, then it cannot access any
// memory location that cannot be accessed by instruction fetches.

Architectural Constraints on UNPREDICTABLE Behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the Armv8 and later architectures. It contains the following sections:

- AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-11562.
- AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-11584.
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

From the introduction of Armv8, the architecture defines architecturally required constraints on many behaviors that are UNPREDICTABLE in Armv7. The following sections define those constraints:

- Overview of the constraints on Armv7 UNPREDICTABLE behaviors on page K1-11563.
- Using R13 by instruction on page K1-11563.
- Using R15 by instruction on page K1-11563.
- Branching into an IT block on page K1-11564.
- Branching to an unaligned PC on page K1-11564.
- Loads and Stores to unaligned locations on page K1-11564.
- CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-11564.
- Unallocated System register access instructions on page K1-11565.
- SBZ or SBO fields T32 and A32 in instructions on page K1-11566.
- UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-11566.
- UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions on page K1-11566.
- CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values on page K1-11567.
- CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-11567.
- Translation Table Base Address alignment on page K1-11568.
- Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-11568.
- Mapping of non-idempotent memory locations using the Normal memory type on page K1-11569.
- The Performance Monitors Extension on page K1-11569.
- The Activity Monitors Extension on page K1-11571.
- Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-11572.
- Out of range VA on page K1-11572.
- Instruction fetches from Device memory on page K1-11572.
- Multi-access instructions that load the PC from Device memory on page K1-11572.
- Programming CSSEL.R Level for a cache level that is not implemented on page K1-11572.
- Crossing a page boundary with different memory types or Shareability attributes on page K1-11573.
- Crossing a 4KB boundary with a Device access on page K1-11573.
- UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-11573.
- CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-11574.
- Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-11574.
- CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-11575.
- CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions on page K1-11577.
- CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR on page K1-11581.
- CONSTRAINED UNPREDICTABLE behavior of EL2 features on page K1-11581.
- Reserved values in System and memory-mapped registers and translation table entries on page K1-11583.
- CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-11583.
K1.1.1 Overview of the constraints on Armv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, from the introduction of Armv8-A the architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note
Software designed to be compatible with the Armv8-A and later architectures must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13 by instruction

In prior versions of the architecture, the use of R13 by instruction as a named register specifier was described as UNPREDICTABLE in the pseudocode. From the introduction of the Armv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as SBZP in the Armv7 architecture or RES0 in the Armv8 and later architectures, but can hold any values programmed into them.

K1.1.3 Using R15 by instruction

All uses of R15 by instruction as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Read the program counter with the standard offset that applies for the current instruction set.
- Read the program counter with the standard offset that applies for the current instruction set with alignment to a word boundary.
- Read 0. This is Arm preferred behavior.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, R12, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of PSTATE.\{N, Z, C, V\}, PSTATE.Q, and PSTATE.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN.

In addition, for MRRC instructions that use R15 as the destination register descriptor, and therefore target APSR.\_nzcv where these are described as being CONSTRAINED UNPREDICTABLE, PSTATE.\{N, Z, C, V\} becomes UNKNOWN.
K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the Condition code check.

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates a Prefetch Abort on the first instruction using the unaligned PC value.
  
  If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

  If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

  If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

  In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D17-5673.

- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-8972.

  — Note ————

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR, HIFAR, or FAR_ELx is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the Armv8-A and later architectures are described as CONSTRAINED UNPREDICTABLE to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the Condition code check.
- The instructions execute as NOPs. This means that they behave as if they had failed the Condition code check.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.
Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- **PSTATE.IT** is cleared to 0.
- **PSTATE.IT** advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

**Note**

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in *Branching into an IT block on page K1-11564.*

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to ‘00000000’. The reserved values are:

```
PSTATE.IT[7:4] != ‘0000’ && PSTATE.IT[3:0] == ‘0000’
PSTATE.IT[2:0] != ‘000’ when SCTLR/SCTLR_EL_1.ITD == ‘1’
```

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than ‘00000000’.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case, the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block on page K1-11564.*

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to ‘00000000’.

### K1.1.8 Unallocated System register access instructions

From the introduction of the Armv8-A architecture, accesses to unallocated System register encodings are UNDEFINED.

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of \{coproc, Crn, opc1, Crm, opc2\} values that the Armv7 architecture defined as UNPREDICTABLE.
• MCRR and MRRC instructions with unallocated values of opc1 or Crm that are described as UNPREDICTABLE are UNDEFINED in the Armv8-A and later architectures.

K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction operates as if the bit had the should-be value.
• Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:
• LDM, LDMIA, LDMFD on page F5-7600.
• LDMDB, LDMEA on page F5-7610.
• LDR (literal) on page F5-7619.
• LDRB (literal) on page F5-7629.
• LDRD (immediate) on page F5-7637.

• LDRD (literal) on page F5-7640.
• LDRH (literal) on page F5-7658.
• LDRSB (literal) on page F5-7669.
• LDRSH (literal) on page F5-7680.
• POP on page F5-7789.
• PUSH on page F5-7797.
• SDIV on page F5-7878.
• STM, STMIA, STMEA on page F5-7972.
• STMDB, STMFD on page F5-7980.
• UDIV on page F5-8096.

K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing Modified immediate constants in T32 instructions on page F1-7242 include constant values that were UNPREDICTABLE in Armv7. Instruction encodings on page F1-7224 describes 32-bit T32 instructions as \{hw1, hw2\}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

• hw2[7:0] == 0b0000000.
• hw1[10] == 0 and either:
  — hw2[14:12] == 0b001.
  — hw2[14:12] == 0b100.
  — hw2[14:12] == 0b111.

From the introduction of the Armv8 architecture, the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F1-7245 include constant values that were UNPREDICTABLE in Armv7. The UNPREDICTABLE cases are those where:

• The bits that the encoding diagram shows as abcd are all 0.
  In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits \{hw1[12, 2:0], hw2[3:0]\}.
  The bits that the encoding diagram shows as cmode[3:1] are one of \{0b001, 0b10, 0b11, 0b10\}.
In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

From the introduction of the Armv8 architecture, the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

**K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of System register control or data values**

The Arm architecture allows copies of System register control or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes FEAT_TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

--- Note ---

If the Effective value of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values, then that Effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see TLB conflict aborts on page G5-9218.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

**K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization**

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.
In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14 Unallocated values with register fields of CP15 registers and Translation Table entries

Unless stated elsewhere, all unallocated or reserved values of fields with allocated values within CP15 registers and Translation Table entries behave in one in one of the following ways:

- The encoding maps onto any of the allocated values but otherwise does not cause UNPREDICTABLE behavior.
- The encodings cause effects that could be achieved by a combination of more than one of the allocated encodings.
- The encodings cause the field to have no functional effect.

K1.1.15 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains a nonzero value.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contains a nonzero value.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.16 Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in Background to the System register interface on page G1-8994, each of the CPACR, HCPTR, and NSACR has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- CPACR.{cp10, cp11}.
- HCPTR.{TCP10, TCP11}.
- NSACR.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11 or TCP11 control field was equal to the cp10 or TCP10 field. This is in all respects except for the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

Note

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

CONSTRANGED UNPREDICTABLE CPACR and NSACR settings

If CPACR.cp<n> contains the encoding ‘18’, then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
Note

In Armv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in Armv8-A and later architectures, and the corresponding bits in the two registers are RES0.

K1.1.17  Mapping of non-idempotent memory locations using the Normal memory type

If non-idempotent memory locations are mapped using the Normal memory type, the state of the non-idempotent memory location may become corrupted in the following circumstances:

- Speculative read accesses may cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution.
- Writes to non-idempotent memory locations might be merged or split. In this case, the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution.

K1.1.18  The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

- CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR.
- CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n> on page K1-11570.
- CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN on page K1-11570.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMXEVCNTR and PMXEVTYPER are not CONSTRAINED UNPREDICTABLE.

Otherwise, if PMSELR.SEL is greater than the number of event counters accessible at this Exception level, accesses to PMXEVTYPER or PMXEVCNTR can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

- If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in EL2 or EL3.
- If FEAT_SEL2 is disabled or is not implemented, PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure EL1 or Secure EL0.
- If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in EL1 or EL0.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPER or PMXEVCNTR from that mode are UNDEFINED.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as RAZ/WI.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode execute as NOPs.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to PMXEVTYPER or PMXEVCNTR behave as if PMSELR.SEL is 31.
- If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of accessible event counters but greater than the number of accessible counters at this Exception level, access to PMXEVTYPER or PMXEVCNTR from EL1 or permitted access from EL0 is trapped to EL2.

If PMSELR.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to PMXEVCNTR are UNDEFINED.
- Accesses to PMXEVCNTR behave as RAZ/WI.
- Accesses to PMXEVCNTR execute as NOPs.
• Accesses to **PMXEVCNTR** behave as if **PMSELR.SEL** contains an **UNKNOWN** value that is less than the number of counters accessible at the current Exception level and Security state.

• If EL2 is implemented and enabled in the current Security state, for an access to **PMXEVCNTR** from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

**Note**

If EL2 is implemented and enabled in the current Security state, **HDCR.HPMN**, or **MDCR_EL2.HPMN**, identifies the number of accessible counters at EL0 or EL1. Otherwise, the number of accessible counters is the number of accessible event counters.

Accesses from EL0 to **PMXEVCNTR** are permitted when:

• EL1 is using AArch32 and the values of **PMUSERENR.{ER, EN}** are both 1.

• EL1 is using AArch64 and the values of **PMUSERENR_EL0.{ER, EN}** are both 1.

Accesses from EL0 to **PMXEVTRYP** are permitted when:

• EL1 is using AArch32 and the value of **PMUSERENR.EN** is 1.

• EL1 is using AArch64 and the value of **PMUSERENR_EL0.EN** is 1.

**CONSTRANGED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>**

If **FEAT_FGT** is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to **PMEVCNTR<n>** and **PMEVTYPER<n>** are not **CONSTRANGED UNPREDICTABLE**.

Otherwise, if <n> is greater than the number of event counters available in the current Exception level and state, reads and writes of **PMEVCNTR<n>** and **PMEVTYPER<n>** are **CONSTRANGED UNPREDICTABLE**, and the following behaviors are permitted:

• Accesses to the register are **UNDEFINED**.

• Accesses to the register behave as **RAZ/WI**.

• Accesses to the register execute as a **NOP**.

• If EL2 is implemented and enabled in the current Security state, for an access to **PMEVCNTR<n>** or **PMEVTYPER<n>** from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

Accesses from EL0 are permitted to **PMEVCNTR<n>** when:

— EL1 is using AArch32 and the values of **PMUSERENR.{ER, EN}** are both 1.

— EL1 is using AArch64 and the values of **PMUSERENR_EL0.{ER, EN}** are both 1.

Accesses from EL0 are permitted to **PMEVTYPER<n>** when:

— EL1 is using AArch32 and the value of **PMUSERENR.EN** is 1.

— EL1 is using AArch64 and the value of **PMUSERENR_EL0.EN** is 1.

**Note**

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1, **HDCR.HPMN**, or **MDCR_EL2.HPMN**, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of accessible event counters.

**CONSTRANGED UNPREDICTABLE behavior caused by HDCR.HPMN**

If **PMCR.N** is nonzero, and one of the following is true:

• **FEAT_HPMN0** is not implemented and **HDCR.HPMN** is set to 0.

• **HDCR.HPMN** is set to a value greater than **PMCR.N**.

The **CONSTRANGED UNPREDICTABLE** behavior is:

• The value returned by a direct read of **HDCR.HPMN** is **UNKNOWN**.
• Either:
  — An **UNKNOWN** number of counters are reserved for EL2 use. That is, the PE behaves as if
    `HDCR.HPMN` is set to an **UNKNOWN** nonzero value less than `PMCR.N`.
  — All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

**K1.1.19 The Activity Monitors Extension**

The following subsections describe **CONSTRAINED UNPREDICTABLE** behaviors when accessing the Activity Monitors
registers in AArch32 state:

- **CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>**.

- **CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>**.

- **CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1**.

**CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>**

If `<n>` is greater than the number of architectured activity monitor event counters, reads and writes of
`AMEVCNTR0<n>` and `AMEVTYPER0<n>` are **CONSTRAINED UNPREDICTABLE**, and the following behaviors are permitted:

- Accesses to the register are **UNDEFINED**.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

______ **Note** ________

`AMCGCR.CG0NC` identifies the number of architectured activity monitor event counters.

**CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>**

If `<n>` is greater than the number of auxiliary activity monitor event counters, reads and writes of
`AMEVCNTR1<n>` and `AMEVTYPER1<n>` are **CONSTRAINED UNPREDICTABLE**, and the following behaviors are permitted:

- Accesses to the register are **UNDEFINED**.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

______ **Note** ________

`AMCGCR.CG1NC` identifies the number of auxiliary activity monitor event counters.

**CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1**

If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of
`AMCNTENCLR1` and `AMCNTENSET1` are **CONSTRAINED UNPREDICTABLE**, and the following behaviors are permitted:

- Accesses to the register are **UNDEFINED**.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

______ **Note** ________

The number of auxiliary activity monitor event counters that are implemented is zero exactly when `AMCFGR.NCG`
is `0b0000`.  

______ **Note** ________
K1.1.20 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64, then ESR_ELx is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the HSR is unknown.

Note
The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.21 Out of range VA

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

K1.1.22 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.23 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. From the introduction of the Armv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a Permission fault.

K1.1.24 Programming CSSEL.R.Level for a cache level that is not implemented

If CSSEL.R.Level is programmed to a cache level that is not implemented, then a read of CSSEL.R returns an UNKNOWN value in CSSEL.R.Level.

If CSSEL.R.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read is treated as a NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.
When `FEAT_CCIDX` is implemented, `CCSIDR2` is implemented. If `CSSEL.R.Level` is programmed to a cache level that is not implemented, then on a read of `CCSIDR2` an implementation must perform one of the following behaviors:

- The `CCSIDR2` read is treated as a NOP.
- The `CCSIDR2` read is UNDEFINED.
- The `CCSIDR2` read returns an UNKNOWN value.

**K1.1.25 Crossing a page boundary with different memory types or Shareability attributes**

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the mismatch, the resulting exception is taken to PL1.
- If the stage 2 translation causes the mismatch, the resulting exception is taken to PL2.
- If both stages of translation cause the mismatch, the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

**K1.1.26 Crossing a 4KB boundary with a Device access**

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed, the resulting exception is taken to PL1.
- If the stage 2 translation causes the boundary to be crossed, the resulting exception is taken to PL2.
- If both stages of translation cause the boundary to be crossed, the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

**Note**

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

**K1.1.27 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs**

`Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-7217` defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in Armv7. In summary, these cases are:

- The target virtual address of a `StoreExcl` instruction is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution.
- The transaction size of a `StoreExcl` instruction is different from the transaction size of the preceding `LoadExcl` instruction in the same thread of execution.
The memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, either:

- Because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction.
- Because the `LoadExcl` instruction and the `StoreExcl` instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-7217* for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

---

**Note**

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-11575*.

---

**K1.1.28**  CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

**CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings**

In the A32 and T32 instruction sets, there are encodings of the CRC32 and CRC32C instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- *Cyclic Redundancy Check on page F4-7382* for the A32 instruction set, with \(sz = 11\).
- *Data-processing (two source registers) on page F3-7367* for the T32 instruction set, with \(\text{op1} = 10\) and \(\text{op2} = 11\).

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in *CRC32 on page F5-7540* and *CRC32C on page F5-7543*.

**CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings**

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- *Miscellaneous on page F4-7421*.
- *Memory hints and barriers on page F4-7431*.
- *Barriers on page F4-7432*.

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as a NOP.

**K1.1.29**  Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
• The instruction performs cache maintenance on one of:
  — No cache lines.
  — A single arbitrary cache line.
  — Multiple arbitrary cache lines.

—— Note ————
This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW.

K1.1.30 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 System instructions.

—— Note ————
If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

SRS (T32)
For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-7936.

CONSTRAINED UNPREDICTABLE behavior
For all encodings:
• If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — R13 of the current mode is used.
  — The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)
For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-7936.

CONSTRAINED UNPREDICTABLE behavior
For all encodings:
• If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — R13 of the current mode is used.
  — The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SUBS PC, LR and related instructions (T32)
For a description of this instruction and the encoding, see the exception return form of SUB, SUBS (immediate) on page F5-8039.
**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

---

**Note**

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

---

For encoding T5:

- If hw1[3:0] are not 0b1110, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if hw1[3:0] are 0b1110.
  - The program counter is set using the value in the register specified by hw1[3:0].

**SUBS PC. LR and related instructions (A32)**

For a description of this instruction and the encoding, see the exception return forms of *MOV, MOVs (register)* on page F5-7719 and *SUB, SUBs (immediate)* on page F5-8039.

**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

---

**Note**

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
K1.1.31 CONSTRUCTED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRUCTED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in Alphabetical list of Advanced SIMD and floating-point instructions on page F6-8166.

---

**Note**

- The pseudocode used in this section to describe cases that can result in CONSTRUCTED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.

- If an instruction can result in CONSTRUCTED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRUCTED UNPREDICTABLE behavior.

---

**VCVT (between floating-point and fixed-point)**

For a description of this instruction and the encoding, see [VCVT (between floating-point and fixed-point, floating-point)] on page F6-8329.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRUCTED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRUCTED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRUCTED UNPREDICTABLE.

**VLD1 (multiple single elements)**

For a description of this instruction and the encoding, see [VLD1 (multiple single elements)] on page F6-8429.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRUCTED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRUCTED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRUCTED UNPREDICTABLE.

**VLD1 (single element to all lanes)**

For a description of this instruction and the encoding, see [VLD1 (single element to all lanes)] on page F6-8426.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRUCTED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRUCTED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRUCTED UNPREDICTABLE.

**VLD2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see [VLD2 (multiple 2-element structures)] on page F6-8445.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRUCTED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRUCTED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRUCTED UNPREDICTABLE.

**VLD2 (single 2-element structure to one lane)**

For a description of this instruction and the encoding, see [VLD2 (single 2-element structure to one lane)] on page F6-8436.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD2 (single 2-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to all lanes)* on page F6-8442.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VLD3 (multiple 3-element structures)* on page F6-8459.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to one lane)* on page F6-8450.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to all lanes)* on page F6-8456.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VLD4 (multiple 4-element structures)* on page F6-8472.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to one lane)* on page F6-8462.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to all lanes)**

For a description of this instruction and the encoding, see VLD4 (single 4-element structure to all lanes) on page F6-8468.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLDM**

For a description of this instruction and the encoding, see VLDM, VLDMDB, VLDMIA on page F6-8476.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see VMOV (between two general-purpose registers and two single-precision registers) on page F6-8556.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and a doubleword floating-point register)**

For a description of this instruction and the encoding, see VMOV (between two general-purpose registers and a doubleword floating-point register) on page F6-8535.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST1 (multiple single elements)**

For a description of this instruction and the encoding, see VST1 (multiple single elements) on page F6-8803.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see VST2 (multiple 2-element structures) on page F6-8817.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (single 2-element structure from one lane)**

For a description of this instruction and the encoding, see *VST2 (single 2-element structure from one lane)* on page F6-8811.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VST3 (multiple 3-element structures)* on page F6-8828.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (single 3-element structure from one lane)**

For a description of this instruction and the encoding, see *VST3 (single 3-element structure from one lane)* on page F6-8822.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VST4 (multiple 4-element structures)* on page F6-8838.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (single 4-element structure from one lane)**

For a description of this instruction and the encoding, see *VST4 (single 4-element structure from one lane)* on page F6-8831.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VSTM**

For a description of this instruction and the encoding, see *VSTM, VSTMDB, VSTMIA* on page F6-8842.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.
K1.1.32 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- **Misprogramming VTCR.S.**
- **Misprogramming VTCR.{SL0, T0SZ}**

### Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. From the introduction of the Armv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

- **Note**

The CONSTRAINED UNPREDICTABLE behavior described in **Misprogramming VTCR.{SL0, T0SZ)** means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

### Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.33 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections, and the instruction descriptions, describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- **ERET in User mode or System mode.**
- **Accessing Hyp mode from outside Hyp mode.**
- **Modifying PSTATE.M when in Hyp mode.**
- **Use of Hyp mode in Secure state on page K1-11582.**
- **Exception return to Hyp mode on page K1-11582.**
- **Stage 1 default memory type on page K1-11582.**
- **Trapping of general exceptions to Hyp mode on page K1-11582.**
- **MSR (banked register) and MRS (banked register) on page K1-11582.**

### ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in **SUBS PC, LR and related instructions (T32)** on page K1-11575.

### Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in **SRS (T32)** on page K1-11575 and **SRS (A32)** on page K1-11575.

### Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in **SRS (T32)** on page K1-11575 and **SRS (A32)** on page K1-11575.
Architectural Constraints on UNPREDICTABLE Behaviors

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-11575 and SRS (A32) on page K1-11575.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the illegal exception return.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
- HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when HCR.TGE == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS.

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of this bit.
- HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.

MSR (banked register) and MRS (banked register)

If the target register specified by the {R, SYSm} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed (see Usage restrictions on the banked register transfer instructions on page F5-8161), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MSR (banked register) instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR (banked register) instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise, the instruction is a NOP.

If the instruction was executed specifying an unallocated {R, SYSm} field value or an unimplemented register (see Encoding the register argument in the banked register transfer instructions on page F5-8162), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
• The instruction executes as a NOP.
• An allocated MRS (banked register) or MSR (banked register) instruction is executed.

**K1.1.34 Reserved values in System and memory-mapped registers and translation table entries**

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

• The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
• The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
• The encoding causes the field to have no functional effect.

**Note**

These constraints are identical to those for the equivalent AArch64 definitions, as given in Reserved values in System and memory-mapped registers and translation table entries on page K1-11600.

Unless otherwise stated, when a direct write of a System register or memory-mapped register writes an unallocated value to a field, if that value is unallocated in all contexts then a subsequent read of the field returns an UNKNOWN value.

**K1.1.35 CONSTRAINED UNPREDICTABLE behavior in Debug state**

*Behavior in Debug state on page H2-10242* of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- Overview of the constraints on AArch64 UNPREDICTABLE behaviors.
- SBZ or SBO fields in A64 instructions.
- CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-11585.
- CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-11585.
- Translation table base address alignment on page K1-11586.
- The Performance Monitors Extension on page K1-11586.
- The Activity Monitors Extension on page K1-11588.
- Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-11588.
- Out of range virtual address on page K1-11588.
- Mapping of non-idempotent memory locations using the Normal memory type on page K1-11589.
- Instruction fetches from Device memory on page K1-11589.
- Programming the CSSELRL_EL1.[Level, InD, TnD] for a cache level that is not implemented on page K1-11589.
- Crossing a page boundary with different memory types or Shareability attributes on page K1-11589.
- Crossing a peripheral boundary with a Device access on page K1-11590.
- CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-11591.
- CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-11591.
- Out of range values of the Set/ Way/ Index fields in cache maintenance instructions on page K1-11600.
- Reserved values in System and memory-mapped registers and translation table entries on page K1-11600.
- CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-11601.

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the Armv8-A and later architectures specify a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note
Software designed to be compatible with the Armv8-A and later architectures must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO, as described in Fixed values in AArch64 instruction and System register descriptions on page C2-243. Except for specific cases identified in CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-11591, if the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the should-be value.
- Any destination registers of the instruction become UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.
### K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes FEAT_TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

---

**Note**

If the *Effective value* of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values, then that *Effective value* must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

---

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see *TLB conflict abort* on page D8-5183.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

### K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.
K1.2.5   Translation table base address alignment

In the translation table base registers TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, VTTBR_EL2, and TTBR0_EL3, register bits[48:x] hold the translation table base address, where x depends on the translation table granule size and the size of the addressed translation table, as described in Translation granules on page D8-5081. Register bits[(x-1):0], unless redefined for another purpose, correspond to bits[(x-1):0] of the translation table base address and therefore are RES0.

Note

• When FEAT_LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.

• When FEAT_TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(x-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

• The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  — The value read back might be the value written or it might be zero.

• The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate TTBR.BADDR field description.

K1.2.6   The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch64 state:

• CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPE_EL0 or PMXEVTYPE_EL0.
• CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPE<n>_EL0 on page K1-11587.
• CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN on page K1-11587.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPE_EL0 or PMXEVTYPE_EL0

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMXEVTYPE_EL0 and PMXEVCNTR_EL0 are not CONSTRAINED UNPREDICTABLE.

Otherwise, if PMSELR_EL0.SEL is greater than the number of event counters accessible at this Exception level, accesses to PMXEVTYPE_EL0 and PMXEVCNTR_EL0 can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

• If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in EL2 or EL3.

• If FEAT_SEL2 is disabled or is not implemented, PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in Secure EL1 or Secure EL0.

• If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in EL0 or EL1.

In these cases, one of the following behaviors must occur:

• Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state are UNDEFINED.

• Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as RAZ/WI.

• Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state execute as NOPs.

• Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

• Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL is 31.
• If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of accessible event counters but greater than or equal to the number of accessible counters at the current Exception level, access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from EL1 or a permitted access from EL0 is trapped to EL2.

**Note**
If EL2 is implemented and enabled in the current Security state, MDCR_EL2.HPMN identifies the number of accessible event counters.

Accesses from EL0 to PMXEVCNTR_EL0 are permitted when:
- EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.
- EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.
Accesses from EL0 to PMXEVTYPER_EL0 are permitted when:
- EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors must occur:
• Accesses to PMXEVCNTR_EL0 are UNDEFINED.
• Accesses to PMXEVCNTR_EL0 behave as RAZ/WI.
• Accesses to PMXEVCNTR_EL0 execute as NOPs.
• Accesses to PMXEVCNTR_EL0 behave as if PMSELR_EL0.SEL contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

**CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0**

If FEAT_FGT is implemented, and EL2 is implemented in the current Security state, and EL1 is using AArch64, permitted access to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 are not CONSTRAINED UNPREDICTABLE.

Otherwise, if <n> is greater than the number of event counters available in the current Exception level and state, reads and writes of PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, the following behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as NOPs.
• If EL2 is implemented and enabled in the current Security state, for an access to PMEVCNTR<n>_EL0 or PMEVTYPER<n>_EL0 from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.
Accesses from EL0 to PMEVCNTR<n>_EL0 are permitted when:
- EL1 is using AArch32 and the value of PMUSERENR.{ER, EN} are both 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.{ER, EN} are both 1.
Accesses from EL0 to PMEVTYPER<n>_EL0 are permitted when:
- EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

**CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN**

If PMCR_EL0.N is nonzero, and one of the following is true:
• FEAT_HPMN0 is not implemented and MDCR_EL2.HPMN is set to 0.
• MDCR_EL2.HPMN is set to a value greater than PMCR_EL0.N.

The following CONSTRAINED UNPREDICTABLE behavior applies:
• The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
• Either:
  — An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if
    MDCR_EL2.HPMN is set to an UNKNOWN nonzero value less than PMCR_EL0.N.
  — All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

K1.2.7 The Activity Monitors Extension

If \(<n>\) is greater than the number of architected activity monitor event counters, reads and writes of
AMEVCNTR0<\(n>\)_EL0 and AMEVTYPE0<\(n>\)_EL0 are CONSTRAINED UNPREDICTABLE, and the following
behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

—— Note ————
AMCGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

——— Note ———
If \(<n>\) is greater than the number of auxiliary activity monitor event counters, reads and writes of
AMEVCNTR1<\(n>\)_EL0 and AMEVTYPE1<\(n>\)_EL0 are CONSTRAINED UNPREDICTABLE, and the following
behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

——— Note ———
AMCGCR_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of
AMCNTENCLR1_EL0 and AMCNTENSET0_EL0 are CONSTRAINED UNPREDICTABLE, and the following
behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

——— Note ———
The number of auxiliary activity monitor event counters that are implemented is zero exactly when
AMCFGR_EL0.NCG is 0b0000.

K1.2.8 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as
UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, ESR_ELx is UNKNOWN.

—— Note ————
The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception
from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED
UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.9 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and
where the computed virtual address, total access size, and alignment mean that it accesses the bytes at 0xFFFF FFFF
FFFF FFFF and 0x0000 0000 0000 0000, then the bytes that appear to be from 0x0000 0000 0000 0000 onwards are
accessed at an UNKNOWN address.
If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at 0xFFFF FFFF FFFF FFFF and 0x0000 0000 0000 0000, then the bytes that appear to be from 0x0000 0000 0000 0000 onwards are accessed at an unknown address and the tags associated with address also become unknown.

Note

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address 0xFFFF FFFF FFFF FFFF and the byte at virtual address 0x0000 0000 0000 0000.

### K1.2.10 Mapping of non-idempotent memory locations using the Normal memory type

If non-idempotent memory locations are mapped using the Normal memory type, the state of the non-idempotent memory location may become corrupted in following circumstances:

- Speculative read accesses may cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution.
- Writes to non-idempotent memory locations might be merged or split. In this case, the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution.

### K1.2.11 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- Take a Permission fault.

### K1.2.12 Programming the CSSELR_EL1.{Level, InD, TnD} for a cache level that is not implemented

If the CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.{Level, InD, TnD}.

If CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read is treated as a NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

When FEAT_CCIDX is implemented, CCSIDR2_EL1 is implemented. If CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then on a read of CCSIDR2_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR2_EL1 read is treated as a NOP.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

### K1.2.13 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.
For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
— If the stage 1 translation generated the mismatch, the resulting exception is taken to EL1.
— If the stage 2 translation generated the mismatch, the resulting exception is taken to EL2.
— If both stages of translation generate the mismatch, the exception can be taken to either EL1 or EL2.
• The instruction executes as a NOP.

K1.2.14 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:
• All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
• All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
• The instruction generates an alignment fault caused by the memory type.

For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
— If the stage 1 translation causes the boundary to be crossed, the resulting exception is taken to EL1.
— If the stage 2 translation causes the boundary to be crossed, the resulting exception is taken to EL2.
— If both stages of translation cause the boundary to be crossed, the resulting exception can be taken to either EL1 or EL2.
• The instruction executes as a NOP.

Note
The boundary referred to is between two Device memory regions that are both:
• Of the size of the smallest implemented translation granule.
• Aligned to the size of the smallest implemented translation granule.

K1.2.15 CONSTRAINED UNPREDICTABLE behaviors with SVE memory accesses

The CONSTRAINED UNPREDICTABLE behaviors that are associated with memory accesses due to loads and stores also apply to SVE vector load and store instructions. The CONSTRAINED UNPREDICTABLE behaviors are described in Crossing a page boundary with different memory types or Shareability attributes on page K1-11589 and Crossing a peripheral boundary with a Device access.

