Release Information

For information on the change history and known issues for this release, see the Release Notes in the A64 ISA XML for Armv8.8 (2021-12).

Proprietary Notice

This document is protected by copyright and other related rights and the practice or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm. No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether implementations infringe any third party patents.

THIS DOCUMENT IS PROVIDED “AS IS”. ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, patents, copyrights, trade secrets, or other rights.

This document may include technical inaccuracies or typographical errors.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

This document consists solely of commercial items. You shall be responsible for ensuring that any use, duplication or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word “partner” in reference to Arm’s customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of the Agreement shall prevail.

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

This release covers multiple versions of the architecture. The content relating to different versions is given different quality ratings.

The information related to the 2021 Architecture Extensions is at Alpha quality. Alpha quality means that most major features of the specification are described in the manual, some features and details might be missing.

The information related to the remaining Armv8-A features which was also published in previous releases, is at Beta quality. Beta quality means that all major features of the specification are described, some details might be missing.

Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact terms@arm.com.
A64 -- Base Instructions (alphabetic order)

**ADC**
Add with Carry.

**ADCS**
Add with Carry, setting flags.

**ADD (extended register)**
Add (extended register).

**ADD (immediate)**
Add (immediate).

**ADD (shifted register)**
Add (shifted register).

**ADDG**
Add with Tag.

**ADDS (extended register)**
Add (extended register), setting flags.

**ADDS (immediate)**
Add (immediate), setting flags.

**ADDS (shifted register)**
Add (shifted register), setting flags.

**ADR**
Form PC-relative address.

**ADRP**
Form PC-relative address to 4KB page.

**AND (immediate)**
Bitwise AND (immediate).

**AND (shifted register)**
Bitwise AND (shifted register).

**ANDS (immediate)**
Bitwise AND (immediate), setting flags.

**ANDS (shifted register)**
Bitwise AND (shifted register), setting flags.

**ASR (immediate)**
Arithmetic Shift Right (immediate): an alias of SBFM.

**ASR (register)**
Arithmetic Shift Right (register): an alias of ASRV.

**ASRV**
Arithmetic Shift Right Variable.

**AT**
Address Translate: an alias of SYS.

**AUTDA, AUTDZA**
Authenticate Data address, using key A.

**AUTDB, AUTDZB**
Authenticate Data address, using key B.

**AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA**
Authenticate Instruction address, using key A.

**AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB**
Authenticate Instruction address, using key B.

**AXFLAG**
Convert floating-point condition flags from Arm to external format.

**B**
Branch.

**B.cond**
Branch conditionally.

**BC.cond**
Branch Consistent conditionally.

**BFC**
Bitfield Clear: an alias of BFM.

**BFI**
Bitfield Insert: an alias of BFM.

**BFM**
Bitfield Move.

**BFXIL**
Bitfield extract and insert at low end: an alias of BFM.

**BIC (shifted register)**
Bitwise Bit Clear (shifted register).

**BICS (shifted register)**
Bitwise Bit Clear (shifted register), setting flags.

**BL**
Branch with Link.
BLR: Branch with Link to Register.

BLRAA, BLRAAZ, BLRAB, BLRABZ: Branch with Link to Register, with pointer authentication.

BR: Branch to Register.

BRAA, BRAAZ, BRAB, BRABZ: Branch to Register, with pointer authentication.

BRK: Breakpoint instruction.

BTI: Branch Target Identification.

CAS, CASA, CASAL, CASL: Compare and Swap word or doubleword in memory.

CASB, CASAB, CASALB, CASLB: Compare and Swap byte in memory.

CASH, CASAH, CASALH, CASLH: Compare and Swap halfword in memory.

CASP, CASPA, CASPAL, CASPL: Compare and Swap Pair of words or doublewords in memory.

CBNZ: Compare and Branch on Nonzero.

CBZ: Compare and Branch on Zero.

CCMN (immediate): Conditional Compare Negative (immediate).

CCMN (register): Conditional Compare Negative (register).

CCMP (immediate): Conditional Compare (immediate).

CCMP (register): Conditional Compare (register).

CFINV: Invert Carry Flag.

CFP: Control Flow Prediction Restriction by Context: an alias of SYS.

CINC: Conditional Increment: an alias of CSINC.

CINV: Conditional Invert: an alias of CSINV.

CLREX: Clear Exclusive.

CLS: Count Leading Sign bits.

CLZ: Count Leading Zeros.

CMN (immediate): Compare Negative (immediate): an alias of ADDS (immediate).

CMP (immediate): Compare (immediate): an alias of SUBS (immediate).

CMPP: Compare with Tag: an alias of SUBPS.

CNEG: Conditional Negate: an alias of CSNEG.

CPP: Cache Prefetch Prediction Restriction by Context: an alias of SYS.

CPYFP, CPYFM, CPYFE: Memory Copy Forward-only.

CPYFPN, CPYFMRN, CPYFERN: Memory Copy Forward-only, reads and writes non-temporal.

CPYFPRT, CPYFMRT, CPYFERT: Memory Copy Forward-only, reads unprivileged.
CPYFPRTN, CPYFMRTN, CPYFERTN: Memory Copy Forward-only, reads unprivileged, reads and writes non-temporal.
CPYFPRTN, CPYFMRTN, CPYFERTN: Memory Copy Forward-only, reads unprivileged and non-temporal.
CPYFPRTWN, CPYFMRTWN, CPYFERTWN: Memory Copy Forward-only, reads unprivileged, writes non-temporal.
CPYFP, CPYM, CPYE: Memory Copy.
CPYPN, CPYMN, CPYEN: Memory Copy, reads and writes non-temporal.
CPYPRN, CPYMRN, CPYERN: Memory Copy, reads and writes non-temporal.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged, reads and writes non-temporal.
CPYPRTRN, CPYMRTRN, CPYERTRN: Memory Copy, reads unprivileged and non-temporal.
CPYPRRTWN, CPYMRRTWN, CPYERTWN: Memory Copy, reads unprivileged, writes non-temporal.
CPYPT, CPYMT, CPYET: Memory Copy, reads and writes unprivileged.
CPYPTN, CPYMTN, CPYETN: Memory Copy, reads and writes unprivileged and non-temporal.
CPYP, CPYM, CPYE: Memory Copy.
CPYPN, CPYMN, CPYEN: Memory Copy, reads and writes non-temporal.
CPYPRN, CPYMRN, CPYERN: Memory Copy, reads and writes non-temporal.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged, reads and writes non-temporal.
CPYPRTRN, CPYMRTRN, CPYERTRN: Memory Copy, reads unprivileged and non-temporal.
CPYPRRTWN, CPYMRRTWN, CPYERTWN: Memory Copy, reads unprivileged, writes non-temporal.
CPYPT, CPYMT, CPYET: Memory Copy, reads and writes unprivileged.
CPYPTN, CPYMTN, CPYETN: Memory Copy, reads and writes unprivileged and non-temporal.
CPYP, CPYM, CPYE: Memory Copy.
CPYPN, CPYMN, CPYEN: Memory Copy, reads and writes non-temporal.
CPYPRN, CPYMRN, CPYERN: Memory Copy, reads and writes non-temporal.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged, reads and writes non-temporal.
CPYPRTRN, CPYMRTRN, CPYERTRN: Memory Copy, reads unprivileged and non-temporal.
CPYPRRTWN, CPYMRRTWN, CPYERTWN: Memory Copy, reads unprivileged, writes non-temporal.
CPYPT, CPYMT, CPYET: Memory Copy, reads and writes unprivileged.
CPYPTN, CPYMTN, CPYETN: Memory Copy, reads and writes unprivileged and non-temporal.
CPYP, CPYM, CPYE: Memory Copy.
CPYPN, CPYMN, CPYEN: Memory Copy, reads and writes non-temporal.
CPYPRN, CPYMRN, CPYERN: Memory Copy, reads and writes non-temporal.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged, reads and writes non-temporal.
CPYPRTRN, CPYMRTRN, CPYERTRN: Memory Copy, reads unprivileged and non-temporal.
CPYPRRTWN, CPYMRRTWN, CPYERTWN: Memory Copy, reads unprivileged, writes non-temporal.
CPYPT, CPYMT, CPYET: Memory Copy, reads and writes unprivileged.
CPYPTN, CPYMTN, CPYETN: Memory Copy, reads and writes unprivileged and non-temporal.
CPYP, CPYM, CPYE: Memory Copy.
CPYPN, CPYMN, CPYEN: Memory Copy, reads and writes non-temporal.
CPYPRN, CPYMRN, CPYERN: Memory Copy, reads and writes non-temporal.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged.
CPYPRTN, CPYMRTN, CPYERTN: Memory Copy, reads unprivileged, reads and writes non-temporal.
CPYPRTRN, CPYMRTRN, CPYERTRN: Memory Copy, reads unprivileged and non-temporal.
CPYPRRTWN, CPYMRRTWN, CPYERTWN: Memory Copy, reads unprivileged, writes non-temporal.
CRC32CB, CRC32CH, CRC32CW, CRC32CX: CRC32C checksum.
CSDB: Consumption of Speculative Data Barrier.
CSEL: Conditional Select.
CSET: Conditional Set: an alias of CSINC.
CSETM: Conditional Set Mask: an alias of CSINV.
CSINC: Conditional Select Increment.
CSINV: Conditional Select Invert.
CSNEG: Conditional Select Negation.
DC: Data Cache operation: an alias of SYS.
DCPS1: Debug Change PE State to EL1..
DCPS2: Debug Change PE State to EL2..
DCPS3: Debug Change PE State to EL3.
DGH: Data Gathering Hint.
DMB: Data Memory Barrier.
DRPS: Debug restore process state.
DSB: Data Synchronization Barrier.
DVP: Data Value Prediction Restriction by Context: an alias of SYS.
EON (shifted register): Bitwise Exclusive OR NOT (shifted register).
EOR (immediate): Bitwise Exclusive OR (immediate).
EOR (shifted register): Bitwise Exclusive OR (shifted register).
ERET: Exception Return.
ERETAA, ERETAB: Exception Return, with pointer authentication.
ESR: Error Synchronization Barrier.
EXTR: Extract register.
GMI: Tag Mask Insert.
HINT: Hint instruction.
HLT: Halt instruction.
HVC: Hypervisor Call.
IC: Instruction Cache operation: an alias of SYS.
IRG: Insert Random Tag.
ISB: Instruction Synchronization Barrier.
LD64B: Single-copy Atomic 64-byte Load.
LDADD, LDADDA, LDADDAL, LDADDL: Atomic add on word or doubleword in memory.
LDADDB, LDADDAB, LDADDALB, LDADDLB: Atomic add on byte in memory.
LDADDH, LDADDAH, LDADDALH, LDADDLH: Atomic add on halfword in memory.
LDAPR: Load-Acquire RCpc Register.
LDAPRB: Load-Acquire RCpc Register Byte.
LDAPRH: Load-Acquire RCpc Register Halfword.
LDAPUR: Load-Acquire RCpc Register (unscaled).
LDAPURB: Load-Acquire RCpc Register Byte (unscaled).
LDAPURH: Load-Acquire RCpc Register Halfword (unscaled).
LDAPURSB: Load-Acquire RCpc Register Signed Byte (unscaled).
LDAPURSH: Load-Acquire RCpc Register Signed Halfword (unscaled).
LDAPURSW: Load-Acquire RCpc Register Signed Word (unscaled).
LDAR: Load-Acquire Register.
LDARB: Load-Acquire Register Byte.
LDARH: Load-Acquire Register Halfword.
LDAXP: Load-Acquire Exclusive Pair of Registers.
LDAXR: Load-Acquire Exclusive Register.
LDAXRB: Load-Acquire Exclusive Register Byte.
LDAXRH: Load-Acquire Exclusive Register Halfword.
LDCLR, LDCLRA, LDCLRAL, LDCLRL: Atomic bit clear on word or doubleword in memory.
LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB: Atomic bit clear on byte in memory.
LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH: Atomic bit clear on halfword in memory.
LDEOR, LDEORA, LDEORAL, LDEORL: Atomic exclusive OR on word or doubleword in memory.
LDEORB, LDEORAB, LDEORALB, LDEORLB: Atomic exclusive OR on byte in memory.
LDEORH, LDEORAH, LDEORALH, LDEORLH: Atomic exclusive OR on halfword in memory.
LDG: Load Allocation Tag.
LDGM: Load Tag Multiple.
LDLAR: Load LOAcquire Register.
LDLARB: Load LOAcquire Register Byte.
LDLARH: Load LOAcquire Register Halfword.
LDNP: Load Pair of Registers, with non-temporal hint.
LDP: Load Pair of Registers.
LDPSW: Load Pair of Registers Signed Word.
LDR (immediate): Load Register (immediate).
LDR (literal): Load Register (literal).
LDR (register): Load Register (register).
LDRAA, LDRAA: Load Register, with pointer authentication.
LDRB (immediate): Load Register Byte (immediate).
LDRB (register): Load Register Byte (register).
LDRH (immediate): Load Register Halfword (immediate).
LDRH (register): Load Register Halfword (register).
LDRSB (immediate): Load Register Signed Byte (immediate).
LDRSB (register): Load Register Signed Byte (register).
LDRSH (immediate): Load Register Signed Halfword (immediate).
LDRSH (register): Load Register Signed Halfword (register).
LDRSW (immediate): Load Register Signed Word (immediate).
LDRSW (literal): Load Register Signed Word (literal).
LDRSW (register): Load Register Signed Word (register).
LDSET, LDSETA, LDSETAL, LDSETL: Atomic bit set on word or doubleword in memory.
LDSETB, LDSETAB, LDSETALB, LDSETLB: Atomic bit set on byte in memory.
LDSETH, LDSETAH, LDSETALH, LDSETLH: Atomic bit set on halfword in memory.
LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL: Atomic signed maximum on word or doubleword in memory.
LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB: Atomic signed maximum on byte in memory.
LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH: Atomic signed maximum on halfword in memory.
LDSMIN, LDSMINA, LDSMINAL, LDSMINL: Atomic signed minimum on word or doubleword in memory.
LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB: Atomic signed minimum on byte in memory.
LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH: Atomic signed minimum on halfword in memory.
LDTR: Load Register (unprivileged).
LDTRB: Load Register Byte (unprivileged).
LDTRH: Load Register Halfword (unprivileged).
LDTRSB: Load Register Signed Byte (unprivileged).
LDTRSH: Load Register Signed Halfword (unprivileged).
LDTRSW: Load Register Signed Word (unprivileged).
LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL: Atomic unsigned maximum on word or doubleword in memory.
LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB: Atomic unsigned maximum on byte in memory.
LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH: Atomic unsigned maximum on halfword in memory.
LDumin, LDuminA, LDuminAL, LDuminL: Atomic unsigned minimum on word or doubleword in memory.
LDuminB, LDuminAB, LDuminALB, LDuminLB: Atomic unsigned minimum on byte in memory.
LDuminH, LDuminAH, LDuminALH, LDuminLH: Atomic unsigned minimum on halfword in memory.
LDUR: Load Register (unscaled).
LDURB: Load Register Byte (unscaled).
LDURH: Load Register Halfword (unscaled).
LDURSB: Load Register Signed Byte (unscaled).
LDURSH: Load Register Signed Halfword (unscaled).
LDURSW: Load Register Signed Word (unscaled).
LDXP: Load Exclusive Pair of Registers.
LDXR: Load Exclusive Register.
LDXRB: Load Exclusive Register Byte.
LDXRH: Load Exclusive Register Halfword.
LSI (immediate): Logical Shift Left (immediate): an alias of UBFM.
LSI (register): Logical Shift Left (register): an alias of LSLV.
LSLV: Logical Shift Left Variable.
LSR (immediate): Logical Shift Right (immediate): an alias of UBFM.