The CONSTRAINED UNPREDICTABLE behaviors apply to the following SVE memory accesses:
• When an SVE unpredicated contiguous load or store instruction accesses an address range that crosses a boundary between memory types, Shareability attributes, or peripherals.
• When an SVE predicated contiguous load or store instruction performs memory accesses that are associated with Active elements on both sides of a boundary between different memory types, Shareability attributes, or peripherals.
• When an SVE predicated non-contiguous load or store instruction performs a memory access that is associated with an Active element that crosses a boundary between memory types, Shareability attributes, or peripherals.

Memory addresses that are associated with Inactive elements cannot trigger CONSTRAINED UNPREDICTABLE behaviors.

If SVE vector loads and stores trigger a CONSTRAINED UNPREDICTABLE behavior that then generates an alignment fault, the fault is handled in the same as any other synchronous memory fault caused by an SVE load or store instruction.
K1.2.16 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-218 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExcl instruction is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution.
- The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.
- The StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution.
- The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  - Because the LoadExcl instruction and the StoreExcl instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-218 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.17 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 A64 Base Instruction Descriptions and Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.

LDAXP

For a description of this instruction and the encoding, see LDAXP on page C6-1542.

CONSTRARED UNPREDICTABLE behavior

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value \( 0x0 \). When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

LDNP

For a description of this instruction and the encoding, see LDNP on page C6-1568.

CONSTRARED UNPREDICTABLE behavior

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

**LDNP (SIMD&FP)**

For a description of this instruction and the encoding, see *LDNP (SIMD&FP)* on page C7-2480.

**CONSTRAINED UNPREDICTABLE behavior**

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

**LDP**

For a description of this instruction and the encoding, see *LDP* on page C6-1570.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( (t = n || t_2 = n) \) \&\& \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

**LDP (SIMD&FP)**

For a description of this instruction and the encoding, see *LDP (SIMD&FP)* on page C7-2482.

**CONSTRAINED UNPREDICTABLE behavior**

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

LDPSW

For a description of this instruction and the encoding, see LDPSW on page C6-1574.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and (t == n || t2 == n) && n != 31, then one of the following behaviors must occur:

• The instruction is UNDEFINED.

• The instruction executes as a NOP.

• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If t == t2, then one of the following behaviors must occur:

• The instruction is UNDEFINED.

• The instruction executes as a NOP.

• The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see LDR (immediate) on page C6-1577.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and n == t && n != 31, then one of the following behaviors must occur:

• The instruction is UNDEFINED.

• The instruction executes as a NOP.

• The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.
LDRB (immediate)

For a description of this instruction and the encoding, see LDRB (immediate) on page C6-1586.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value \( 0x0 \). When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRH (immediate)

For a description of this instruction and the encoding, see LDRH (immediate) on page C6-1591.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value \( 0x0 \). When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSB (immediate)

For a description of this instruction and the encoding, see LDRSB (immediate) on page C6-1596.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value \( 0x0 \). When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.
Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see LDRSH (immediate) on page C6-1602.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \) \&\& \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see LDRSW (immediate) on page C6-1608.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \) \&\& \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see LDXP on page C6-1670.

CONSTRAINED UNPREDICTABLE behavior

If \( t = t_2 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.
For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STP

For a description of this instruction and the encoding, see STP on page C6-1892.

CONSTRANGED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \((t == n || t2 == n) \&\& n != 31\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

________ Note __________

Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see STLXP on page C6-1880.

CONSTRANGED UNPREDICTABLE behavior

If \(s == t || (s == t2)\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \(s == n \&\& n != 31\) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STLXR

For a description of this instruction and the encoding, see STLXR on page C6-1883.

CONSTRANGED UNPREDICTABLE behavior

If \(s == t\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( s = n \& \& n \neq 31 \) then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to an UNKNOWN address.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STLXRB

For a description of this instruction and the encoding, see "STLXRB on page C6-1886."

CONSTRANDED UNPREDICTABLE behavior

If \( s = t \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to the specified address, but the value stored is UNKNOWN.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( s = n \& \& n \neq 31 \) then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to an UNKNOWN address.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STLXRH

For a description of this instruction and the encoding, see "STLXRH on page C6-1888."

CONSTRANDED UNPREDICTABLE behavior

If \( s = t \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to the specified address, but the value stored is UNKNOWN.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( s = n \& \& n \neq 31 \) then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to an UNKNOWN address.
• For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.
STR (immediate)

For a description of this instruction and the encoding, see STR (immediate) on page C6-1895.

**CONSTRANDED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \) && \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.

---

STRB (immediate)

For a description of this instruction and the encoding, see STRB (immediate) on page C6-1900.

**CONSTRANDED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \) && \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.

---

STRH (immediate)

For a description of this instruction and the encoding, see STRH (immediate) on page C6-1905.

**CONSTRANDED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \) && \( n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.
STXP

For a description of this instruction and the encoding, see STXP on page C6-1950.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \) \( \mid (s = t_2) \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( s = n \) \&\& \( n \neq 31 \) then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STXR

For a description of this instruction and the encoding, see STXR on page C6-1953.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

If \( s = n \) \&\& \( n \neq 31 \) then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.

STXRB

For a description of this instruction and the encoding, see STXRB on page C6-1955.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and HCR_EL2.TIDCP is 1, the instruction is trapped to EL2 with EC value 0x0. When FEAT_TIDCP1 is implemented, for execution at EL0, this also applies when SCTLR_EL1.TIDCP or SCTLR_EL2.TIDCP is 1.
If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \text{HCR\_EL2\.TIDCP} is 1, the instruction is trapped to EL2 with EC value \text{0x0}. When \text{FEAT\_TIDCP1} is implemented, for execution at EL0, this also applies when \text{SCTLR\_EL1\.TIDCP} or \text{SCTLR\_EL2\.TIDCP} is 1.

\text{STXRH}

For a description of this instruction and the encoding, see \textit{STXRH} on page C6-1957.

\textit{CONSTRAINED UNPREDICTABLE behavior}

If \( s = t \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \text{HCR\_EL2\.TIDCP} is 1, the instruction is trapped to EL2 with EC value \text{0x0}. When \text{FEAT\_TIDCP1} is implemented, for execution at EL0, this also applies when \text{SCTLR\_EL1\.TIDCP} or \text{SCTLR\_EL2\.TIDCP} is 1.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and \text{HCR\_EL2\.TIDCP} is 1, the instruction is trapped to EL2 with EC value \text{0x0}. When \text{FEAT\_TIDCP1} is implemented, for execution at EL0, this also applies when \text{SCTLR\_EL1\.TIDCP} or \text{SCTLR\_EL2\.TIDCP} is 1.

\textbf{K1.2.18 Out of range values of the Set/Way/Index fields in cache maintenance instructions}

In the cache maintenance by set/way instructions \text{DC CISW}, \text{DC CSW}, and \text{DC ISW}, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is \textit{CONSTRAINED UNPREDICTABLE} and one of the following occurs:
- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

\textit{Note}

This \textit{CONSTRAINED UNPREDICTABLE} behavior applies, also, to the AArch32 cache maintenance by set/way instructions \text{DCCISW}, \text{DCCSW}, and \text{DCISW}.

\textbf{K1.2.19 Reserved values in System and memory-mapped registers and translation table entries}

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:
- The unallocated value maps onto any of the allocated values, but otherwise does not cause \textit{CONSTRAINED UNPREDICTABLE} behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.
Note

These constraints are identical to those for the equivalent AArch32 definitions, as given in Reserved values in System and memory-mapped registers and translation table entries on page K1-11583.

Unless otherwise stated, when a direct write of a System register or memory-mapped register writes an unallocated value to a field, if that value is unallocated in all contexts then a subsequent read of the field returns an UNKNOWN value.

K1.2.20 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-10242 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.
Architectural Constraints on UNPREDICTABLE Behaviors
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors
Appendix K2
Recommendations for Reporting Memory Attributes on an Interconnect

This appendix describes the Arm recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

• Arm recommendations for reporting memory attributes on an interconnect on page K2-11604.
K2.1  Arm recommendations for reporting memory attributes on an interconnect

The Arm architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that Arm strongly recommends, but these recommendations do not form part of the Arm architecture.

K2.1.1  Effect of microarchitectural choices on memory attributes

Implementations of the Arm architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, Arm strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early Write Acknowledgment attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

Arm also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses on page D7-5047 for AArch64 and in Enabling and disabling the caching of memory accesses in AArch32 state on page G4-9117 for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.
Appendix K3
ETE Recommended Configurations

This appendix describes the ETE features that Arm recommends are implemented. It contains the following section:
•  Configurations on page K3-11606.
K3.1 Configurations

For optional features not described here, it is IMPLEMENTATION DEFINED whether the feature is implemented. For features which have an IMPLEMENTATION DEFINED size or number, and are not described here, the size or number of that feature is IMPLEMENTATION DEFINED.

Appendix K4
ETE and TRBE Software Usage Examples

This appendix describes a simple trace decompressor. It contains the following sections:

- Trace analyzer on page K4-11608.
- ETE programming on page K4-11654.
- Trace examples on page K4-11660.
- Differences between ETM and ETE on page K4-11671.
- Context switching on page K4-11673.
- Controlling generation of trace buffer management events on page K4-11675.
K4.1 Trace analyzer

K4.1.1 Introduction

Using Trace Info elements to start trace analysis

After the trace analyzer has located an Alignment Synchronization packet and synchronized with the trace byte stream, it must search for the following elements to begin to analyze the trace byte stream:

1. A Trace Info element.
2. A Context element and a Target Address element.

The trace unit might not generate a Context element and Target Address element immediately after it generates a Trace Info element.

If a Cancel element cancels a Trace Info element then the trace analyzer can still use the information from the discarded Trace Info element, but if the Context element and Target Address element are also discarded, then the trace analyzer must wait for the trace unit to generate a new Context element and Target Address element.

Encountering Trace Info elements after trace analysis has started

The trace unit might generate Trace Info elements periodically, as a result of trace protocol synchronization requests. This is useful if trace is stored in a circular buffer, because it provides multiple points where trace analysis can start. After a trace analyzer observes the first Trace Info element, it can ignore subsequent Trace Info elements in the same trace session because the static trace programming cannot change and the speculation depth is updated by other element types during the trace session.

Decompression information

To decompress a trace byte stream, the trace analyzer requires a number of values which differ between implementations. All the information required by the decompressor to analyze the trace byte stream is provided in the TRCIDR0 to TRCIDR13 registers.

Table K4-1 on page K4-11608 lists the static variables required by the decompressing stages and the fields that provide this information.

    R = original;
    I = 0;
    bits(8) BYTE;
    repeat
        BYTE = ReadAndConsume(8, stream);
K4.1.3 Stage 1, parsing the byte stream

The first stage of analyzing the trace is to convert from the bits of the trace byte stream to the elements that are encoded in that trace byte stream.

The ETE architecture enables a trace unit to use techniques that can reduce the trace bandwidth and trace storage requirements. Some of these techniques require the trace analyzer to retain some information between packets so that it can successfully analyze future packets.

Retained state

- The trace analyzer maintains an independent copy of the address history buffer of the last three Target Address elements.
- The address history buffer in the trace analyzer is required to reconstruct the Target Address elements from the trace byte stream.
- The trace analyzer must maintain the current speculation depth of the parsed trace byte stream.
- The trace analyzer must have the maximum speculation depth supported by the trace unit.
- The trace analyzer maintains a copy of the last Timestamp element value decompressed.
- The last Timestamp element value in the trace analyzer is required to reconstruct the full timestamp value for a Timestamp Packet.
- The trace analyzer must maintain a copy of the context:
  - Context identifier.
  - Virtual context identifier.
  - AArch64 or AArch32 state
  - Exception level
  - Security state
- The trace analyzer must maintain a copy of the cycle count threshold.

```typescript
// InstructionParserState()
// // InstructionParserState
// // ===============
// // State of the instruction parser.

type InstructionParserState is (  
bits(64) timestamp,          // The most recently broadcast timestamp value.  
    // The Address History Buffer.  
    array [0..2] of AddressHistoryBufferEntry address_history_buffer,

    // Context parameters.  
    bits(32) context_id,        // Most recently broadcast Context ID.  
    bits(32) vmid,              // Most recently broadcast VMID.  
    bits(2) exception_level,    // Most recently broadcast Exception level.  
);  
```
SecurityLevel security, // Most recently broadcast Security state. 
boolean sixty_four_bit, // Most recently broadcast AArch state
  // (32 or 64).

// Speculation
integer current_spec_depth,  // The current speculation depth.
boolean T,                   // The current transactional state.

// Trace Session static
integer cc_threshold,        // Cycle count threshold value.

// Static state
integer max_spec_depth,      // The maximum speculation depth.
boolean commit_mode,         // Commit mode.
boolean comm_trans           // How transactions traced.
)

Parsing

The first stage of the decompressor is to convert from the trace byte stream to trace element stream. The trace byte stream can start at the an Alignment Sync packet boundary.

Parse_Trace()

// Parse_Trace()
// =============
// Parses a trace bytestream generated by an ETE trace unit.
Parse_Trace(bits(S) stream)
repeat
  header = ReadAndConsume(8, stream);
case header of
  when '00000000' Parse_ExtensionPacket(header, stream);
  when '00000001' Parse_TraceInfoPacket(header, stream);
  when '0000001x' Parse_TimestampPacket(header, stream);
  when '00000100' TraceOnPacket();
  when '00000110' Parse_ExceptionPacket(header, stream);
  when '00001010' TransactionStartPacket();
  when '00001011' TransactionCommitPacket();
  when '0000110x' Parse_CycleCountPackets(header, stream);
  when '0000111x' Parse_CycleCountPackets(header, stream);
  when '0001xxxx' Parse_CycleCountPackets(header, stream);
  when '00101101' Parse_CommitPacket(header, stream);
  when '0010111x' Parse_CancelPackets(header, stream);
  when '001100xx' Parse_MispredictPacket(header, stream);
  when '001101xx' Parse_CancelPackets(header, stream);
  when '00111xxx' Parse_CancelPackets(header, stream);
  when '01100000' // Ignore packet
  when '01100xxx' Parse_EventTracingPacket(header, stream);
  when '10000000' Parse_ContextPacket(header, stream);
  when '10000001' Parse_AddressWithContextPacket(header, stream);
  when '10000101' Parse_AddressWithContextPacket(header, stream);
  when '10000110' Parse_TargetAddressPacket(header, stream);
  when '10000111' Parse_TargetAddressPacket(header, stream);
  when '10001000' Parse_QPacket(header, stream);
  when '10001001' Parse_SourceAddressPacket(header, stream);
  when '1000101x' Parse_SourceAddressPacket(header, stream);
  when '10010000' Parse_CANCEL_Packets(header, stream);
  when '10010010' Parse_TargetAddressPacket(header, stream);
  when '100101xx' Parse_TargetAddressPacket(header, stream);
  when '1001100x' Parse_TargetAddressPacket(header, stream);
  when '1001101x' Parse_TargetAddressPacket(header, stream);
  when '10011101' Parse_TargetAddressPacket(header, stream);
  when '10011110' Parse_TargetAddressPacket(header, stream);
  when '11xxxxxx' Parse_AtomPackets(header, stream);
  otherwise ReservedEncoding();
Alignment Sync packet

The Alignment Sync packet is a unique sequence of bits that identifies the boundary of another packet. The unique sequence is a header byte, 0b00000000, followed by a minimum of ten payload bytes of 0b00000000 and one final payload byte of 0b10000000.

Parse_ExtensionPacket()

// Parse_ExtensionPacket()
// =======================
// Parses Alignment Synchronization, Discard and Overflow packets.

Parse_ExtensionPacket(bits(8) header, bits(S) stream)
extension = ReadAndConsume(8, stream);
case extension of
  when '00000000' // A-sync
    while extension == '00000000' do
      extension = ReadAndConsume(8, stream);
      if extension != '10000000' then
        ReservedEncoding();
    end
  when '00000011' // Discard
    DiscardPacket();
  when '00000101' // Overflow
    OverflowPacket();
  otherwise
    ReservedEncoding();
return;

Discard

The current speculation depth must be reset to 0.

DiscardPacket()

// DiscardPacket()
// ===============
// Processes a Discard packet.

DiscardPacket()
Emit(DiscardElement());
if DSTATE.IA.T then
  Emit(TransactionFailureElement());
DSTATE.IA.current_spec_depth = 0;
DSTATE.IA.T = FALSE;
return;

Overflow

OverflowPacket()

// OverflowPacket()
// ================
// Processes an Overflow packet.

OverflowPacket()
ETE and TRBE Software Usage Examples  
K4.1 Trace analyzer

 emit(DiscardElement());
 emit(OverflowElement());

 if DSTATE.IA.T then
   emit(TransactionFailureElement());

 DSTATE.IA.T = FALSE;
 DSTATE.IA.current_spec_depth = 0;
 return;

**Trace Info**

A Trace Info packet indicates where the compression algorithms used by the trace unit have been set to a known architectural state. As the architectural state of the compression algorithms is known a trace analyzer can start decompression of the trace byte stream at this point.

If the trace unit exposes some trace speculation to the trace analyzer then the trace info packet indicates the trace speculation depth at this point in the trace element stream.

If the trace analyzer starts analysis where the trace speculation depth is nonzero then the analyzer should ignore speculation depth of Commit elements.

A Trace Info Packet sets all entries of the address history buffer to have an address of 0x0 and to sub_isa of IS0.

The current_spec_depth is set to the speculation depth indicated in the trace info element.

**Parse_TraceInfoPacket()**

```c
// Parse_TraceInfoPacket()
// =======================
// Parses a Trace Info packet.

Parse_TraceInfoPacket(bits(8) header, bits(S) stream)
  bits(8) INFO = Zeros();
  bits(96) SPEC = Zeros();
  bits(96) CYCT = Zeros();

  bits(8) PLCTL = ReadAndConsume(8, stream);
  // Extract the INFO section if present
  if PLCTL<0> == '1' then
    INFO = ReadAndConsume(8, stream);
  // Extract the SPEC section if present
  if PLCTL<2> == '1' then
    SPEC = ULEB128(stream);
  // Extract the CYCT section if present
  if PLCTL<3> == '1' then
    CYCT = ULEB128(stream);
  TraceInfoPacket(PLCTL, INFO, SPEC, CYCT);
  return;

TraceInfoPacket()
// TraceInfoPacket()
// ===============
// Processes a Trace Info packet.

TraceInfoPacket(bits(8) PLCTL,
    bits(8) INFO,
    bits(SN) SPEC,
    bits(CN) CYCT)
DSTATE.IA.timestamp = Zeros();
```
DSTATE.IA.context_id = Zeros();
DSTATE.IA.vid = Zeros();
DSTATE.IA.exception_level = EL0;
DSTATE.IA.security = SecurityLevel_SECURE;
DSTATE.IA.sixty_four_bit = FALSE;
AddressHistoryBuffer.Reset();

cc_threshold = if INFO<0> == '1' then UInt(CYCT) else 0;
DSTATE.IA.current_spec_depth = UInt(SPEC);

Emit(TraceInfoElement(INFO<0> == '1',     // cc_enabled
    cc_threshold,
    DSTATE.IA.current_spec_depth,
    INFO<6> == '1'));

return;

**Trace On**

The Trace On packet indicates that there has been a discontinuity in the instruction trace element stream. It is output whenever a gap occurs, after the gap occurs. This means that a Trace On packet is output:

- When trace generation becomes operative, after the first A-Sync and Trace Info packets but before any packet types that indicate any P0 elements.
- After a trace unit buffer overflow. Again, the Trace On packet is output after the A-Sync and Trace Info packets but before any packet types that indicate any P0 elements.
- After gaps caused by filtering. For example, if filtering is applied to the generation of the trace element stream, so that the trace unit only generates trace for a particular program code sequence, the trace unit might spend much of its time in an inactive state, only generating trace periodically. In this case, a Trace On packet is output after each discontinuity in the trace element stream. The Trace On packet must be output before any packet types that indicate any P0 elements.

**TraceOnPacket()**

```cpp
// TraceOnPacket()
// ===============
// Processes a Trace On packet.
```

TraceOnPacket()
Emit(TraceOnElement());
return;

**Speculation**

The Commit element must modify the current speculation depth.

**Parse_CommitPacket()**

```cpp
// Parse_CommitPacket()
// ===============
// Parses a Commit packet.
```

Parse_CommitPacket(bits(8) header, bits(S) stream)
    bits(32) COMMIT = ULEB128(stream);
    CommitPacket(COMMIT);
    return;

**CommitPacket()**

```cpp
// CommitPacket()
// ===============
// Processes a Commit packet.
```

CommitPacket(bits(N) COMMIT)
The **Cancel element** must modify the current speculation depth.

### Parse_CancelPackets()

if DSTATE.stream_ptr == S then
    print ("Reached end of trace\n");
    assert(FALSE);

    bits(N) data = stream[DSTATE.stream_ptr + N - 1: DSTATE.stream_ptr];
    DSTATE.stream_ptr = DSTATE.stream_ptr + N;
    return data;

HandleAtom()

// HandleAtom()
// =============
// Emits an atom, and updates the speculation depth.

HandleAtom(Atom t)
    Emit(AtomElement(t));
    UpdateSpecDepth(1);
    return;

UpdateSpecDepth()

// UpdateSpecDepth()
// ===============
// Update the speculation depth by a number of elements.

UpdateSpecDepth(integer count)
    DSTATE.IA.current_spec_depth = DSTATE.IA.current_spec_depth + count;
    if DSTATE.IA.current_spec_depth > DSTATE.IA.max_spec_depth then
        commit_number = DSTATE.IA.current_spec_depth - DSTATE.IA.max_spec_depth;
        Emit(CommitElement(commit_number));
        DSTATE.IA.current_spec_depth = DSTATE.IA.max_spec_depth;
    
    return;

UpdateAddressHistoryBuffer()

// UpdateAddressHistoryBuffer()
// ============================
// Adds the given address and sub_isa to the AHB.

UpdateAddressHistoryBuffer(bits(64) address, SubISA sub_isa)
    AddressHistoryBuffer.Add(address, sub_isa);
    return;

UnknownAddressHistoryBuffer()

// UnknownAddressHistoryBuffer()
// =============================
// Adds an unknown address and sub_isa to the AHB.

UnknownAddressHistoryBuffer()
    AddressHistoryBuffer.Add(Zeros(), IS0);
    return;

K4.1.4 Stage 2, speculation resolution

IKRXLC The resolution stage operates on the Elements in turn. The Elements are buffered until their resolution is determined.
**ETE and TRBE Software Usage Examples**

**K4.1 Trace analyzer**

---

## Emit

```c
// Emit()
// ======
Emit(Element e)
  e.committed = FALSE;
  case e.kind of
    when ELEM_TRACE_INFO   ProcessTraceInfo(e);
      // Speculation Support
      when ELEMCANCEL
        ProcessCancel(e);
      when ELEM_COMMIT
        ProcessCommit(e);
      when ELEM_DISCARD
        ProcessDiscard(e);
      // Transactional Support
      when ELEM_TRANS_START
        ProcessTransactionStart(e);
      when ELEM_TRANS_COMMIT
        ProcessTransactionCommit(e);
      when ELEM_TRANS_FAILURE
        ProcessTransactionFailure(e);
    when ELEM_TRANS_FAILURE
      otherwise Stack(e);
```

---

## Trace Info element

The *Trace Info element* can be used as a point to start decompression of the trace element stream. When the *Trace Info element* is generated there might still be some speculative *P0 elements*. The number of speculative *P0 elements* is indicated by the current speculation depth member of the *Trace Info element*.

If the analysis of the trace starts with a *Trace Info element* with a non-zero current speculation depth the decompressor must ignore the *Commit element* or *Cancel elements* for these *P0 elements* as they will not have been observed by the decompressor.

```c
ProcessTraceInfo()
// ProcessTraceInfo()
// ===============
// Processes a Trace Info element, resetting the analyzer to a known state.
ProcessTraceInfo(Element e)
  if ResolutionQueue.Uninitialized() then
    ResolutionQueue.Initialize(e.payload.current_spec_depth);
  if e.payload.in_transaction then
    TransactionQueue.StartTransaction();
    Stack(e);
  return;
```

## Commit element

The *Commit element* marks a number of *P0 elements* as resolved, and if at the head of the queue pass these elements onto the next stage of the decompressor.

```c
ProcessCommit()
// ProcessCommit()
// ===============
// Processes a Commit element, committing the given number of speculative
// elements.
ProcessCommit(Element e)
  integer I = 0;
```
repeat
      if !ResolutionQueue.Aligned() then
        I = I + 1;
        ResolutionQueue.Align();
      else
        case ResolutionQueue.Front().kind of
          when ELEM_EXCEPTION, ELEM_ATOM, ELEM_Q, ELEM_SOURCE_ADDRESS
            if !ResolutionQueue.Front().committed then
              I = I + 1;
              ProcessTransaction(ResolutionQueue.Front());
              AnalyzeElement(ResolutionQueue.Front());
              ResolutionQueue.PopFront();
          when ELEM_TRANS_START
            if (TRCIDR0.COMMTRANS == '0' &&
                !ResolutionQueue.Front().committed) then
              I = I + 1;
              ProcessTransaction(ResolutionQueue.Front());
              ResolutionQueue.PopFront();
            otherwise
              ProcessTransaction(ResolutionQueue.Front());
              ResolutionQueue.PopFront();
      until I == e.payload.count;

      return;

Cancel element

For example, if a Cancel element indicates that the three most recent P0 elements are canceled, then the trace analyzer must discard:

- The Cancel element.
- All elements back to, and including, the third most recent P0 element.
- Any Trace On elements encountered in that section of the element stream.

When discarding P0 elements that have been canceled, a trace analyzer must also discard many other element types that occur in the element stream between the Cancel element and the oldest P0 element that the Cancel element cancels. Table K4-2 on page K4-11640 shows which elements must be discarded.

<table>
<thead>
<tr>
<th>Element</th>
<th>Behavior on cancelation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atom</td>
<td>Remove</td>
</tr>
<tr>
<td>Commit</td>
<td>Illegal</td>
</tr>
<tr>
<td>Context</td>
<td>Remove</td>
</tr>
<tr>
<td>Cycle Count</td>
<td>Process</td>
</tr>
<tr>
<td>Discard</td>
<td>Illegal</td>
</tr>
<tr>
<td>Exception</td>
<td>Remove</td>
</tr>
<tr>
<td>Event</td>
<td>Keep</td>
</tr>
<tr>
<td>Mispredict</td>
<td>Remove</td>
</tr>
<tr>
<td>Overflow</td>
<td>Illegal</td>
</tr>
</tbody>
</table>
When a Cancel element occurs, a trace analyzer must not discard Cycle Count elements.

When a Cancel element occurs, a trace analyzer must not discard ETEEvents.

When a Cancel element occurs, a trace analyzer must discard Mispredict elements.

**ProcessCancel()**

```c
// ProcessCancel()
// ===============
// Processes a Cancel element, canceling the given number of speculative elements.
ProcessCancel(Element e)
  integer I = 0;
  repeat
    if !ResolutionQueue.Aligned() then
      I = I + 1;
      ResolutionQueue.Align();
    else
      case ResolutionQueue.Back().kind of
        when ELEM_ATOM, ELEM_EXCEPTION, ELEM_Q, ELEM_SOURCE_ADDRESS
          if !ResolutionQueue.Back().committed then
            I = I + 1;
        when ELEM_TRANS_START
          if (TRCIDR0.COMMTRANS == '0' &&
              !ResolutionQueue.Back().committed) then
            I = I + 1;
            TransactionQueue.EndTransaction();
        when ELEM_CYCLE_COUNT, ELEM_EVENT, ELEM_TRACE_INFO
          AnalyzeElement(ResolutionQueue.Back());
        when ELEM_TIMESTAMP
          AnalyzeElement(ResolutionQueue.Back());
        end case;
      end if
    end if
  until I == e.payload.count;
  return;
```

**Discard element**

A Discard element indicates that tracing has become inactive while uncommitted P0 elements remain.

The trace analyzer must cancel all speculative P0 elements.
ProcessDiscard()
// ProcessDiscard()
//================
// Processes a Discard element, discarding all speculative elements.
ProcessDiscard(Element e)

while !ResolutionQueue.Aligned() do
    ResolutionQueue.Align();

while ResolutionQueue.Length() > 0 do
    case ResolutionQueue.Back().kind of
        when ELEM_EVENT, ELEM_TRACE_INFO, ELEM_TIMESTAMP
            AnalyzeElement(ResolutionQueue.Back());
            ResolutionQueue.PopBack();
        otherwise
            ResolutionQueue.PopBack();

    TransactionQueue.EndTransaction();
    return;

Stack

The Elements processed by this stage of the decompressor must be stored temporarily until the speculation has been resolved.

Stack()
// Stack()
//=======
// Pushes an element onto the resolution queue.
// TODO: Move to ResolutionQueue.asl and rename to Enqueue
Stack(Element e)
    ResolutionQueue.Push(e);
    return;

K4.1.5 Stage 2, transaction resolution

Transaction

ProcessTransaction()
// ProcessTransaction()
//====================
// Push the element into the transaction queue if we are in a transaction,
// else analyze it immediately.
ProcessTransaction(Element e)
    if TransactionQueue.InTransaction() then
        TransactionQueue.Push(e);
    else
        AnalyzeElement(e);

Transaction Start element

ProcessTransactionStart()
// ProcessTransactionStart()
//====================
// Processes a Transaction Start element, marking we are now in a transaction.
ProcessTransactionStart(Element e)
  TransactionQueue.StartTransaction();
  Stack(e);
  return;

Transaction Commit element

ProcessTransactionCommit()

// ProcessTransactionCommit()
// =========================

// Processes a Transaction Commit element, committing all elements in the
// transaction queue and ending the current transaction.

ProcessTransactionCommit(Element e)
  while TransactionQueue.Length() > 0 do
    AnalyzeElement(TransactionQueue.Front());
    TransactionQueue.FrontPop();
    TransactionQueue.EndTransaction();

Transaction Failure element

When a Transaction Failure element occurs, the trace analyzer must process the Cycle Count elements if it is
maintaining a cumulative cycle count. Otherwise it must discard the Cycle Count elements that are associated with
P0 elements within the transaction.

When a Transaction Failure element occurs, a trace analyzer must not discard the ETEEEvents.

ProcessTransactionFailure()

// ProcessTransactionFailure()
// ===========================

// Processes a Transaction Failure element, discarding all elements in
// the transaction queue and ending the transaction.

ProcessTransactionFailure(Element e)
  TransactionQueue.EndTransaction();
  return;

K4.1.6 Stage 3, analysis

Analyze element

AnalyzeElement()

// AnalyzeElement()
// ================

// Analyzes any element.

AnalyzeElement(Element e)
  case e.kind of
    when ELEM_TARGET_ADDRESS AnalyzeTargetAddress(e);
    when ELEM_CONTEXT AnalyzeContext(e);
    when ELEM_MISPREDICT AnalyzeMispredict(e);
    when ELEM_TRACE_ON AnalyzeTraceOn(e);
    when ELEM_ATOM AnalyzeAtom(e);
    when ELEM_EXCEPTION AnalyzeException(e);
    when ELEM_Q AnalyzeQ(e);
    when ELEM_CANCEL ERROR("cancel element reached analysis stage");
    when ELEM_COMMIT ERROR("commit element reached analysis stage");
    when ELEM_DISCARD AnalyzeDiscard(e);
    when ELEM_OVERFLOW AnalyzeOverflow(e);
    when ELEM_EVENT AnalyzeEvent(e);
when ELEM_TRACE_INFO     AnalyzeTraceInfo(e);
when ELEM_TIMESTAMP      AnalyzeTimestamp(e);
when ELEM_CYCLE_COUNT    AnalyzeCycleCount(e);
when ELEM_SOURCE_ADDRESS AnalyzeSourceAddress(e);
otherwise
    ERROR("Unrecognised element kind in analysis stage");
return;

**Retained state**

The trace analyzer must maintain a copy of the context:

- Context identifier.
- Virtual context identifier.
- AArch64 or AArch32 state
- Exception level
- Security state

**ReconstructState()**

```c
// ReconstructState
// ================
// Temporary storage of reconstructor state, can change after resolution.

type ReconstructState is (  
    bits(64) address,       // Current address
    bits(32) context_id,    // Current context ID
    bits(32) vmid,          // Current VMID
    bits(2) exception_level,// Current Exception level
    SecurityLevel security, // Current Security state
    boolean sixty_four_bit, // Are we in AArch64?
    SubISA sub_isa          // Current sub_isa
)
```

**Operation of the return stack**

The trace analyzer maintains an independent copy of the return stack which is used to determine when Target Address elements have been removed and then infer the target of indirect P0 instructions.

The trace analyzer return stack only operates after a certain point in the tracing flow, that is after the trace analyzer has decoded the trace packets and after all the elements that indicate speculative execution, except for Mispredict elements, have been removed from the trace element stream.

Whenever a Branch with Link instruction is initially traced with an E Atom element, the link return address and sub_isa are pushed onto the trace analyzer return stack. This means that the trace unit return stack grows with each new entry, until its maximum depth is reached and the oldest entries start being discarded.

Whenever an indirect P0 instruction is traced with a final E Atom element, and no Target Address element is traced before the next P0 element, the top entry of the trace analyzer return stack is removed and the value of that entry is the target of the indirect P0 instruction.

A trace analyzer is not required to be aware of the depth of the trace unit return stack, and implements a return stack depth of 15 entries.

A trace analyzer return stack push always occurs whenever a Branch with Link instruction is traced with an E Atom element, even if the status of the E Atom element later changes to be an N Atom element as a result of a subsequent Mispredict element.

For example, the following sequence might occur:

1. The PE speculatively executes a Branch with Link instruction that the trace unit traces with an E Atom element. The trace unit pushes the target address of the Branch with Link instruction onto the trace unit return stack.
The trace analyzer receives the E Atom element and pushes the target address of the Branch with Link instruction onto the trace analyzer return stack.

3. The PE then cancels the speculative execution. The trace unit generates a Mispredict element.

4. The trace analyzer receives the Mispredict element and changes the status of the E Atom element so that it becomes an N Atom element. The trace analyzer then knows which direction the program flow has taken, and also knows that the target address stored at the top of the trace analyzer return stack is mispredicted.

Note: Whenever the trace unit generates a Mispredict element to correct a Branch with Link instruction to an N Atom element, the mispredicted address remains in the return stack because there is no reason to remove it. There are no adverse consequences of leaving such a mispredicted address in the stack.

If more than one Mispredict element is output corresponding to a particular Atom element, the status of the Atom element alternates between E and N until it settles in its final E or N state. If the final state of the Atom element is E, then when the PE executes an indirect P0 instruction and the trace unit compares the target address with the top entry in its return stack, an address match might occur. An address match can only occur if the final status of the Atom element is E.

The trace analyzer never needs to discard the entries in its copy of the return stack. If the trace unit discards the entries in its return stack then the entries in the trace analyzer return stack remain. As more entries are pushed on to the return stack, the old entries are discarded when they are pushed off the end of the stack.

The trace analyzer does not need to prevent the return stack from being modified while in a branch broadcasting region. The fact that the trace unit discards the entries in its return stack when entering the branch broadcasting region ensures that the return stack in the trace unit and the return stack in the trace analyzer remain synchronized.

UpdateReturnStack()

// UpdateReturnStack()
// ===================
// Push the given instruction to the return stack if necessary.

UpdateReturnStack(DecodedInst inst)
if inst.is_link then
    nxt_state = DSTATE.current_analyzer_state;
    nxt_state.address = nxt_state.address + inst.size;
    if !nxt_state.sixty_four_bit then
        nxt_state.address<63:32> = Zeros();
    ReturnStack.Push(nxt_state.address, nxt_state.sub_isa);
return;

Atom element

An Atom element implies that one or more instructions have been traced, up to and including the next P0 instruction.

A trace analyzer must analyze each instruction in the program image from the current address until it observes a P0 instruction. This indicates that the PE has executed each instruction between the current address and the P0 instruction.

AnalyzeAtom()

// AnalyzeAtom()
// =============
// Analyzes an atom element.

AnalyzeAtom(Element e)
if e.payload.atom_type == Atom_E then
    DSTATE.most_recent_branch_was_taken = TRUE;
else
    DSTATE.most_recent_branch_was_taken = FALSE;
CheckForReturnStackMatch();
if DSTATE.sync_state == ADDRESS_STATE then
    DSTATE.sync_state = NOT_SYNC_STATE;
if DSTATE.sync_state != FULL_SYNC_STATE then
    // If we are unsure of context or address then we cannot meaningfully
    // analyze the atom.
    return;

boolean cur_inst_is_branch = FALSE;
// Continue logging instructions until we hit a P0 instruction.
while !cur_inst_is_branch do
    if !ProgramImage.DecodeAvailable() then
        DSTATE.sync_state = CONTEXT_STATE;
        if DSTATE.return_stack_clear_pending then
            ReturnStack.Reset();
            return;
        decoded_inst = ProgramImage.DecodeNextInst();

        case decoded_inst.branchtype of
            when InstType_BRANCH_DIR, InstType_BRANCH_INDIR
                ProcessBranchInstruction(decoded_inst,
                                   DSTATE.most_recent_branch_was_taken);
            cur_inst_is_branch = TRUE;
            UpdateReturnStack(decoded_inst);
            when InstType_WFX, InstType_ISB
                ProcessBranchInstruction(decoded_inst,
                                   DSTATE.most_recent_branch_was_taken);
            cur_inst_is_branch = TRUE;
            when InstType_OTHER
                ReconstructState nxt_state = DSTATE.current_analyzer_state;
                nxt_state.address = nxt_state.address + decoded_inst.size;
                if !nxt_state.sixty_four_bit then
                    // mask off the left-most bits
                    nxt_state.address<63:32> = Replicate('0', 32);
                DSTATE.next_analyzer_state = nxt_state;
        OutputInstruction(decoded_inst);
        DSTATE.current_analyzer_state = DSTATE.next_analyzer_state;
        if DSTATE.return_stack_clear_pending then
            ReturnStack.Reset();
            return;

Context element

AnalyzeContext()

// AnalyzeContext()
// ================
// Analyzes a context element.

AnalyzeContext(Element e)
    DSTATE.current_analyzer_state.context_id = e.payload.context_id;
    DSTATE.current_analyzer_state.vmid = e.payload.vmid;
    DSTATE.current_analyzer_state.security = e.payload.security;
    DSTATE.current_analyzer_state.exception_level = e.payload.exception_level;
    DSTATE.current_analyzer_state.sixty_four_bit = e.payload.sixty_four_bit;

    case DSTATE.sync_state of
        when NOT_SYNC_STATE
            DSTATE.sync_state = CONTEXT_STATE;
        when ADDRESS_STATE
            DSTATE.sync_state = FULL_SYNC_STATE;
        otherwise
return;

Exception element

For an Exception element, a trace analyzer must analyze each instruction from the current address, up to but not including the exception return address that the element provides. The PE has executed each instruction in that address range. The number of instructions that are executed can be zero.

Note: Trace analysis tools must be aware, that if PE execution is at the top of memory space, the address that the Exception element provides might be lower than the target address of the most recent P0 element.

AnalyzeException()

// AnalyzeException()
// ===============
// Analyzes an exception element.

AnalyzeException(Element e)
    CheckForReturnStackMatch();
    if DSTATE.sync_state == CONTEXT_STATE then
        DSTATE.sync_state = NOT_SYNC_STATE;
    if DSTATE.sync_state != FULL_SYNC_STATE then
        return;

    integer PER = UInt(e.payload.address);
    if (ExceptionWithUnknownAddress(e)) then
        continue_forward = FALSE;
    elsif UInt(DSTATE.current_analyzer_state.address) < PER then
        continue_forward = TRUE;
    else
        continue_forward = FALSE;

    // Continue logging instructions until we reach the specified address.
    while continue_forward do
        if !ProgramImage.DecodeAvailable() then
            DSTATE.sync_state = CONTEXT_STATE;
            if DSTATE.return_stack_clear_pending then
                ReturnStack.Reset();
            return;

        decoded_inst = ProgramImage.DecodeNextInst();
        if decoded_inst.branchtype == InstType_OTHER then
            ReconstructState nxt_state = DSTATE.current_analyzer_state;
            nxt_state.address = nxt_state.address + decoded_inst.size;
            DSTATE.next_analyzer_state = nxt_state;
            if !DSTATE.next_analyzer_state.sixty_four_bit then
                // mask off the left-most bits
                DSTATE.next_analyzer_state.address<63:32> = Replicate('0', 32);
            else
                ProcessBranchInstruction(decoded_inst, FALSE);
                UpdateReturnStack(decoded_inst);
                OutputInstruction(decoded_inst);

        bits(64) next_addr = DSTATE.current_analyzer_state.address + decoded_inst.size;
        DSTATE.current_analyzer_state.address = next_addr;
        if !DSTATE.current_analyzer_state.sixty_four_bit then
            // mask off the left-most bits
            DSTATE.current_analyzer_state.address<63:32> = Replicate('0', 32);
        if UInt(DSTATE.current_analyzer_state.address) >= PER then
            continue_forward = FALSE;

        if DSTATE.return_stack_clear_pending then
            ReturnStack.Reset();

    return;
return;

Source address element

A Source Address element indicates that one or more instructions have been traced, up to and including the instruction at the address associated with the element.

A Source Address element indicates that the instruction at the address associated with the element was taken.

A trace analyzer must analyze each instruction in the program image from the current address until it analyzes the instruction at the address associated with the Source Address element. This indicates that the PE has executed each instruction between the current address and that instruction, and each P0 instruction except the final instruction was not taken.

AnalyzeSourceAddress()

// AnalyzeSourceAddress()
// ======================
// Analyzes a source address element.
AnalyzeSourceAddress(Element e)
CheckForReturnStackMatch();

if DSTATE.sync_state == ADDRESS_STATE then
DSTATE.sync_state = NOT_SYNC_STATE;
if DSTATE.sync_state != FULL_SYNC_STATE then
// If we are unsure of context or address then we cannot meaningfully
// analyze the source address.
return;

DSTATE.most_recent_branch_was_taken = FALSE;
integer address = UInt(e.payload.address);

// Continue logging instructions until we hit the specified address.
while (UInt(DSTATE.current_analyzer_state.address) <= address) do
if !ProgramImage.DecodeAvailable() then
DSTATE.sync_state = CONTEXT_STATE;
if DSTATE.return_stack_clear_pending then
ReturnStack.Reset();
return;

decoded_inst = ProgramImage.DecodeNextInst();
if decoded_inst.branchtype == InstType_OTHER then
ReconstructState nxt_state = DSTATE.current_analyzer_state;
nxt_state.address = nxt_state.address + decoded_inst.size;
DSTATE.next_analyzer_state = nxt_state;
if DSTATE.next_analyzer_state.sixty_four_bit then
DSTATE.next_analyzer_state.address<63:32> = Replicate('0', 32);
else
if DSTATE.current_analyzer_state.address == e.payload.address then
DSTATE.most_recent_branch_was_taken = TRUE;
ProcessBranchInstruction(decoded_inst, DSTATE.most_recent_branch_was_taken);
cur_inst_is_branch = TRUE;
UpdateReturnStack(decoded_inst);
OutputInstruction(decoded_inst);
DSTATE.current_analyzer_state = DSTATE.next_analyzer_state;
if DSTATE.return_stack_clear_pending then
ReturnStack.Reset();
return;
Target Address element

AnalyzeTargetAddress()

// AnalyzeTargetAddress()
// ================
// Analyzes a target address element.

AnalyzeTargetAddress(Element e)
  DSTATE.current_analyzer_state.address = e.payload.address;
  DSTATE.current_analyzer_state.sub_isa = e.payload.sub_isa;
  case DSTATE.sync_state of
    when NOT_SYNC_STATE
      DSTATE.sync_state = ADDRESS_STATE;
    when CONTEXT_STATE
      DSTATE.sync_state = FULL_SYNC_STATE;
    otherwise
      return;

Trace Info element

AnalyzeTraceInfo()

// AnalyzeTraceInfo()
// ================
// Analyzes a trace info element.

AnalyzeTraceInfo(Element e)
  CheckForReturnStackMatch();
  return_stack_clear_pending = TRUE;
  return;

Trace On element

AnalyzeTraceOn()

// AnalyzeTraceOn()
// ================
// Analyzes a trace on element.

AnalyzeTraceOn(Element e)
  return_stack_clear_pending = TRUE;
  DSTATE.sync_state = NOT_SYNC_STATE;
  return;

Mispredict element

When a Mispredict element corresponds to an Atom element for a direct P0 instruction, before the trace analyzer can calculate the target of the direct P0 instruction, it must apply any applicable Mispredict elements so that it can determine whether it is an E Atom element or an N Atom element.

AnalyzeMispredict()

// AnalyzeMispredict()
// ================
// Analyzes a mispredict element.

AnalyzeMispredict(Element e)
  DSTATE.most_recent_branch_was_taken = !DSTATE.most_recent_branch_was_taken;
  ReconstructState nxt_state;
  nxt_state = UpdateBranchState(DSTATE.most_recent_branch_decoded_inst,
DSTATE.most_recent_branch_state,
DSTATE.most_recent_branch_was_taken);

DSTATE.current_analyzer_state = nxt_state;
return;

ETEvent element

AnalyzeEvent()
// AnalyzeEvent()
// ==============
// Analyzes an event element.
AnalyzeEvent(Element e);

Discard element

When a trace analyzer encounters a Discard element it must be aware that if the last committed P0 element is a conditional P0 instruction, the E or N status of that Atom element might not be correct. This is because the trace unit might be unable to generate any Mispredict elements that the conditional P0 instruction might require.

If the last P0 instruction is an indirect P0 instruction then the target address indicated in the trace stream might be incorrect. This is because the trace unit might be unable to generate any Target Address elements that the indirect P0 instruction might require.

AnalyzeDiscard()
// AnalyzeDiscard()
// ================
// Analyzes a discard element.
AnalyzeDiscard(Element e)

Overflow element

AnalyzeOverflow()
// AnalyzeOverflow()
// =================
// Analyzes an overflow element.
AnalyzeOverflow(Element e)

Q element

When a trace analyzer encounters a Q element which has a count of M executed instructions, it must proceed through the program image, analyzing each instruction until it has analyzed M instructions. If it encounters a conditional P0 instruction, the status of the condition code check for that instruction is UNKNOWN. The status of these P0 instructions is not explicitly given in the trace element stream but it might be possible to infer the status of a given P0 instruction that is based on other trace that is generated. After the trace analyzer has analyzed M instructions, the following Target Address element indicates where PE execution continues.

AnalyzeQ()
// AnalyzeQ()
// =========
// Analyzes a Q element.
AnalyzeQ(Element e)
    CheckForReturnStackMatch();

    q_with_count = e.payload.count > 0;
    if q_with_count then
        further_analysis_possible = TRUE;
    else
        further_analysis_possible = FALSE;
        DSTATE.sync_state = CONTEXT_STATE;
        // If we have no count then just wait to resync, it is not safe to guess
    
    i = 0;
    while further_analysis_possible do
        if ProgramImage.DecodeAvailable() then
            decoded_inst = ProgramImage.DecodeNextInst();
            addr = DSTATE.current_analyzer_state.address + decoded_inst.size;
            DSTATE.current_analyzer_state.address = addr;
        else
            DSTATE.sync_state = CONTEXT_STATE;
            return;
        
        i = i + 1;
        further_analysis_possible = (i < e.payload.count);
        OutputInstruction(decoded_inst);
        return;

Timestamp element

AnalyzeTimestamp()

    // AnalyzeTimestamp()
    // ================
    // Analyzes a timestamp element.
    
    AnalyzeTimestamp(Element e);

Cycle Count element

To produce a total cycle count, a trace analyzer can cumulatively add the values from all Cycle Count elements.

A trace analyzer must not use the cycle count values in Timestamp elements to produce a total cycle count. Such cycle count values are not a Cycle Count element.

AnalyzeCycleCount()

    // AnalyzeCycleCount()
    // ===============
    // Analyzes a cycle count element.
    
    AnalyzeCycleCount(Element e);

Functions

OutputInstruction()

    // OutputInstruction()
    // ================
    // Log that an instruction has been executed.
    
    OutputInstruction(DecodedInst inst)
        DSTATE.inst_out_count = DSTATE.inst_out_count + 1;
        return;
CheckReturnStackMatch()
// CheckReturnStackMatch()
// =======================
// Check if there is a return stack match, and log the result.
CheckReturnStackMatch()
if DSTATE.sync_state == CONTEXT_STATE then
  if !ReturnStack.IsEmpty() then
    ReturnStackEntry top = ReturnStack.Pop();
    DSTATE.current_analyzer_state.address = top.address;
    DSTATE.current_analyzer_state.sub_isa = top.sub_isa;
    DSTATE.sync_state = FULL_SYNC_STATE;
  return;

UpdateBranchState()
// UpdateBranchState()
// =======================
// Returns an updated state based on what was executed.
UpdateBranchState(DecodedInst inst, boolean branch_was_taken)
out_state = DSTATE.current_analyzer_state;
out_state.address = in_state.address;
out_state.sixty_four_bit = in_state.sixty_four_bit;
out_state.sub_isa = in_state.sub_isa;
if branch_was_taken then
  if inst.branchtype == InstType_BRANCH_INDIR then
    DSTATE.sync_state = CONTEXT_STATE;
  else
    if inst.branchtype == InstType_BRANCH_DIR then
      out_state.address = out_state.address + inst.addressoffset;
    else
      out_state.address = out_state.address + inst.size;
      if !in_state.sixty_four_bit then
        out_state.address<63:32> = Zeros();
      out_state.sub_isa = inst.next_sub_isa;
    else
      out_state.address = out_state.address + inst.size;
      if !out_state.sixty_four_bit then
        out_state.address<63:32> = Zeros();
  return out_state;

ProcessBranchInstruction()
// ProcessBranchInstruction()
// ===========================
// Store current state before a branch instruction, as it could change if there
// is a misprediction.
ProcessBranchInstruction(DecodedInst inst, boolean branch_was_taken)
DSTATE.most_recent_branch_state = DSTATE.current_analyzer_state;
DSTATE.most_recent_branch_decoded_inst = inst;
DSTATE.most_recent_branch_was_taken = branch_was_taken;
DSTATE.next_analyzer_state = UpdateBranchState(inst,
  DSTATE.current_analyzer_state, branch_was_taken);
return;
DecodedInst()

// DecodedInst
// ===========
// Data extracted from an instruction.

type DecodedInst is (  
    bits(32) instruction, // The instruction itself  
    InstType branchtype, // Type of P0 instruction  
    boolean is_link, // Is it a linking branch?  
    integer size, // Size (32 or 16)  
    SubISA next_sub_isa, // sub_isa of the following instruction to be  
        // executed  
    bits(64) addressoffset
)

**K4.2 ETE programming**

### K4.2.1 Example code sequences

**SPWXHJ** The enabling sequence should be from the trace sink, such as the trace buffer, to the trace unit. This is to ensure the trace sink is ready to capture trace before the trace unit generates any trace.

**SWPVBX** The disabling sequence should be from the trace unit to the trace sink. This is to ensure that any buffered trace reaches the trace sink while the trace sink is still enabled.

**Enabling the trace unit**

**SXCRYM** The following example describes the code sequence to enable the trace unit.

```
;; Program the trace unit registers, except TRCPRGCTRL
ISB              ;; Synchronize the System Register updates.
MOV x0, #0x1
MSR TRCPRGCTRL, x0 ;; Enable the ETE.
;; Wait for TRCSTATR.IDLE==0
poll_idle
ISB              ;; Synchronize the write to TRCPRGCTRL
MRS x1, TRCSTATR
TBNZ x1, #1, poll_idle
```

**Disabling the trace unit**

**SVRJNB** The following example describes the code sequence to disable the trace unit.

```
STP x0, x1, [sp, #-16]!
MRS x0, TRFCR_EL1 ;; Save the current programming of TRFCR_EL1.
MOV x1, #0x3
BIC x1, x0, x1
MSR TRFCR_EL1, x1 ;; Clear the values of TRFCR_EL1.ExTRE.
;; to put the PE in to a Trace Prohibited region
ISB                ;; Synchronize the entry to the Trace Prohibited region
TSB CSYNC          ;; Ensure that all trace has reached the trace buffer and address translations have taken place.
MDV x1, #0x0
MSR TRCPRGCTRL, x1 ;; Disable the trace unit
;; Wait for TRCSTATR.IDLE==1 and TRCSTATR.PMSTABLE==1
poll_idle
ISB
MRS x1, TRCSTATR
AND x1, x1, #3
CMP x1, #3
B.NE poll_idle
MSR TRFCR_EL1, x0 ;; Restore the programming of TRFCR_EL1.
LDP x0, x1, [sp], #16
```

**Example save restore routine**

**SXJRPO** The following example describes the code sequence for saving the trace unit state over a power down.

```
STP x0, x1, [sp, #-16]!
;; Enter a Trace Prohibited region
MRS x0, TRFCR_EL1 ;; Save the current programming of TRFCR_EL1.
MOV x1, #0x3
BIC x1, x0, x1
MSR TRFCR_EL1, x1 ;; Clear the values of TRFCR_EL1.ExTRE.
ISB                ;; Synchronizes the entry to the Trace Prohibited region
TSB CSYNC          ;; Ensure the trace unit is synchronized
```
MOV x1, #1
MSR OSLAR_EL1, x1    ;; Lock the OS lock
;; Wait for TRCSTATR.PMSTABLE==1
_poll_pmstable
    ISB
MRS x1, TRCSTATR
TST x1, #2
B.EQ poll_pmstable

MSR TRFCR_EL1, x0    ;; Restore the programming of TRFCR_EL1.

<save the trace unit registers, including TRCPRGCTL>

;; Wait for TRCSTATR.IDLE==1
_poll_idle
    ISB
MRS x1, TRCSTATR
TST x1, #1
B.EQ poll_idle
LDP x0, x1, [sp], #16

SDNGPX The following example describes the code sequence for restoring the trace unit state when power is restored.

<restore the trace unit registers, including TRCPRGCTL>

    STP x0, x1, [sp, #-16]!
MOV x0, #0
MSR OSLAR_EL1, x0    ;; Clear the OS lock
LDP x0, x1, [sp], #16
ISB

IDHQGM When programming the trace unit, it is important to be aware that the loops that poll TRCSTATR in Figure D4-2 on page D4-4769 might never complete. Arm recommends that such scenarios are avoided except in rare conditions. However, some system conditions might prevent a trace unit from either leaving the idle state or becoming idle. In particular, a trace unit might never become idle if the trace unit is unable to output all trace data to a system condition.

STTPKR If multiple reads of TRCSTATR are required, a Context synchronization event is required between each read of TRCSTATR to ensure any change to the trace unit state is observed.

K4.2.2 Minimal programming

Table K4-3 on page K4-11655 gives the values for programming the trace unit to enable trace for tracing of a single process at EL0.

<table>
<thead>
<tr>
<th>Register</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| TRCCONFIGR        | 0x000018C1 | Enable:
|                   |       | • The return stack.                                                         |
|                   |       | • Global timestamping.                                                      |
|                   |       | • Context identifier tracing.                                               |
|                   |       | • Virtual context identifier tracing.                                      |
| TRCEVENTCTLR0     | 0x00000000 | Disable all event tracing                                                   |
| TRCEVENTCTLR1     | 0x00000000 |                                                               |
| TRCSTALLCTLR      | 0x00000000 | Disable stalling, if implemented                                            |
| TRCSYNCPR         | 0x0000000C | Enable trace protocol synchronization every 4096 bytes of trace             |
| TRCTRACEIDR       | Nonzero | Set a value for the trace ID                                                |
SHBZVM Disabling tracing of Secure state might not be strictly necessary as secure tracing might be disabled by MDCR_EL3.STE, but Arm recommends not enabling trace for un-required Exception levels, to limit the amount of trace.

SQCWTJ Disabling tracing of EL1 and EL2 of Non-secure state might not be strictly necessary as non-secure tracing might be disabled by TRFCR_EL2.E2TRE and TRFCR_EL1.E1TRE, but Arm recommends not enabling trace for un-required Exception levels to limit the amount of trace.

K4.2.3 Filtering models

IVDBGM Different trace applications require different usage models of a trace unit. For example, one trace application might only require basic program flow trace, whereas another might require tracing of a specific program function.

The ETE architecture provides for each of these usage models. A trace unit can be implemented with a particular set of implementation options, so that a trade-off between functionality and cost can be achieved in meeting the requirements of a trace application. Discovery of the particular set of implementation is achieved by reading TRCIDR0 to TRCIDR13.

In a trace unit that includes all implementation options, the simplest way to use the trace unit is to turn on tracing of all aspects of PE operation and let the trace analyzer pick out the required information. However, full trace comes at a high cost in terms of port bandwidth and trace storage. These costs have an impact on the design of a system, so that a higher pin count and larger buffers might be required.

A trace unit provides on-chip filtering, that facilitates a reduction of the trace bandwidth and therefore provides for a lower system cost. By suspending and enabling trace during a trace that is run to suit the particular requirements of the trace run, the best use of both port bandwidth and trace storage can be made.

The ETE architecture provides the following basic filtering models:

Continuous tracing

This is where no filtering is applied. The following modes can be used:

- Continuous instruction tracing only, where only the instruction trace stream is output.

Instruction-based filtering

This is where instruction tracing, and data tracing if it is implemented and enabled, is active only for certain code sequences, such as for a particular process or function.

For all the possible filtering modes, the trace unit can be programmed before a trace run to enable various options, including:

- Context identifier tracing, if implemented, to indicate to a trace analyzer the Context identifier value.
- Virtual context identifier tracing, if implemented, to distinguish between different virtual machines.
- Cycle counting, to enable a trace analyzer to analyze program performance.

<table>
<thead>

</tr>
</tbody>
</table>

Table K4-3 Minimal programming values (continued)
• Global timestamping, if implemented, to enable correlation of the two trace streams with other trace sources in the system.
• Branch broadcasting, if implemented, to force all taken *P0 instruction* targets to be traced with an explicit target address.

A trace unit is programmed for continuous instruction tracing when no filtering is applied to the instruction trace stream.

When a trace unit is programmed for continuous instruction tracing, ViewInst is always active during a trace run. See *Filtering trace generation* on page D4-4814.

### K4.2.4 Filtering used the exclude function

The following table describes the programming for excluding a single address range:

<table>
<thead>
<tr>

K4.2.6 OS save and restore routines

When the PE is context switching of trace unit the following registers need to save and restored. Not all these registers are necessarily implemented for all implementations. Please refer to the register description page for information on if the register is implemented.

- TRCPRGCTRLR
- TRCCONFIGR
- TRCAUXCTRLR
- TRCEVENTCTL0R
- TRCEVENTCTL1R
- TRCRSR
- TRCSTALLCTRLR
If the trace unit has not been programmed since the last context switch then there is no requirement to save and restore the registers.
**K4.3 Trace examples**

**K4.3.1 Basic Examples**

The following example shows basic program trace.

**Table K4-4 Example of program trace**

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000 B -> 0x2000 | trace_info(...) | Tracing begins here, therefore the trace unit must generate both:  
• A Context element.  
• A Target Address element.  
The instruction executed is a taken branch, so in addition, the trace unit must generate an E Atom element. |
| 0x2000 MOV | | |
| 0x2004 LDR | | |
| 0x2008 CMP | | |
| 0x200C BEQ -> 0x3000 | atom(N) | This branch is not taken, so the trace unit generates an N Atom element. The N Atom element implies the execution of the three previous instructions and the BEQ instruction. |
| 0x2010 STR | | |
| | IRQ exception (IRQ,0x2014) | An IRQ occurs. The Exception element indicates the STR instruction was executed. |

The following example shows basic program trace when filtering is applied. In this example, the trace unit is programmed to exclude all instructions in the address range 0x2000 to 0x200F inclusive, and the trace unit is programmed to start tracing when the instruction at 0x1000 is accessed.

**Table K4-5 Example of program trace with filtering**

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000 B -> 0x2000 | trace_info(...) | Tracing begins here, therefore the trace unit must generate both:  
• A Context element.  
• An Target Address element.  
The instruction executed is a taken branch, so in addition, the trace unit must generate an E Atom element. |
| 0x2000 MOV | N | |
| 0x2004 LDR | N | |
| 0x2008 CMP | N | |
| 0x200C BEQ -> 0x3000 | N | |
| 0x2010 STR | Y trace_on() address(0x2010) | An IRQ occurs. The Exception element indicates the STR instruction was executed. |
| | IRQ exception (IRQ,0x2014) | |
The example in Table K4-6 on page K4-11661 shows basic program trace and demonstrates the canceling of some speculative execution because of an exception. In this example the trace unit is programmed to start tracing when the instruction at 0x1000 is accessed.