LSR (register): Logical Shift Right (register): an alias of LSRV.

LSRV: Logical Shift Right Variable.

MADD: Multiply-Add.

MNEG: Multiply-Negate: an alias of MSUB.

MOV (bitmask immediate): Move (bitmask immediate): an alias of ORR (immediate).

MOV (inverted wide immediate): Move (inverted wide immediate): an alias of MOVN.

MOV (to/from SP): Move between register and stack pointer: an alias of ADD (immediate).

MOV (wide immediate): Move (wide immediate): an alias of MOVZ.

MOVK: Move wide with keep.

MOVN: Move wide with NOT.

MOVZ: Move wide with zero.

MRS: Move System Register.

MSR (immediate): Move immediate value to Special Register.

MSR (register): Move general-purpose register to System Register.

MSUB: Multiply-Subtract.

MUL: Multiply: an alias of MADD.

MVN: Bitwise NOT: an alias of ORN (shifted register).

NEGS: Negate, setting flags: an alias of SUBS (shifted register).

NGC: Negate with Carry: an alias of SBC.

NGCS: Negate with Carry, setting flags: an alias of SBCS.

NOP: No Operation.

ORN (shifted register): Bitwise OR NOT (shifted register).

ORR (immediate): Bitwise OR (immediate).

ORR (shifted register): Bitwise OR (shifted register).

PACDA, PACDZA: Pointer Authentication Code for Data address, using key A.

PACDB, PACDZB: Pointer Authentication Code for Data address, using key B.

PACGA: Pointer Authentication Code, using Generic key.

PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA: Pointer Authentication Code for Instruction address, using key A.

PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB: Pointer Authentication Code for Instruction address, using key B.

PRFM (immediate): Prefetch Memory (immediate).

PRFM (literal): Prefetch Memory (literal).

PRFM (register): Prefetch Memory (register).

PRFUM: Prefetch Memory (unscaled offset).
PSB CSYNC: Profiling Synchronization Barrier.

PSSBB: Physical Speculative Store Bypass Barrier: an alias of DSB.

RBIT: Reverse Bits.

RET: Return from subroutine.

RETA, RETB: Return from subroutine, with pointer authentication.

REV: Reverse Bytes.

REV16: Reverse bytes in 16-bit halfwords.

REV32: Reverse bytes in 32-bit words.

REV64: Reverse Bytes: an alias of REV.

RMIF: Rotate, Mask Insert Flags.

ROR (immediate): Rotate right (immediate): an alias of EXTR.

ROR (register): Rotate Right (register): an alias of RORV.

RORV: Rotate Right Variable.

SB: Speculation Barrier.

SBC: Subtract with Carry.

SRCS: Subtract with Carry, setting flags.

SBFIZ: Signed Bitfield Insert in Zero: an alias of SBFM.

SBFM: Signed Bitfield Move.

SBFX: Signed Bitfield Extract: an alias of SBFM.

SDIV: Signed Divide.

SETF8, SETF16: Evaluation of 8 or 16 bit flag values.

SETGP, SETGM, SETGE: Memory Set with tag setting.

SETGPN, SETGMN, SETGEN: Memory Set with tag setting, non-temporal.

SETGPT, SETGMT, SETGET: Memory Set with tag setting, unprivileged.

SETGPTN, SETGMTN, SETGETN: Memory Set with tag setting, unprivileged and non-temporal.

SETP, SETM, SETE: Memory Set.

SETPN, SETMN, SETEN: Memory Set, non-temporal.

SETPT, SETMT, SETET: Memory Set, unprivileged.

SETPTN, SETMTN, SETETN: Memory Set, unprivileged and non-temporal.

SEV: Send Event.

SEVL: Send Event Local.

SMADDL: Signed Multiply-Add Long.

SMC: Secure Monitor Call.

SMNEGL: Signed Multiply-Negate Long: an alias of SMSUBL.

SMSUBL: Signed Multiply-Subtract Long.

SMUL: Signed Multiply High.
**SMULL**: Signed Multiply Long: an alias of SMADDL.

**SSBB**: Speculative Store Bypass Barrier: an alias of DSB.

**ST2G**: Store Allocation Tags.

**ST64B**: Single-copy Atomic 64-byte Store without Return.

**ST64BV**: Single-copy Atomic 64-byte Store with Return.

**ST64BV0**: Single-copy Atomic 64-byte EL0 Store with Return.

**STADD, STADDL**: Atomic add on word or doubleword in memory, without return: an alias of LDADD, LDADDA, LDADDAL, LDADDL.

**STADDB, STADDLB**: Atomic add on byte in memory, without return: an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB.

**STADDDH, STADDDLH**: Atomic add on halfword in memory, without return: an alias of LDADDDH, LDADDDAH, LDADDDLH, LDADDLH.

**STCLR, STCLRL**: Atomic bit clear on word or doubleword in memory, without return: an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL.

**STCLRB, STCLRLB**: Atomic bit clear on byte in memory, without return: an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.

**STCLRH, STCLRLH**: Atomic bit clear on halfword in memory, without return: an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.

**STEO, STEORL**: Atomic exclusive OR on word or doubleword in memory, without return: an alias of LDEOR, LDEORA, LDEORAL, LDEORL.

**STEOB, STEORLB**: Atomic exclusive OR on byte in memory, without return: an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB.

**STEORH, STEORLH**: Atomic exclusive OR on halfword in memory, without return: an alias of LDEORH, LDEORAH, LDEORALH, LDEORLH.

**STG**: Store Allocation Tag.

**STGM**: Store Tag Multiple.

**STGP**: Store Allocation Tag and Pair of registers.

**STLLR**: Store LORelease Register.

**STLLRB**: Store LORelease Register Byte.

**STLLRH**: Store LORelease Register Halfword.

**STLR**: Store-Release Register.

**STLRB**: Store-Release Register Byte.

**STLRH**: Store-Release Register Halfword.

**STLUR**: Store-Release Register (unscaled).

**STLURB**: Store-Release Register Byte (unscaled).

**STLURH**: Store-Release Register Halfword (unscaled).

**STLXP**: Store-Release Exclusive Pair of registers.

**STLXR**: Store-Release Exclusive Register.

**STLXRB**: Store-Release Exclusive Register Byte.

**STLXRH**: Store-Release Exclusive Register Halfword.

**STNP**: Store Pair of Registers, with non-temporal hint.
**STP**: Store Pair of Registers.

**STR (immediate)**: Store Register (immediate).

**STR (register)**: Store Register (register).

**STRB (immediate)**: Store Register Byte (immediate).

**STRB (register)**: Store Register Byte (register).

**STRH (immediate)**: Store Register Halfword (immediate).

**STRH (register)**: Store Register Halfword (register).

**STSET, STSETL**: Atomic bit set on word or doubleword in memory, without return: an alias of LDSET, LDSETA, LDSETAL, LDSETL.

**STSETB, STSETLB**: Atomic bit set on byte in memory, without return: an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB.

**STSETH, STSETLH**: Atomic bit set on halfword in memory, without return: an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH.

**STSMAX, STSMAXL**: Atomic signed maximum on word or doubleword in memory, without return: an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.

**STSMAXB, STSMAXLB**: Atomic signed maximum on byte in memory, without return: an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.

**STSMAXH, STSMAXLH**: Atomic signed maximum on halfword in memory, without return: an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.

**STSMIN, STSMINL**: Atomic signed minimum on word or doubleword in memory, without return: an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.

**STSMINB, STSMINLB**: Atomic signed minimum on byte in memory, without return: an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.

**STSMINH, STSMINLH**: Atomic signed minimum on halfword in memory, without return: an alias of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.

**STTR**: Store Register (unprivileged).

**STTRB**: Store Register Byte (unprivileged).

**STTRH**: Store Register Halfword (unprivileged).

**STUMAX, STUMAXL**: Atomic unsigned maximum on word or doubleword in memory, without return: an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.

**STUMAXB, STUMAXLB**: Atomic unsigned maximum on byte in memory, without return: an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.

**STUMAXH, STUMAXLH**: Atomic unsigned maximum on halfword in memory, without return: an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.

**STUMIN, STUMINL**: Atomic unsigned minimum on word or doubleword in memory, without return: an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.

**STUMINB, STUMINLB**: Atomic unsigned minimum on byte in memory, without return: an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

**STUMINH, STUMINLH**: Atomic unsigned minimum on halfword in memory, without return: an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.

**STUR**: Store Register (unscaled).

**STURB**: Store Register Byte (unscaled).

**STURH**: Store Register Halfword (unscaled).

**STXP**: Store Exclusive Pair of registers.
**STXR**: Store Exclusive Register.

**STXRB**: Store Exclusive Register Byte.

**STXRH**: Store Exclusive Register Halfword.

**STZ2G**: Store Allocation Tags, Zeroing.

**STZG**: Store Allocation Tag, Zeroing.

**STZGM**: Store Tag and Zero Multiple.

**SUB (extended register)**: Subtract (extended register).

**SUB (immediate)**: Subtract (immediate).

**SUB (shifted register)**: Subtract (shifted register).

**SUBG**: Subtract with Tag.

**SUBP**: Subtract Pointer.

**SUBPS**: Subtract Pointer, setting Flags.

**SUBS (extended register)**: Subtract (extended register), setting flags.

**SUBS (immediate)**: Subtract (immediate), setting flags.

**SUBS (shifted register)**: Subtract (shifted register), setting flags.

**SVC**: Supervisor Call.

**SWP, SWPA, SWPAL, SWPL**: Swap word or doubleword in memory.

**SWPB, SWPAB, SWPALB, SWPLB**: Swap byte in memory.

**SWPH, SWPAH, SWPALH, SWPLH**: Swap halfword in memory.

**SXTB**: Signed Extend Byte: an alias of SBFM.

**SXTH**: Sign Extend Halfword: an alias of SBFM.

**SXTW**: Sign Extend Word: an alias of SBFM.

**SYS**: System instruction.

**SYSL**: System instruction with result.

**TBNZ**: Test bit and Branch if Nonzero.

**TBZ**: Test bit and Branch if Zero.

**TLBI**: TLB Invalidate operation: an alias of SYS.

**TSB CSYNC**: Trace Synchronization Barrier.

**TST (immediate)**: Test bits (immediate): an alias of ANDS (immediate).

**TST (shifted register)**: Test (shifted register): an alias of ANDS (shifted register).

**UBFIZ**: Unsigned Bitfield Insert in Zero: an alias of UBFM.

**UBFM**: Unsigned Bitfield Move.

**UBFX**: Unsigned Bitfield Extract: an alias of UBFM.

**UDF**: Permanently Undefined.

**UDIV**: Unsigned Divide.

**UMADDL**: Unsigned Multiply-Add Long.
UMNEGL: Unsigned Multiply-Negate Long: an alias of UMSUBL.

UMSUBL: Unsigned Multiply-Subtract Long.

UMULH: Unsigned Multiply High.

UMULL: Unsigned Multiply Long: an alias of UMADDL.