### Table K4-6 Example of basic program trace when an exception occurs, example one

<table>

</tr>
<tr>
<td></td>
<td></td>
<td>Although PE execution has also canceled execution of the STR instruction, the trace analyzer is unaware of this, because the STR instruction was never traced. This is because no P0 elements were generated that would indicate execution of the STR instruction.</td>
</tr>
<tr>
<td>IRQ</td>
<td>exception(IRQ,0x2000)</td>
<td>The trace unit generates an Exception element with the address 0x2000, which indicates no instructions have executed since the target of the branch at 0x1000.</td>
</tr>
<tr>
<td></td>
<td>commit(2)</td>
<td>This commits the E Atom element that was generated for the Branch instruction at 0x1000, plus the Exception element that was generated for the IRQ exception.</td>
</tr>
</tbody>
</table>
The example in Table K4-7 on page K4-11662 shows basic program trace, and shows the trace generated when a synchronous Data Abort occurs. In this example the trace unit is programmed to start tracing when the instruction at 0x1000 is accessed.

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000    | trace_info()   | Tracing begins here, therefore the trace unit must generate both:
|           | trace_on()     | • A Context element. |
|           | context()      | • A Target Address element. |
|           | address(0x1000)| The instruction executed is a taken branch, so in addition, the trace unit must generate an E Atom element. |
|           | atom(E)        | |
| 0x2000    | MOV            | None of these instructions are traced as P0 elements, therefore no trace elements are generated. |
| 0x2004    | LDR            | |
| 0x2008    | CMP            | |
| 0x200C    | BEQ -> 0x3000  | This branch is not taken, so the trace unit generates an N Atom element. The N Atom element implies the execution of the three previous instructions and the BEQ instruction. |
|           | (not taken)    | |
|           | atom(N)        | |
| 0x2010    | STR            | This instruction is not traced as a P0 element, therefore no trace element is generated. |
| LDR aborts Cancel back to and including 0x2004 | cancel(1) | This cancels the N Atom element that was generated for the branch at 0x200C. The trace analyzer must discard the N Atom element, plus the four instructions that it implied. |
|           | exception_(data fault, 0x2004) | |
| commit all execution | commit(2) | This commits the E Atom element that was generated for the Branch instruction at 0x1000, plus the Exception element that was generated for the IRQ exception. |
The example in Table K4-8 on page K4-11663 extends the example shown in Table K4-7 on page K4-11662, and shows how exceptions are traced when two exceptions occur without any execution between them. In this example the trace unit is programmed to start tracing when the instruction at 0x1000 is accessed.

Table K4-8 Example of basic program trace when two consecutive exceptions occur

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000 B -> 0x2000 | trace_info() trace_on() context() address(0x1000) atom(E) | Tracing begins here, therefore the trace unit must generate both:  
  • A Context element.  
  • A Target Address element.  
The instruction executed is a taken branch, so in addition, the trace unit must generate an E Atom element. |
| 0x2000 MOV | None of these instructions are traced as P0 elements, therefore no trace elements are generated. |
| 0x2004 LDR | |
| 0x2008 CMP | |
| 0x200C BEQ -> 0x3000 (not taken) | atom(N) | This branch is not taken, so the trace unit generates an N Atom element. The N Atom element implies the execution of the three previous instructions and the BEQ instruction. |
| 0x2010 STR | This instruction is not traced as a P0 element, therefore no trace element is generated. |
| LDR aborts Cancel back to and including 0x2004 | cancel(1) exception_(data fault, 0x2004) | This cancels the N Atom element that was generated for the branch at 0x200C. The trace analyzer must discard the N Atom element, plus the four instructions that it implied.  
Note  
Although PE execution has also canceled execution of the STR instruction, the trace analyzer is unaware of this, because the STR instruction was never traced. This is because no P0 elements were generated that would indicate execution of the STR instruction.  
The data fault exception occurred at 0x2004. The Exception element indicates the MOV instruction at 0x2000 was executed.  
In summary:  
1. The MOV instruction was first implied by the N Atom element at 0x200C. However, the trace analyzer canceled this because of the Cancel element.  
2. The MOV instruction is now implied by the Exception element. |
| IRQ | address(0x4000) exception(IRQ, 0x4000) | This Exception element contains the address of the exception vector of the DataFault exception. This implies that no instructions have executed since the DataFault exception. |
| commit all execution | commit(3) | This commits the E Atom element that was generated for the Branch instruction at 0x1000, plus the Exception element generated for the Data fault exception and the Exception element that was generated for the IRQ exception. |
## K4.3.2 Examples of changes in context

When the PE executes an instruction that changes the execution context, the exact time at which the new element is traced depends on the PE operation after the write. An example of an instruction that changes the execution context is an instruction that writes a value to the CONTEXTIDR_EL1. See [Context element on page D4-4786](#) for more information about the rules controlling the generation of Context elements. This section provides examples of PE trace that contain changes of execution context to illustrate these rules. This section is split into the following:

- Exception in software executed after context synchronization.
- Exception immediately after ISB.
- Exception immediately before ISB.

Table K4-9 on page K4-11664 shows a write to the CONTEXTIDR_EL1 register, followed by an ISB to synchronize that write, followed by an exception that changes the context again.

### Table K4-9 Program trace containing a context changing operation

<table>
<thead>
<tr>
<th>Execution</th>
<th>Context</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000 B -> 0x2000 | 0xAA | trace_info() trace_on() context(0xAA) address(0x1000) atom(E) | Tracing begins here, therefore the trace unit must generate both:  
  - A Context element.  
  - A Target Address element.  
The instruction executed is a taken branch, so in addition, the trace unit must generate an E Atom element. |
| 0x2000 MSR CONTEXTIDR | 0xAA | None of these instructions are traced as P0 elements, therefore no trace elements are generated. The instructions might be executed from context 0xAA or 0xBB but they are always traced as occurring from context 0xAA. |
| 0x2004 ADD | 0xAA or 0xBB | atom(E) | The trace unit generates an E Atom element, because the ISB is a Context synchronization event. All execution is traced as executing in context 0xAA. |
| 0x2008 ISB | 0xAA or 0xBB | atom(E) | A Context element is traced to indicate the new context. |
| 0x200C SUB | 0xBB | context(0xBB) | An IRQ exception occurs. The trace unit generates an Exception element. |
| IRQ | 0xBB | exception(IRQ,0x2010) | |
| 0x3000 B -> 0x4000 | 0xCC | context(0xCC) address(0x3000) atom(E) | A Context element is traced to indicate the new context.  
A Target Address element is also traced, because an Exception element is always followed by a Target Address element to indicate the address that the exception has been taken to.  
Finally, the instruction executed is a taken branch, so the trace unit must generate an E Atom element. |
Table K4-10 Program trace containing a context changing operation (exception immediately after ISB)

K4.3.3 An example of the use of the trace unit return stack

This section contains two examples of tracing the same piece of program code. However:
- In the first example the trace unit return stack is disabled.
- In the second example trace unit the return stack is enabled.

The examples demonstrate that use of the trace unit return stack can help to reduce the amount of trace generated. Table K4-12 on page K4-11666 shows the first example, and Table K4-13 on page K4-11667 shows the second example. In these examples, the trace unit is programmed for basic program flow, where only branch instructions are traced as P0 instructions, and is programmed to start tracing when the instruction at 0x1000 is accessed.

</tr>
</tbody>
</table>
| commit all execution | commit(4) | This commits all four of the following:  
  • The E **Atom element** generated for the branch at 0x1000.  
  • The N **Atom element** generated for the branch at 0x200C.  
  • The E **Atom element** generated for the branch at 0x2014.  
  • The E **Atom element** generated for the branch at 0x1008. |

### Table K4-13 Basic program trace when Branch with Link instructions are executed and the return stack is enabled

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 0x1000    | BL \rightarrow 0x2000 | trace_info()  
 trace_on()  
 context()  
 address(0x1000)  
 atom(E) Tracing begins here, therefore the trace unit must generate both:  
  • A **Context element**.  
  • A **Target Address element**.  
 The instruction executed is a taken branch, so in addition, the trace unit must generate an E **Atom element**. In addition, because the return stack is enabled, the Branch with Link instruction causes the address 0x1004 to be pushed onto the trace unit return stack. |
| 0x2000    | MOV            | None of these instructions are traced as P0 elements, therefore no trace elements are generated. |
| 0x2004    | LDR            |       |
| 0x2008    | CMP            |       |
| 0x200C    | BLEQ \rightarrow 0x3000 (not taken) | atom(E) This branch is not taken, so the trace unit generates an N **Atom element**. The N **Atom element** implies the execution of the three previous instructions and the BLEQ instruction. Nothing is pushed onto the trace unit return stack because the branch is not taken. |
| 0x2010    | STR            |       |
| 0x2014    | BX LR          | atom(E) This branch is taken, so the trace unit generates an E **Atom element**. The E **Atom element** implies the execution of the STR and the BX instructions. |
K4.3.4 Transactions

The following is an example of a successful transaction traced by a trace unit with no speculation in the trace element stream.

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0x1000$ MOV</td>
<td>This instruction is not traced as a \textit{P0 element}, therefore no trace element is generated. The address of this instruction matches the top entry on the trace unit return stack. Therefore, the trace analyzer knows to restart program execution here and an \textit{Target Address element} is not required. The top entry on the return stack, address $0x1004$, is popped from the return stack.</td>
<td></td>
</tr>
<tr>
<td>$0x1008$ B -&gt; $0x4000$ atom(E)</td>
<td>This branch is taken, so the trace unit generates an \textit{E Atom element}. The \textit{E Atom element} implies the execution of the \textit{MOV} instruction at $0x1004$ and the \textit{B} instruction.</td>
<td></td>
</tr>
</tbody>
</table>
| commit all execution | commit(4) | This commits all four of the following:  
  • The \textit{E Atom element} generated for the branch at $0x1000$.  
  • The \textit{N Atom element} generated for the branch at $0x200C$.  
  • The \textit{E Atom element} generated for the branch at $0x2014$.  
  • The \textit{E Atom element} generated for the branch at $0x1008$. |

<table>
<thead>

<td></td>
<td></td>
</tr>
<tr>
<td>0x2804</td>
<td>B -&gt; 0x3000</td>
<td>Atom(E)</td>
</tr>
</tbody>
</table>

Transaction fails

Transaction_failure()

Cancel(2)

Transaction fails.

0x2004 TST          Target_address(0x2004)

0x2008 BEQ          Atom(E)

{…}

The following is an example of a transaction which is started speculatively and is traced using speculative trace elements, but that speculation is subsequently resolved as misspeculation. The Cancel elements are used to cancel execution back past the start of the transaction.
### Table K4-17 Example of trace with a transaction failure

<table>
<thead>
<tr>
<th>Execution</th>
<th>Trace elements</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>{...}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x1000</td>
<td>B -&gt; 0x2000</td>
<td>Atom(E)</td>
</tr>
</tbody>
</table>
| 0x2000    | TSTART         | Atom(E) | The transaction starts.  
|           |                | Transaction_start() | |
| 0x2004    | TST            |        | |
| 0x2008    | BEQ            | Atom(N) | |
| {...}     |                |       |
| 0x2804    | B -> 0x3000    | Atom(E) | The transaction was only speculatively started. It is optional if a Transaction Failure element is traced, because the Cancel element cancels the Transaction Start element. The Mispredict element corrects the incorrectly speculated first branch. |
|           | Cancel(4)      | Mispredict | |

0x1004    | {...}         |       |
| {...}    |                |       |
ETE and TRBE Software Usage Examples

K4.4 Differences between ETM and ETE

This section describes the primary functional differences between ETMv4 and ETE.

- Removal of data trace documentation, since this is not permitted in A-profile.
- Removal of conditional non-branch documentation, since this is not permitted in A-profile.
- TRCDEVARCH.PRESENT == 1 is mandatory.
- TRCDEVARCH.ARCHVER and TRCDEVARCH.REVISION take new values.
- TRCIFR1.TRCARCHMAJ and TRCIFR1.TRCARCHMIN take new values.
- TRCIDR9 is fixed at zero.
- Context identifier tracing is mandatory, defined in TRCIDR2.CIDSIZE.
- Virtual context identifier tracing is mandatory when the PE implements EL2, defined in TRCIDR2.VMIDSIZE.
- The Virtual context identifier is always based on CONTEXTIDR_EL2, with support for tracing VTTBR_EL2.VMID removed.
- 64-bit timestamp is the only supported timestamp size.
- Timestamping is mandatory in ETE.
- TRCIDR2.IASIZE is only permitted to indicate a 64-bit instruction address size.
- External Inputs are unified with the PMU event space, with new TRCEXTINSEL<n> registers introduced.
- TRCIDR5.NUMEXTIN indicates the unified External Input model.
- Added TRCRSR.EXITIN for reading and setting the External Input Selectors state.
- Added TRCRSR.EVENT for reading and setting the ETEEvent state.
- Added TRCRSR.TA for reading and setting whether tracing was active.
- Changed requirements for the tracing of Exceptions to be dependent on the new TRCRSR.TA field.
- Removal of memory-mapped accesses. This was deprecated in ETMv4.4 for Armv8-A.
- Removal of trace unit sharing.
- Added a requirement that trace must be output within finite time.
- Added a requirement that the trace unit resources are paused when entering a Trace Prohibited region.
- Added a bit to TRCSSCSR<n> to indicate that the Single-shot Comparator Control fired while the resources are paused.
- Added requirements for dependencies on the TSB CSYNC instruction.
- Execution of TSB CSYNC instruction requests a timestamp element.
- The Unified Power Domain Model from ETMv4.5 for Armv8-A is mandatory in ETE.
- Changes to the enable and disable code sequences.
- Addition of the tracing of Transactional state.
- Tightened the requirements for obeying the order of start point and stop points for the ViewInst start/stop function, and tightened the rules for programming the start/stop function.
- Addition of Source Address elements.
- Added rules to require no trace to be generated in Trace Prohibited regions, under some circumstances.
- Added constraints for the effect of system instructions causing the trace unit to become enabled or disabled.
- Additional constraints for the forced tracing of exceptions around Trace Prohibited regions, to ensure trace is not generated in Trace Prohibited regions.
- Removed the flexibility around tracing of an Exceptional occurrence immediately after a Trace Prohibited region or when trace generation becomes operative. Such Exceptional occurrences are not traced.
- Added a requirement that the resource operations must complete before a TSB instruction completes.
• Defined the behavior of the visibility of reads and writes to trace unit registers from system instructions, external debugger and by the trace unit.
• Changed branch broadcasting to be required in all implementations, see TRCIDR0.TRCCB.
• TRCSYNCPR is read/write in all implementations, see TRCIDR3.SYNCPR.
• Forced tracing of System Error exceptions is required in all implementations, see TRCIDR3.TRCERR.
• Changed cycle counting to be required in all implementations, see TRCIDR0.TRCCCI.
• Removed the trace unit OS Lock mechanism, and changed to require the PE OS Lock to affect the trace unit.
• Removed the Exception Return element and Exception Return packet.
• Constrained TRCCLAIMCLR and TRCCLAIMSET to not require explicit synchronization.
• Added more constraints to the operation of the Single-shot Comparator Controls when the trace unit becomes disabled, or when entering a Trace Prohibited region.
• Added more constraints to the operation of the ViewInst start/stop function when the trace unit becomes disabled, or when entering a Trace Prohibited region.
• Constrained the behavior of cycle counting after a trace unit buffer overflow, to require the cycle count to be traced as UNKNOWN on the first Cycle Count element after an overflow.
• Export of PMU events to the trace unit is not affected by PMCR.X or PMCR_EL0.X.
• Event elements are permitted to be generated before the first Trace Info element.
K4.5  Context switching

When switching out a process being traced, to save the current trace context and ensure all trace operations are written to the correct context:

1. Prohibit program-flow trace using TRFCR_ELx. In many cases this is done before the process is traced. For example if all of the following are true:
   - TRFCR_EL1.E0TRE is 1 to allow tracing of a process executed at EL0.
   - TRFCR_EL1.E1TRE is 0 to prohibit tracing of the Operating System performing the context switch executed at EL1.

2. Execute a Context synchronization event to guarantee no new program-flow trace is generated. In the common case, this Context synchronization event is an exception taken to an Exception level where tracing is prohibited.
   - If the trace unit is an ETE and the ETE is enabled, this also pauses the ETE Resources.

3. Execute a TSB CSYNC instruction to ensure the program-flow trace is flushed.

4. If necessary, disable the trace unit.
   - For an ETE this is necessary if context is being switched. Software must set TRCPRGCTLR.EN to zero. This is necessary as:
     - The ETE must be disabled if saving the ETE state, as the ETE System registers can only be read when the ETE is disabled.
     - ETE trace compression logic is stateful, and disabling the ETE resets this compression state.

5. Disable the Trace Buffer Unit. Set TRBLIMITR_EL1.E to zero.
   - This must be done before changing the VMSA System registers to prevent the Trace Buffer Unit from speculatively accessing translation table entries.

6. Execute a DSB operation.
   - This is required if software will be reading the trace buffer contents, to ensure the writes to memory are Complete.

7. Execute a further Context synchronization event.
   - This is required to synchronize the effects of any System register writes since the previous Context synchronization event.
   - This is also required if software will be reading the Trace Buffer Unit or trace unit System registers as part of the context switch, to capture indirect writes to those registers by trace operations synchronized by the TSB CSYNC.
   - For a subsequent direct read to capture the indirect write to TRBSR_EL1 resulting from an External abort on a completed write, this Context synchronization event must follow the DSB above.

8. Save and/or change the context. For example, save the MDCR_EL3, MDCR_EL2 (if applicable), Trace Buffer Unit, trace unit, and TRFCR_ELx System registers, and update the VMSA System registers for the new process.

In other uses cases, tracing is not prohibited when software wants to save the trace context. For this case, if using an ETE, the sequence is slightly different:

1. Disable the ETE. Set TRCPRGCTLR.EN to zero.
2. Execute a Context synchronization event to guarantee no new program-flow trace is generated.
3. Execute a TSB CSYNC instruction to ensure the program-flow trace is flushed.
4. Execute a DSB and/or Context synchronization event as required by the previous example.
5. Save and/or change the context.

For an ETE this sequence does not guarantee that all instructions before disabling the ETE are traced. The ETE might discard trace for preceding instructions when it is disabled.
To restore the state of the Trace Buffer Unit and trace unit for switching in a process being traced, while tracing is prohibited:

1. Restore the context. For example:
   - Restore MDCR_EL3, MDCR_EL2 (if applicable), and the Trace Buffer Unit System registers, other than TRBLIMITR_EL1.
   - Restore the trace unit System registers, other than enabling the trace unit.
   - Ensure the TRFCR_ELx System registers are correct for the process being traced.
   - Update VMSA System registers for the process being returned to.

2. Execute a Context synchronization event to guarantee the trace unit and Trace Buffer Unit will observe the new values of the System registers written by the previous step.

3. Enable the Trace Buffer Unit by setting TRBLIMITR_EL1.E to 1. This must be done after setting up the correct VMSA System registers for the trace buffer, as the Trace Buffer Unit might now speculatively prefetch and cache address translations. See BSMLW and YKCND.

4. If necessary, enable the trace unit. If using an ETE, software must set TRCPRGCTRLR.EN to one.

5. Execute a Context synchronization event to guarantee tracing is allowed. In the common case, this is an ERET instruction that returns to a different Exception level where tracing is allowed.

This must be done after saving the state from the previous process, if applicable.

Because the Trace Buffer Unit can prefetch and cache address translations when the Trace Buffer Unit is enabled:

- Software must not enable the Trace Buffer Unit before programming the System registers for the owning translation regime. In particular, during a context switch operation:
  - If switching from a context using the Trace Buffer Unit, the Trace Buffer Unit must be disabled before modifying the System registers for the owning translation regime being switched from.
  - If switching to a context using the Trace Buffer Unit, the Trace Buffer Unit must not be enabled until after modifying the System registers for the owning translation regime being switched to.

- The Trace Buffer Unit must not be enabled when the PE is not executing in the owning Security state or when executing at EL3 and SCR_EL3.NS does not indicate the owning Security state.

- In normal conditions, enabling the Trace Buffer Unit early before returning to the context being traced might be advantageous if the implementation does prefetch address translations.
K4.6 Controlling generation of trace buffer management events

The TRBE does not include a direct capability to program the Trace Buffer Unit to generate a maintenance interrupt when the trace buffer reaches a programmed level below the Limit pointer, and continue collecting trace until either the interrupt is serviced or (possibly) the trace buffer fills (whichever comes first). This allows an almost lossless collection of trace.

However, the Trace Buffer Unit can be programmed to give similar behavior in one of the following ways:

1. Using Wrap mode. At the start of a trace session, configure the Base pointer and Limit pointer for the trace buffer as normal, but set the trace buffer mode to Wrap mode the current write pointer to point part way through the trace buffer, such that the remaining space in the trace buffer is the watermark level. When the amount of trace collected reaches the watermark level, the current write pointer is wrapped and a trace buffer management event is generated, but trace continues to be collected. This approach has the following advantages and disadvantages:
   • The trace buffer management event is generated and the trace unit receives the TRB_WRAP event at the watermark level.
   • The oldest trace in the trace buffer will be lost if more trace is generated than fits in the trace buffer, because it is overwritten by newer trace. Note that some loss of trace is inevitable if more trace is generated than fits in the trace buffer.
   • The trace history does not start at the start of the trace buffer, and must be aligned by software.

2. Use a Trigger Event. At the start of a trace session, configure the Base pointer and Limit pointer for the trace buffer as normal, and set the trace buffer mode to Fill mode and the current write pointer to the start of the trace buffer. Set the trigger mode to IRQ on trigger, the Trigger Counter to the watermark level, and TRBSR_EL1.TRG to 1. When the amount of trace collected reaches the watermark level, a Trigger Event occurs and a trace buffer management event is generated, but trace continues to be collected. This approach has the following advantages and disadvantages:
   • The trace buffer management event is generated and the trace unit receives the TRB_TRIG event at the watermark level.
   • The newest trace in the trace buffer will be discarded if more trace is generated than fits in the trace buffer. To overwrite the oldest trace instead, set the trace buffer mode to Circular Buffer mode.
   • This method cannot be used if also searching for a Detected Trigger event from the trace unit.
   • The current write pointer does not have to be set to the start of the trace buffer. If the trace buffer already contains data that software does not want to be overwritten, the current write pointer can be set to point to after this data. In this case using Circular Buffer mode or Stop on trigger can also be used to control when collection is stopped and what data is overwritten.
K4.6 Controlling generation of trace buffer management events
Appendix K5
Stages of execution

This appendix shows the relationship between the stages of execution and the Transactional Memory Extension. It contains the following sections:

• *Stages of execution without the Transactional Memory Extension (TME)* on page K5-11678.
• *Stages of execution with the TME* on page K5-11679.
K5.1  Stages of execution without the Transactional Memory Extension (TME)

Figure K5-1 shows the stages of execution in a PE that does not implement FEAT_TME.
K5.2 Stages of execution with the TME

Figure K5-2 shows the stages of execution in a PE that does implement FEAT_TME.
Stages of execution

Appendix K6
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

• About the recommended external debug interface on page K6-11682.
• PMUEVENT bus on page K6-11686.
• Recommended authentication interface on page K6-11687.
• Management registers and CoreSight compliance on page K6-11688.

Note

This recommended external debug interface specification is not part of the Arm architecture specification. Implementers and users of the architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

• As reference material for users of Arm products that implement this interface.
• As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any Arm products might, or might not, implement this external debug interface. For details of the implemented external debug interface, you must always see the appropriate product documentation.
K6.1 About the recommended external debug interface

See the Note on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for Armv8 and later architectures to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection. Table K6-1 on page K6-11682 shows the signals in the recommended interface.

a. This is the port where the PE completes debug APB transactions. Arm recommends a single port for all integrated debug components.
b. The value of \( n \) depends on the size of the address space occupied by the Debug port.
c. This is the port where the PE outputs trace.

Figure K6-1 shows the recommended debug interface.

![Recommended External Debug Interface Diagram](image-url)

Figure K6-1 Recommended external debug interface, including the APB4 Completer port
K6.1.1 EDBGRQ and DBGACK

EDBGRQ is an IMPLEMENTATION DEFINED means of generating the External Debug Request debug event described in External Debug Request debug event on page H3-10291.

The PE asserts DBGACK when the PE is in Debug state. The PE might also include variants of this signal:

DBGTRIGGER
Asserted by the PE when it commits to entering Debug state.

DBGCPUDONE
Asserted by the PE when it has completed all Non-debug state memory accesses and Debug state entry is complete. DBGCPUDONE indicates that memory accesses issued by the PE result from operations originating from debugger commands.

In previous architecture versions, these signals provide an interface between the PE and cross-trigger logic. In Armv8, the architectural Cross-Trigger Interface provides this functionality for external debuggers.

K6.1.2 Secure and Non-secure views of the debug registers

If FEAT_Debugv8p4 is implemented, the external debug interface has views of Secure and Non-secure debug registers. The DAP must ensure that accesses are made only when permitted. The Arm debug interface describes a standard APB-AP programmers model for APB4 which signals Secure and Non-secure accesses on the PPRTDBG[1] signal, and is recommended for new designs.

If FEAT_Debugv8p4 is implemented, and an APB-AP implements an APB3 Requester port, which does not support Secure and Non-secure views, Arm recommends that the following is implemented:

• If SPIDEN is HIGH and DBGEN is HIGH, all external debug accesses are treated as Secure.
• If either SPIDEN is LOW or DBGEN is LOW, all external debug accesses are treated as Non-secure.

If the PE APB Completer port is APB4, this might be implemented by, for example, fixing PPRTDBG[1] to the inverse of (SPIDEN & DBGEN) when bridging from APB3 to APB4.
# K6.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. Arm recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. Arm recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If an ETMv4 Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact Arm.

When **FEAT_ETE** is implemented, PMU events are connected to the trace unit, however the PMUEVENT bus is not used to connect the PMU events to the trace unit. See *External inputs on page D4-4870.*
Recommended authentication interface

An implementation of the Armv8 and later architectures must support debug authentication described in Required debug authentication on page H1-10230.

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but Arm recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.

If FEAT_Debugv8p4 is not implemented, Arm also recommends using the following signals:

- **NIDEN**.
- **SPNIDEN**.

Arm recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == 0b00.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == 0b00.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. Arm recommends that any Trace extension has the same authentication interface as the PE it is connected to.

If FEAT_Debugv8p4 and CoreSight ETR are both implemented, the ETR has an independent **DBGEN** signal that must be tied HIGH to enable self-hosted use of trace.

Table K6-2 on page K6-11687 shows the debug authentication pseudocode functions and the recommended implementations.

Table K6-2 Recommended implementation of debug enable pseudocode functions

<table>
<thead>
<tr>
<th>Pseudocode function</th>
<th>Description</th>

</tr>
</tbody>
</table>

a. If FEAT_Debugv8p4 is implemented, ExternalSecureNoninvasiveDebugEnabled() == ExternalSecureInvasiveDebugEnabled().

b. If FEAT_Debugv8p4 is implemented, the NIDEN signal is not implemented.

c. If FEAT_Debugv8p4 is implemented, the SPNIDEN signal is not implemented.

d. If FEAT_Debugv8p4 is implemented, ExternalNoninvasiveDebugEnabled() == TRUE.

The Debug_authentication() pseudocode function on shared/debug on page J1-11354 defines the authentication signals DBGEN, SPIDEN, NIDEN, and SPNIDEN.
K6.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but Arm recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

K6.4.1 CoreSight interface register map

Table K6-3 on page K6-11688 shows the external management register maps for the following registers:

- **ED**: These are the external debug register.
- **CTI**: These are the Cross-trigger interface registers.
- **PMU**: These are the Performance Monitors registers.

K6.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

Table K6-4 on page K6-11690, Table K6-5 on page K6-11691, Table K6-6 on page K6-11692, Table K6-7 on page K6-11693, and Table K6-8 on page K6-11694 show the response to accesses by the external debug interface to the CoreSight management registers.

Note

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

Table K6-4 on page K6-11690, Table K6-5 on page K6-11691, Table K6-6 on page K6-11692, Table K6-7 on page K6-11693, and Table K6-8 on page K6-11694 include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in Reserved and unallocated registers on page H8-10366 do not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See Register access permissions for memory-mapped accesses on page H8-10362.

When HaveSecureExtDebugView() == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

The terms in Table K6-4 on page K6-11690, Table K6-5 on page K6-11691, Table K6-6 on page K6-11692, Table K6-7 on page K6-11693, and Table K6-8 on page K6-11694 are defined as follows:

**Domain**
This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

If FEAT_DoPD is implemented, most External debug interface registers are in the Core power domain, as shown in Table K6-4 on page K6-11690 and Table K6-7 on page K6-11693.

If FEAT_DoPD is not implemented, most of the registers are in the Debug Power Domain, as shown in Table K6-5 on page K6-11691 and Table K6-8 on page K6-11694.

**Conditions**
This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column that lists the condition as being true.
The conditions are:

**Off**  
\[ \text{EDPRSR.PU} = 0. \] The Core power domain is completely off, or in low-power state. In these cases, the Core power domain registers cannot be accessed.

--- **Note** ---

When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error.

**DLK**  
If the OS Double Lock is implemented and `DoubleLockStatus() == TRUE`. The OS Double Lock is locked.

**OSLK**  
\[ \text{OSLSR.OSLK} = 1. \] The OS Lock is locked.

**Default**  
This provides the default access permissions, if there are no conditions that prevent access to the register.

**SLK**  
This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-10362. If FEAT_DoPD is implemented, the Software Lock is not locked, or not implemented, this column is ignored.

The access permissions are:

- **-**  
  This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

- **RO**  
  This means that the register or field is read-only.

- **RW**  
  This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

- **RC**  
  This means that the bit clears to 0 after a read.

- **(SE)**  
  This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

- **WO**  
  This means that the register or field is write-only.

- **WI**  
  This means that the register or field ignores writes.

- **IMP DEF**  
  This means that the access permissions are IMPLEMENTATION DEFINED.

---

K6.4.3 Management register resets

Table K6-9 on page K6-11695 shows the management register resets. This table does not include:
- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID[n], DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K6-9 on page K6-11695 shows a summary of the management register resets.

K6.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the Arm® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the Arm® CoreSight™ Architecture Specification.

Table K6-10 on page K6-11696 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

| Table K6-10 Peripheral Identification Registers |

Figure K6-2 shows the register field allocation scheme for the Peripheral ID Registers.