UXTB: Unsigned Extend Byte: an alias of UBFM.

UXTH: Unsigned Extend Halfword: an alias of UBFM.

WFE: Wait For Event.

WFET: Wait For Event with Timeout.

WFI: Wait For Interrupt.

WFIT: Wait For Interrupt with Timeout.

XAFLAG: Convert floating-point condition flags from external format to Arm format.

XPACD, XPACI, XPACLRI: Strip Pointer Authentication Code.

YIELD: YIELD.
ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

op S

32-bit (sf == 0)

ADC <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

ADC <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit (sf == 0)

ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit (sf == 1)

ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R> Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>
If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
bias(datasize) operand1 = if n == 31 then SP[] else X[n];
bias(datasize) operand2 = ExtendReg(m, extend_type, shift);
(result, -) = AddWithCarry(operand1, operand2, '0');
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. This instruction is used by the alias MOV (to/from SP).

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

32-bit (sf == 0)

ADD <Wd>, <Wn|WSP>, #<imm>{, <shift>}

64-bit (sf == 1)

ADD <Xd>, <Xn|SP>, #<imm>{, <shift>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

bits(datasize) imm;

case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Alias Conditions

<tbody>
<tr>
<td>CMN (immediate)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

Operation

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDS (shifted register)

Add (shifted register), setting flags, adds a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (shifted register).

### 32-bit (sf == 0)

ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

### 64-bit (sf == 1)

ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

### Assembler Symbols

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Xm>** Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<shift>** Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- **<amount>** For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>

Operation

```c
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

```
0 | immlo | 1 | 0 | 0 | 0 | 0 | immhi |
   op

ADR <Xd>, <label>

integer d = UInt(Rd);
bits(64) imm;
imm = SignExtend(immhi:immlo, 64);
```

**Assembler Symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<label>` Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

**Operation**

```
bits(64) base = PC[];
Xd[d] = base + imm;
```

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

\[
\begin{array}{cccccccccccccc}
\hline
\text{immlo} & 1 & 0 & 0 & 0 & 0 & \text{immhi} & \text{Rd} \\
\end{array}
\]

**Asmplers Symbols**

- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<label>** Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

**Operation**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd) \\
\text{bits(64)} &\text{ imm;} \\
\text{imm} &= \text{SignExtend}(\text{immhi:immlo}:\text{Zeros}(12), 64); \\
\text{bits(64) } &\text{base} = \text{PC}[]; \\
\text{base}<11:0> &= \text{Zeros}(12); \\
X[d] &= \text{base} + \text{imm};
\end{align*}
\]
AND (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

<table>

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

| sf | 0 0 0 1 0 0 1 1 | N | immr | x | 1 | 1 | 1 | 1 | Rn | Rd |
|----|----------------|----|------|---|---|---|---|---|---|----|----|
| opc | imms |

32-bit (sf == 0 && N == 0 && imms == 011111)

ASR <Wd>, <Wn>, #<shift>

is equivalent to

SBFM <Wd>, <Wn>, #<shift>, #31

and is always the preferred disassembly.

64-bit (sf == 1 && N == 1 && imms == 111111)

ASR <Xd>, <Xn>, #<shift>

is equivalent to

SBFM <Xd>, <Xn>, #<shift>, #63

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <shift> For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**ASR (register)**

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of **ASRV**. This means:

- The encodings in this description are named to match the encodings of **ASRV**.
- The description of **ASRV** gives the operational pseudocode for this instruction.

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
**AUTDA, AUTDZA**

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

**Integer**

AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication fails, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```java
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthDB(X[d], SP[], FALSE);
    else
        X[d] = AuthDB(X[d], X[n], FALSE);
```
AUTHIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

BFC <Xd>, #<lsb>, #<width>
is equivalent to

BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BFI

Bitfield Insert copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

• The encodings in this description are named to match the encodings of BFM.
• The description of BFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

BFI <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 & N == 1)

BFI <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If `imms` is greater than or equal to `immr`, this copies a bitfield of \((imms - immr + 1)\) bits starting from bit position `immr` in the source register to the least significant bits of the destination register. If `imms` is less than `immr`, this copies a bitfield of \((imms + 1)\) bits from the least significant bits of the source register to bit position \(\text{regsize} - \text{immr}\) of the destination register, where `regsize` is the destination register size of 32 or 64 bits. In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases `BFC`, `BFI`, and `BFXIL`.

### 32-bit \((sf == 0 \&\& N == 0)\)

```plaintext
BFM <Wd>, <Wn>, #<immr>, #<imms>
```

### 64-bit \((sf == 1 \&\& N == 1)\)

```plaintext
BFM <Xd>, <Xn>, #<immr>, #<imms>
```

integer \(d = \text{UInt}(Rd)\);
integer \(n = \text{UInt}(Rn)\);
integer datasize = if \(sf == '1'\) then 64 else 32;

integer \(R\);
bits(datasize) \(wmask\);
bits(datasize) \(tmask\);

if \(sf == '1' \&\& N != '1'\) then UNDEFINED;
if \(sf == '0' \&\& (N != '0' || immr<5> != '0' || imms<5> != '0')\) then UNDEFINED;

\(R = \text{UInt}(immr)\);
\((wmask, tmask) = \text{DecodeBitMasks}(N, imms, immr, FALSE)\);

### Assembler Symbols

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Wn>` is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Xn>` is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.
- `<immr>` is the right rotate amount, in the range 0 to 31, encoded in the “immr” field.
- `<imms>` is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the “imms” field.
- `<immr>` for the 32-bit variant is the right rotate amount, in the range 0 to 63, encoded in the “immr” field.
- `<imms>` for the 32-bit variant is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the “imms” field.

### Alias Conditions

<table>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 32-bit (sf == 0)

BIC `<Wd>`, `<Wn>`, `<Wm>{, <shift> #<amount>}`

### 64-bit (sf == 1)

BIC `<Xd>`, `<Xn>`, `<Xm>{, <shift> #<amount>}`

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

```plaintext
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 AND operand2;
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
sf 1 1 0 1 0 1 0 shift 1 Rm imm6 Rn Rd
```

**32-bit (sf == 0)**

BICS `<Wd>, <Wn>, <Wm>{, <shift> #<amount>}`

**64-bit (sf == 1)**

BICS `<Xd>, <Xn>, <Xm>{, <shift> #<amount>}`

```
integer d = Uint(Rd);
integer n = Uint(Rn);
integer m = Uint(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = Uint(imm6);
```

**Assembler Symbols**

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

</tbody>
</table>

- `<amount>`: For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

\[
\text{bits}(\text{datasize}) \text{ operand1} = X[n];
\]
\[
\text{bits}(\text{datasize}) \text{ operand2} = \text{ShiftReg}(m, \text{shift_type}, \text{shift_amount});
\]
\[
\text{bits}(\text{datasize}) \text{ result};
\]
\[
\text{operand2} = \text{NOT}(%s); \quad \text{result} = \text{operand1 AND operand2};
\]
\[
\text{PSTATE.<N,Z,C,V>} = \text{result<datasize-1>:IsZeroBit(result)':'00'};
\]
\[
X[d] = \text{result};
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.

![Binary representation](image)

**BL**

\[
\begin{array}{ccccccccccccccccccccccc}
1 & 0 & 0 & 1 & 0 & 1 & \text{imm26}
\end{array}
\]

\text{op}

**BL <label>**

bits(64) offset = \text{SignExtend}(\text{imm26}:`00', 64);

**Assembler Symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

**Operation**

\[
X[30] = \text{PC}[] + 4;
\]

\text{BranchTo} (\text{PC}[] + \text{offset}, \text{BranchType_DIRCALL}, \text{FALSE});
BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

```
|   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| 1 1 0 1 0 1 1 0 0 0 1 1 1 1 1 1 0 0 0 0 0 0 Rn 0 0 0 0 0 Rm |
| Z   op  A  M   | Rn  | Rm     |

BLR <Xn>

integer n = UINT(Rn);

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
bits(64) target = X[n];

X[30] = PC[] + 4;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL, FALSE);
```
BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

```

BRK #<imm>