---

### Figure K6-2 Peripheral ID register format

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RES0 | Periopheral ID data |
```
Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K6-3.

Figure K6-3  Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value

Figure K6-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:
• Have fixed values, including the bits that are reserved.
• Have fixed values in an implementation that is designed by Arm.

For more information about the fields and their values, see Table K6-11 on page K6-11697.

</tbody>
</table>

For implementations designed by Arm, the continuation code is 0x4, indicating bank 5, and the identity code is 0x3B.
A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.
- RevAnd.

For components with a Component class of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight Device type. However, Arm strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see About the Component Identification scheme on page K6-11699.
- About the CoreSight Device type, see EDDEVTYPE, CTIDEVTYPE, or PMDEVTYPE.
- About CoreSight components and their identification, see the Arm® Debug Interface Architecture Specification.

### Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.
  
  **Note**
  
  Arm recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.
  
  **Note**
  
  Arm recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:
  - Two component designs can have the same part number so long as they are sub-components of the same part and the programmers’ model for the part has the means to disambiguate sub-components.
  - Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.
A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

**K6.4.5 About the Component Identification scheme**

The Component Identification Registers identify the processor as an Arm Debug Interface v5 component. For more information, see the *Arm® Debug Interface Architecture Specification* and the *Arm® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Figure K6-5 shows the register field allocation scheme for the Component ID Registers.

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K6-6.

Appendix K7

Additional Information for Implementations of the Generic Timer

This appendix gives additional information about implementations of the Generic Timer. It contains the following sections:

• Providing a complete set of features in a system level implementation on page K7-11702.
• Gray-count scheme for timer distribution scheme on page K7-11704.
Providing a complete set of features in a system level implementation

As an example system design, using memory-mapped Generic Timer components as described in Chapter 12 System Level Implementation of the Generic Timer, the feature set of a System registers counter and timer, in an implementation that includes Non-secure EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLBase control frame.
- The following CNTBaseNN timer frames:
  - **Frame 0** Accessible by Non-secure accesses, with second view and virtual capability. This provides the Non-secure EL1&0 timers.
  - **Frame 1** Accessible by Non-secure accesses, with no second view and no virtual capability. This provides the Non-secure EL2 timers.
  - **Frame 2** Accessible only by Secure accesses, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
    - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
    - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.
  - **Frame 3** Accessible only by Secure accesses, with no second view and no virtual capability. This provides the Secure EL3 timers.

**Note**
This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and accessibility as memory pages in the different translation regimes, is as follows:

**CNTCTLBase**
The control frame. This frame is accessible in both the Secure and Non-secure memory maps, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase0**
The first view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

**CNPTE0Base0**
The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

**CNTBase1**
The first and only view of the Non-secure EL2 timers. This frame is accessible only in Non-secure memory map, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
• In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase2

The first view of the Secure EL1&0, or PL1&0 timers.

--- Note ---

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see Security state, Exception levels, and AArch32 execution privilege on page G1-8908.

This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

--- Note ---

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3

The first and only view of the EL3 timers. This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is not accessible.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, this frame is not accessible.

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.
K7.2 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

\[
\begin{align*}
\text{Gray}[N] &= \text{Count}[N] \\
\text{Gray}[i] &= (\text{XOR(Gray}[N:i+1])) \text{ XOR Count}[i] \text{ for } N-1 \geq i \geq 0 \\
\text{Count}[i] &= \text{XOR(Gray}[N:i]) \text{ for } N \geq i \geq 0
\end{align*}
\]

This is for an \(N+1\) bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

--- Note ---

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be \(2^n\), where \(n\) is an integer. A switch-over can occur only on the \(2n+1\) boundary to avoid losing the Gray-coding property on a switch-over.
Appendix K8

Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the Arm instruction sets, and their Unified Assembler Language (UAL) equivalents. It contains the following section:

• Legacy Instruction Syntax on page K8-11706.
K8.1 Legacy Instruction Syntax

Early versions of the Arm Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K8.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K8-1 on page K8-11706 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

K8.1.3 FCONST

The syntax of FCONST is

FCONST<dest>{<c>} <Fd>, #<imm8>

where:

<dest> Specifies the destination data type. It must be one of:
S Single-precision floating-point.
D Double-precision floating-point.

<c> This is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F1-7229 for the range of available conditions and their encoding. If <c> is omitted, it defaults to always (AL).

<Fd> Specifies the destination register. It must be one of:
<6d> 64-bit name of the SIMD&FP destination register.
<5d> 32-bit name of the SMID&FP destination register.

<imm8> Specifies the immediate value used to generate the floating-point constant.

FCONSTD{<c>} <6d>, #<imm8> maps to VMOV.F64 <6d>, #<fpimm>
FCONSTS{<c>} <5d>, #<imm8> maps to VMOV.F32 <5d>, #<fpimm>
Appendix K9
Address Translation Examples

This appendix gives examples of address translations using the translation regimes described in Chapter D8 The AArch64 Virtual Memory System Architecture and Chapter G5 The AArch32 Virtual Memory System Architecture. It contains the following sections:

- AArch64 Address translation examples on page K9-11714.
- AArch32 Address translation examples on page K9-11726.

--- Note ---

This chapter gives examples of translation table lookups for the Armv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in Chapter D8 The AArch64 Virtual Memory System Architecture or Chapter G5 The AArch32 Virtual Memory System Architecture then the information in Chapter D8 or Chapter G5 must be taken as the definition of the required behavior.
K9.1 AArch64 Address translation examples

The VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64 are described in Relationhip between translation regimes and implemented Exception levels on page D8-5084. Address translation on page D8-5080 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D8-5086 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-TnSZ)}$.

This section describes:

• Performing the initial lookup, for an address for which the initial lookup is either:
  — At the highest lookup level used for the appropriate translation granule size.
  — Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

— The IA size is smaller than the largest size for the translation level, see Input address size configuration on page D8-5090.
— For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see Concatenated translation tables on page D8-5094.

For examples of performing the initial lookup, see Examples of performing the initial lookup.

• The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see Full translation flows for VMSAv8-64 address translation on page K9-11720.

K9.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

• Performing the initial lookup using the 4KB translation granule.
• Performing the initial lookup using the 16KB granule on page K9-11716.
• Performing the initial lookup using the 64KB translation granule on page K9-11718.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Stage 2 address translation using the 4KB translation granule on page D8-5103 describes as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in Translation process on page D8-5093.

Note

For stage 2 translations, the same principles apply to an initial lookup that Stage 2 address translation using the 4KB translation granule on page D8-5103 describes as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

• Initial lookup at level 0, 4KB translation granule on page K9-11715.
• Initial lookup at level 1, 4KB translation granule on page K9-11715.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Stage 2 address translation using the 4KB translation granule on page D8-5103.
Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As described in Translation using the 4KB granule on page D8-5100, a stage 1 or stage 2 initial lookup at level 0 is required when \(39 \leq n \leq 47\). For these lookups:

- \(TTBR\_ELx[47:(n-35)]\) specify the translation table base address.
- \(Bits[n:39]\) of the input address are \(bits[(n-36):3]\) of the descriptor offset in the translation table.

---

**Note**

This means that, when the input address width is less than 48 bits:

- The size of the translation table is reduced.
- More low-order bits of the \(TTBR\_ELx\) are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB.
- \(TTBR\_ELx\) bits\(47:10\) specify the translation table base address.
- Input address bits\(45:39\) specify bits\(9:3\) of the descriptor offset.

Figure K9-1 shows this lookup.

---

Figure K9-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As described in Translation using the 4KB granule on page D8-5100, this applies to \(IA[n:0]\), where \(30 \leq n \leq 38\). For these lookups:

- There is a single translation table at this level.
- \(TTBR\_ELx[47:(n-26)]\) specify the translation table base address.
- \(Bits[n:30]\) of the input address are \(bits[(n-27):3]\) of the descriptor offset in the translation table.

Register-defined

Translation table base address [47:x]

Supported input address range is IA[y:0], 4 ≤ x ≤ 12, y = x + 26.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K9-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As described in Stage 2 address translation using the 4KB translation granule on page D8-5103, this applies to IA[n:0], where 39 ≤ n ≤ 42. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)} \times 4KB$. This means TTBR_ELx[47:(n-27):12] must be zero.
- TTBR_ELx[47:(n-26)] specify the base address of the block of concatenated translation tables.
- Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K9-3 shows this lookup.

```

Register-defined

Translation table base address [47:x]

Supported input address range is IPA[y:0], 4 ≤ x ≤ 16, y = x + 26. The field marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K9-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Stage 2 address translation using the 16KB translation granule on page D8-5109 describes as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in Translation process on page D8-5093.
Note

For stage 2 translations, the same principles apply to an initial lookup that Stage 2 address translation using the 16KB translation granule on page D8-5109 describes as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- Initial lookup at level 0, 16KB translation granule.
- Initial lookup at level 1, 16KB translation granule.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Stage 2 address translation using the 16KB translation granule on page D8-5109.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is IA\([n:0]\). As described in Translation using the 16KB granule on page D8-5106, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, IA\([47:0]\). For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.
- TTBR_ELx[47:4] specify the translation table base address.

Figure K9-4 shows this lookup.

![Figure K9-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0](image)

Supported input address range is IA\([47:0]\). The field marked ‡ is RES0*. For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor. * Field has additional properties to the default RES0 definition, see the register description for more information.

Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is IA\([n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As described in Translation using the 16KB granule on page D8-5106, this applies to IA\([n:0]\), where \(36 \leq n \leq 46\). For these lookups:

- There is a single translation table at this level.
- TTBR_ELx\([47:(n-32)]\) specify the translation table base address.
- Bit[n:36] of the input address are bits\([(n-33):3]\) of the descriptor offset in the translation table.
**Figure K9-5 shows this lookup.**

For a stage 2 initial lookup at level 1, with concatenated translation tables

As described in *Stage 2 address translation using the 16KB translation granule* on page D8-5109, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2 \times 16\text{KB}$. This means TTBR_ELx[14] must be zero.
- TTBR_ELx[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

**Figure K9-6 shows this lookup.**

For a stage 2 initial lookup at level 1, without concatenation of translation tables

As described in *Stage 2 address translation using the 16KB translation granule* on page D8-5109, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2 \times 16\text{KB}$. This means TTBR_ELx[14] must be zero.
- TTBR_ELx[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

**Figure K9-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation**

**Performing the initial lookup using the 64KB translation granule**

This subsection describes examples of the initial lookup when using the 64KB translation granule that *Stage 2 address translation using the 64KB translation granule* on page D8-5115 describes as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *Translation process on page D8-5093*. 

**Figure K9-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation**

Supported input address range is IA[y:0], $4 \leq x \leq 14$, $y = x + 32$.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K9-6 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1, with concatenation**

Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.
Note

For stage 2 translations, the same principles apply to an initial lookup that *Stage 2 address translation using the 64KB translation granule* on page D8-5115 describes as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 1, 64KB translation granule.*
- *Initial lookup at level 2, 64KB translation granule.*

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Stage 2 address translation using the 64KB translation granule* on page D8-5115.

**Initial lookup at level 1, 64KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As described in *Translation using the 64KB granule* on page D8-5112, a stage 1 or stage 2 initial lookup at level 1 is required when \(42 \leq n \leq 47\). For these lookups:

- The size of the translation table is \(2^{(n-39)}\) bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits\([n:42]\) of the input address are bits\([n-39:3]\) of the descriptor offset in the translation table.
- Bits\([47:(n-38)]\) of the TTBR_ELx specify the translation table base address.

Figure K9-7 shows this lookup.

![Figure K9-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1](image)

Supported input address range is \(IA[y:x] = x + 38\). When \(y = 47\) the field marked ‡ is absent.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

**Initial lookup at level 2, 64KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\).

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As described in *on page D8-5112*, this applies to \(IA[n:0]\), where \(29 \leq n \leq 41\). For these lookups:

- There is a single translation table at this level.
- TTBR_ELx\([47:(n-25)]\) of the specify the translation table base address.
- Bits\([n:29]\) of the input address are bits\([n-26:3]\) of the descriptor offset in the translation table.
Figure K9-8 shows this lookup.

![Figure K9-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation](image)

For a stage 2 initial lookup at level 2, with concatenated translation tables

As described in *Stage 2 address translation using the 64KB translation granule* on page D8-5115, this applies to IA[n:0], where 42 ≤ n ≤ 45. For these lookups:

- There are 2^(m-41) concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2^(m-41)×64KB. This means TTBR_ELx[(n-26):16] must be zero.
- TTBR_ELx[47:(n-25)] specify the base address of the block of translation tables.
- Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K9-9 shows this lookup.

![Figure K9-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation](image)

Supported input address range is IPA[y:0], 4 ≤ x ≤ 20, y = x + 25.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K9-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

**K9.1.2 Full translation flows for VMSAv8-64 address translation**

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR_ELx. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.
This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

**Examples of performing the initial lookup** on page K9-11714 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

--- **Note** ---

Reducing the IA range or concatenating translation tables affects only the initial lookup.

---

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- **The address and properties fields shown in the translation flows.**
- **Full translation flow using the 4KB granule and starting at level 0** on page K9-11722.
- **Full translation flow using the 4KB granule and starting at level 1** on page K9-11723.
- **Full translation flow using the 64KB granule and starting at level 1** on page K9-11724.
- **Full translation flow using the 64KB granule and starting at level 2** on page K9-11725.

**The address and properties fields shown in the translation flows**

For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see **Translation table descriptor formats** on page D8-5123.
Full translation flow using the 4KB granule and starting at level 0

Figure K9-10 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows on page K9-11721.

For details of Properties fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K9-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule**
If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K9-10 on page K9-11722 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Full translation flow using the 4KB granule and starting at level 1

Figure K9-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure, see The address and properties fields shown in the translation flows on page K9-11721.

For details of Properties fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K9-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K9-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.
Comparing this translation with the translation for a 48-bit address, shown in Figure K9-10 on page K9-11722, shows how the translation for the 42-bit address start the same lookup process one stage later.

**Full translation flow using the 64KB granule and starting at level 1**

Figure K9-12 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure, see *The address and properties fields shown in the translation flows on page K9-11721*.

![Full translation flow diagram](diagram.png)

**Figure K9-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule**

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K9-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.
The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule on page K9-11718*, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR_ELx is extended, at the low-order end, to be bits[47:9].

**Full translation flow using the 64KB granule and starting at level 2**

Figure K9-13 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure, see *The address and properties fields shown in the translation flows on page K9-11721*.

![Translation Flow Diagram](image)

**Figure K9-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule**

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K9-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K9-12 on page K9-11724, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR_ELx is bits[47:16].
K9.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSAv8-32 address translation formats:

- Address translation examples using the VMSAv8-32 Short descriptor translation table format.
- Address translation examples using the VMSAv8-32 Long descriptor translation table format on page K9-11731.

K9.2.1 Address translation examples using the VMSAv8-32 Short descriptor translation table format

VMSAv8-32 Short-descriptor Translation Table format descriptors on page G5-9164 describes the memory section and page option for a single VMSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- Translation flow for a Supersection.
- Translation flow for a Section on page K9-11728.
- Translation flow for a Large page on page K9-11729.
- Translation flow for a Small page on page K9-11730.

The address and Properties fields shown in the translation flows on page K9-11730 summarizes the information returned by the lookup.

Translation flow for a Supersection

Figure K9-14 on page K9-11727 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K9-11730.
Address Translation Examples

K9.2 AArch32 Address translation examples

Figure K9-14 VMSAv8-32 Short-descriptor Supersection address translation

For a translation based on TTBR0, N is the value of TTBCR.N.
For a translation based on TTBR1, N is 0.
For details of Properties fields, see the register or descriptor description.

‡ This field is absent if N is 0.
BA = Base address.

Figure K9-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the Supersection index bits of the address overlap the bottom four bits of the Table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-9167.
Translation flow for a Section

Figure K9-15 shows the complete translation flow for a Section. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K9-11730.

For a translation based on TTBR0, N is the value of TTBCR.N.
For a translation based on TTBR1, N is 0.
For details of Properties fields, see the register or descriptor description.

Figure K9-15 VMSAv8-32 Short-descriptor Section address translation
Translation flow for a Large page

Figure K9-16 shows the complete translation flow for a Large page. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows on page K9-11730.

- **Input address**
- **TTBR**
- **Level 1 descriptor address**
- **Level 1 descriptor**
- **Level 2 descriptor address**
- **Level 2 descriptor**
- **Output address, A[39:0]

† This field is absent if N is 0.
L1 = Level 1, L2 = Level 2.
For a translation based on TTBR0, N is the value of TTBCR.N.
For a translation based on TTBR1, N is 0.
For details of Properties fields, see the register or descriptor description.

---

**Note**

Figure K9-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the page index bits of the address overlap the bottom four bits of the level 1 table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-9167.
Translation flow for a Small page

Figure K9-17 shows the complete translation flow for a Small page. For more information about the fields shown in this figure, see The address and Properties fields shown in the translation flows.

Output address, A[39:0]

كات bleibt the address and Properties fields shown in the translation flows.

For the Non-secure PL1&0 stage 1 translation tables:
- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.
Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see *Information returned by a translation table lookup* on page G5-9159, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor Translation Table format descriptors* on page G5-9164 describes the descriptors formats.

### K9.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G5-9187, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- *Full translation flow, starting at level 1 lookup.*
- *Full translation flow, starting at level 2 lookup* on page K9-11733.

*The address and Properties fields shown in the translation flows* on page K9-11730 summarizes the information returned by the lookup.

#### Full translation flow, starting at level 1 lookup

Figure K9-18 on page K9-11732 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure, see *The address and Properties fields shown in the translation flows* on page K9-11730.
Figure K9-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see Address size fault on page G5-9240.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure K9-18 only as follows:

- The possible values of $n$ are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.
**Full translation flow, starting at level 2 lookup**

Figure K9-19 shows the complete translation flow for a stage 1 VMSA v8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure, see The address and Properties fields shown in the translation flows on page K9-11730.

For details of Properties fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

**Figure K9-19 Complete VMSA v8-32 Long-descriptor format stage 1 translation, starting at level 2**

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see Address size fault on page G5-9240.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure K9-19 only as follows:

- The possible values of \( n \) are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.
For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information, see *Information returned by a translation table lookup* on page G5-9159, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, *VMSA v8-32 Long-descriptor Translation Table format descriptors* on page G5-9173 describes the descriptors formats.
Appendix K10
Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a Debug implementation using the V8A or later architectures. It contains the following sections:
- Save Debug registers on page K10-11736.
- Restore Debug registers on page K10-11738.
K10.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

; (1) Set OS Lock.
MOV     X2,#1                       ; Set the OS Lock. In AArch64 state, the OS Lock
MSR     OSLAR_EL1,X2                ; is writable via OSLAR.
ISB                                 ; Context synchronization event

; (2) Walk through the registers, saving them
MRS     X1,OSDTRRX_EL1              ; Read DTRRX
MRS     X2,OSDTRTX_EL1              ; Read DTRTX
STP     W1,W2,[X0],#8               ; Save { DTRRX, DTRTX }
MRS     X1,OSECCR_EL1               ; Read ECCR
MRS     X2,MDSCR_EL1                ; Read DSCR
STP     W1,W2,[X0],#8               ; Save { ECCR, DSCR }
[ AARCH32_SUPPORTED

Appendix K11
Recommended Upload and Download Processes for External Debug

This appendix contains the following section:
• Using memory access mode in AArch64 state on page K11-11742.

Note
This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.
K11.1 Using memory access mode in AArch64 state

Figure K11-1 and Figure K11-2 on page K11-11743 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer \( n \) words of data:
- The download sequence needs \( n+6 \) accesses by the external debug interface.
- The upload sequence needs \( n+8 \) accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

--- Note ---
- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

Figure K11-1 Fast code download in AArch64 state (external host to target)
In Figure K11-1 on page K11-11742, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to `EDITR`. The PE executes this instruction.
   d. Set `EDSCR.MA` to 1.

2. Loop \( n \) times. From the external debug interface:
   a. Write to `DBGDTRRX_EL0`. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear `EDSCR.MA` to 0.
   b. Read `EDSCR` to check for overruns or Data Aborts during download.

---

In Figure K11-2, the sequence for the fast data upload in AArch64 state (target to external host) is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.

---

**Figure K11-2 Fast data upload in AArch64 state (target to external host)**
b. Write address [63:32] to DBGDTRTX_EL0.
c. Write MSR X0, DBGDTR_EL0 to EDITR.
d. Write MSR DBGDTR_EL0, X0 to EDITR. This dummy operation ensures EDSCR.TXfull == 1.
e. Set EDSCR.MA to 1.
f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.

2. Loop \( n-1 \) times. From the external debug interface:
   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read DBGDTRTX_EL0 for the \( n \)th value.
   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.
Appendix K12
Software Usage Examples

This appendix gives software usage examples, for cases where these are likely to contribute significantly to an understanding of the Arm architecture.

It contains the following sections:

• Use of the Advanced SIMD complex number instructions on page K12-11746.
• Use of the Armv8.2 extensions to the Cryptographic Extension on page K12-11748.
K12.1 Use of the Advanced SIMD complex number instructions

FEAT_FCMA provides instructions to aid floating-point computations of complex numbers. This section illustrates the use of these instructions for complex arithmetic. It is not part of the Arm architecture definition.

This section uses the AArch64 instructions FCA00 and FOILA - usage of the AArch32 instructions VCA00 and VOMLA is similar.

When using the instructions implemented by FEAT_FCMA, a complex number is represented in a SIMD&FP register as a pair of adjacent elements, each holding a floating-point number, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number.

K12.1.1 Complex addition

Simple complex addition on a vector of complex numbers is already provided by the vector form of the FADD instruction.

The functionality that FCA00 adds is to rotate each complex number in the second vector by 90 degrees or 270 degrees counterclockwise (considering the complex numbers on an Argand diagram) before performing the addition. Mathematically, this is equivalent to multiplying the second complex number by i or -i before addition.

This means, given a complex number z stored in a pair of elements in one vector, and a complex number w stored in the corresponding element pair in another vector:

- FADD calculates z + w.
- FCA00 calculates z ± iw.

K12.1.2 Complex multiplication

The FOILA instruction does not provide functionality for complex multiplication directly. However, a pair of FOILA instructions can provide this function.

The FOILA instruction operates on corresponding pairs of complex numbers stored in SIMD&FP vector registers, and adds the result to the corresponding complex number in the destination SIMD&FP vector register. This computation is as follows:

1. The second complex number is rotated by 0, 90, 180 or 270 degrees counterclockwise.
2. That complex number is multiplied by either the real or imaginary part of the first complex number:
   - When the rotation is 0 or 180 degrees, the real part is used.
   - When the rotation is 90 or 270 degrees, the imaginary part is used.
3. The resulting complex number is added to the corresponding complex number in the destination register.

Mathematically, considering the complex numbers on an Argand diagram:

- Rotation by 180 degrees is equivalent to negation.
- Rotation by 90 degrees is equivalent to multiplying by i.
- Rotation by 270 degrees is equivalent to multiplying by -i.

This means that, for a first complex number z, where z = a+bi, and a second complex number w, if initially the corresponding complex number in the destination register is zero:

- When the rotation is 0 degrees the result of the multiply-add is aw.
- When the rotation is 180 degrees, the result is -aw.
- When the rotation is 90 degrees, the result is biw.
- When the rotation is 270 degrees, the result is -biw.

This means that, if the destination register is zeroed and an FOILA instruction is executed with a rotation parameter of 0, and then the same instruction is executed with a rotation parameter of 90:

- The first execution returns aw in the destination register.
- The second execution accumulates biw to this, meaning the result is aw+biw.
- This result is the product of (a+bi)w, which is the product zw.
So, this pair of instructions can be used to implement complex multiplication.

After zeroing V0, the syntax of a pair of instructions to perform this complex number multiplication might be:

\[ \text{FCMLA V0.4S, V1.4S, V2.4S, #0} \]
\[ \text{FCMLA V0.4S, V1.4S, V2.4S, #90} \]

Other simple pairs of \text{FCMLA} instructions perform useful computations. For example, considering a first complex number \( z \) and second complex number \( w \), defined as before, and a destination register that has been zeroed before the first \text{FCMLA} instruction is executed:

1. The following pair of instructions calculates the complex conjugate of \( z \) multiplied by \( w \).
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #0} \]
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #270} \]

2. The following pair of instructions calculates the negation of \( z \) multiplied by \( w \).
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #180} \]
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #270} \]

3. The following pair of instructions calculates the negation of the complex conjugate of \( z \) multiplied by \( w \).
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #180} \]
   \[ \text{FCMLA V0.4S, V1.4S, V2.4S, #90} \]

\textbf{Note}

For these examples, the following caveats must be considered:

- \text{FCMLA} performs a fused multiply-add, meaning there is no intermediate rounding. This lack of intermediate rounding can give unexpected results in some cases. Arm expects that these instructions are only used in situations where the effect of the rounding of these results is not material to the calculation.

- When using the \text{FCMLA} instructions, the behavior of \((\infty + \infty i)\) multiplied by \((0+i)\) is \((\text{NaN}+\text{NaNi})\), rather than the result expected by ISO C, which is complex \( \infty \).
K12.2 Use of the Armv8.2 extensions to the Cryptographic Extension

K12.2.1 Use of the SHA512 instructions

These instructions are implemented when FEAT_SHA512 is implemented.

The following code sequence shows the use of the SHA512 instructions to calculate a SHA512 hash iteration of 80 rounds. This code is not fully optimized.

```assembly
// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above that message to hold a further 64 + 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
// the SHA2 specification
// X2 contains a loop variable
// V4,V5,V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0
MOV  X2, #0
loop1:
    LD1  {V0.2D}, [X0]              // Data
    LD1  {V1.2D}, [X1]              // K values
    ADD  X1, X1, #16
    ADD  X0, X0, #16
    ADD  X2, X2, #16
    ADD  V2.2D, V0.2D, V1.2D
    EXT  V2.16B, V2.16B, V2.16B, #8
    EXT  V8.16B, V6.16B, V7.16B, #8
    EXT  V9.16B, V5.16B, V6.16B, #8
    ADD  V7.2D, V7.2D, V2.2D
    SHA512H Q7, Q8, V9.2D
    ADD  V10.2D, V5.2D, V7.2D
    SHA512H2 Q7, Q5, V4.2D
    MOV  V5.16B, V4.16B
    MOV  V4.16B, V7.16B
    MOV  V7.16B, V6.16B
    MOV  V6.16B, V10.16B
    CMP  X2, #128
    BLT   loop1

// work out pointers to previous words in the data
SUB  X3, X0, #128
SUB  X4, X0, #112
SUB  X5, X0, #16
SUB  X6, X0, #56
loop2:
    LD1  {V11.2D}, [X3]
    LD1  {V12.2D}, [X4]
    LD1  {V13.2D}, [X5]
    LD1  {V14.2D}, [X6]
    SHA512SU0 V11.2D, V12.2D
    SHA512SU1 V11.2D, V13.2D, V14.2D
    ST1  {V11.2D}, [X0]
    LD1  {V1.2D}, [X1]              // K values
    ADD  X0, X0, #16
    ADD  X1, X1, #16
    ADD  X3, X3, #16
    ADD  X4, X4, #16
    ADD  X5, X5, #16
    ADD  X6, X6, #16
    ADD  X2, X2, #16
    ADD  V2.2D, V11.2D, V1.2D
    EXT  V2.16B, V2.16B, V2.16B, #8
    EXT  V8.16B, V6.16B, V7.16B, #8
    EXT  V9.16B, V5.16B, V6.16B, #8
    ADD  V7.2D, V7.2D, V2.2D
    SHA512H Q7, Q8, V9.2D
```

// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above that message to hold a further 64 + 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
// the SHA2 specification
// X2 contains a loop variable
// V4,V5,V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0
K12.2.2 Use of the SHA3 instructions

These instructions are implemented when FEAT_SHA3 is implemented.

The following code sequence shows the use of the SHA3 instructions to obtain the combined theta, phi, rho and chi operations of a SHA3 iteration. Arm expects the iota operation to be performed using a lookup table.

This code is not fully optimized for multiple iterations.

```
// Input State:
//   x=0  x=1  x=2  x=3  x=4
// y=0  v12  v13  v14  v10  v11
// y=1  v7   v8   v9   v5   v6
// y=2  v2   v3   v4   v0   v1
// y=3  v22  v23  v24  v20  v21
// y=4  v17  v18  v19  v15  v16

Appendix K13
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the Arm architecture. It contains the following sections:

• Introduction on page K13-11756.
• Load-Acquire, Store-Release and barriers on page K13-11759.
• Load-Acquire Exclusive, Store-Release Exclusive and barriers on page K13-11763.
• Using a mailbox to send an interrupt on page K13-11768.
• Cache and TLB maintenance instructions and barriers on page K13-11769.
• Armv7 compatible approaches for ordering, using DMB and DSB barriers on page K13-11781.

Note
This information is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.
K13.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the Arm architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K13.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the Sequential Execution Model (SEM), and in this Manual it is described as Simple sequential execution of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as Arm, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the Arm architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of memory consistency. Processor architectures have adopted one or more memory consistency models, or memory models, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and Arm recommends the Memory Consistency Models for Shared Memory-Multiprocessors paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the Arm architecture from Armv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K13.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

- **DMB**

- **ISB**
  See Instruction Synchronization Barrier (ISB) on page B2-175.

- **Observer, Completion**
  See Definition of the Arm memory model on page B2-159.
  See Completion and endpoint ordering on page B2-168.
Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K13.1.3 Conventions

Many of the examples are written in a stylized extension to Arm assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
  LDR R12, [Rx]
  CMP R12, #1
  BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
loop
  LDA R12, [Rx]       ; load acquire ensures it is ordered before subsequent loads/stores
  CMP R12, #1
  BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
  LDR W12, [Xx]
  CMP W12, #1
  B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` describes the following sequence:

```
loop
  LDAR W12, [Xx]      ; load acquire ensures it is ordered before subsequent loads/stores
  CMP W12, #1
  B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1…Px refer to caching coherent PEs that implement the Armv9 or Armv8 architecture and are in the same shareability domain.
- E0, E1…Ex refer to non-caching observers that do not participate in the coherency protocol, but execute Armv9 or Armv8 instructions and have a weakly ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system Requesters.

These observers are unsynchronized other than as required by the documented code sequence.

Note

Throughout this appendix, `Armv9 or Armv8 instruction` and `instruction` refer to instructions from the A64, A32, or T32 instruction set, provided by Armv9 or Armv8 implementations.
Results are expressed in terms of `<agent>:<register>`, such as `P0:R5`. The results can be described as:

**Permissible**
This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

**Not permissible**
Results that the architecture expressly forbids.

**Required**
Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of `DMB` and `DSB` instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a `DMB ST`, that is a barrier to stores only, this is shown by the use of `DMB [ST]`. This indicates that the `ST` qualifier can be omitted without affecting the result of the test. In some implementations `DMB ST` is faster than `DMB`.

For AArch64 code, the shareability domain of the `DMB` or `DSB` must be included. This is shown in this manual using the notation `DMB <domain>` and `DSB <domain>` respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- `R0` and `W0` contain the value 1.
- `R1` - `R4` and `W1` - `W4` contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in `R1` and `R2` are in Write-Back Cacheable Normal memory.
  - The address held in `R3` is in Write-Through Cacheable Normal memory.
  - The address held in `R4` is in Non-cacheable Normal memory.
- `R5` - `R8` and `W5` - `W8` contain:
  - When used with an `STR` instruction, `0x55`, `0x66`, `0x77`, and `0x88` respectively.
  - When used with an `LDR` instruction, the value 0.
- `R11` and `W11` contain a new instruction or new translation table entry, as appropriate, and `R10` contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- Cache maintenance system instructions on page K17-11905.
- TLB maintenance system instructions on page K17-11907.
K13.2 Load-Acquire, Store-Release and barriers

The following sections show that most of the examples in sections Simple ordering and barrier cases on page K13-11781 and Load-Exclusive, Store-Exclusive and barriers on page K13-11785 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K13.2.1 Message passing

The following sections describe:

- Resolving weakly-ordered message passing by using Acquire and Release.
- Resolving message passing by the use of Store-Release and address dependency on page K13-11760.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in Weakly-ordered message passing problem on page K13-11781 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

**AArch32**

P1

```assembly
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```assembly
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

**AArch64**

P1

```assembly
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready, which is ordered after the STR
```

P2

```assembly
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2::R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

**AArch32**

P3

```assembly
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

**AArch64**

P3

```assembly
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```
Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in Message passing with multiple observers on page K13-11782 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

**AArch32**

P1

```assembly
STR R5, [R1] ; sets new data
STL R0, [R2] ; sends flag indicating data ready using a Store-Release
```

P2

```assembly
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
               ; and so is ordered after the flag has been seen
```

**AArch64**

P1

```assembly
STR W5, [X1] ; sets new data
STLR W0, [X2] ; sends flag indicating data ready using a Store-Release
```

P2

```assembly
WAIT([X2]==1)
AND W12, W12, WZR ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, W12] ; the load has an address dependency on W12
               ; and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

**AArch32**

P3

```assembly
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
               ; and so is ordered after the flag has been seen
```

**AArch64**

P3

```assembly
WAIT([X2]==1)
AND W12, W12, WZR ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, W12] ; the load has an address dependency on W12
               ; and so is ordered after the flag has been seen
```
K13.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2] ; updates base address
```

P2

```
LDR R1, [R2] ; reads base address
CMP R1, #0 ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2] ; updates base address
```

P2

```
LDR X1, [X2] ; reads base address
CMP X1, #0 ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.
K13.2.3  **WFE and WFI and barriers**

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit `DSB` barrier instruction is required if it is necessary to ensure memory accesses made before the `WFI` or `WFE` are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanisms that would guarantee the required visibility are the `DMB` described in *Posting a store before polling for acknowledgement on page K13-11784*, or a dependency on a load.

The following example requires the `DSB` to ensure that the store is visible:

**AArch32**

```
P1
  STR R0, [R2]
  DSB
Loop
  WFI
  B Loop
```

**AArch64**

```
P1
  STR W0, [X2]
  DSB <domain>
Loop
  WFI
  B Loop
```

This requirement is unchanged in Armv8 and later architectures by the presence of Load-Acquire or Store-Release.
K13.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The Armv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using LDREX and STREX).
- Acquire only semantics (using LDAEX and STREX).
- Release only semantics (using LDREX and STLEX).
- Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the Armv8 and later specifications require that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of WFE, by removing the need for a DSB barrier and SEV instruction.

K13.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

Note

The inclusion of AArch32 PLDw instructions or AArch64 PRFM PST+ instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

Px

```
PLDw[R1]            ; preload into cache in unique state
Loop
  LDAEX R5, [R1]    ; read lock with acquire
  CMP R5, #0        ; check if 0
  STREXEQ R5, R0, [R1] ; attempt to store new value
  CMPEQ R5, #0      ; test if store succeeded
  BNE Loop          ; retry if not

; loads and stores in the critical region can now be performed
```

AArch64

Px

```
PRFM PSTLKKEEP, [X1] ; preload into cache in unique state
Loop
  LDAXR W5, [X1]     ; read lock with acquire
  CBNZ W5, Loop     ; check if 0
  STXR W5, W0, [X1] ; attempt to store new value
  CBNZ W5, Loop     ; test if store succeeded and retry if not

; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.
**K13.3.2 Releasing a lock**

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

**AArch32**

```
Px

; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock with release semantics
```

**AArch64**

```
Px

; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock with release semantics
```

**K13.3.3 Ticket locks**

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

--- Note ---

- The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

- The inclusion of AArch32 `PLDW` instructions or AArch64 `PFRM PST` instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

This is shown in the implementation below:

**AArch32**

```
Px

; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number
PLDW[R1] ; preload into cache in unique state
Loop1
LDAEX R5, [R1] ; read current and next
ADD R3, R5, #0x10000 ; increment the next number
STREX R6, R3, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
MOV R6, R5
BEQ block_start
Loop2
LDAH R6, [R1] ; read current value
```
CMP R6, R5, LSR #16 ; compare it with our allocated ticket
BNE Loop2 ; retry (spin) if it is not the same
block_start

AArch64

Px

; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTLIKEEP, [X1] ; preload into cache in unique state
Loop1
LDAW R5, [X1] ; read current and next
ADD W5, W5, #0x10000 ; increment the next number
STXR W6, W5, [X1] ; and update the value
CBNZ W6, Loop1 ; did the exclusive pass - retry if not

AND W6, W5, #0xFFFF
CMP W6, W5, LSR #16 ; is the current ticket ours
B.EQ block_start

Loop2
LDAH R6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
B.NE Loop2 ; retry (spin) if it isn't the same
block_start

Releasing the ticket lock simply involves incrementing the current ticket number, which is assumed in this example to be in R6, and doing a Store-Release:

AArch32

ADD R6, R6, #1
STLH R6, [R1]

AArch64

ADD W6, W6, #1
STLH W6, [X1]

K13.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 and later architectures can use the Wait For Event mechanism to minimize the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In Armv8 and later architectures, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

--- Note ---

The inclusion of AArch32 PLDW instructions or AArch64 PRFM PSTL instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

---

Simple lock

The following is an example of lock acquire code using WFE:

AArch32

Px

PLDW[R1] ; preload into cache in unique state
Barrier Litmus Tests

K13.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

Loop
LDAEX R5, [R1]        ; read lock with acquire
CMP R5, #0            ; check if 0
WFENE                 ; sleep if the lock is held
STREXEQ R5, R0, [R1]  ; attempt to store new value
CMPEQ R5, #0          ; test if store succeeded
BNE Loop              ; retry if not

AArch64

Px

SEVL                  ; invalidates the WFE on the first loop iteration
PRFM PSTL1KEEP, [X1]  ; allocate into cache in unique state
Loop
WFE
LDAXR W5, [X1]        ; read lock with acquire
CBNZ W5, Loop         ; check if 0
STXR W5, W0, [X1]     ; attempt to store new value
CBNZ W5, Loop         ; test if store succeeded and retry if not

; loads and stores in the critical region can now be performed

And the following is an example of lock release code:

AArch32

Px

; loads and stores in the critical region
MOV R0, #0
STL R0, [R1]          ; clear the lock

AArch64

Px

; loads and stores in the critical region
STLR WZR, [X1]        ; clear the lock

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for
the express purpose of creating an event when the monitor changes state:

AArch32

Px

; R1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

K13.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

**AArch32**

P1

```assembly
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```assembly
; interrupt service routine
LDR R5, [R1]
```

**AArch64**

P1

```assembly
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```assembly
; interrupt service routine
LDR W5, [X1]
```
K13.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- Data cache maintenance instructions.
- Instruction cache maintenance instructions on page K13-11773.
- TLB maintenance instructions and barriers on page K13-11776.

K13.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- Message passing to non-caching observers.
- Multiprocessing message passing to non-caching observers.
- Invalidating DMA buffers, non-functional example on page K13-11770.
- Invalidating DMA buffers, functional example with single PE on page K13-11771.
- Invalidating DMA buffers, functional example with multiple coherent PEs on page K13-11772.

Message passing to non-caching observers

The Armv8 and later architectures require the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

**AArch32**

P1

```assembly
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
DCCMVAC R1            ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)

E1

WAIT_ACQ ([R4] == 1)  ; waits for the flag (with order)
LDR R5, [R1]          ; reads the data
```

**AArch64**

P1

```assembly
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC.CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)

E1

WAIT_ACQ ([X4] == 1)  ; waits for the flag (with order)
LDR W5, [X1]          ; reads the data
```

In this example, it is required that E1:R5 == 0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

**AArch32**

P1

```assembly
```
Barrier Litmus Tests
K13.5 Cache and TLB maintenance instructions and barriers

```assembly
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
STL R0, [R2]          ; sends a flag for P2 (ordered by the store release)

P2
WAIT ([R2] == 1)      ; waits for P1 flag
DMB                   ; ensures cache clean is observed after P1 flag is observed
DCMVAC R1             ; cleans cache to point of coherency – will clean P1 cache
DMB                   ; ensures effects of the clean will be observed before the
                        ; flag to E1 is set
STR R0, [R4]          ; sends flag to E1

E1
WAIT_ACQ ([R4] == 1)  ; waits for P2 flag (ordered)
LDR R5, [R1]          ; reads data

AArch64

P1
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
STLR W0, [X2]         ; sends a flag for P2 (ordered)

P2
WAIT ([X2] == 1)      ; waits for P1 flag
DMB SY                ; ensures cache clean is observed after P1 flag is observed
DCMVAC, X1            ; cleans cache to point of coherency, will clean P1 cache
DMB SY                ; ensures effects of the clean will be observed before the
                        ; flag to E1 is set
STR W0, [X4]          ; sends flag to E1

E1
WAIT_ACQ ([X4] == 1)  ; waits for P2 flag
LDR W5, [X1]          ; reads data

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the
P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note
The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable
memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute
can be allocated into a cache at any time, for example as a result of speculation. The following example shows this
possibility:

AArch32

P1

DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                        ; but as the DMA will subsequently overwrite this region an
                        ; invalidate operation is sufficient and usually more efficient
DMB                   ; ensures cache invalidation is observed before the next store
                        ; is observed
STR R0, [R3]          ; sends flag to external agent
WAIT_ACQ ([R4]==1)    ; waits for a different flag from an external agent
LDR R5, [R1]          ; reads data
```
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1
DC IVAC, X1 ; ensure cache is not dirty. A clean operation could be used
; but as the DMA will subsequently overwrite this region an
DMB SY ; invalidate operation is sufficient and usually more efficient
; is observed
STR W0, [X3] ; sends flag to external agent
WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
LDR W5, [X1]

E1
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1] ; stores new data
STLR W0, [X4] ; sends a flag

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into
the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1
DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be used
; but as the DMA will subsequently overwrite this region an
DMB ; invalidate operation is sufficient and usually more efficient
; is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB ; ensures that cache invalidate is observed after the flag
; from external agent is observed
DCIMVAC R1 ; ensures cache discards stale copies before use
LDR R5, [R1]

E1
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1
DC IVAC, X1 ; ensures cache is not dirty. A clean operation could be used
; but as the DMA will subsequently overwrite this region an
DMB SY ; invalidate operation is sufficient and usually more efficient
; is observed
STR W0, [X3] ; sends flag to external agent
WAIT ([X4]==1) ; waits for a different flag from an external agent
DMB SY ; ensures that cache invalidate is observed after the flag
; from external agent is observed
DC IVAC, X1 ; ensures cache discards stale copies before use
LDR W5, [X1]

E1
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1] ; stores new data
STLR W0, [X4] ; sends a flag

In this example, the result P1:R5 = 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

**AArch32**

**P0**

(Use data from [R1], potentially using [R1] as scratch space)

STL R0, [R2] ; signals release of [R1]
WAIT_ACQ ([R2] == 0) ; waits for new value from DMA
LDR R5, [R1]

**P1**

WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1 ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3] ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1 ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2] ; signals availability of new [R1]

**E1**

WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1] ; sends new [R1]
DMB [ST]
STR R0, [R2] ; indicates that new data is available to P1

**AArch64**

**P0**

(Use data from [X1], potentially using [X1] as scratch space)

STLR W0, [X2] ; signals release of [X1]
WAIT_ACQ ([X2] == 0) ; waits for new value from DMA
LDR W5, [X1]

**P1**

WAIT ([X2] == 1) ; waits for release of [R1] by P0
DC IVAC, X1 ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3] ; requests new data for [R1]
WAIT ([X4] == 1) ; waits for new data
DMB SY
DCIMVAC X1 ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2] ; signals availability of new [R1]

**E1**

WAIT ([X3] == 1) ; waits for new data request
STR W5, [X1] ; sends new [R1]
STR W0, [X4] ; indicates new data is available to P1
In this example, the result $P0:R5 = 0x55$ is required. The $DMB$ issued by $P1$ after the first data cache invalidation ensures that effect of the cache invalidation on $P0$ is seen by $E1$ before the store by $E1$ to $[R1]$. The $DMB$ issued by $P1$ after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in $[R2]$.

K13.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- Ensuring the visibility of updates to instructions for a uniprocessor.
- Ensuring the visibility of updates to instructions for a multiprocessor.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a $DSB$ instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a $DSB$, and an $ISB$ is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

**AArch32**

```
P1
  STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
  DCOMAU R1            ; clean to PoU makes the new instruction visible to the instruction cache
  DSB                  ; clean to PoU makes new instruction cache state visible
  ICIMVAU R1           ; ensures instruction cache/branch predictor discards stale data
  BPIMVA R1            ; ensures completion of the invalidation
  DSB                  ; ensures completion of the invalidation
  ISB                  ; ensures instruction fetch path sees new instruction cache state
  BX R1                ; branch to new instruction
```

In AArch64 state, the branch predictor maintenance is not required.

**AArch64**

```
P1
  STR W11, [X1]         ; W11 contains a new instruction to be stored in program memory
  DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
  DSB ISH              ; clean to PoU makes new instruction cache state visible
  IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
  DSB ISH              ; ensures completion of the invalidation
  ISB                  ; ensures instruction fetch path sees new instruction cache state
  BR X1                ; branch to new instruction
```

**Note**
Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The Armv8 and later architectures require a PE that executes an instruction cache maintenance instruction to execute a $DSB$ instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An $ISB$ is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own $ISB$ synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:
**AArch32**

P1

```
STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1            ; clean to PoU makes the new instruction visible to the instruction cache
DSB                   ; ensures completion of the clean on all PEs
ICIMVAU R1            ; ensures instruction cache discards stale data
BPIMVA R               ; ensures branch predictor discards stale data
DSB                   ; ensures completion of the instruction cache and branch predictor
          ; invalidation on all PEs
STR R0, [R2]          ; sets flag to signal completion
ISB                   ; synchronizes context on this PE
BX R1                 ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)      ; waits for flag signalling completion
ISB                   ; synchronizes context on this PE
BX R1                 ; branches to new code
```

**AArch64**

P1

```
STR X11, [X1]         ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1           ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH               ; ensures completion of the clean on all PEs
IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
DSB ISH               ; ensures completion of the instruction cache/branch predictor
          ; invalidation on all PEs
STR W0, [X2]          ; sets flag to signal completion
ISB                   ; synchronizes context on this PE
BR X1                 ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1)      ; waits for flag signalling completion
ISB                   ; synchronizes context on this PE
BR X1                 ; branches to new code
```

**Nonfunctional approach**

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

**AArch32**

P1

```
STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1            ; clean to PoU makes the new instruction visible to the instruction cache
DSB                   ; ensures completion of the clean on all PEs
ICIMVAU R1            ; ensures instruction cache discards stale data
BPIMVA R               ; ensures branch predictor discards stale data
DMB                   ; ensures ordering of the store after the invalidation
          ; DOES NOT guarantee completion of instruction cache/branch
          ; predictor on other PEs
STR R0, [R2]          ; sets flag to signal completion
DSB                   ; ensures completion of the invalidation on all PEs
ISB                   ; synchronizes context on this PE
BX R1                 ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)      ; waits for flag signalling completion
DSB                   ; this DSB does not guarantee completion of P1
           ; ICIMVAU/BPIMVA
ISB                   ; synchronizes context on this PE
BX R1                 ; branches to new code
```
AArch64

P1

```
STR W11, [X1]         ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH               ; ensures completion of the clean on all PEs
IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
DMB ISH               ; ensures ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other PEs
STR W0, [X2]          ; sets flag to signal completion
DSB ISH               ; ensures completion of the invalidation on all PEs
ISB                    ; synchronizes context on this PE
BR X1                  ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1)      ; waits for flag signalling completion
DSB ISH               ; this DSB does not guarantee completion of P1
; ICIMVAU/BPIMVA
ISB                    
BR X1                  
```

In this example, P2…Px might not see the updated region of code at R1.
K13.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- Ensuring the visibility of updates to translation tables for a uniprocessor.
- Ensuring the visibility of updates to translation tables for a multiprocessor.
- Paging memory in and out on page K13-11777.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The Armv8 and later architectures require that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]         ; updates the translation table entry
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                   ; ensures completion of the BP and TLB invalidation
ISB                   ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; updates the translation table entry
DSB ISH               ; ensures visibility of the update to translation table walks
TLBI VAE1, X10        ; assumes we are in the EL1
DSB ISH               ; ensures completion of the TLB invalidation
ISB                   ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The Armv8 and later architectures require a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.
AArch32

P1

STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB ; ensures completion of the BP and TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

AArch64

P1

STR X11, [X1] ; updates the translation table entry
DSB ISH ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10
DSB ISH ; ensures completion of the TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the `DSB` that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

STR R11, [R1] ; updates the translation table for the region being paged out
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10 ; invalidates the old entry
DSB ; ensures completion of the invalidation on all PEs
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore)
ICIALLUIS ; also invalidates the branch predictor
DSB ; ensures completion of the instruction cache
; and branch predictor invalidation
STR R9, [R1] ; creates a new translation table entry with a new mapping
DSB ; ensures visibility of the new translation table mapping
Barrier Litmus Tests

K13.5 Cache and TLB maintenance instructions and barriers

ISB ; ensures synchronisation of this instruction stream

AArch64

P1

STR X11, [X1] ; updates the translation table for the region being paged out
DSB ISH ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10 ; invalidates the old entry
DSB ISH ; ensures completion of the invalidation on all PEs
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH ; ensures completion of the memory transfer (this could be part of
 ; LoadMemoryFromBackingStore)
IC IALLUIS ; also invalidates the branch predictor
DSB ISH ; ensures completion of the instruction cache
 ; and branch predictor invalidation
STR X9, [X1] ; creates a new translation table entry with a new mapping
DSB ISH ; ensures visibility of the new translation table mapping
ISB ; ensures synchronisation of this instruction stream

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state and IC IVAU operations in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

Using break-before-make when updating translation table entries

The Arm Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see Using break-before-make when updating translation table entries on page D8-5198 for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read/write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

AArch32
**K13.5 Cache and TLB maintenance instructions and barriers**

**P1**

; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry

STR R1, R2, [R3]          ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R4               ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
ICIALLUIS                  ; also invalidates the branch predictor
STR R5, R6, [R3]           ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                        ; ensures synchronisation of this instruction stream

--- Note ---

This example shows an update to an entry in a translation table that is using the long-descriptor format.

**AArch64**

**P1**

; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry

STR X1, [X2]              ; stores invalid entry
DSB ISH                   ; ensures visibility of the update to translation table walks
TLB IVAEIS, X3            ; invalidates the old entry
DSB ISH                   ; ensures completion of the invalidation on all PEs
IC IALLUIS                ; also invalidates the branch predictor
STR X4, [X2]              ; store new mapping
DSB ISH                   ; ensures visibility of the update to translation table walks
ISB                       ; ensures synchronisation of this instruction stream

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

**K13.5.4 Ordering of Memory-mapped device control with payloads**

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.

- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. This is shown by the following code:

**AArch32**
P1

```
STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
```

**AArch64**

P1

```
STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a Completer, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

**AArch32**

P1

```
WAIT ([R4] == 1)      ; R4 contains the address of the status register,
; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; reads data from the data buffer
```

**AArch64**

P1

```
WAIT ([X4] == 1)      ; X4 contains the address of the status register,
; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; reads data from the data buffer
```
K13.6 **Armv7 compatible approaches for ordering, using DMB and DSB barriers**

The following sections describe the Armv7 compatible approaches for ordering, using DMB and DSB barriers:

- Simple ordering and barrier cases.
- Load-Exclusive, Store-Exclusive and barriers on page K13-11785.
- Using a mailbox to send an interrupt on page K13-11787.
- Cache and TLB maintenance instructions and barriers on page K13-11787.

**K13.6.1 Simple ordering and barrier cases**

Arm implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

**Simple weakly consistent ordering example**

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

**Message passing**

The following sections describe:

- Weakly-ordered message passing problem.
- Message passing with multiple observers on page K13-11782.

**Weakly-ordered message passing problem**

P1

```
STR R5, [R1] ; sets new data
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1) ; waits on flag
LDR R5, [R1] ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

**Resolving by the addition of barriers**

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2: R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1) ; waits on flag
```
DMB                      ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]

**Resolving by the use of barriers and address dependency**

There is a rule within the Arm architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an **address dependency**. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a **control dependency**.

Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K13-1 on page K13-11782 shows examples of address dependencies, control dependencies, and an address and control dependency.

**Table K13-1 Dependency examples**

<table>
<thead>
<tr>
<th>Address dependency</th>
<th>Control dependency</th>
<th>Address and control dependency^a</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDR r1, [r0]</td>
<td>LDR r1, [r0]</td>
<td>LDR r1, [r0]</td>
</tr>
<tr>
<td>LDR r2, [r1]</td>
<td>AND r1, r1, #0</td>
<td>CMP r1, #55</td>
</tr>
<tr>
<td>LDR r2, [r3, r1]</td>
<td>LDRNE r2, [r3]</td>
<td>MOVNE r4, #22</td>
</tr>
<tr>
<td></td>
<td>LDR r2, [r3, r4]</td>
<td></td>
</tr>
</tbody>
</table>

[a. The address dependency takes priority.]

This means that the data transfer example of *Weakly-ordered message passing problem* on page K13-11781 can also be satisfied as shown in the following example:

**P1**

```
STR R5, [R1]          ; sets new data
DMB [ST]              ; ensures all observers observe data before the flag
STR R0, [R2]          ; sends flag indicating data ready
```

**P2**

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                      ; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

**Message passing with multiple observers**

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:
Barrier Litmus Tests

K13.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

P1

STR R5, [R1] ; sets new data
STR R0, [R2] ; sends flag indicating data ready

P2

WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen

P3

WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

P1

STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready

P2

WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen

P3

WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1

STR R5, [R1, #offset] ; sets new data in a field
DMB [ST] ; ensures all observers observe data before base address is updated
STR R1, [R2] ; updates base address

P2

LDR R1, [R2] ; reads for base address
CMP R1, #0 ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field

If the null_trap is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.
P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

**Posting a store before polling for acknowledgement**

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

```plaintext
P1
  STR R0, [R2]
  WAIT ([R3]==1)

P2
  WAIT ([R2]==1)
  STR R0, [R3]
```

In Armv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For Armv7 implementations with the Multiprocessing Extensions, for Armv8, and for later architectures, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a `DMB` instruction prevents this deadlock in Armv7 implementations that do not include the Multiprocessing Extensions:

```plaintext
P1
  STR R0, [R2]
  DMB
  WAIT ([R3]==1)

P2
  WAIT ([R2]==1)
  STR R0, [R3]
```

The `DMB` executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

```plaintext
P1
  STR R0, [R2]
  WAIT ([R2]==2)

P2
  WAIT ([R2]==1)
  LDR R0, [R2]
  ADD R0, R0, #1
  STR R0, [R2]
```

In this example, the same deadlock can occur in Armv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a `DMB` instruction prevents this deadlock:

```plaintext
P1
  STR R0, [R2]
  DMB
  WAIT ([R2]==2)

P2
  WAIT ([R2]==1)
  LDR R0, [R2]
```
ADD R0, R0, #1
STR R0, [R2]

**WFE and WFI and barriers**

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement* on page K13-11784, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

```
STR R0, [R2]
DSB
Loop
  WFI
  B Loop
```

However, if the example in *Posting a store before polling for acknowledgement* on page K13-11784 is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
STR R0, [R2]
DMB
Loop
  LDR R12, [R3]
  CMP R12, #1
  WFENE
  BNE Loop
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
DSB
SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks* on page K13-11786.

**K13.6.2 Load-Exclusive, Store-Exclusive and barriers**

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores* on page B2-211, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

**Acquiring a lock**

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.
Barrier Litmus Tests
K13.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

Px

Loop
LDREX R5, [R1] ; reads lock
CMP R5, #0 ; checks if 0
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0 ; tests if store succeeded
BNE Loop ; retries if not
DMB ; ensures that all subsequent accesses are observed after the gaining of the lock is observed
; loads and stores in the critical region can now be performed

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

Px

; loads and stores in the critical region
MOV R0, #0
DMB ; ensures all previous accesses are observed before the lock is cleared
STR R0, [R1] ; clears the lock

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 and later architectures include Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or spinlock, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

Px

Loop
LDREX R5, [R1] ; reads lock
CMP R5, #0 ; checks if 0
WFE ; sleeps if the lock is held
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0 ; tests if store succeeded
BNE Loop ; retries if not
DMB ; ensures that all subsequent accesses are observed after the gaining of the lock is observed
; loads and stores in the critical region can now be performed

And the following is an example of lock release code using SEV:

Px

; loads and stores in the critical region
MOV R0, #0
DMB ; ensures all previous accesses are observed before the lock is cleared
K13.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a `DSB` instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

```
P1
  STR R5, [R1]            ; message stored to shared memory location
  DSB [ST]                ; R4 contains the address of a mailbox
  STR R1, [R4]            ; ensures completion of the store that cleared the lock before
                         ; sending the event
P2
  ; interrupt service routine
  LDR R5, [R1]
```

**Note**
The `DSB` executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K13.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- **Data cache maintenance instructions** on page K13-11790.
- **Instruction cache maintenance instructions** on page K13-11791.
- **TLB maintenance instructions and barriers** on page K13-11791.

**Data cache maintenance instructions**

The following sections describe the use of barriers with data cache maintenance instructions:

- **Message passing to non-caching observers** on page K13-11788.
- **Multiprocessing message passing to non-caching observers** on page K13-11788.
- **Invalidating DMA buffers, non-functional example** on page K13-11788.
- **Invalidating DMA buffers, functional example with single PE** on page K13-11789.
- **Invalidating DMA buffers, functional example with multiple coherent PEs** on page K13-11789.

**Message passing to non-caching observers**

The Armv8 and later architectures require the use of `DMB` instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

```
P1
  STR R5, [R1]               ; updates data (assumed to be in P1's cache)
  DCOMVAC R1                 ; cleans cache to point of coherency
  DMB                        ; ensures effects of the clean will be observed before the flag is set
  STR R0, [R4]               ; sends flag to external agent (Non-cacheable location)
```
### Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in Armv8 and later architectures, and in Armv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

**P1**

- `STR R5, [R1]` ; updates data (assumed to be in P1's cache)
- `DMB [ST]` ; ensures new data is observed before the flag to P2 is set
- `STR R0, [R2]` ; sends flag to P2

**P2**

- `WAIT ([R2] == 1)` ; waits for flag from P1
- `DMB` ; ensures cache clean is observed after P1 flag is observed
- `DCMVAC R1` ; cleans cache to point of coherency - this cleans the cache of P1
- `DMB` ; ensures effects of the clean are observed before the flag to E1 is set
- `STR R0, [R4]` ; sends flag to E1

**E1**

- `WAIT ([R4] == 1)` ; waits for flag from P2
- `DMB` ; ensures that flag has been observed before reading the data
- `LDR R5, [R1]` ; reads the data

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

### Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

**P1**

- `DCMVAC R1` ; ensures caches are not dirty. A clean operation could be used but the DMA overwrites this region so an invalidate operation is sufficient and usually more efficient
- `DMB` ; ensures cache invalidation is observed before the next store is observed
- `STR R0, [R3]` ; sends flag to external agent
- `WAIT ([R4]==1)` ; waits for a different flag from an external agent
- `DMB` ; observes flag from external agent before reading new data. However [R1] could have been brought into cache earlier
- `LDR R5, [R1]`

**E1**

- `WAIT ([R3] == 1)` ; waits for flag
- `STR R5, [R1]` ; stores new data
- `DMB` ; sends a flag

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.
Invalidate DMA buffers, functional example with single PE

P1

DCIMVAC R1  ; ensures cache is not dirty. A clean operation could be
             ; used but the DMA overwrites this region so an invalidate operation
             ; is sufficient and usually more efficient
DMB         ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB         ; ensures that cache invalidate is observed after the flag
            ; from external agent is observed
DCIMVAC R1  ; ensures cache discards stale copies before use
LDR R5, [R1]

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1]  ; stores new data
DMB [ST]      ; sends a flag

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidate DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2]  ; signals release of [R1]
WAIT ([R2] == 0) ; waits for new value from DMA
DMB
LDR R5, [R1]

P1

WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1  ; ensures caches are not dirty, invalidate is sufficient
DMB
STR R0, [R3] ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1  ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]  ; signals availability of new [R1]

E1

WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1]  ; sends new [R1]
DMB [ST]      ; indicates new data available to P1
STR R0, [R4]  ; sends flag

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].
Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- **Ensuring the visibility of updates to instructions for a uniprocessor.**
- **Ensuring the visibility of updates to instructions for a multiprocessor.**

### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a `DSB`, and an `ISB` is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

```
P1
  STR R11, [R1]            ; R11 contains a new instruction to store in program memory
  DCCMVAU R1               ; clean to PoU makes new instructions visible to instruction cache
  DSB                      ; ensures completion of the invalidation
  ICIMVAU R1               ; ensures instruction cache and branch predictor discard stale data
  BPIMVA R1
  DSB                      ; ensures completion of the instruction cache/branch predictor discard stale data
  ISB                      ; ensures instruction fetch path observes new instruction cache state
  BX R1
```

### Ensuring the visibility of updates to instructions for a multiprocessor

Armv8 and later architectures, and an Armv7 implementation that includes the Multiprocessing Extensions, require a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

```
P1
  STR R11, [R1]            ; R11 contains a new instruction to store in program memory
  DCCMVAU R1               ; clean to PoU makes new instructions visible to instruction cache
  DSB                      ; ensures completion of the clean on all processors
  ICIMVAU R1               ; ensures instruction cache/branch predictor discards stale data
  BPIMVA R1
  DSB                      ; ensures completion of the instruction cache and branch predictor invalidation on all PEs
  STR R0, [R2]             ; sets flag to signal completion
  ISB                      ; synchronizes context on this PE
  BX R1
```