```c
if HaveBTEExt() then
  SetBTypeCompatible(TRUE);
```

**Assembler Symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

**Operation**

AArch64.SoftwareBreakpoint(imm16);
**BTI**

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while \textit{PSTATE.BTYPE} \neq 0b00, a BTI instruction compatible with the current value of \textit{PSTATE.BTYPE} will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand <targets> passed to a BTI instruction determines the values of \textit{PSTATE.BTYPE} which the BTI instruction is compatible with.

**Note**

Within a guarded memory region, when \textit{PSTATE.BTYPE} \neq 0b00, all instructions will generate a Branch Target Exception, other than BRK, BTI, HLT, PACIASP, and PACIBSP, which might not. See the individual instructions for more information.

CAS, CASA, CASAL, CASL

Compare and Swap word or doubleword in memory reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASA and CASAL load from memory with acquire semantics.
- CASL and CASAL store to memory with release semantics.
- CAS has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

bits(datasize) imm = ZeroExtend(imm5, datasize);

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<imm> Is a five bit unsigned (positive) immediate encoded in the “imm5” field.
<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

if ConditionHolds(cond) then
    bits(datasize) operand1 = X[n];
    (, flags) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = flags;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Control Flow Prediction Restriction by Context prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see **CFP RCTX, Control Flow Prediction Restriction by Context**.

This is an alias of **SYS**. This means:

- The encodings in this description are named to match the encodings of **SYS**.
- The description of **SYS** gives the operational pseudocode for this instruction.

**CFP RCTX, <Xt>**

is equivalent to

**SYS #3, C7, C3, #4, <Xt>**

and is always the preferred disassembly.

**Assembler Symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of **SYS** gives the operational pseudocode for this instruction.
CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CINC. This means:

- The encodings in this description are named to match the encodings of CINC.
- The description of CINC gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CINC <Wd>, <Wn>, <cond>

is equivalent to

CINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CINC <Xd>, <Xn>, <cond>

is equivalent to

CINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

• The encodings in this description are named to match the encodings of CSINV.
• The description of CSINV gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CINV <Wd>, <Wn>, <cond>

is equivalent to

CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CINV <Xd>, <Xn>, <cond>

is equivalent to

CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CLREX

Clear Exclusive clears the local monitor of the executing PE.

\[
\begin{array}{cccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & CRm & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

CLREX {\#<imm>}

// CRm field is ignored

Assembler Symbols

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

\texttt{ClearExclusiveLocal(ProcessorID());}

integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

integer result;
bits(datasize) operand1 = X[n];
result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**CMN (extended register)**

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the \(<Rm>\) register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of **ADDS (extended register)**. This means:

- The encodings in this description are named to match the encodings of **ADDS (extended register)**.
- The description of **ADDS (extended register)** gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

\[ \text{CMN \,<Wn|WSP>, \,<Wm>{, \,<extend> \{#<amount>\}}} \]

is equivalent to

\[ \text{ADDS \,WZR, \,<Wn|WSP>, \,<Wm>{, \,<extend> \{#<amount>\}}} \]

and is always the preferred disassembly.

### 64-bit (sf == 1)

\[ \text{CMN \,<Xn|SP>, \,<R><m>{, \,<extend> \{#<amount>\}}} \]

is equivalent to

\[ \text{ADDS \,XZR, \,<Xn|SP>, \,<R><m>{, \,<extend> \{#<amount>\}}} \]

and is always the preferred disassembly.

**Assembler Symbols**

- **<Wn|WSP>** Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<Xn|SP>** Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- **<R>** Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- **<m>** Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- **<extend>** For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":
If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '1111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:
  - The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMN <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

ADDS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit (sf == 1)

CMN <Xn|SP>, #<imm>{, <shift>}

is equivalent to

ADDS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP>  Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xn|SP>    Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>      Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>    Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

| sf | 0 | 1 | 0 | 1 | 0 | 1 | 1 | shift | 0 | Rm | imm6 | Rn | 1 | 1 | 1 | 1 | Rd |
|----|---|---|---|---|---|---|---|-------|---|----|------|----|---|---|---|---|
| op | S |

32-bit (sf == 0)

CMN <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ADDS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

64-bit (sf == 1)

CMN <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ADDS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

Assembler Symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (extended register). This means:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit (sf == 1)

CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option".
If “Rn” is ‘11111’ (WSP) and “option” is ‘010’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If “Rn” is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

 CMP <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

 SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit (sf == 1)

 CMP <Xn|SP>, #<imm>{, <shift>}

is equivalent to

 SUBS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**CMP (shifted register)**

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

<table>

</tr>
</tbody>
</table>

**32-bit (sf == 0)**

CMP <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

SUBS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

**64-bit (sf == 1)**

CMP <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

SUBS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

**Assembler Symbols**

- <Wn>: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm>: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn>: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm>: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift>: Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>

<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- <amount>: For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This is an alias of SUBPS. This means:

- The encodings in this description are named to match the encodings of SUBPS.
- The description of SUBPS gives the operational pseudocode for this instruction.

### Integer
(Armv8.5)

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>

</tbody>
</table>

CMPP `<Xn|SP>`, `<Xm|SP>`

is equivalent to

SUBPS XZR, `<Xn|SP>`, `<Xm|SP>`

and is always the preferred disassembly.

### Assembler Symbols

- `<Xn|SP>`: Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Xn” field.
- `<Xm|SP>`: Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the “Xm” field.

### Operation

The description of SUBPS gives the operational pseudocode for this instruction.
CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSNEG. This means:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CNEG <Wd>, <Wn>, <cond> is equivalent to

CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CNEG <Xd>, <Xn>, <cond> is equivalent to

CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Cache prefetch predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot influence speculative execution occurring after the instruction is complete and synchronized.

For more information, see **CPP RCTX, Cache Prefetch Prediction Restriction by Context**.

This is an alias of **SYS**. This means:

- The encodings in this description are named to match the encodings of **SYS**.
- The description of **SYS** gives the operational pseudocode for this instruction.

and is always the preferred disassembly.

### Assembler Symbols

\langle X_t \rangle \quad \text{Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.}

### Operation

The description of **SYS** gives the operational pseudocode for this instruction.

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
CPYFP, CPYFM, CPYFE

Memory Copy Forward-only. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFP, then CPYFM, and then CPYFE. CPYFP performs some preconditioning of the arguments suitable for using the CPYFM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFE performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

end
Memory Copy Forward-only, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPN, then CPYFMN, and then CPYFEN.

CPYFPN performs some preconditioning of the arguments suitable for using the CPYFMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPN, option A (which results in encoding PSTATE.C = 0):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + saturated Xn.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPN, option B (which results in encoding PSTATE.C = 1):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
• Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
• Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  ◦ the value of Xs is written back with the lowest address that has not been copied from.
  ◦ the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

CPYFPRN, CPYFMRN, CPYFERN

Memory Copy Forward-only, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRN, then CPYFMRN, and then CPYFERN.

CPYFPRN performs some preconditioning of the arguments suitable for using the CPYFMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRN, option A (which results in encoding PSTATE.C = 0):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + saturated Xn.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.(N,Z,V) are set to {0,0,0}.

After execution of CPYFPRN, option B (which results in encoding PSTATE.C = 1):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
• Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
• Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.(N,Z,V) are set to {0,0,0}.

For CPYFMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  ◦ the value of Xs is written back with the lowest address that has not been copied from.
  ◦ the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, reads unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRT, then CPYFMRT, and then CPYFERT.

CPYFPRT performs some preconditioning of the arguments suitable for using the CPYFMRT instruction, and performs an implementation-defined amount of the memory copy. CPYFMRT performs an implementation-defined amount of the memory copy. CPYFERT performs the last part of the memory copy.

**Note**

The inclusion of implementation-defined amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is implementation-defined.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRT, option A (which results in encoding PSTATE.C = 0):

- If \( Xn<63> == 1 \), the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- \( Xs \) holds the original \( Xs + \) saturated \( Xn \).
- \(Xd\) holds the original \( Xd + \) saturated \( Xn \).
- \(Xn\) holds \(-1\) saturated \( Xn + \) an implementation-defined number of bytes copied.
- PSTATE.(N,Z,V) are set to \( \{0,0,0\} \).

After execution of CPYFPRT, option B (which results in encoding PSTATE.C = 1):

- If \( Xn<63> == 1 \), the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- \( Xs \) holds the original \( Xs + \) an implementation-defined number of bytes copied.
- \(Xd\) holds the original \( Xd + \) an implementation-defined number of bytes copied.
- \(Xn\) holds the saturated \( Xn - \) an implementation-defined number of bytes copied.
- PSTATE.(N,Z,V) are set to \( \{0,0,0\} \).

For CPYFMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- \( Xn \) is treated as a signed 64-bit number and holds \(-1\) the number of bytes remaining to be copied in the memory copy in total.
- \( Xs \) holds the lowest address that the copy is copied from -\( Xn \).
- \(Xd\) holds the lowest address that the copy is made to -\( Xn \).
- At the end of the instruction, the value of \( Xn \) is written back with \(-1\) the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- \( Xn \) holds the number of bytes remaining to be copied in the memory copy in total.
- \( Xs \) holds the lowest address that the copy is copied from.
- \(Xd\) holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of \( Xn \) is written back with \( Xn \).
  - the value of \( Xs \) is written back with the lowest address that has not been copied from.
  - the value of \( Xd \) is written back with the lowest address that has not been copied to.

For CPYFERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- \( Xn \) is treated as a signed 64-bit number and holds \(-1\) the number of bytes remaining to be copied in the memory copy in total.
- \( Xs \) holds the lowest address that the copy is copied from -\( Xn \).
- \(Xd\) holds the lowest address that the copy is made to -\( Xn \).
- At the end of the instruction, the value of \( Xn \) is written back with 0.

For CPYFERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- \( Xn \) holds the number of bytes remaining to be copied in the memory copy in total.
- \( Xs \) holds the lowest address that the copy is copied from.
- \(Xd\) holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of \( Xn \) is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value ofXd is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, reads unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTN, then CPYFMRTN, and then CPYFERTN.

CPYFPRTN performs some preconditioning of the arguments suitable for using the CPYFMRTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value ofXd is written back with the lowest address that has not been copied to.

            X[s] = fromaddress;
Memory Copy Forward-only, reads unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTRN, then CPYFMRTRN, and then CPYFERTRN. CPYFPRTRN performs some preconditioning of the arguments suitable for using the CPYFMRTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTRN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTRN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFF
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTRN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFF
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.

For CPYFERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTRN option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
- the value of Xs is written back with the lowest address that has not been copied from.
- the value of Xd is written back with the lowest address that has not been copied to.

**CPYFPRTWN, CPYFMRTWN, CPYFERTWN**

Memory Copy Forward-only, reads unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTWN, then CPYFMRTWN, and then CPYFERTWN.

CPYFPRTWN performs some preconditioning of the arguments suitable for using the CPYFMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTWN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTWN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
-Xd holds the original Xd + saturated Xn.
-Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTWN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
-Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
-Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
-Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
-Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
-Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
-Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
- the value of Xs is written back with the lowest address that has not been copied from.
- the value of Xd is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, reads and writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPT, then CPYFMT, and then CPYFET.

CPYFPT performs some preconditioning of the arguments suitable for using the CPYFMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFET performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPT, option A (which results in encoding PSTATE.C = 0):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + saturated Xn.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPT, option B (which results in encoding PSTATE.C = 1):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
• Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
• Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
• PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  ◦ the value of Xs is written back with the lowest address that has not been copied from.
  ◦ the value of Xd is written back with the lowest address that has not been copied to.

For CPYFET, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from -Xn.
• Xd holds the lowest address that the copy is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For CPYFET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be copied in the memory copy in total.
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

CPYFPTRN, CPYFMTRN, CPYFETRN

Memory Copy Forward-only, reads and writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTRN, then CPYFMTRN, and then CPYFETRN.

CPYFPTRN performs some preconditioning of the arguments suitable for using the CPYFMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTRN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

After execution of CPYFPTRN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

For CPYFMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
- the value of Xs is written back with the lowest address that has not been copied from.
- the value of Xd is written back with the lowest address that has not been copied to.

CPYFPTWN, CPYFMTWN, CPYFETWN

Memory Copy Forward-only, reads and writes unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTWN, then CPYFMTWN, and then CPYFETWN.

CPYFPTWN performs some preconditioning of the arguments suitable for using the CPYFMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTWN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTWN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
- the value of Xs is written back with the lowest address that has not been copied from.
- the value of Xd is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWN, then CPYFMWN, and then CPYFEWN.

CPYFPWN performs some preconditioning of the arguments suitable for using the CPYFMWN instruction, and performs an implementation defined amount of the memory copy. CPYFMWN performs an implementation defined amount of the memory copy. CPYFEWN performs the last part of the memory copy.

Note

The inclusion of implementation defined amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is implementation defined.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an implementation defined number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an implementation defined number of bytes copied.
- Xd holds the original Xd + an implementation defined number of bytes copied.
- Xn holds the saturated Xn - an implementation defined number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
the value of $X_s$ is written back with the lowest address that has not been copied from.
the value of $X_d$ is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWT, then CPYFMWT, and then CPYFEWT.

CPYFPWT performs some preconditioning of the arguments suitable for using the CPYFMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value ofXd is written back with the lowest address that has not been copied to.

  X[s] = fromaddress;

Memory Copy Forward-only, writes unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTN, then CPYFMWTN, and then CPYFEWTN.

CPYFPWTN performs some preconditioning of the arguments suitable for using the CPYFMWTN instruction, and performs an implementation defined amount of the memory copy. CPYFMWTN performs an implementation defined amount of the memory copy. CPYFEWTN performs the last part of the memory copy.

Note

The inclusion of implementation defined amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is implementation defined.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an implementation defined number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

After execution of CPYFPWTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an implementation defined number of bytes copied.
- Xd holds the original Xd + an implementation defined number of bytes copied.
- Xn holds the saturated Xn - an implementation defined number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

For CPYFMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

Memory Copy Forward-only, writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTRN, then CPYFMWTRN, and then CPYFEWTRN.

CPYFPWTRN performs some preconditioning of the arguments suitable for using the CPYFMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTRN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
-Xd holds the original Xd + saturated Xn.
-Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
-PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTRN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
-Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
-Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
-Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
-PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
-Xd holds the lowest address that the copy is made to -Xn.
-At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
-Xd holds the lowest address that the copy is made to.
-At the end of the instruction:
  ◦ the value of Xn is written back with the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  ◦ the value of Xs is written back with the lowest address that has not been copied from.
  ◦ the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
-Xd holds the lowest address that the copy is made to -Xn.
-At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
-Xd holds the lowest address that the copy is made to.
-At the end of the instruction:
  ◦ the value of Xn is written back with 0.
the value of Xs is written back with the lowest address that has not been copied from.
the value of Xd is written back with the lowest address that has not been copied to.

CPYFPWTWN, CPYFMWTWN, CPYFEWTWN

Memory Copy Forward-only, writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTWN, then CPYFMWTWN, and then CPYFEWTWN. CPYFPWTWN performs some preconditioning of the arguments suitable for using the CPYFMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

After execution of CPYFPWTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.(N,Z,V) are set to {0,0,0}.

For CPYFMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
- the value of $X_s$ is written back with the lowest address that has not been copied from.
- the value of $X_d$ is written back with the lowest address that has not been copied to.

Memory Copy. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYP, then CPYM, and then CPYE. CPYP performs some preconditioning of the arguments suitable for using the CPYM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYE performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYP, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.
After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elseif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYP, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
  • If the copy is in the forward direction, then:
    ◦ Xs holds the original Xs + saturated Xn.
    ◦ Xd holds the original Xd + saturated Xn.
    ◦ Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
  • If the copy is in the backward direction, then:
    ◦ Xs and Xd are unchanged.
    ◦ Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYP, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  ◦ Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  ◦ Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYM, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is copied to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYM, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
• Xs holds the lowest address that the copy is copied from.
• Xd holds the lowest address that the copy is copied to.
• At the end of the instruction:
  ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  ■ the value of Xs is written back with the lowest address that has not been copied from.
  ■ the value of Xd is written back with the lowest address that has not been copied to.

  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
      ■ the value of Xs is written back with the highest address that has not been copied from +1.
      ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYE, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is made to.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYE, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from.
  ◦ Xd holds the highest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

CPYPN, CPYMN, CPYEN

Memory Copy, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPN, then CPYMN, and then CPYEN.

CPYPN performs some preconditioning of the arguments suitable for using the CPYMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPN, the following saturation logic is applied:
If \( Xn < 63:55 \neq 000000000 \), the copy size \( Xn \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
- If \( (Xs > Xd) \&\& (Xd + saturated Xn) > Xs \), then direction = forward
- Elsif \( (Xs < Xd) \&\& (Xs + saturated Xn) > Xd \), then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPN, option A (which results in encoding PSTATE.C = 0):
- PSTATE.{N,Z,V} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - \( Xs \) holds the original \( Xs + saturated Xn \).
  - \( Xd \) holds the original \( Xd + saturated Xn \).
  - \( Xn \) holds -1* saturated \( Xn \) + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - \( Xs \) and \( Xd \) are unchanged.
  - \( Xn \) holds the saturated value of \( Xn \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPN, option B (which results in encoding PSTATE.C = 1):
- If the copy is in the forward direction, then:
  - \( Xs \) holds the original \( Xs + an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( Xd \) holds the original \( Xd + an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( Xn \) holds the saturated \( Xn - an IMPLEMENTATION DEFINED number of bytes copied \).
  - PSTATE.{N,Z,V} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - \( Xs \) holds the original \( Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( Xd \) holds the original \( Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied \).
  - \( Xn \) holds the saturated \( Xn - an IMPLEMENTATION DEFINED number of bytes copied \).
  - PSTATE.{N,Z,V} are set to \{1,0,0\}.

For CPYMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- \( Xn \) is treated as a signed 64-bit number.
- If the copy is in the forward direction (\( Xn \) is a negative number), then:
  - \( Xn \) holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - \( Xs \) holds the lowest address that the copy is copied from \(-Xn\).
  - \( Xd \) holds the lowest address that the copy is made to \(-Xn\).
  - At the end of the instruction, the value of \( Xn \) is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (\( Xn \) is a positive number), then:
  - \( Xn \) holds the number of bytes remaining to be copied in the memory copy in total.
  - \( Xs \) holds the highest address that the copy is copied from \(-Xn+1\).
  - \( Xd \) holds the highest address that the copy is copied to \(-Xn+1\).
  - At the end of the instruction, the value of \( Xn \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- \( Xn \) holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is made to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  • If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1
    ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
  • If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the lowest address that has not been copied from.
      ■ the value of Xd is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the highest address that has not been copied from +1.
      ■ the value of Xd is written back with the highest address that has not been copied to +1.

CPYPRN, CPYMRN, CPYERN

Memory Copy, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRN, then CPYMRN, and then CPYERN.

CPYPRN performs some preconditioning of the arguments suitable for using the CPYMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elseif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds \(-1\times\) the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from \(-Xn\).
  ◦ Xd holds the lowest address that the copy is made to \(-Xn\).
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from \(-Xn+1\).
  ◦ Xd holds the highest address that the copy is copied to \(-Xn+1\).
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, reads unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRT, then CPYMRT, and then CPYERT.

CPYPRT performs some preconditioning of the arguments suitable for using the CPYMRT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRT, the following saturation logic is applied:
If \( X_n < 63:55 \) \(!= 0000000000 \), the copy size \( X_n \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If \( (X_s > X_d) \) \&\& \( (X_d + \text{saturated } X_n) > X_s \), then direction = forward
Elsif \( (X_s < X_d) \) \&\& \( (X_s + \text{saturated } X_n) > X_d \), then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRT, option A (which results in encoding PSTATE.C = 0):
• PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
  • If the copy is in the forward direction, then:
    ◦ \( X_s \) holds the original \( X_s + \text{saturated } X_n \).
    ◦ \( X_d \) holds the original \( X_d + \text{saturated } X_n \).
    ◦ \( X_n \) holds -1* \( \text{saturated } X_n \) + an IMPLEMENTATION DEFINED number of bytes copied.
  • If the copy is in the backward direction, then:
    ◦ \( X_s \) and \( X_d \) are unchanged.
    ◦ \( X_n \) holds the saturated value of \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRT, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  ◦ \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  ◦ \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  ◦ \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
• If the copy is in the backward direction, then:
  ◦ \( X_s \) holds the original \( X_s + \text{saturated } X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ \( X_d \) holds the original \( X_d + \text{saturated } X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.\{N,Z,V\} are set to \{1,0,0\}.

For CPYMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• \( X_n \) is treated as a signed 64-bit number.
• If the copy is in the forward direction (\( X_n \) is a negative number), then:
  ◦ \( X_n \) holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ \( X_s \) holds the lowest address that the copy is copied from -\( X_n \).
  ◦ \( X_d \) holds the lowest address that the copy is made to -\( X_n \).
  ◦ At the end of the instruction, the value of \( X_n \) is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
• If the copy is in the backward direction (\( X_n \) is a positive number), then:
  ◦ \( X_n \) holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ \( X_s \) holds the highest address that the copy is copied from -\( X_n + 1 \).
  ◦ \( X_d \) holds the highest address that the copy is copied to -\( X_n + 1 \).
  ◦ At the end of the instruction, the value of \( X_n \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• \( X_n \) holds the number of bytes to be copied in the memory copy in total.
If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.

If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
  ◦ Xn is treated as a signed 64-bit number.
  If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is made to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1.
    ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
  ◦ Xn holds the number of bytes to be copied in the memory copy in total
  If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ▪ the value of Xn is written back with 0.
      ▪ the value of Xs is written back with the lowest address that has not been copied from.
      ▪ the value of Xd is written back with the lowest address that has not been copied to.
  If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ▪ the value of Xn is written back with 0.
      ▪ the value of Xs is written back with the highest address that has not been copied from +1.
      ▪ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, reads unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTN, then CPYMRTN, and then CPYERTN.

CPYPRTN performs some preconditioning of the arguments suitable for using the CPYMRTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTN, the following saturation logic is applied:

If \( X_n < 63:55 \) != 0000000000, the copy size \( X_n \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If \((X_s > X_d) \&\& (X_d + \text{saturated } X_n) > X_s\), then direction = forward
- Elsif \((X_s < X_d) \&\& (X_s + \text{saturated } X_n) > X_d\), then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated } X_n \).
  - \( X_d \) holds the original \( X_d + \text{saturated } X_n \).
  - \( X_n \) holds \(-1^* \text{saturated } X_n + \text{ an IMPLEMENTATION DEFINED number of bytes copied.}\)
- If the copy is in the backward direction, then:
  - \( X_s \) and \( X_d \) are unchanged.
  - \( X_n \) holds the saturated value of \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{ an IMPLEMENTATION DEFINED number of bytes copied.}\)
  - \( X_d \) holds the original \( X_d + \text{ an IMPLEMENTATION DEFINED number of bytes copied.}\)
  - \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated } X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - \( X_d \) holds the original \( X_d + \text{saturated } X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{1,0,0\}.

For CPYMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- \( X_n \) is treated as a signed 64-bit number.
- If the copy is in the forward direction (\( X_n \) is a negative number), then:
  - \( X_n \) holds \(-1^*\) the number of bytes remaining to be copied in the memory copy in total.
  - \( X_s \) holds the lowest address that the copy is copied from \(-X_n\).
  - \( X_d \) holds the lowest address that the copy is made to \(-X_n\).
  - At the end of the instruction, the value of \( X_n \) is written back with \(-1^*\) the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (\( X_n \) is a positive number), then:
  - \( X_n \) holds the number of bytes remaining to be copied in the memory copy in total.
  - \( X_s \) holds the highest address that the copy is copied from \(-X_n+1\).
  - \( X_d \) holds the highest address that the copy is copied to \(-X_n+1\).
  - At the end of the instruction, the value of \( X_n \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- \( X_n \) holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, reads unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTRN, then CPYMRTRN, and then CPYERTRN.

CPYPRTRN performs some preconditioning of the arguments suitable for using the CPYMRTRN instruction, and performs an implementation-defined amount of the memory copy. CPYMRTRN performs an implementation-defined amount of the memory copy. CPYERTRN performs the last part of the memory copy.

**Note**

The inclusion of implementation-defined amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTRN, the following saturation logic is applied:
If Xn\text{<}_63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elseif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = implementation-defined choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is implementation-defined.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTRN, option A (which results in encoding PSTATE.C = 0):
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an implementation-defined number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an implementation-defined number of bytes copied.

After execution of CPYPRTRN, option B (which results in encoding PSTATE.C = 1):
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an implementation-defined number of bytes copied.
  - Xd holds the original Xd + an implementation-defined number of bytes copied.
  - Xn holds the saturated Xn - an implementation-defined number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an implementation-defined number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an implementation-defined number of bytes copied.
  - Xn holds the saturated Xn - an implementation-defined number of bytes copied.
  - PSTATE.\{N,Z,V\} are set to \{1,0,0\}.

For CPYMRTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
  - If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
  - If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is made to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYERTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with 0.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, reads unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTWN, then CPYMRTWN, and then CPYERTWN.

CPYPRTWN performs some preconditioning of the arguments suitable for using the CPYMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTWN performs the last part of the memory copy.

Note
The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTWN, the following saturation logic is applied:
If \( X_n < 63:55 \) != 0000000000, the copy size \( X_n \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If \( (X_s > X_d) \) && \( (X_d + \text{saturated } X_n) > X_s \), then direction = forward
Elsif \( (X_s < X_d) \) && \( (X_s + \text{saturated } X_n) > X_d \), then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note
Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTWN, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  ◦ \( X_s \) holds the original \( X_s + \text{saturated } X_n \).
  ◦ \( X_d \) holds the original \( X_d + \text{saturated } X_n \).
  ◦ \( X_n \) holds \(-1\times \text{saturated } X_n + \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
• If the copy is in the backward direction, then:
  ◦ \( X_s \) and \( X_d \) are unchanged.
  ◦ \( X_n \) holds the saturated value of \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTWN, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  ◦ \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ \( X_n \) holds the saturated \( X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ PSTATE.{N,Z,V} are set to \{0,0,0\}.
• If the copy is in the backward direction, then:
  ◦ \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ \( X_n \) holds the saturated \( X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied.}\)
  ◦ PSTATE.{N,Z,V} are set to \{1,0,0\}.

For CPYMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• \( X_n \) is treated as a signed 64-bit number.
• If the copy is in the forward direction (\( X_n \) is a negative number), then:
  ◦ \( X_n \) holds \(-1\times \text{the number of bytes remaining to be copied in the memory copy in total.}\)
  ◦ \( X_s \) holds the lowest address that the copy is copied from -\( X_n \).
  ◦ \( X_d \) holds the lowest address that the copy is made to -\( X_n \).
  ◦ At the end of the instruction, the value of \( X_n \) is written back with \(-1\times \text{the number of bytes remaining to be copied in the memory copy in total.}\)
• If the copy is in the backward direction (\( X_n \) is a positive number), then:
  ◦ \( X_n \) holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ \( X_s \) holds the highest address that the copy is copied from -\( X_n +1 \).
  ◦ \( X_d \) holds the highest address that the copy is copied to -\( X_n +1 \).
  ◦ At the end of the instruction, the value of \( X_n \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• \( X_n \) holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is made to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  • If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1.
    ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total.
  • If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the lowest address that has not been copied from.
      ■ the value of Xd is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the highest address that has not been copied from +1.
      ■ the value of Xd is written back with the highest address that has not been copied to +1.

CPYPT, CPYMT, CPYET

Memory Copy, reads and writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPT, then CPYMT, and then CPYET.

CPYPT performs some preconditioning of the arguments suitable for using the CPYMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYET performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPT, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPT, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
  • If the copy is in the forward direction, then:
    o Xs holds the original Xs + saturated Xn.
    o Xd holds the original Xd + saturated Xn.
    o Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
  • If the copy is in the backward direction, then:
    o Xs and Xd are unchanged.
    o Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPT, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  o Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  o Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  o Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  o PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  o Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  o Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  o Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  o PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    o Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    o Xs holds the lowest address that the copy is copied from -Xn.
    o Xd holds the lowest address that the copy is made to -Xn.
    o At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
  • If the copy is in the backward direction (Xn is a positive number), then:
    o Xn holds the number of bytes remaining to be copied in the memory copy in total.
    o Xs holds the highest address that the copy is copied from -Xn+1.
    o Xd holds the highest address that the copy is copied to -Xn+1.
    o At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total.
If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.

If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYET, option A (encoded by PSTATE.C = 0), the format of the arguments is:
  • Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is copied to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  • If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1.
    ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
  • Xn holds the number of bytes to be copied in the memory copy in total
  • If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the lowest address that has not been copied from.
      ■ the value of Xd is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the highest address that has not been copied from +1.
      ■ the value of Xd is written back with the highest address that has not been copied to +1.

CPYPTN, CPYMTN, CPYETN

Memory Copy, reads and writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTN, then CPYMTN, and then CPYETN.

CPYPTN performs some preconditioning of the arguments suitable for using the CPYMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTN, the following saturation logic is applied:

If Xn<63:55> != 0000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is copied to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

**CPYPTRN, CPYMTRN, CPYETRN**

Memory Copy, reads and writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTRN, then CPYMTRN, and then CPYETRN.

CPYPTRN performs some preconditioning of the arguments suitable for using the CPYMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETRN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
- Elsid (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is made to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is made to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  • If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1.
    ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
  • If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ▪ the value of Xn is written back with 0.
      ▪ the value of Xs is written back with the lowest address that has not been copied from.
      ▪ the value of Xd is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ▪ the value of Xn is written back with 0.
      ▪ the value of Xs is written back with the highest address that has not been copied from +1.
      ▪ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, reads and writes unprivileged, writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTWN, then CPYMTWN, and then CPYETWN.

CPYPTWN performs some preconditioning of the arguments suitable for using the CPYMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTWN, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
ElseIf (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is made to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.

For CPYETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
If the copy is in the forward direction (PSTATE.N == 0), then:
- $X_s$ holds the lowest address that the copy is copied from.
- $X_d$ holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of $X_n$ is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of $X_s$ is written back with the lowest address that has not been copied from.
  - the value of $X_d$ is written back with the lowest address that has not been copied to.

If the copy is in the backward direction (PSTATE.N == 1), then:
- $X_s$ holds the highest address that the copy is copied from +1.
- $X_d$ holds the highest address that the copy is copied to +1.
- At the end of the instruction:
  - the value of $X_n$ is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of $X_s$ is written back with the highest address that has not been copied from +1.
  - the value of $X_d$ is written back with the highest address that has not been copied to +1.

For CPYETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- $X_n$ is treated as a signed 64-bit number.
- If the copy is in the forward direction ($X_n$ is a negative number), then:
  - $X_n$ holds $-1 \times$ the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the lowest address that the copy is copied from $-X_n$.
  - $X_d$ holds the lowest address that the copy is made to $-X_n$.
  - At the end of the instruction, the value of $X_n$ is written back with 0.
- If the copy is in the backward direction ($X_n$ is a positive number), then:
  - $X_n$ holds the number of bytes remaining to be copied in the memory copy in total.
  - $X_s$ holds the highest address that the copy is copied from $-X_n+1$.
  - $X_d$ holds the highest address that the copy is copied to $-X_n+1$.
  - At the end of the instruction, the value of $X_n$ is written back with 0.

For CPYETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- $X_n$ holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - $X_s$ holds the lowest address that the copy is copied from.
  - $X_d$ holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of $X_n$ is written back with 0.
    - the value of $X_s$ is written back with the lowest address that has not been copied from.
    - the value of $X_d$ is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - $X_s$ holds the highest address that the copy is copied from +1.
  - $X_d$ holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of $X_n$ is written back with 0.
    - the value of $X_s$ is written back with the highest address that has not been copied from +1.
    - the value of $X_d$ is written back with the highest address that has not been copied to +1.

After execution of CPYPWN, option A (which results in encoding PSTATE.C = 0):

• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  ◦ Xs holds the original Xs + saturated Xn.
  ◦ Xd holds the original Xd + saturated Xn.
  ◦ Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• If the copy is in the backward direction, then:
  ◦ Xs and Xd are unchanged.
  ◦ Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWN, option B (which results in encoding PSTATE.C = 1):

• If the copy is in the forward direction, then:
  ◦ Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  ◦ Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is made to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the lowest address that has not been copied from.
    ■ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ■ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ■ the value of Xs is written back with the highest address that has not been copied from +1.
    ■ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
  • If the copy is in the forward direction (Xn is a negative number), then:
    ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the lowest address that the copy is copied from -Xn.
    ◦ Xd holds the lowest address that the copy is copied to -Xn.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
  • If the copy is in the backward direction (Xn is a positive number), then:
    ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ Xs holds the highest address that the copy is copied from -Xn+1.
    ◦ Xd holds the highest address that the copy is copied to -Xn+1.
    ◦ At the end of the instruction, the value of Xn is written back with 0.
For CPYEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
  • If the copy is in the forward direction (PSTATE.N == 0), then:
    ◦ Xs holds the lowest address that the copy is copied from.
    ◦ Xd holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the lowest address that has not been copied from.
      ■ the value of Xd is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction (PSTATE.N == 1), then:
    ◦ Xs holds the highest address that the copy is copied from +1.
    ◦ Xd holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      ■ the value of Xn is written back with 0.
      ■ the value of Xs is written back with the highest address that has not been copied from +1.
      ■ the value of Xd is written back with the highest address that has not been copied to +1.

Memory Copy, writes unprivileged. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWT, then CPYMWT, and then CPYEWT.

CPYPWT performs some preconditioning of the arguments suitable for using the CPYMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWT performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWT, the following saturation logic is applied: If \( X_n < 63:55 > ! = 000000000 \), the copy size \( X_n \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If \( (X_s > X_d) \&\& (X_d + \text{saturated } X_n) > X_s \), then direction = forward
- Elsif \( (X_s < X_d) \&\& (X_s + \text{saturated } X_n) > X_d \), then direction = backward
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWT, option A (which results in encoding \( \text{PSTATE.C} = 0 \)):

- \( \text{PSTATE.}\{\text{N,Z,V}\} \) are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated } X_n \).
  - \( X_d \) holds the original \( X_d + \text{saturated } X_n \).
  - \( X_n \) holds \( -1^* \text{saturated } X_n + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
- If the copy is in the backward direction, then:
  - \( X_s \) and \( X_d \) are unchanged.
  - \( X_n \) holds the saturated value of \( X_n \) - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWT, option B (which results in encoding \( \text{PSTATE.C} = 1 \)):

- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( \text{PSTATE.}\{\text{N,Z,V}\} \) are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated } X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{saturated } X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( \text{PSTATE.}\{\text{N,Z,V}\} \) are set to \{1,0,0\}.

For CPYMWT, option A (encoded by \( \text{PSTATE.C} = 0 \)), the format of the arguments is:

- \( X_n \) is treated as a signed 64-bit number.
- If the copy is in the forward direction (\( X_n \) is a negative number), then:
  - \( X_n \) holds \( -1^* \text{the number of bytes remaining to be copied in the memory copy in total} \).
  - \( X_s \) holds the lowest address that the copy is copied from \(-X_n\).
  - \( X_d \) holds the lowest address that the copy is made to \(-X_n\).
  - At the end of the instruction, the value of \( X_n \) is written back with \( -1^* \text{the number of bytes remaining to be copied in the memory copy in total} \).
- If the copy is in the backward direction (\( X_n \) is a positive number), then:
  - \( X_n \) holds the number of bytes remaining to be copied in the memory copy in total.
  - \( X_s \) holds the highest address that the copy is copied from \(-X_n+1\).
  - \( X_d \) holds the highest address that the copy is copied to \(-X_n+1\).
  - At the end of the instruction, the value of \( X_n \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWT, option B (encoded by \( \text{PSTATE.C} = 1 \)), the format of the arguments is:

- \( X_n \) holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

CPYPWTN, CPYMWTN, CPYEWTN

Memory Copy, writes unprivileged, reads and writes non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTN, then CPYMWTN, and then CPYEWTN.

CPYPWTN performs some preconditioning of the arguments suitable for using the CPYMWTN instruction, and performs an implementation defined amount of the memory copy. CPYMWTN performs an implementation defined amount of the memory copy. CPYEWTN performs the last part of the memory copy.

Note

The inclusion of implementation defined amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTN, the following saturation logic is applied:
If Xn<63:55> != 0000000000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = implementation defined choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is implementation defined.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTN, option A (which results in encoding PSTATE.C = 0):
- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an implementation defined number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an implementation defined number of bytes copied.

After execution of CPYPWTN, option B (which results in encoding PSTATE.C = 1):
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an implementation defined number of bytes copied.
  - Xd holds the original Xd + an implementation defined number of bytes copied.
  - Xn holds the saturated Xn - an implementation defined number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an implementation defined number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an implementation defined number of bytes copied.
  - Xn holds the saturated Xn - an implementation defined number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes to be copied in the memory copy in total.
If the copy is in the forward direction (PSTATE.N == 0), then:
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

If the copy is in the backward direction (PSTATE.N == 1), then:
- Xs holds the highest address that the copy is copied from +1.
- Xd holds the highest address that the copy is copied to +1.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the highest address that has not been copied from +1.
  - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is copied to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes to be copied in the memory copy in total
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

Assembler Symbols

$<Xd>$ For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.

For the prologue variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field.

$<Xs>$ For the epilogue and main variant: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.

For the prologue variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field.

$<Xn>$ For the epilogue variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

For the main variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field.

For the prologue variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field.

Memory Copy, writes unprivileged, reads non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTRN, then CPYMWTRN, and then CPYEWTRN.

CPYPWTRN performs some preconditioning of the arguments suitable for using the CPYMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTRN performs the last part of the memory copy.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTRN, the following saturation logic is applied:

If \( X_n < 63:55 \neq 000000000 \), the copy size \( X_n \) is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

- If \( (X_s > X_d) \&\& (X_d + \text{saturated } X_n) > X_s \), then direction = forward.
- Elseif \( (X_s < X_d) \&\& (X_s + \text{saturated } X_n) > X_d \), then direction = backward.
- Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{saturated } X_n \).
  - \( X_d \) holds the original \( X_d + \text{saturated } X_n \).
  - \( X_n \) holds \(-1\times \text{saturated } X_n + \text{an IMPLEMENTATION DEFINED number of bytes copied}\).
- If the copy is in the backward direction, then:
  - \( X_s \) and \( X_d \) are unchanged.
  - \( X_n \) holds the saturated value of \( X_n \) - \text{an IMPLEMENTATION DEFINED number of bytes copied}.

After execution of CPYPWTRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n - \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - PSTATE.\{N,Z,V\} are set to \{0,0,0\}.
- If the copy is in the backward direction, then:
  - \( X_s \) holds the original \( X_s + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_d \) holds the original \( X_d + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - \( X_n \) holds the saturated \( X_n + \text{an IMPLEMENTATION DEFINED number of bytes copied} \).
  - PSTATE.\{N,Z,V\} are set to \{1,0,0\}.

For CPYMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- \( X_n \) is treated as a signed 64-bit number.
- If the copy is in the forward direction (\( X_n \) is a negative number), then:
  - \( X_n \) holds \(-1\times \text{the number of bytes remaining to be copied in the memory copy in total}\).
  - \( X_s \) holds the lowest address that the copy is copied from \(-X_n\).
  - \( X_d \) holds the lowest address that the copy is made to \(-X_n\).
  - At the end of the instruction, the value of \( X_n \) is written back with \(-1\times \text{the number of bytes remaining to be copied in the memory copy in total}\).
- If the copy is in the backward direction (\( X_n \) is a positive number), then:
  - \( X_n \) holds the number of bytes remaining to be copied in the memory copy in total.
  - \( X_s \) holds the highest address that the copy is copied from \(-X_n+1\).
  - \( X_d \) holds the highest address that the copy is copied to \(-X_n+1\).
  - At the end of the instruction, the value of \( X_n \) is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- \( X_n \) holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction ($\text{PSTATE.N} == 0$), then:
  ◦ $Xs$ holds the lowest address that the copy is copied from.
  ◦ $Xd$ holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    - the value of $Xn$ is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of $Xs$ is written back with the lowest address that has not been copied from.
    - the value of $Xd$ is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction ($\text{PSTATE.N} == 1$), then:
  ◦ $Xs$ holds the highest address that the copy is copied from +1.
  ◦ $Xd$ holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    - the value of $Xn$ is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of $Xs$ is written back with the highest address that has not been copied from +1.
    - the value of $Xd$ is written back with the highest address that has not been copied to +1.

For CPYEWTRN, option A (encoded by $\text{PSTATE.C} == 0$), the format of the arguments is:
• $Xn$ is treated as a signed 64-bit number.
  • If the copy is in the forward direction ($\text{PSTATE.N}$ is a negative number), then:
    ◦ $Xn$ holds $-1 \times$ the number of bytes remaining to be copied in the memory copy in total.
    ◦ $Xs$ holds the lowest address that the copy is copied from $-Xn$.
    ◦ $Xd$ holds the lowest address that the copy is made to $-Xn$.
    ◦ At the end of the instruction, the value of $Xn$ is written back with 0.
  • If the copy is in the backward direction ($\text{Xn}$ is a positive number), then:
    ◦ $Xn$ holds the number of bytes remaining to be copied in the memory copy in total.
    ◦ $Xs$ holds the highest address that the copy is copied from $-Xn+1$.
    ◦ $Xd$ holds the highest address that the copy is copied to $-Xn+1$.
    ◦ At the end of the instruction, the value of $Xn$ is written back with 0.

For CPYEWTRN, option B (encoded by $\text{PSTATE.C} == 1$), the format of the arguments is:
• $Xn$ holds the number of bytes to be copied in the memory copy in total.
  • If the copy is in the forward direction ($\text{PSTATE.N} == 0$), then:
    ◦ $Xs$ holds the lowest address that the copy is copied from.
    ◦ $Xd$ holds the lowest address that the copy is copied to.
    ◦ At the end of the instruction:
      - the value of $Xn$ is written back with 0.
      - the value of $Xs$ is written back with the lowest address that has not been copied from.
      - the value of $Xd$ is written back with the lowest address that has not been copied to.
  • If the copy is in the backward direction ($\text{PSTATE.N} == 1$), then:
    ◦ $Xs$ holds the highest address that the copy is copied from +1.
    ◦ $Xd$ holds the highest address that the copy is copied to +1.
    ◦ At the end of the instruction:
      - the value of $Xn$ is written back with 0.
      - the value of $Xs$ is written back with the highest address that has not been copied from +1.
      - the value of $Xd$ is written back with the highest address that has not been copied to +1.

CPYPWTWN, CPYMWTWN, CPYEWTWN

Memory Copy, writes unprivileged and non-temporal. These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTWN, then CPYMWTWN, and then CPYEWTWN.

CPYPWTWN performs some preconditioning of the arguments suitable for using the CPYMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTWN, the following saturation logic is applied:
If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFF.
After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:
If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward
ElseIf (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward
Else direction = IMPLEMENTATION DEFINED choice between forward and backward.
The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTWN, option A (which results in encoding PSTATE.C = 0):
• PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the forward direction, then:
  ◦ Xs holds the original Xs + saturated Xn.
  ◦ Xd holds the original Xd + saturated Xn.
  ◦ Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
• If the copy is in the backward direction, then:
  ◦ Xs and Xd are unchanged.
  ◦ Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTWN, option B (which results in encoding PSTATE.C = 1):
• If the copy is in the forward direction, then:
  ◦ Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {0,0,0}.
• If the copy is in the backward direction, then:
  ◦ Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  ◦ PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is made to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.

• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with the number of bytes remaining to be copied in the
      memory copy in total.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• If the copy is in the forward direction (Xn is a negative number), then:
  ◦ Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the lowest address that the copy is copied from -Xn.
  ◦ Xd holds the lowest address that the copy is made to -Xn.
  ◦ At the end of the instruction, the value of Xn is written back with 0.
• If the copy is in the backward direction (Xn is a positive number), then:
  ◦ Xn holds the number of bytes remaining to be copied in the memory copy in total.
  ◦ Xs holds the highest address that the copy is copied from -Xn+1.
  ◦ Xd holds the highest address that the copy is copied to -Xn+1.
  ◦ At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes to be copied in the memory copy in total.
• If the copy is in the forward direction (PSTATE.N == 0), then:
  ◦ Xs holds the lowest address that the copy is copied from.
  ◦ Xd holds the lowest address that the copy is copied to.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the lowest address that has not been copied from.
    ▪ the value of Xd is written back with the lowest address that has not been copied to.
• If the copy is in the backward direction (PSTATE.N == 1), then:
  ◦ Xs holds the highest address that the copy is copied from +1.
  ◦ Xd holds the highest address that the copy is copied to +1.
  ◦ At the end of the instruction:
    ▪ the value of Xn is written back with 0.
    ▪ the value of Xs is written back with the highest address that has not been copied from +1.
    ▪ the value of Xd is written back with the highest address that has not been copied to +1.

CRC32, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

// Poly32Mod2 on a bitstring does a polynomial Modulus over \{0,1\} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction. No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

Note

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