```
P2-Px
  WAIT ([R2] == 1)         ; waits for flag signaling completion
  ISB                      ; synchronizes context on this processor
  BX R1
```

### Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

```
P1
  STR R11, [R1]            ; R11 contains a new instruction to store in program memory
  DCCMVAU R1               ; clean to PoU makes new instructions visible to instruction cache
```
Barrier Litmus Tests

K13.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSB</td>
<td>; ensure completion of the clean on all PEs</td>
</tr>
<tr>

<td>; ensure ordering of the store after the invalidation</td>
</tr>
<tr>
<td>DMB</td>
<td>; DOES NOT guarantee completion of instruction cache/branch</td>
</tr>
<tr>
<td>STR R0, [R2]</td>
<td>; sets flag to signal completion</td>
</tr>
<tr>
<td>DSB</td>
<td>; ensures completion of the invalidation on all PEs</td>
</tr>
<tr>
<td>ISB</td>
<td>; synchronizes context on this PE</td>
</tr>
<tr>
<td>BX R1</td>
<td>; branches to new code</td>
</tr>
</tbody>
</table>

P2-Px

WAIT ([R2] == 1) ; waits for flag signaling completion
DSB ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1

In this example, P2...Px might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- **Ensuring the visibility of updates to translation tables for a uniprocessor**.
- **Ensuring the visibility of updates to translation tables for a multiprocessor** on page K13-11792.
- **Paging memory in and out** on page K13-11792.

### Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the Armv8 and later architectures, and in an Armv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STR R11, [R1]</td>
<td>; updates the translation table entry</td>
</tr>
<tr>
<td>DSB</td>
<td>; ensures visibility of the update to translation table walks</td>
</tr>
<tr>
<td>TLBIMVA R10</td>
<td></td>
</tr>
<tr>
<td>BPIMVA</td>
<td></td>
</tr>
<tr>
<td>DSB</td>
<td>; ensures completion of the BP and TLB invalidation</td>
</tr>
<tr>
<td>ISB</td>
<td>; synchronizes context on this PE</td>
</tr>
<tr>
<td>BX R1</td>
<td>; new translation table entry can be relied upon at this point and all accesses</td>
</tr>
<tr>
<td></td>
<td>; generated by this observer using the old mapping have been completed</td>
</tr>
</tbody>
</table>

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.
Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the Armv8 and later architectures, and in an Armv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB ; ensures completion of the BP and TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally on other PEs
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1] ; updates the translation table for the region being paged out
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
; invalidates the old entry
DSB ; ensures completion of the invalidation on all processors
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore
ICIALLUIS ; also invalidates the branch predictor
DSB ; ensures completion of the instruction cache
; and branch predictor invalidation
STR R9, [R1] ; creates a new translation table entry with a new mapping
DSB ; ensures visibility of the new translation table mapping
ISB ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.
In this example, the use of ICIALLUIS to invalidate the entire instruction cache is a simplification that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.
Appendix K14
Random Number Generation

This appendix provides further information on the generation of random numbers using FEAT_RNG. It contains the following sections:

- Properties of the generated random number on page K14-11796.
Properties of the generated random number

When FEAT_RNG is implemented, reads of the RNDR and RNDRRS registers return a 64-bit random number. The random numbers must meet the properties and conform to the standards that are detailed in this section.

The output random number is from a Deterministic Random Bit Generator (DRBG), which is seeded from a True Random Number Generator (TRNG).

The TRNG provides entropy in the form of random numbers, from the sampled output of an unpredictable physical process.

The TRNG should conform to:
- The NIST SP800-90B standard.
- The NIST SP800-22 standard.
- The FIPS 140-2 standard.
- The BSI AIS-31 standard.

The DRBG produces random numbers from a cryptographically secure algorithm.

The DRBG is seeded from the TRNG.

The DRBG algorithm should conform to the NIST SP800-90A Rev 1 standard.

The DRBG is reseeded after an IMPLEMENTATION DEFINED number of random numbers has been generated and read using the RNDR register.

The DRBG is reseeded immediately before the random number is generated and read using the RNDRRS register.

The entire random number generation should conform to the NIST SP800-90C standard.

Note

- Since a TRNG can only generate random bits at a limited rate, the random number bits are commonly collected in an “entropy pool” until needed. An implementation should ensure that lower privileged software cannot impact the performance of higher privileged software by entirely draining this “entropy pool”. The refill time cost of the “entropy pool” should be paid for by the persistent caller.

- When FEAT_RNG_TRAP is implemented, reads of the RNDR and RNDRRS registers may be trapped to EL3. For more information about this trapping behavior, see control fields ID_AA64PFR1_EL1.RNDR_trap and SCR_EL3.TRNDR.
Appendix K15
Legacy Feature Naming Convention

This appendix maps the legacy feature names for the Armv8.x extensions. It contains the following sections:

- *The Armv8.0 architecture* on page K15-11798.
- *The Armv8.1 architecture extension* on page K15-11799.
- *The Armv8.2 architecture extension* on page K15-11800.

Appendix K16
Arm Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some helper procedures and functions that are used by pseudocode. It contains the following sections:

• About the Arm pseudocode on page K16-11808.
• Pseudocode for instruction descriptions on page K16-11809.
• Data types on page K16-11811.
• Operators on page K16-11816.
• Statements and control structures on page K16-11822.
• Built-in functions on page K16-11827.
• Miscellaneous helper procedures and functions on page K16-11830.
• Arm pseudocode definition index on page K16-11832.

--- Note ---
This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of Arm pseudocode. This appendix is not complete. Changes are planned for future releases.
K16.1 About the Arm pseudocode

The Arm pseudocode provides precise descriptions of some areas of the Arm architecture. This includes description of the decoding and operation of all valid instructions. Pseudocode for instruction descriptions on page K16-11809 gives general information about this instruction pseudocode, including its limitations.

The following sections describe the Arm pseudocode in detail:

• Data types on page K16-11811.
• Operators on page K16-11816.
• Statements and control structures on page K16-11822.

Built-in functions on page K16-11827 and Miscellaneous helper procedures and functions on page K16-11830 describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. Arm pseudocode definition index on page K16-11832 contains the indexes to the pseudocode.

K16.1.1 General limitations of Arm pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

• Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
• No subsequent behavior indicated by the pseudocode occurs.

For more information, see Special statements on page K16-11826.
K16.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in General limitations of Arm pseudocode on page K16-11808 and Limitations of the instruction pseudocode on page K16-11810.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. Instruction encoding diagrams and instruction pseudocode gives more information about the pseudocode provided for each instruction.

K16.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.

- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the EncodingSpecificOperations() function, either at its start or only after a condition code check performed by if ConditionPassed() then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.

- A should be 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see SBZ or SBO fields T32 and A32 in instructions on page K1-11566.

- A named single bit or a bit in a named multi-bit field. The cond field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.

- The encoding diagram is for an A32/T32 instruction that does not have a cond field in bits[31:28].

- The encoding diagram is for an A32/T32 instruction that has a cond field in bits[31:28], and bits[31:28] of the instruction are not 0b1111.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.

2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.

3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the Consistent() function to specify what happens if they are not identical. Consistent() returns TRUE if all instruction bits or fields with the same name as its argument have the same value, and FALSE otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.
There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is CONSTRAINED UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as CONSTRAINED UNPREDICTABLE, see SBZ or SBO fields T32 and A32 in instructions on page K1-11566.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The ConditionPassed() call in the common pseudocode, if present, performs step 2, and the EncodingSpecificOperations() call performs steps 3 and 4.

### K16.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses, see Ordering constraints on page E2-7174.
- Pseudocode does not describe the exact rules when an instruction that generates any of the following fails its condition code check:
  - UNDEFINED instruction.
  - Hyp trap.
  - Monitor trap.
  - Trap to AArch64 exception.

In such cases, the UNDEFINED pseudocode statement or call to the applicable trap function lies inside the if ConditionPassed() then ... structure, either directly or in the EncodingSpecificOperations() function call, and so the pseudocode indicates that the instruction executes as a NOP. For the exact rules, see:

- Conditional execution of undefined instructions on page G1-8966.
- EL2 configurable controls on page G1-9010.
- EL3 configurable controls on page G1-9030.
- Configurable instruction controls on page D1-4665.

- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. Combinations of floating-point exceptions on page E1-7151 describes the exact rules.

--- **Note**

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

---

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as Abort(), or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in Handling exceptions that are taken to an Exception level using AArch32 on page G1-8929.
K16.3 Data types

This section describes:

- General data type rules.
- Bitstrings.
- Integers on page K16-11812.
- Reals on page K16-11812.
- Booleans on page K16-11812.
- Enumerations on page K16-11813.
- Structures on page K16-11813.
- Tuples on page K16-11814.
- Arrays on page K16-11815.

K16.3.1 General data type rules

Arm architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables \( x \), \( y \) and \( z \) to have types integer, bitstring of length 1, and Boolean, respectively.

\[
x = 1;
y = '1';
z = TRUE;
\]

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named \( \text{count} \) is an integer.

\[
\text{integer} \ \text{count};
\]

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K16.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

\[
\text{bits(N)} \quad \text{The type name of a bitstring of length N.}
\]

\[
\text{bit} \quad \text{A synonym of bits(1).}
\]

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.
Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right N-1 to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit N-1 is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard little-endian order. That is, the leftmost bit of a bitstring of length N is bit (N-1) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

K16.3.3  Integers

This section describes the data type for integer numbers.

**Syntax**

```plaintext
integer
```

The type name for the integer data type.

**Description**

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer +2^31. If -2^31 needs to be written in hexadecimal, it must be written as -0x80000000.

K16.3.4  Reals

This section describes the data type for real numbers.

**Syntax**

```plaintext
real
```

The type name for the real data type.

**Description**

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

K16.3.5  Booleans

This section describes the Boolean data type.

**Syntax**

```plaintext
boolean
```

The type name for the Boolean data type.
TRUE  The two values a Boolean variable can take.

**Description**

A Boolean is a logical TRUE or FALSE value.

--- **Note** ---

This is not the same type as bit, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

---

**K16.3.6 Enumerations**

This section describes the enumeration data type.

**Syntax and examples**

```
enumeration      Keyword to defined a new enumeration type.

enumeration Example {Example_One, Example_Two, Example_Three};
```

A definition of a new enumeration called Example, which can take on the values Example_One, Example_Two, Example_Three.

**Description**

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

---

**K16.3.7 Structures**

This section describes the structure data type.

**Syntax and examples**

```
type              The keyword used to declare the structure data type.

type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called ShiftSpec that contains a bitstring member called shift and an integer member named amount. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable named abc of type ShiftSpec.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

**Description**

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.
In the syntax section, the example defines a structure called ShiftSpec with two members. The first is a bitstring of length 2 named shift and the second is an integer named amount. After declaring a variable of that type named abc, the members of this structure are referred to as abc.shift and abc.amount.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)

ShiftSpec1 and ShiftSpec2 are two different types despite having identical definitions. This means that the value in a variable of type ShiftSpec1 cannot be assigned to variable of type ShiftSpec2.

K16.3.8 Tuples

This section describes the tuple data type.

Examples

(bits(32) shifter_result, bit shifter_carry_out)
   An example of the tuple syntax.

(shift_t, shift_n) = ('00', 0);
   An example of assigning values to a tuple.

Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function Shift_C(), which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type bits(32) and the second of type bit.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type (bits(32), bit). The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

• shift_t to be of type bits(2).
• shift_n to be of type integer.
• (shift_t, shift_n) to be a tuple of type (bits(2), integer).
K16.3.9 Arrays

This section describes the array data type.

Syntax

array

The type name for the array data type.

array data_type array_name[A..B];

Declaration of an array of type data_type, which might be compound data type. It is named array_name and is indexed with an integer range from A to B.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then ..., then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

array bits(64) _R[0..30];

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

• Enumerations always contain at least one symbolic constant named value.
• Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as R[i], MemU[address, size] or Elem[vector, i, size]. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See Function and procedure calls on page K16-11822.
K16.4 Operators

This section describes:

- Relational operators.
- Boolean operators.
- Bitstring operators on page K16-11817.
- Arithmetic operators on page K16-11817.
- The assignment operator on page K16-11818.
- Precedence rules on page K16-11820.
- Conditional expressions on page K16-11820.
- Operator polymorphism on page K16-11820.

K16.4.1 Relational operators

The following operations yield results of type boolean.

**Equality and non-equality**

If two variables \( x \) and \( y \) are of the same type, their values can be tested for equality by using the expression \( x == y \) and for non-equality by using the expression \( x != y \). In both cases, the result is of type boolean.

Both \( x \) and \( y \) must be of type \text{bits}(N), \text{real}, \text{enumeration}, \text{boolean}, \text{or integer}. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a \( d==15 \) test.

A special form of comparison is defined with a bitstring literal that can contain bit values '0', '1', and 'x'. Any bit with value 'x' is ignored in determining the result of the comparison. For example, if \( \text{opcode} \) is a 4-bit bitstring, the expression \( \text{opcode} == '1x0x' \) matches the values '1000', '1100', '1001', and '1101'. This is known as a bitmask.

---

**Note**

This special form is permitted in the implied equality comparisons in the when parts of case .. of .. structures.

**Comparisons**

If \( x \) and \( y \) are integers or reals, then \( x < y, x <= y, x > y, \) and \( x >= y \) are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

**Set membership with IN**

\(<\text{expression}> \ IN \ \{<\text{set}>\} \) produces TRUE if \( \text{expression} \) is a member of \( \text{set} \). Otherwise, it is FALSE. \( \text{set} \) must be a list of expressions separated by commas.

K16.4.2 Boolean operators

If \( x \) is a Boolean expression, then \( !x \) is its logical inverse.

If \( x \) and \( y \) are Boolean expressions, then \( x \ & \ y \) is the result of ANDing them together. As in the C language, if \( x \) is FALSE, the result is determined to be FALSE without evaluating \( y \).

---

**Note**

This is known as short circuit evaluation.

---

If \( x \) and \( y \) are booleans, then \( x \ || \ y \) is the result of ORing them together. As in the C language, if \( x \) is TRUE, the result is determined to be TRUE without evaluating \( y \).
Note

If \( x \) and \( y \) are booleans or Boolean expressions, then the result of \( x \neq y \) is the same as the result of exclusive-ORing \( x \) and \( y \) together. The operator EOR only accepts bitstring arguments.

K16.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

Logical operations on bitstrings

If \( x \) is a bitstring, \( \text{NOT}(x) \) is the bitstring of the same length obtained by logically inverting every bit of \( x \).

If \( x \) and \( y \) are bitstrings of the same length, \( x \text{ AND } y \), \( x \text{ OR } y \), and \( x \text{ EOR } y \) are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of \( x \) and \( y \) together.

Bitstring concatenation and slicing

If \( x \) and \( y \) are bitstrings of lengths \( N \) and \( M \) respectively, then \( x:y \) is the bitstring of length \( N+M \) constructed by concatenating \( x \) and \( y \) in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is \( x<i, j, k, \ldots, n> \), where \( x \) is the integer or bitstring being sliced, and \( <integer_list> \) is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in \( <integer_list> \). In \( x<i> \), each of the integers in \( <integer_list> \) must be:

- \( \geq 0 \).
- \( < \text{Len}(x) \) if \( x \) is a bitstring.

The definition of \( x<i> \) depends on whether \( integer_list \) contains more than one integer:

- If \( integer_list \) contains just one integer \( i \), \( x<i> \) is defined to be:
  - If \( x \) is a bitstring, \( '0' \) if bit \( i \) of \( x \) is a zero and \( '1' \) if bit \( i \) of \( x \) is a one.
  - If \( x \) is an integer, and \( y \) is the unique integer in the range 0 to \( 2^{(i+1)}-1 \) that is congruent to \( x \) modulo \( 2^{i+1} \). Then \( x<i> \) is \( '0' \) if \( y < 2^i \) and \( '1' \) if \( y \geq 2^i \).

Loosely, this definition treats an integer as equivalent to a sufficiently long two’s complement representation of it as a bitstring.

The notation for a range expression is \( i:j \) with \( i \geq j \) is shorthand for the integers in order from \( i \) down to \( j \), with both end values included. For example, \( \text{instr}<31:28> \) represents \( \text{instr}<31, 30, 29, 28> \).

\( x<i> \) is assignable provided \( x \) is an assignable bitstring and no integer appears more than once in \( <integer_list> \). In particular, \( x<i> \) is assignable if \( x \) is an assignable bitstring and \( 0 \leq i < \text{Len}(x) \).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as \( N \). In such cases, the syntax APSR.<N> is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

K16.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.
Unary plus and minus

If \( x \) is an integer or real, then \(+x\) is \( x \) unchanged, \(-x\) is \( x \) with its sign reversed. Both are of the same type as \( x \).

Addition and subtraction

If \( x \) and \( y \) are integers or reals, \( x+y \) and \( x-y \) are their sum and difference. Both are of type \textit{integer} if \( x \) and \( y \) are both of type \textit{integer}, and \textit{real} otherwise.

There are two cases where the types of \( x \) and \( y \) can be different. A bitstring and an integer can be added together to allow the operation \( PC + 4 \). An integer can be subtracted from a bitstring to allow the operation \( PC - 2 \).

If \( x \) and \( y \) are bitstrings of the same length \( N \), so that \( N = \text{Len}(x) = \text{Len}(y) \), then \( x+y \) and \( x-y \) are the least significant \( N \) bits of the results of converting \( x \) and \( y \) to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

\[
\begin{align*}
x+y &= (\text{SInt}(x) + \text{SInt}(y))_{N-1:0} \\
     &= (\text{UInt}(x) + \text{UInt}(y))_{N-1:0} \\
x-y &= (\text{SInt}(x) - \text{SInt}(y))_{N-1:0} \\
     &= (\text{UInt}(x) - \text{UInt}(y))_{N-1:0}
\end{align*}
\]

If \( x \) is a bitstring of length \( N \) and \( y \) is an integer, \( x+y \) and \( x-y \) are the bitstrings of length \( N \) defined by \( x+y = x + y_{N-1:0} \) and \( x-y = x - y_{N-1:0} \). Similarly, if \( x \) is an integer and \( y \) is a bitstring of length \( M \), \( x+y \) and \( x-y \) are the bitstrings of length \( M \) defined by \( x+y = x_{M-1:0} + y \) and \( x-y = x_{M-1:0} - y \).

Multiplication

If \( x \) and \( y \) are integers or reals, then \( x \times y \) is the product of \( x \) and \( y \). It is of type \textit{integer} if \( x \) and \( y \) are both of type \textit{integer}, and \textit{real} otherwise.

Division and modulo

If \( x \) and \( y \) are reals, then \( x/y \) is the result of dividing \( x \) by \( y \), and is always of type \textit{real}.

If \( x \) and \( y \) are integers, then \( x \div y \) and \( x \mod y \) are defined by:

\[
\begin{align*}
x \div y &= \text{RoundDown}(x/y) \\
x \mod y &= x - y \times (x \div y)
\end{align*}
\]

It is a pseudocode error to use any of \( x/y \), \( x \mod y \), or \( x \div y \) in any context where \( y \) can be zero.

Scaling

If \( x \) and \( n \) are of type \textit{integer}, then:

- \( x \ll n = \text{RoundDown}(x \times 2^n) \).
- \( x \gg n = \text{RoundDown}(x \times 2^{\neg n}) \).

Raising to a power

If \( x \) is an integer or a real and \( n \) is an integer, then \( x^n \) is the result of raising \( x \) to the power of \( n \), and:

- If \( x \) is of type \textit{integer}, then \( x^n \) is of type \textit{integer}.
- If \( x \) is of type \textit{real}, then \( x^n \) is of type \textit{real}.

K16.4.5 The assignment operator

The assignment operator is the \( = \) character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

\[
<\text{assignable_expression}> = <\text{expression}>
\]

This following subsection defines valid expression syntax.
General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word `UNKNOWN` preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an Arm architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

--- Note ---

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.
  
  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

--- Note ---

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.
  - A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
• For a function, the definition of the function determines the data type.

K16.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see Boolean operators on page K16-11816.
2. Operators on integers follow the normal operator precedence rules of exponentiation before multiply/divide before add/subtract, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if i, j and k are integer variables, i > 0 && j > 0 && k > 0 is acceptable, but i > 0 && j > 0 || k > 0 is not.

K16.4.7 Conditional expressions

If x and y are two values of the same type and t is a value of type boolean, then if t then x else y is an expression of the same type as x and y that produces x if t is TRUE and y if t is FALSE.

K16.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator + has forms that act on various combinations of integers, reals and bitstrings.

Table K16-1 on page K16-11820 summarizes the operand types valid for each unary operator and the result type. Table K16-2 on page K16-11820 summarizes the operand types valid for each binary operator and the result type.

K16.5  Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- **Statements and Indentation.**
- **Function and procedure calls.**
- **Conditional control structures** on page K16-11824.
- **Loop control structures** on page K16-11825.
- **Special statements** on page K16-11826.
- **Comments** on page K16-11826.

K16.5.1  Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if ... then ... else ...` or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K16.5.2  Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.
Procedure and function definitions

A procedure definition has the form:

<procedure name>(<argument prototypes>)

<statement 1>
<statement 2>
...
<statement n>

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

<return type> <function name>(<argument prototypes>)

<statement 1>
<statement 2>
...
<statement n>

Note

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

<return type> <function name>[<argument prototypes>]

<statement 1>
<statement 2>
...
<statement n>

Its related function definition with no return type is equivalent to writing to an array. For example:

<function name>[<argument prototypes>] = <value prototype>

<statement 1>
<statement 2>
...
<statement n>

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

<procedure_name>(<arguments>);

Return statements

A procedure return has the form:

return;

A function return has the form:
return <expression>;

where <expression> is of the type declared in the function prototype line.

K16.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

if <boolean_expression> then
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
elsif <boolean_expression> then
  <statement a>;
  <statement b>;
  ...
  <statement z>;
else
  <statement A>;
  <statement B>;
  ...
  <statement Z>;

The block of lines consisting of elsif and its indented statements is optional, and multiple elsif blocks can be used.

The block of lines consisting of else and its indented statements is optional.

Abbreviated one-line forms can be used when the then part, and in the else part if it is present, contain only simple statements such as:

if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;

Note

In these forms, <statement 1>, <statement 2>, and <statement A> must be terminated by semicolons. This, and the fact that the else part is optional, distinguish its use as a control structure from its use as a ternary operator.

case ... of ...

A case ... of ... structure has the form:

case <expression> of
  when <literal values1>
    <statement 1>;
    <statement 2>;
    ...
    <statement m>;
  when <literal values2>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
  ... more "when" groups if required ...
  otherwise
<statement A>;
<statement B>;
...
<statement Z>;

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details, see Equality and non-equality on page K16-11816.

K16.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

repeat ... until ...

A repeat ... until ... structure has the form:

repeat
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
until <boolean_expression>;

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while ... do

A while ... do structure has the form:

while <boolean_expression> do
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for ...

A for ... structure has the form:

for <assignable_expression> = <integer_expr1> to <integer_expr2>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer_expr2>.

There is an alternate form:

for <assignable_expression> = <integer_expr1> downto <integer_expr2>

where <integer_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal to <integer_expr2>. 
K16.5.5 Special statements

This section describes statements with particular architecturally defined behaviors.

UNDEFINED

This subsection describes the statement:

UNDEFINED;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

UNPREDICTABLE

This subsection describes the statement:

UNPREDICTABLE;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE...

This subsection describes the statement:

SEE <reference>;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

IMPLEMENTATION_DEFINED {"<text>"};

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION DEFINED. An optional <text> field can give more information.

K16.5.6 Comments

The pseudocode supports two styles of comments:

• // starts a comment that is terminated by the end of the line.
• /* starts a comment that is terminated by */.

/**/ statements might not be nested, and the first */ ends the comment.

Note

Comment lines do not require a terminating semicolon.
K16.6 Built-in functions

This section describes:

- Bitstring manipulation functions.
- Arithmetic functions on page K16-11828.

K16.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

**Bitstring length and most significant bit**

If \( x \) is a bitstring:

- The bitstring length function \( \text{Len}(x) \) returns the length of \( x \) as an integer.

**Bitstring concatenation and replication**

If \( x \) is a bitstring and \( n \) is an integer with \( n \geq 0 \):

- \( \text{Replicate}(x, n) \) is the bitstring of length \( n \times \text{Len}(x) \) consisting of \( n \) copies of \( x \) concatenated together.
- \( \text{Zeros}(n) = \text{Replicate}(\text{'0'}, n) \).
- \( \text{Ones}(n) = \text{Replicate}(\text{'1'}, n) \).

**Bitstring count**

If \( x \) is a bitstring, \( \text{BitCount}(x) \) is an integer result equal to the number of bits of \( x \) that are ones.
Testing a bitstring for being all zero or all ones

If x is a bitstring:
- IsZero(x) produces TRUE if all of the bits of x are zeros and FALSE if any of them are ones.
- IsZeroBit(x) produces '1' if all of the bits of x are zeros and '0' if any of them are ones.

IsOnes(x) and IsOnesBit(x) work in the corresponding ways. This means:

\[
\begin{align*}
\text{IsZero}(x) & = (\text{BitCount}(x) == 0) \\
\text{IsOnes}(x) & = (\text{BitCount}(x) == \text{Len}(x)) \\
\text{IsZeroBit}(x) & = \text{if IsZero}(x) \text{ then '1' else '0'} \\
\text{IsOnesBit}(x) & = \text{if IsOnes}(x) \text{ then '1' else '0'}
\end{align*}
\]

Lowest and highest set bits of a bitstring

If x is a bitstring, and \( N = \text{Len}(x) \):
- LowestSetBit(x) is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, \( \text{LowestSetBit}(x) = N \).
- HighestSetBit(x) is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, \( \text{HighestSetBit}(x) = -1 \).
- CountLeadingZeroBits(x) is the number of zero bits at the left end of x, in the range 0 to \( N \). This means:
  \[
  \text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x).
  \]
- CountLeadingSignBits(x) is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to \( N-1 \). This means:
  \[
  \text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(<N-1:1> \text{ EOR } x<N-2:0>).
  \]

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then ZeroExtend(x, i) is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if i == \( \text{Len}(x) \), then ZeroExtend(x, i) = x, and if i > \( \text{Len}(x) \), then:

\[
\text{ZeroExtend}(x, i) = \text{Replicate('0', i-\text{Len}(x)}) : x
\]

If x is a bitstring and i is an integer, then SignExtend(x, i) is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if i == \( \text{Len}(x) \), then SignExtend(x, i) = x, and if i > \( \text{Len}(x) \), then:

\[
\text{SignExtend}(x, i) = \text{Replicate(\text{TopBit}(x), i-\text{Len}(x)}) : x
\]

It is a pseudocode error to use either ZeroExtend(x, i) or SignExtend(x, i) in a context where it is possible that i < \( \text{Len}(x) \).

Converting bitstrings to integers

If x is a bitstring, SInt() is the integer whose two’s complement representation is x.

UInt() is the integer whose unsigned representation is x.

\text{Int}(x, \text{unsigned}) returns either SInt(x) or UInt(x) depending on the value of its second argument.

K16.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, Abs(x) returns the absolute value of x. The result is the same type as x.
Rounding and aligning

If \( x \) is a real:
- \( \text{RoundDown}(x) \) produces the largest integer \( n \) such that \( n \leq x \).
- \( \text{RoundUp}(x) \) produces the smallest integer \( n \) such that \( n \geq x \).
- \( \text{RoundTowardsZero}(x) \) produces:
  - \( \text{RoundDown}(x) \) if \( x > 0.0 \).
  - 0 if \( x = 0.0 \).
  - \( \text{RoundUp}(x) \) if \( x < 0.0 \).

If \( x \) and \( y \) are both of type integer, \( \text{Align}(x, y) = y \times (x \text{ DIV } y) \), and is of type integer.

If \( x \) is of type bitstring and \( y \) is of type integer, \( \text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y))<\text{Len}(x)-1:0> \), and is a bitstring of the same length as \( x \).

It is a pseudocode error to use either form of \( \text{Align}(x, y) \) in any context where \( y \) can be 0. In practice, \( \text{Align}(x, y) \) is only used with \( y \) a constant power of two, and the bitstring form used with \( y = 2^n \) has the effect of producing its argument with its \( n \) low-order bits forced to zero.

Maximum and minimum

If \( x \) and \( y \) are integers or reals, then \( \text{Max}(x, y) \) and \( \text{Min}(x, y) \) are their maximum and minimum respectively. \( x \) and \( y \) must both be of type integer or of type real. The function returns a value of the same type as its operands.
K16.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous helper procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

Note

Chapter J1 Armv8 Pseudocode also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in Chapter J1, this section will be removed from the manual.

K16.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

EndOfInstruction();

K16.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

Hint_Debug(bits(4) option);

K16.7.3 Hint_PreloadData()

This procedure performs a preload data hint.

Hint_PreloadData(bits(32) address);

K16.7.4 Hint_PreloadDataForWrite()

This procedure performs a preload data hint with a probability that the use will be for a write.

Hint_PreloadDataForWrite(bits(32) address);

K16.7.5 Hint_PreloadInstr()

This procedure performs a preload instructions hint.

Hint_PreloadInstr(bits(32) address);

K16.7.6 Hint_Yield()

This procedure performs a Yield hint.

Hint_Yield();

K16.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an External abort and FALSE otherwise. It is used only in exception entry pseudocode.

boolean IsExternalAbort(Fault type)
    assert type != Fault_None;

boolean IsExternalAbort(FaultRecord fault);
K16.7.8 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```c
boolean IsAsyncAbort(Fault type) {
    assert type != Fault_None;
    boolean IsAsyncAbort(FaultRecord fault);
}
```

K16.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the HSR.

```c
bits(11) LSInstructionSyndrome();
```

K16.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```c
integer ProcessorID();
```

K16.7.11 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```c
boolean RemapRegsHaveResetValues();
```

K16.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally defined reset values to those values. For more information about the affected registers, see:

- Reset behavior on page D1-4674.
- PE state on reset into AArch32 state on page G1-8986.

```c
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

K16.7.13 ThisInstr()

This function returns the bitstring encoding of the currently executing instruction.

```c
bits(32) ThisInstr();
```

Note: Currently, this function is used only on 32-bit instruction encodings.