```
1 1 0 1 0 1 0 0 0 0 1 1 0 0 1 0 0 0 1 0 1 0 0 1 1 1 1

- \texttt{<Xn>}: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \texttt{<Xm>}: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \texttt{<cond>}: Is one of the standard conditions, encoded in the "cond" field in the standard way.

Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{CNEG}</td>
<td>\texttt{cond} != '111x' &amp;&amp; Rn == Rm</td>
</tr>
</tbody>
</table>

Operation

bits(datasize) result;
if \texttt{ConditionHolds} (cond) then
  result = X[n];
else
  result = X[m];
  result = \texttt{NOT} (result);
  result = result + 1;
X[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
Data Cache operation. For more information, see $op0==0b01$, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

```
1 1 0 1 0 1 0 0 0 1 0 1 1 1 0
1 0 1 1 0 0 0 0 0 1 op1 0 1 1 1 CRm op2 Rt
```

DC <dc_op>, <Xt>
is equivalent to
SYS #<op1>, C7, <Cm>, #<op2>, <Xt>

and is the preferred disassembly when SysOp(op1, '0111', CRm, op2) == Sys_DC.

**Assembler Symbols**

<dc_op> is a DC instruction name, as listed for the DC system instruction group, encoded in "op1:CRm:op2":

</table>

<op1> is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
Operation

The description of SYS gives the operational pseudocode for this instruction.
DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTL R_ELx EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and HCR_EL2.TGE == 1.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS.

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(LL);

if !Halted() then UNDEFINED;
DCPS2

Debug Change PE State to EL2, when executed in Debug state:
• If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
• Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:
• EL2 if the instruction is executed at an exception level that is not EL3.
• EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:
• ELR_ELx becomes UNKNOWN.
• SPSR_ELx becomes UNKNOWN.
• ESR_ELx becomes UNKNOWN.
• DLR_EL0 and DSPSR_EL0 become UNKNOWN.
• The endianness is set according to SCTLR_ELx EE.

This instruction is UNDEFINED at the following exception levels:
• All exception levels if EL2 is not implemented.
• At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS.

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(LL);

if !Halted() then UNDEFINED;
DCPS3

Debug Change PE State to EL3, when executed in Debug state:
- If executed at EL3 selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:
- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:
- EDSR.SDD == 1.
- EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS.

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(LL);

if !Halted() then UNDEFINED;
Data Gathering Hint is a hint instruction that indicates that it is not expected to be performance optimal to merge memory accesses with Normal Non-cacheable or Device-GRE attributes appearing in program order before the hint instruction with any memory accesses appearing after the hint instruction into a single memory transaction on an interconnect.

```
if !HaveDGHExt() then EndOfInstruction();

Operation

Hint_DGH();
```
Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier*.

```

```

**Assembler Symbols**

<option> Specifies the limitation on the barrier operation. Values are:

- **SY**: Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

- **ST**: Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

- **LD**: Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

- **ISH**: Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

- **ISHST**: Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

- **ISHLD**: Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

- **NSH**: Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

- **NSHST**: Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

- **NSHLD**: Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST
Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

<imm>
Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the “CRm” field.

Operation

```
DataMemoryBarrier(domain, types);
```

Internal version only: isa v33.16decrel, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

```

if !Halted() || PSTATE.EL == EL0 then UNDEFINED;

Operation

```
DRPSInstruction();
```
DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see Data Synchronization Barrier.

A DSB instruction with the nXS qualifier is complete when the subset of these memory accesses with the XS attribute set to 0 are complete. It does not require that memory accesses with the XS attribute set to 1 are complete.

This instruction is used by the aliases PSSBB, and SSBB.

It has encodings from 2 classes: Memory barrier and Memory nXS barrier.

Memory barrier

Assembler Symbols

<option> For the memory barrier variant: specifies the limitation on the barrier operation. Values are:
SY  Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST  Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD  Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH  Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST  Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD  Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH  Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST  Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD  Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH  Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST  Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD  Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm, other than the values 0b0000 and 0b0100, that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

Note

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

For the memory nXS barrier variant: specifies the limitation on the barrier operation. Values are:

SY  Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm<3:2> = 0b11.
ISH
Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b10.

NSH
Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b01.

OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b00.

<imm>
For the memory barrier variant: is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

For the memory nXS barrier variant: is a 5-bit unsigned immediate, encoded in "imm2":

<table>
<thead>
<tr>
<th>imm2</th>
<th>&lt;imm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>16</td>
</tr>
<tr>

  DataSynchronizationBarrier(domain, types, nXS);
otherwise
  Unreachable();
DVP

Data Value Prediction Restriction by Context prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

• The encodings in this description are named to match the encodings of SYS.
• The description of SYS gives the operational pseudocode for this instruction.

System

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

32-bit (sf == 0)

EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit (sf == 1)

EON <Xd>, <Xn>, < Xm>{, <shift> #<amount>}

Integer d = UInt(Rd);
Integer n = UInt(Rn);
Integer m = UInt(Rm);
Integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
Integer shift_amount = UInt(imm6);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 EOR operand2;
X[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

32-bit (sf == 0 && N == 0)

EOR <Wd|WSP>, <Wn>, #<imm>

64-bit (sf == 1)

EOR <Xd|SP>, <Xn>, #<imm>

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<imm> For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".

For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
result = operand1 EOR imm;
if d == 31 then
   SP[] = result;
else
   X[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**EOR (shifted register)**

Bitwise Exclusive OR (shifted register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>1 0 1 0 1 0</th>
<th>shift</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>opc</td>
<td>N</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 32-bit (sf == 0)

EOR `<Wd>`, `<Wn>`, `<Wm>{, <shift> #<amount>}`

### 64-bit (sf == 1)

EOR `<Xd>`, `<Xn>`, `< Xm>{, <shift> #<amount>}`

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

```python
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(datasize) result;
result = operand1 EOR operand2;
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores `PSTATE` from the SPSR, and branches to the address held in the ELR.
The PE checks the SPSR for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state*.

ERET is UNDEFINED at EL0.

```
1 1 0 1 0 1 1 0 1 0 0 1 1 1 1 0 0 0 0 0 0 1 1 1 1 0 0 0 0 0
```

![Binary representation of ERET](image)

**ERET**

if PSTATE.EL == **EL0** then UNDEFINED;

**Operation**

```
AArch64.CheckForERetTrap(FALSE, TRUE);
bits(64) target = ELR[];
AArch64.ExceptionReturn(target, SPSR[]);
```

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**ERETAA, ERETAB**

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See [Illegal return events from AArch64 state](#).

ERETAA and ERETAB are **UNDEFINED** at EL0.

### Integer (FEAT_PAuth)

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
A 1 1 0 1 0 1 1 0 1 0 0 1 1 1 1 0 0 0 0 1 M 1 1 1 1 1 1 1 1
```

**ERETAA (M == 0)**

ERETAA

**ERETAB (M == 1)**

ERETAB

if PSTATE.EL == EL0 then UNDEFINED;
boolean use_key_a = (M == '0');
if !HavePACExt() then
  UNDEFINED;

**Operation**

```plaintext
AArch64.CheckForERetTrap(TRUE, use_key_a);
bits(64) target;
if use_key_a then
target = AuthIA(ELR[], SP[], TRUE);
else
target = AuthIB(ELR[], SP[], TRUE);
AArch64.ExceptionReturn(target, SPSR[]);
```
**ESB**

Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2. This instruction can be used at all Exception levels and in Debug state. In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the Arm(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a NOP.

**System**

(FEATURE_RAS)

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

ESB

```
if !HaveRASExt() then EndOfInstruction();
```

**Operation**

```
SynchronizeErrors();
AArch64_ESB0peration();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch64_vESB0peration();
TakeUnmaskedSErrorInterrupts();
```

Internal version only: isa v33.16decrel, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**EXTR**

Extract register extracts a register from a pair of registers.
This instruction is used by the alias **ROR (immediate)**.

<table>
<thead>
<tr>
<th>sf</th>
<th>0 0 1 0 0 1 1 1</th>
<th>N</th>
<th>0</th>
<th>Rm</th>
<th>imms</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
</table>

**32-bit (sf == 0 && N == 0 && imms == 0xxxxx)**

EXTR <Wd>, <Wn>, <Wm>, #<lsb>

**64-bit (sf == 1 && N == 1)**

EXTR <Xd>, <Xn>, <Xm>, #<lsb>

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
integer lsb;
if N != sf then UNDEFINED;
if sf == '0' && imms<5> == '1' then UNDEFINED;
lsb = UInt(imms);
```

**Assembler Symbols**

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<lsb>` For the 32-bit variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the "imms" field.
  
  For the 64-bit variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the "imms" field.

**Alias Conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ROR (immediate)</strong></td>
<td>Rn == Rm</td>
</tr>
</tbody>
</table>

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(2*datasize) concat = operand1:operand2;
result = concat<lsb+datasize-1:lsb>;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Tag Mask Insert inserts the tag in the first source register into the excluded set specified in the second source register, writing the new excluded set to the destination register.

**HINT**

Hint instruction is for the instruction set space that is reserved for architectural hint instructions. Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

```
1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 1 0     CRm   op2  1 1 1 1 1
```

**HINT #<imm>**

```systemhintop op;
```

```case CRm:op2 of

                    SetBTypeCompatible(BTypeCompatible_BTI(op2<2:1>));
                otherwise EndOfInstruction();
```

**Assembler Symbols**

- `<imm>` Is a 7-bit unsigned immediate, in the range 0 to 127 encoded in the “CRm:op2” field. The encodings that are allocated to architectural hint functionality are described in the “Hints” table in the “Index by Encoding”.

---

**HINT**

Page 343
Note

For allocated encodings of "CRm:op2":
- A disassembler will disassemble the allocated instruction, rather than the HINT instruction.
- An assembler may support assembly of allocated encodings using HINT with the corresponding <imm> value, but it is not required to do so.

Operation

case op of
  when SystemHintOp_YIELD

HVC

Hypervisor Call causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and SCR_EL3.HCE is set to 0.
- When EL3 is not implemented and HCR_EL2.HCD is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC value 0x16, and the value of the immediate argument.

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
  1 1 0 1 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

HVC #<imm>

// Empty.

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && (!IsSecureEL2Enabled() && !IsSecure())) then UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then UNDEFINED;
else AArch64.CallHypervisor(imm16);
```

</tbody>
</table>

- \texttt{<op1>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- \texttt{<Cm>} Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- \texttt{<op2>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- \texttt{<Xt>} Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of \textit{SYS} gives the operational pseudocode for this instruction.
IRG

Insert Random Tag inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

  X[d] = result;
ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see Instruction Synchronization Barrier (ISB).

```
ISB {<option>|<imm>}

// No additional decoding required
```

### Assembler Symbols

- **<option>** Specifies an optional limitation on the barrier operation. Values are:
  - **SY**
    - Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.
    - All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

- **<imm>** Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

### Operation

```
InstructionSynchronizationBarrier();
```

Single-copy Atomic 64-byte Load derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers, Xt to X(t+7). The data that is loaded is atomic and is required to be 64-byte aligned.

LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDADDA and LDADDAL load from memory with acquire semantics.
- LDADDL and LDADDAL store to memory with release semantics.
- LDADD has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STADD, STADDL**.

**Integer**

LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes*.

- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```c
bits(64) address;
bits(16) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType.ORDERED];
X[t] = ZeroExtend(data, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAPUR

Load-Acquire RCpc Register (unscaled) calculates an address from a base register and an immediate offset, loads a
32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register.
The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release,
except that:
• There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release,
  created by having a Store-Release followed by a Load-AcquirePC instruction.
• The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does
  not make the write of the Store-Release globally observed.
This difference in memory ordering is not described in the pseudocode.
For information about memory accesses, see Load/Store addressing modes.

LDARB <Wt>, [<Xn|SP>{,#0}]

integer n = Uint(Rn);
integer t = Uint(Rt);
boolean tag_checked = n != 31;

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(8) data;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDARH**

Load-Acquire Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about memory accesses, see *Load/Store addressing modes*.

**Note**

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

```

boolean tag_checked = n != 31;
```

**Assembler Symbols**

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```
bits(64) address;
bits(16) data;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[0];
else
    address = X[n];
data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Annotated for readability.

**Load-Acquire Exclusive Pair of Registers** derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Store-Release*. For information about memory accesses, see *Load/Store addressing modes*.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDEORB, LDEORAB, LDEORALB, LDEORLB

Atomic exclusive OR on byte in memory atomically loads an 8-bit byte from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDEORAB and LDEORALB load from memory with acquire semantics.
- LDEORLB and LDEORALB store to memory with release semantics.
- LDEORB has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release.*

For information about memory accesses see *Load/Store addressing modes.*

This instruction is used by the alias STEORB, STEORLB.

Assembler Symbols

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared Decode

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc<0> == '1' then UNDEFINED;
integer scale = 2 + UInt(opc<1>);
integer datasize = 8 << scale;
bits(64) offset = LSL(SignExtend(imm7, 64), scale);
boolean tag_checked = n != 31;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDR (immediate)

Load Register (immediate) loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset

         X[t] = data;
   when MemOp_PREFETCH
      Prefetch(address, t<4:0>);
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see *Load/Store addressing modes*.

### 32-bit (size == 10)

LDR <Wt>, [<Xn|SP>,, (<Wm>|<Xm>){, <extend> {<amount>}}]

### 64-bit (size == 11)

LDR <Xt>, [<Xn|SP>,, (<Wm>|<Xm>){, <extend> {<amount>}}]

integer scale = UInt(size);
if option<1> == '0' then UNDEFINED;  // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

**Assembler Symbols**

- **<Wt>** Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- **<Xt>** Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- **<Xn|SP>** Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- **<Wm>** When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- **<Xm>** When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- **<extend>** Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- **<amount>** For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#3</td>
</tr>
</tbody>
</table>
Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;

Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(datasize) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then

    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];
X[t] = ZeroExtend(data, regsize);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRAA, LDRAB

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB. If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see Load/Store addressing modes.

Unscaled offset

LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes*.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| 0 0 1 1 1 0 0 0 0 1 1 | Rm | option | S | 1 | 0 | Rn | Rt |

Extended register (option != 011)

LDRB <Wt>, [<Xn|SP>, (<Wm>|< Xm>), <extend> {<amount>}]  

Shifted register (option == 011)

LDRB <Wt>, [<Xn|SP>, <Xm> {, LSL <amount>}]  

if option<1> == '0' then UNDEFINED; // sub-word index  
ExtendType extend_type = DecodeRegExtend(option);

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.  
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.  
<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.  
<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.  
<extend> Is the index extend specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared Decode

integer n = UInt(Rn);  
integer t = UInt(Rt);  
integer m = UInt(Rm);
Operation

```c
bits(64) offset = ExtendReg(m, extend_type, 0);
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(TRUE);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDRH (immediate)**

Load Register Halfword (immediate) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes.