K16.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```c
integer ThisInstrLength();
```
K16.8 Arm pseudocode definition index

This section contains the following tables:

- Table K16-3 on page K16-11832 which contains the pseudocode data types.
- Table K16-4 on page K16-11832 which contains the pseudocode operators.
- Table K16-5 on page K16-11833 which contains the pseudocode keywords and control structures.
- Table K16-6 on page K16-11834 which contains the statements with special behaviors.

Table K16-3 Index of pseudocode data types

<table>
<thead>
<tr>
<th>Keyword</th>

<td>One of two values a Boolean can take (other than TRUE)</td>
</tr>
<tr>
<td>for ... = ...to ...</td>
<td>Loop control structure, counting up from the initial value to the upper limit</td>
</tr>
<tr>
<td>for ... = ... downto ...</td>
<td>Loop control structure, counting down from the initial value to the lower limit</td>
</tr>
<tr>
<td>if ... then ... else ...</td>
<td>Conditional control structure</td>
</tr>
<tr>
<td>otherwise</td>
<td>Introduces default case in case ... of ... control structure</td>
</tr>
</tbody>
</table>
repeat ... until ...
Loop control structure that runs at least once until the termination condition is satisfied

return
Procedure or function return

TRUE
One of two values a Boolean can take (other than FALSE)

when
Introduces specific case in case ... of ... control structure

while ... do ...
Loop control structure that runs until the termination condition is satisfied

Table K16-6 Index of special statements

Keyword | Meaning
---|---
IMPLEMENTATION_DEFINED | Describes IMPLEMENTATION DEFINED behavior
SEE | Points to other pseudocode to use instead
UNDEFINED | Cause Undefined Instruction exception
UNKNOWN | Unspecified value
UNPREDICTABLE | Unspecified behavior
Appendix K17
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation* on page K17-11836.
- *Alphabetical index of AArch64 registers and System instructions* on page K17-11848.
- *Functional index of AArch64 registers and System instructions* on page K17-11868.
- *Alphabetical index of AArch32 registers and System instructions* on page K17-11889.
- *Functional index of AArch32 registers and System instructions* on page K17-11899.
- *Alphabetical index of memory-mapped registers* on page K17-11911.
- *Functional index of memory-mapped registers* on page K17-11923.
K17.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a general name, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception level suffix, _EL0, _EL1, _EL2, or _EL3.

The following sections disambiguate the general register names:

- **Register name disambiguation by Execution state.**
- **Register name disambiguation by Exception level on page K17-11846.**

K17.1.1 Register name disambiguation by Execution state

Table K17-1 on page K17-11836 disambiguates the general names of the registers by Execution state.

</tr>
</tbody>
</table>
There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table K17-6 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

Table K17-6 AArch64 registers for accessing registers that are only used in AArch32 state

<table>
<thead>
<tr>
<th>AArch32 register</th>
<th>Register for access from AArch64 state</th>

K17.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers on page K17-11869.
- ID registers on page K17-11870.
- Performance monitors registers on page K17-11871.
- Activity monitors registers on page K17-11872.
- Debug registers on page K17-11873.
- Trace registers on page K17-11874.
- Branch Record Buffer registers on page K17-11876.
- RAS registers on page K17-11876.
- Root Security state registers on page K17-11877.
- Generic timer registers on page K17-11877.
- Cache maintenance system instructions on page K17-11878.
- Address translation system instructions on page K17-11879.
- TLB maintenance system instructions on page K17-11880.
- Prediction restriction System instructions on page K17-11883.
- Base system registers on page K17-11883.

K17.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

Table K17-10 Special-purpose registers

K17.5  Functional index of AArch32 registers and System instructions

This section is an index of the AArch32 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers on page K17-11900.
- ID registers on page K17-11900.
- Performance monitors registers on page K17-11901.
- Activity Monitors registers on page K17-11902.
- Debug registers on page K17-11903.
- RAS registers on page K17-11904.
- Generic timer registers on page K17-11905.
- Cache maintenance system instructions on page K17-11905.
- Address translation system instructions on page K17-11906.
- TLB maintenance system instructions on page K17-11907.
- Legacy feature registers and system instructions on page K17-11908.
- Base system registers on page K17-11908.

K17.5.1  Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

K17.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

- ID registers.
- Performance monitors registers.
- Debug registers on page K17-11925.
- RAS registers on page K17-11926.
- Cross-trigger interface registers on page K17-11927.

K17.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

**Glossary**

**A32 instruction**
A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

*See also* A32 state, A64 instruction, T32 instruction.

**A32 state**
The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

*See also* T32 instruction, T32 state.

**A64 instruction**
A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

*See also* A32 instruction, T32 instruction.

**AArch32**
The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

*See also* AArch64, A32 instruction, T32 instruction.

**AArch64**
The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

*See also* AArch32, A64 instruction.

**Abort**
An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

**Active element**
An Active element is an SVE vector element or predicate element that is a source register element or destination register element used by an SVE instruction. When the corresponding element in the instruction's Governing predicate is TRUE, the element is Active. If an instruction is unpredicated, all of the vector elements or predicate elements are implicitly Active.
Addressing mode

Means a method for generating the memory address used by a load/store instruction.

Advanced SIMD

A feature of the Arm architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

Aligned

A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

Analysis of the trace element stream

Refers to the process of:

- Tracing elements that carry information that a trace analyzer requires to enable it to analyze the trace successfully.
- Tracing elements that either directly indicate program execution, or carry information about program execution.

A trace element stream might also contain trace elements that contain timing information.

This term is distinct from analysis of program execution.

Architecturally executed

An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been architecturally executed. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check, Simple sequential execution.

Architecturally mapped

Where this manual describes a register as being architecturally mapped to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

Architecturally UNKNOWN

An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

See also IMPLEMENTATION DEFINED.

ARM core registers

Some older documentation uses ARM core registers to refer to the following set of registers for execution in AArch32 state:

- The 13 general-purpose registers, R0-R12, that software can use for processing.
- SP, the stack pointer, that can also be referred to as R13.
- LR, the link register, that can also be referred to as R14.
- PC, the program counter, that can also be referred to as R15.

See also General-purpose registers.

ARM instruction

See A32 instruction.

Associativity

See Cache associativity.

Asynchronous accumulation

Faults that are accumulated in a status register, where the update to the register is asynchronous to the instruction that causes the fault.
Atomicity
Describes either single-copy atomicity or multi-copy atomicity. Atomicity in the Arm architecture on page B2-154 defines these forms of atomicity for the Arm architecture.
See also Multi-copy atomicity, Single-copy atomicity.

Banked register
A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register
A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Behaves as if
Where this manual indicates that a PE behaves as if a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory
Means that, for example:
- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.
See also Endianness, Little-endian memory.

Blocking
Describes an operation that does not permit following instructions to be executed before the operation completes.
A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction
Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.
See also Prefetching.

Breakpoint
A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte
An 8-bit data item.

Cache associativity
The number of locations in a cache set to which an address can be assigned. Each location is identified by its way value.

Cache level
The position of a cache in the cache hierarchy. In the Arm architecture, the lower numbered levels are those closest to the PE. For more information, see Terms used in describing the cache maintenance instructions on page D7-5050.

Cache line
The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A memory cache line is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown
Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss
A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets
Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.
Cache way
A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to \((\text{Associativity}-1)\). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way \(n\) consists of the cache line with index \(n\) from each cache set.

Coherence order
See Coherent.

Coherent
Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the coherence order for that byte in memory.

Commit window
The Commit window defines the range of \(P^0\) elements that are committed by a Commit element. The oldest \(P^0\) element in the Commit window is the first \(P^0\) element committed when a Commit element occurs. By default, the Commit window starts on the oldest uncommitted \(P^0\) element and moves forward to the next uncommitted \(P^0\) element, with each \(P^0\) element committed by a Commit element. The Commit Window Move element moves the start of the Commit window by a number of \(P^0\) elements, to allow a Commit element to commit \(P^0\) elements that are younger than the oldest uncommitted \(P^0\) elements, leaving these older \(P^0\) elements uncommitted.

Completer
An agent in a computing system that responds to and completes a memory transaction that was initiated by a Requester.

See also Requester.

Constructive instruction encoding
A constructive instruction encoding is an instruction encoding where the destination register is encoded independently of the source registers.

Condition code check
The process of determining whether a conditional instruction executes normally or is treated as a \(\text{NOP}\). For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of \(\text{PSTATE}.\text{IT}\) determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field
A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.

Condition flags
The N, Z, C, and V bits of \(\text{PSTATE}\), an SPSR, or FPSCR. See the register descriptions for more information.

See also Condition code check, \(\text{PSTATE}\).

Conditional execution
When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a \(\text{NOP}\).

See also Condition code check.

CONSTRANDED UNPREDICTABLE
Where an instruction can result in UNPREDICTABLE behavior, the Armv8 and later architectures specify a narrow range of permitted behaviors. This range is the range of CONSTRANDED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRANDED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRANDED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRANDED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRANDED UNPREDICTABLE is shown in SMALL CAPITALS.

See also UNPREDICTABLE.
**Context switch**  The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

**Context synchronization event**

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Exception entry, if FEAT_ExS is not implemented or the exception is taken to AArch32 or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EIS bit is set.
- Return from an exception, if FEAT_ExS is not implemented, or the exception is returning from AArch32 or if FEAT_ExS is implemented and the appropriate SCTLR_ELx.EOS bit is set.
- Exit from Debug state.
- Executing a DCPs instruction.
- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.
- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

---

**Note**

- The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.
- *Context synchronization events* were previously described as *context synchronization operations*.

**Conventional memory**

Memory locations from which generic OSs and application run-times will expect to create allocations for general software use.

**CoreSight Address Translation Unit**

A form of System MMU for trace streams.
Data independent timing (DIT)
The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see About PSTATE.DIT on page B1-147 and About the DIT bit on page E1-7139.

Debugger
In most of this manual, debugger refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:
- Definition of a debugger in the context of self-hosted debug on page D2-4692.
- Definition of a debugger in the context of self-hosted debug on page G2-9038.
- Definition and constraints of a debugger in the context of external debug on page H1-10228.

Deprecated
Something that is present in the Arm architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the Arm architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the Arm architecture.

See also OPTIONAL.

Destructive instruction encoding
A destructive instruction encoding is an instruction encoding where one of the source registers is also used as the destination register.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read
A direct read of a System register is a read performed by a System register access instruction.

For more information, see Direct read on page D17-5549.

See also Direct write, Indirect read, Indirect write.

Direct write
A direct write of a System register is a write performed by a System register access instruction.

For more information, see Direct write on page D17-5549.

See also Direct read, Indirect read, Indirect write.

DMA
See Direct Memory Access (DMA).

DNM
See Do-Not-Modify (DNM).

Domain
In the Arm architecture, domain is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain
When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the Domain Access Control Register (DACR). Arm deprecates any use of memory regions domains.

Do-Not-Modify (DNM)
Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value
Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

Doubleword
A 64-bit data item. Doublewords are normally at least word-aligned in Arm systems.
**Doubleword-aligned**
Means that the address is divisible by 8.

**DSP**
See Digital signal processing (DSP).

**Effective value**
A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an **Effective value**:

- In some cases, the description of a control $a$ specifies that when control $a$ is active it causes a register control field $b$ to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field $b$. When control $a$ is active that fixed value is described as the **Effective value** of register control field $b$. For example, when the value of HCR.DC is 1, the **Effective value** of HCR.VM is 1, regardless of its actual value.

  - **Note**
    Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an **Effective value** in that earlier version of the architecture.

  - Otherwise, the **Effective value** of a register control field is the value of that field.

**Effective SVE vector length**
The current accessible SVE vector length as constrained by ZCR_ELx and the Maximum implemented SVE vector length.

**Element number**
For a given element size of $N$ bits, elements within a vector or predicate register are numbered with element[0] always representing bits[(N-1):0], element[1] always representing bits[(2N-1):N], and so on.

**Endianness**
An aspect of the system memory mapping.
See also Big-endian memory and Little-endian memory.

**ETEEvent**
A feature of the trace unit that is used to generate **Event elements** and drive External Outputs. Each ETEEvent can be programmed to be sensitive to resource events.

**Event trace**
The trace uses **Event elements** that indicate certain events have occurred in the program that the PE is executing. The program events to be indicated are selected before a trace session.

**Exceptional occurrence**
Events indicated by an **Exception element** by the ETE architecture, including the following:

- PE architectural exceptions.
- ETE defined exceptions.
- IMPLEMENTATION DEFINED exceptions.

**Exception vector**
Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

**Execution stream**
The stream of instructions that would have been executed by sequential execution of the program.

**Explicit memory effect**
A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses, as well as instruction fetches and SPE writes to the profiling buffer, are not explicit memory effects.

**External abort**
An abort that is generated by the external memory system.
Fast Context Switch Extension (FCSE)
Modifies the behavior of an Arm memory system to enable multiple programs running on the Arm PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. The FCSE is:
• Deprecated from Armv6 and not supported in Armv8.
• Obsolete from the introduction of the Multiprocessing Extensions.

See Fast Context Switch Extension (FCSE).

First active element
The First active element of an SVE vector or predicate register is the lowest numbered element that is an Active element.

First-fault load
SVE provides a First-fault option for some SVE vector load instructions. This option causes memory access faults to be suppressed if they do not occur as a result of the First active element of the vector. Instead, the FFR is updated to indicate which of the active vector elements were not successfully loaded.

Flat address mapping
Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode
A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and Intermediate results with zeros, without significantly affecting the accuracy of their final results.

Gather-load
Gather-load is a mechanism that allows the elements of a vector to be read from non-contiguous memory locations using a vector of addresses, where the addresses are constructed according to the addressing mode.

General-purpose registers
The registers that the base instructions use for processing:

• In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Older documentation defines the AArch32 general-purpose registers as R0-R12, and the Arm core registers as R0-R12, SP, LR, and PC.</td>
</tr>
</tbody>
</table>

• In AArch64 state the general-purpose registers are:
  --- W0-W30 when accessed as 32-bit registers.
  --- X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Generated by
The memory model is written in terms of reads from memory and writes to memory. These reads and writes:

• Are generated by instructions such as loads, stores, and atomic memory accesses.
• Correspond to the memory accesses, other than translation table walks, that are defined in the instruction pseudocode.

Some instructions generate more than one read or write.

Governing predicate
The predicate register that is used to determine the Active elements of a predicated instruction is known as the Governing predicate for that instruction.

Halfword
A 16-bit data item. Halfwords are normally halfword-aligned in Arm systems.

Halfword-aligned
Means that the address is divisible by 2.
High registers
In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

Note
In some contexts, high registers refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors
An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED
Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields
Are unsigned unless otherwise stated.

Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP
An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Inactive element
An Inactive element is an SVE vector element or predicate element that is an unused source register element or destination register element for the associated instruction. When the corresponding element of an instruction's Governing predicate is FALSE, the element is inactive.

Index register
A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect read
When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see Indirect read on page D17-5549.

See also Direct read, Direct write, Indirect write.

Indirect write
An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a Direct write to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see Indirect write on page D17-5549.

See also Direct read, Direct write, Indirect read.

Inline literals
These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate physical address (IPA)
An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also Physical address (PA), Virtual address (VA).

Interworking
A method of working that permits branches between software using the A32 and T32 instruction sets.
IPA  
See Intermediate physical address (IPA).

Last active element  
The Last active element of an SVE vector or predicate register is the highest numbered element that is an Active element.

Level  
See Cache level.

Level of Coherence (LoC)  
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see Terms used in describing the cache maintenance instructions on page D7-5050.

See also Cache level, Point of coherency (PoC).

Level of Unification, Inner Shareable (LoUIS)  
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see Terms used in describing the cache maintenance instructions on page D7-5050.

See also Cache level, Point of unification (PoU).

Level of Unification, uniprocessor (LoUU)  
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see Terms used in describing the cache maintenance instructions on page D7-5050.

See also Cache level, Point of unification (PoU).

Line  
See Cache line.

Little-endian memory  
Means that, for example:

• A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.

• A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also Big-endian memory, Endianness.

Load/Store architecture  
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC  
See Level of Coherence (LoC).

LoUIS  
See Level of Unification, Inner Shareable (LoUIS).

LoUU  
See Level of Unification, uniprocessor (LoUU).

Lockdown  
See Cache lock down.

Low registers  
In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers, High registers.

Maximum implemented SVE vector length  
The maximum SVE vector length supported by an implementation.

Memory barrier  
See Memory barriers on page B2-174.

Memory coherency  
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.
Memory element
An item of data in memory that is transferred to or from a vector element by an SVE load or store instruction. Each memory element has an access size and a type. The memory element access size is specified by each load and store instruction independently of the vector element size.

Memory Management Unit (MMU)
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Merging predication
When a predicated SVE instruction specifies merging predication, the Inactive elements of the destination register remain unchanged.

Microarchitecturally-finished
An operation that has finished all of its operational pseudocode, although the results of any memory accesses, including translation table walks and updates, are not yet coherent with other observers.

Microarchitecturally-unfinished
An operation that has not completed all of its operational pseudocode.

Miss
See Cache miss.

MMU
See Memory Management Unit (MMU).

MPU
See Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in Requirements for multi-copy atomicity on page B2-156.
See also Atomicity, Single-copy atomicity.

NaN
Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a quiet NaN, that propagate through most floating-point operations, or a signaling NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the IEEE Standard for Floating-point Arithmetic.
See also Quiet NaN, Signaling NaN.

Natural eviction
A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Non-fault load
SVE provides a Non-fault option for some SVE vector load instructions. This option causes all memory access faults to be suppressed. Instead, the FFR is updated to indicate which of the active vector elements were not successfully loaded.

Observer
A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Obsolete
Obsolete indicates something that is no longer supported by Arm. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL
When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the Arm architecture:

• If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. Arm expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.
A feature that is **OPTIONAL** and deprecated might not be present in future versions of the architecture.

- A feature that is **OPTIONAL** but not deprecated is, typically, a feature added to a version of the Arm architecture after the initial release of that version of the architecture. Arm recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term **OPTIONAL** are shown in **SMALL CAPITALS**.

--- **Note** ---

Do not confuse these Arm-specific uses of **OPTIONAL** with other uses of **optional**, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an Armv7-R implementation, where the SCTLR.IE bit indicates the implemented option.

---

*See also* Deprecated.

**PA**

*See* Physical address (PA).

**Packed access**

A memory access that is performed as a result of an SVE load or store instruction for which the vector element size and the memory element size are the same.

**PE**

*See* Processing element (PE).

**Physical address (PA)**

An address that identifies a location in the physical memory map. *See also* Intermediate physical address (IPA), Virtual address (VA).

**PoC**

*See* Point of coherency (PoC).

**PoP**

*See* Point of persistence (PoP).

**PoU**

*See* Point of unification (PoU).

**Point of coherency (PoC)**

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the cache maintenance instructions* on page D7-5050.

**Point of persistence (PoP)**

The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed. For more information, see *Terms used in describing the cache maintenance instructions* on page D7-5050.

**Point of unification (PoU)**

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the cache maintenance instructions* on page D7-5050.

**Post-indexed addressing**

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

**Predicate**

A one-dimensional array of predicate elements of the same size.

**Predicate element**

Individual subdivisions of a predicate register that can be 1, 2, 4, or 8 bits in size. The predicate element size is specified independently by each instruction and is always one-eighth the size of the corresponding vector element. The lowest-numbered bit of each predicate element holds the Boolean value of that element, where 1 represents TRUE and 0 represents FALSE.
**Predicated instruction**
An SVE instruction that has a Governing predicate operand, which determines the Active and Inactive elements for that instruction.

**Predicate register**
An SVE predicate register, P0-P15, having a length that is a multiple of 16 bits, in the range 16 to 256, inclusive.

**Prefetching**
Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

--- **Note** ---
The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

---

**Prefixed instruction**
The instruction that immediately follows a MOVPRFX instruction in program order.

**Pre-indexed addressing**
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

**Processing element (PE)**

**Protection region**
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

**Protection Unit**
See Memory Protection Unit (MPU).

**Pseudo-instruction**
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, MOV <Rd>, <Rm>, LSL #<n> is a pseudo-instruction that is expected to disassemble as LSL <Rd>, <Rm>, #<n>.

**PSTATE**
An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also Condition flags.

**Quadword**
A 128-bit data item. Quadwords are normally at least word-aligned in Arm systems.

**Quadword-aligned**
Means that the address is divisible by 16.

**Quiet NaN**
A NaN that propagates unchanged through most floating-point operations.

See also NaN, Signaling NaN.

**RAO**
See Read-As-One (RAO).

**RAZ**
See Read-As-Zero (RAZ).

**RAO/SBOP**
In versions of the Arm architecture before Armv8, Read-As-One, Should-Be-One-or-Preserved on writes.

From the introduction of the Armv8 architecture, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).
RAO/WI    
Read-As-One, Writes Ignored.  
Hardware must implement the field as Read-as-One, and must ignore writes to the field.  
Software can rely on the field reading as all 1s, and on writes being ignored.  
This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.  
See also Read-As-One (RAO).

RAZ/SBZP 
In versions of the Arm architecture before Armv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.  
From the introduction of the Armv8 architecture, RES0 replaces this description.  
See also UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).

RAZ/WI    
Read-As-Zero, Writes Ignored.  
Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.  
Software can rely on the field reading as all 0s, and on writes being ignored.  
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.  
See also Read-As-Zero (RAZ).

Read-allocate cache  
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)  
Hardware must implement the field as reading as all 1s.  
Software:  
• Can rely on the field reading as all 1s.  
• Must use a SBOP policy to write to the field.  
This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.  
See also RAO/SBOP, RAO/WI, RES1.

Read-As-Zero (RAZ)  
Hardware must implement the field as reading as all 0s.  
Software:  
• Can rely on the field reading as all 0s  
• Must use a SBZP policy to write to the field.  
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.  
See also RAZ/SBZP, RAZ/WI, RES0.

Read, modify, write  
In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

Requester  
An agent in a computing system that is capable of initiating memory transactions.  
See also Completer.

RES0    
A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.  
Within the architecture, there are some cases where a register bit or field:  
• Is RES0 in some defined architectural context.  
• Has different defined behavior in a different architectural context.  

Note  
RES0 is not used in descriptions of instruction encodings.
• Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for fields in read/write registers is:

**If a bit is RES0 in all contexts**

For a bit in a read/write register, it is *IMPLEMENTATION DEFINED* whether:

1. The bit is hardwired to 0. In this case:
   • Reads of the bit always return 0.
   • Writes to the bit are ignored.
2. The bit can be written. In this case:
   • An indirect write to the register sets the bit to 0.
   • A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
   If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an *UNKNOWN* value.
   • A direct write to the bit must update a storage location associated with the bit.
   • The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is *IMPLEMENTATION DEFINED* on a bit-by-bit basis.

**If a bit is RES0 only in some contexts**

For a bit in a read/write register, when the bit is described as RES0:

• An indirect write to the register sets the bit to 0.
• A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an *UNKNOWN* value.
• A direct write to the bit must update a storage location associated with the bit.
• While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is *IMPLEMENTATION DEFINED* whether:

• Writes to the bit are ignored, and reads of the bit return an *UNKNOWN* value.
• The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

• For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as *UNKNOWN*.
• For a write-only bit, RES0 indicates that software must treat the bit as *SBZ*.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

• Must not rely on the bit reading as 0.
• Must use an *SBZP* policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.
In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), RES0H, RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

**RES0H**

A reserved bit or field with SBZP. This behavior uses the hardwired to 0 subset of the RES0 definition.

See also Read-As-Zero (RAZ), RES0, RES1, Should-Be-Zero-or-Preserved (SBZP).

**RES1**

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

--- **Note**

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES1 for fields in read/write registers is:

**If a bit is RES1 in all contexts**

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   - Reads of the bit always return 1.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 1.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
   - If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

**If a bit is RES1 only in some contexts**

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

--- **Note**

As indicated in this list, this value might be written by an indirect write to the register.

---

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
• While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:
  • Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
  • The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:
  • For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
  • For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:
  • Must not rely on the bit reading as 1.
  • Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), RES0, RES0H, Should-Be-One-or-Preserved (SBOP), UNKNOWN.

Reserved

Unless otherwise stated:
  • Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
  • Bit positions described as reserved are:
    — In an RW or WO register, RES0.
    — In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES0H, RES1, UNDEFINED, UNK, UNPREDICTABLE.

RESS

Reserved, Sign extended. A register value is extended by copying the sign bit into all of the reserved bits to the left of the most significant bit of the field. The values of these bits are identical to the most significant bit of the value being extended.

Within the architecture, a register bit or field can be treated:
  • As RESS in few defined architectural contexts.
  • In a different defined behavior in other architectural contexts.

Rewind point

A rewind point is a point in the program flow to which execution can return if all subsequent execution is found to have been incorrectly speculatively executed.

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the IEEE Standard for Floating-point Arithmetic, see Floating-point standards, and terminology on page A1-57.

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in Arm processors, in which overflowing results wrap around from +2^{31}–1 to –2^{31} or vice versa.

SBO

See Should-Be-One (SBO).

SBOP

See Should-Be-One-or-Preserved (SBOP).
**Glossary**

**SBZ**  
See Should-Be-Zero (SBZ).

**SBZP**  
See Should-Be-Zero-or-Preserved (SBZP).

**Scalable vector register**  
An SVE vector register, Z0-Z31, having a length that is a multiple of 128 bits, in the range 128 bits to 2048 bits, inclusive.

**Scalar base register**  
A scalar base register refers to an AArch64 general-purpose register, X0-X31, or the current stack pointer, SP.

**Scalar index register**  
A scalar index register refers to an AArch64 general-purpose register, X0-X31, or for certain instructions, XZR.

**Scatter-store**  
Scatter-store is a mechanism that allows the elements of a vector to be written to non-contiguous memory locations using a vector of addresses, where the addresses are constructed according to the addressing mode.

**Security hole**  
A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The Arm architecture forbids security holes.  
See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Self-modifying code**  
Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see Caches and memory hierarchy on page B2-184.

**Set**  
See Cache sets.

**Should-Be-One (SBO)**  
Hardware must ignore writes to the field.  
Arm strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.  
This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.  
See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-One-or-Preserved (SBOP)**  
From the introduction of the Armv8 architecture, the description Should-Be-One-or-Preserved (SBOP) is superseded by RES1.  
Hardware must ignore writes to the field.  
When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.  
This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.  
See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero (SBZ)**  
Hardware must ignore writes to the field.  
Arm strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.  
This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.  
See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero-or-Preserved (SBZP)**  
From the introduction of the Armv8 architecture, the description Should-Be-Zero-or-Preserved (SBZP) is superseded by RES0.
Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Signaling NaN**

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also NaN, Quiet NaN.

**Signed immediate and offset fields**

Are encoded in two’s complement notation unless otherwise stated.

**SIMD**

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in *Parallel addition and subtraction instructions on page F2-7266*.
- The Advanced SIMD instructions summarized in *Advanced SIMD and floating-point instructions on page E1-7140*, when operating on vectors.

**Simple sequential execution**

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and Arm does not expect this model to correspond to a realistic implementation of the architecture.

**Single-copy atomicity**

The form of atomicity described in *Properties of single-copy atomic accesses on page B2-156*.

See also Atomicity, Multi-copy atomicity.

**Single-precision value**

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

**Spatial locality**

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

**Special-purpose register**

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- *Special-purpose registers on page C5-671* specifies the AArch64 Special-purpose registers.
- *AArch32 Special-purpose registers on page G1-8918* lists the AArch32 Special-purpose registers.

**Speculative**

Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
• Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.

• Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

• Memory effects (M2) generated by load or store instructions (LS2) appearing in program order after load or store instructions (LS1) that generate memory effects (M1) where all of the following apply:
  — M1 is locally-ordered-before M2.
  — LS1 has not been executed before LS2.

See also Execution stream.

Speculative Microarchitecturally-finished
An operation that has finished all of its operational pseudocode, on a predicted execution path.

Speculative Microarchitecturally-unfinished
An operation that is in progress on a predicted execution path.

Superpriority
An attribute that is used to denote virtual and physical IRQ and FIQ interrupts as non-maskable. IRQ and FIQ interrupts with Superpriority can be taken under certain conditions where usually they would be masked by the PSTATE.{I, F} bits.

T32 instruction
One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 state
The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 instruction, A64 instruction, T32 state.

Taken locally
Taken locally is a qualifier that determines which instances of an exception are counted by particular PMU events. See Counting exceptions taken locally or not taken locally on page D11-5273.

In this context, an exception that is Taken locally means an exception that is one of:
• Taken to the current Exception level.
  
  Note
  This is not possible when the current Exception level is EL0.

• Taken from EL0 to EL1.
• Taken from EL0 to EL2 because the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

  Note
  An exception taken from EL0 to EL2 because the Effective value of HCR_EL2.{E2H, TGE} is {0, 1} is not Taken locally. This includes exceptions taken to EL2 using AArch32 when HCR.TGE is 1.

Temporal locality
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction
See T32 instruction.

TLB
See Translation Lookaside Buffer (TLB).

TLB lockdown
A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.
Translation Lookaside Buffer (TLB)
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the Arm implementation.

Translation table
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk
The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits
In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned
An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated
Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

UNDEFINED
Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

Note
On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also Undefined Instruction exception on page G1-8964.

Unified cache
Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing
Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

UNK
An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP
Hardware must implement the field as Read-As-One, and must ignore writes to the field.
Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP
Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.
Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

UNKNOWN
An UNKNOWN value does not contain valid data, and can vary from implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value can vary from moment to moment, and instruction to instruction, unless it has previously been assigned, other than at reset, to one of the following registers:
• Any of the general-purpose registers.
• Any of the Advanced SIMD and floating-point registers.
• Any of the Scalable Vector Extension registers.
• Any of the PSTATE N, Z, C, or V flags.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

Unpacked access
A memory access that is performed as a result of a load or store instruction for which the vector element size is larger than the memory element size.

Unpredicated instruction
An SVE instruction that does not have a Governing predicate operand and implicitly treats all other vector and predicate elements as Active.

UNPREDICTABLE
Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED.

VA
See Virtual address (VA).

VFP
In Armv7, an extension to the Arm architecture, that provides single-precision and double-precision floating-point arithmetic.

Vector
A one-dimensional array of vector elements of the same size and data type.
Vector element
Individual subdivisions of a vector register that can be 8, 16, 32, 64 or 128 bits in size. The vector element size and data type is specified independently by each instruction.

Virtual address (VA)
An address generated by an Arm PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also Intermediate physical address (IPA), Physical address (PA).

Watchpoint
A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way
See Cache way.

Wl
Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

Word
A 32-bit data item. Words are normally word-aligned in Arm systems.

Word-aligned
Means that the address is divisible by 4.

Write-allocate cache
A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache
A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a copy-back cache.

Write-through cache
A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer
A block of high-speed memory that optimizes stores to main memory.

Zeroing predication
When a predicated instruction specifies zeroing predication, the Inactive elements of the destination register are set to zero.