It has encodings from 3 classes: **Post-index**, **Pre-index** and **Unsigned offset**.

### Post-index

X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRSB (immediate)

Load Register Signed Byte (immediate) loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset.

Post-index

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### LDRSH (immediate)

Load Register Signed Halfword (immediate) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes*. It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset.

#### Post-index

<table>
<thead>
<tr>
<th>32-bit (opc == 11)</th>
<th>64-bit (opc == 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDRSH &lt;Wt&gt;, [&lt;Xn</td>
<td>SP&gt;], #&lt;simm&gt;</td>
</tr>
</tbody>
</table>

```java
boolean wback = TRUE;
boolean postindex = TRUE;
bounds(64) offset = SignExtend(imm9, 64);
```

#### Pre-index

<table>
<thead>
<tr>
<th>32-bit (opc == 11)</th>
<th>64-bit (opc == 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDRSH &lt;Wt&gt;, [&lt;Xn</td>
<td>SP&gt;], #&lt;simm&gt;!</td>
</tr>
</tbody>
</table>

```java
boolean wback = TRUE;
boolean postindex = FALSE;
bounds(64) offset = SignExtend(imm9, 64);
```

#### Unsigned offset

<table>
<thead>
<tr>
<th>32-bit (opc == 11)</th>
<th>64-bit (opc == 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDRSH &lt;Wt&gt;, [&lt;Xn</td>
<td>SP&gt;], #&lt;simm&gt;!</td>
</tr>
</tbody>
</table>

```java
boolean wback = TRUE;
boolean postindex = FALSE;
bounds(64) offset = SignExtend(imm12, 64);
```
32-bit (opc == 11)

LDRSH \(<Wt>, [<Xn|SP>{, #<pimm}>]\)

64-bit (opc == 10)

LDRSH \(<Xt>, [<Xn|SP>{, #<pimm}>]\)

boolean wback = FALSE;
boolean postindex = FALSE;
binary(64) offset = LSL(ZeroExtend(imm12, 64), 1);

For information about the constrained unpredictable behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSH (immediate).

Assembler Symbols

### Assembler Symbols

- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <simm> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- <pimm> Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.
Shared Decode

```c
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb_unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
```

Operation

```c
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elseif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

**Asm code**

<table>
<thead>
<tr>
<th>opc</th>
<th>LDRSW &lt;Xt&gt;, &lt;label&gt;</th>
</tr>
</thead>
</table>

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

**Assembler Symbols**

<Xt>  Is the 64-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<label>  Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as “imm19" times 4.

**Operation**

bits(64) address = PC[] + offset;
bits(32) data;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);
data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRSW (register)

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see Load/Store addressing modes.

![Register Diagram]

LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 2 else 0;

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.
<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.
<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(32) data;

if HaveMTE2Ext() then
  SetTagCheckedInstruction(TRUE);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n];

address = address + offset;
data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSETA and LDSETAL load from memory with acquire semantics.
- LDSETL and LDSETAL store to memory with release semantics.
- LDSET has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

This instruction is used by the alias STSET, STSETL.

```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDTRSB**

Load Register Signed Byte (unprivileged) loads a byte from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:
- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL

Atomic unsigned maximum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDUMAXA and LDUMAXAL load from memory with acquire semantics.
- LDUMAXL and LDUMAXAL store to memory with release semantics.
- LDUMAX has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

This instruction is used by the alias STUMAX, STUMAXL.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB

Atomic unsigned minimum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, **LDUMINAB** and **LDUMINALB** load from memory with acquire semantics.
- **LDUMINLB** and **LDUMINALB** store to memory with release semantics.
- **LDUMINB** has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STUMINB, STUMINLB**.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH

Atomic unsigned minimum on halfword in memory atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMINAH and LDUMINALH load from memory with acquire semantics.
- LDUMINLH and LDUMINALH store to memory with release semantics.
- LDUMINH has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release.*
For information about memory accesses see *Load/Store addressing modes.*

This instruction is used by the alias STUMINH, STUMINLH.

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit
doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment
requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The PE marks the physical
address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions.
See Synchronization and semaphores. For information about memory accesses, see Load/Store addressing modes.

32-bit (sz == 0)

LDXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit (sz == 1)

LDXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;

if t == t2 then
    Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
case c of
    when Constraint_UNKNOWN rt unknown = TRUE; // result is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on
UNPREDICTABLE behaviors, and particularly LDXP.

Assembler Symbols

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### 32-bit (sf == 0 && N == 0 && imms != 011111)

**LSL** `<Wd>, <Wn>, #<shift>`

is equivalent to

**UBFM** `<Wd>, <Wn>, #(<shift> MOD 32), #(31-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

### 64-bit (sf == 1 && N == 1 && imms != 111111)

**LSL** `<Xd>, <Xn>, #<shift>`

is equivalent to

**UBFM** `<Xd>, <Xn>, #(<shift> MOD 64), #(63-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<shift>` For the 32-bit variant: is the shift amount, in the range 0 to 31.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63.

**Operation**

The description of **UBFM** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This is an alias of LSLV. This means:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode for this instruction.

### Assembler Symbols

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `< Xm>` is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of LSLV gives the operational pseudocode for this instruction.

### Operational information

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MNEG <Wd>, <Wn>, <Wm>

is equivalent to

MSUB <Wd>, <Wn>, <Wm>, WZR

and is always the preferred disassembly.

64-bit (sf == 1)

MNEG <Xd>, <Xn>, < Xm>

is equivalent to

MSUB <Xd>, <Xn>, < Xm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
sf 0 1 1 0 0 1 0 0 N immr imms 1 1 1 1 1 Rd
```

**operation**

The description of ORR (immediate) gives the operational pseudocode for this instruction.

**Assembler Symbols**

- `<Wd|WSP>` is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<imm>` is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

32-bit ($sf == 0 \&\& hw == 0x$)

MOV <Wd>, #<imm>

is equivalent to

MOVN <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when $!(\text{IsZero}(\text{imm16}) \&\& \text{hw} != '00') \&\& !\text{IsOnes}(\text{imm16})$.

64-bit ($sf == 1$)

MOV <Xd>, #<imm>

is equivalent to

MOVN <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when $!(\text{IsZero}(\text{imm16}) \&\& \text{hw} != '00')$.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <imm> For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff.
  For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
- <shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOV (register)**

Move (register) copies the value in a source register to the destination register.

This is an alias of **ORR (shifted register)**. This means:

- The encodings in this description are named to match the encodings of **ORR (shifted register)**.
- The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

| sf | 0 | 1 | 0 | 1 | 0 | 0 | 0 | Rm | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | Rd |
|----|---|--|--|--|--|--|--|--|--|--|--|--|--|--|--|---|--|--|--|---|
| opc| shift | N | imm6 | Rn |

32-bit (sf == 0)

MOV <Wd>, <Wm>

is equivalent to

ORR <Wd>, WZR, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

MOV <Xd>, <Xm>

is equivalent to

ORR <Xd>, XZR, <Xm>

and is always the preferred disassembly.

**Assembler Symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

**Operation**

The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (to/from SP)

Move between register and stack pointer

: Rd = Rn.

This is an alias of ADD (immediate). This means:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MOV <Wd|WSP>, <Wn|WSP>

is equivalent to

ADD <Wd|WSP>, <Wn|WSP>, #0

and is the preferred disassembly when (Rd == '11111' || Rn == '11111').

64-bit (sf == 1)

MOV <Xd|SP>, <Xn|SP>

is equivalent to

ADD <Xd|SP>, <Xn|SP>, #0

and is the preferred disassembly when (Rd == '11111' || Rn == '11111').

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.
MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

sf | 1 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | hw | imm16 | Rd
opc

32-bit (sf == 0 && hw == 0x)

MOV <Wd>, #<imm>

is equivalent to

MOVZ <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

64-bit (sf == 1)

MOV <Xd>, #<imm>

is equivalent to

MOVZ <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<imm> For the 32-bit variant: is a 32-bit immediate which can be encoded in “imm16:hw”.
For the 64-bit variant: is a 64-bit immediate which can be encoded in “imm16:hw”.

<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOVK**

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

<table>
<thead>
<tr>
<th>sf</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>

</tbody>
</table>

**opc**

32-bit (sf == 0 && hw == 0x)

```asm
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

64-bit (sf == 1)

```asm
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

```java
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;
if sf == '0' && hw<1> == '1' then UNDEFINED;
pos = UInt(hw:'0000');
```

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<imm>` Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
- `<shift>` For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as `<shift>/16`.
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as `<shift>/16`.

**Operation**

```java
bits(datasize) result;
result = X[d];
result<pos+15:pos> = imm16;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOVN**

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register. This instruction is used by the alias **MOV (inverted wide immediate)**.

32-bit (sf == 0 & hw == 0x)

MOVN <Wd>, #<imm>{, LSL #<shift>}

64-bit (sf == 1)

MOVN <Xd>, #<imm>{, LSL #<shift>}

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;
if sf == '0' && hw<1> == '1' then UNDEFINED;
pos = UInt(hw:'0000');
```

**Assembler Symbols**

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<imm>** Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
- **<shift>** For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

**Alias Conditions**

**Operation**

bits(datasize) result;

result = Zeros();

result<pos+15:pos> = imm16;
X[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Move System Register allows the PE to read an AArch64 System register into a general-purpose register.

\[
\begin{array}{cccccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & o0 & op1 & CRn & CRm & op2 & Rt \\
\end{array}
\]

\( MRS \langle Xt \rangle, (\langle \text{systemreg}\rangle | <\text{op0}> | <\text{op1}> | <\text{Cn}> | <\text{Cm}> | <\text{op2}> ) \)

integer \( t = \text{UInt}(Rt) \);
integer \( \text{sys_op0} = 2 + \text{UInt}(o0) \);
integer \( \text{sys_op1} = \text{UInt}(op1) \);
integer \( \text{sys_op2} = \text{UInt}(op2) \);
integer \( \text{sys_crn} = \text{UInt}(CRn) \);
integer \( \text{sys_crm} = \text{UInt}(CRm) \);

**Assembler Symbols**

\(<Xt>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
\(<\text{systemreg}>\) Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".

The System register names are defined in 'AArch64 System Registers' in the System Register XML.

\(<\text{op0}>\) Is an unsigned immediate, encoded in "o0":

<table>
<thead>
<tr>
<th>(&lt;\text{op0}&gt;)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
</table>
\(\text{sys_op0}\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
\(\text{Cn}\) Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
\(\text{Cm}\) Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
\(\text{op2}\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

**Operation**

\( \text{AArch64.SysRegRead}(\text{sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t}); \)
MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see *Process state, PSTATE*.

The bits that can be written by this instruction are:
- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If *FEAT_SSBS* is implemented, PSTATE.SSBS.
- If *FEAT_PAN* is implemented, PSTATE.PAN.
- If *FEAT_UAO* is implemented, PSTATE.UAO.
- If *FEAT_UAO* is implemented, PSTATE.UAO.
- If *FEAT_DIT* is implemented, PSTATE.DIT.
- If *FEAT_MTE* is implemented, PSTATE.TCO.
- If *FEAT_NMI* is implemented, PSTATE.ALLINT.

MSR (<systemreg>|<op0>|<op1>|<Cn>|<Cm>|<op2>), <Xt>

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys.crm = UInt(CRm);

Assembler Symbols

<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2". The System register names are defined in 'AArch64 System Registers' in the System Register XML.

<op0> Is an unsigned immediate, encoded in "o0":

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys.crm, sys_op2, t);
MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

MSUB <Xd>, <Xn>, <Xm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Wa> Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MNEG</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Operation

bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
X[d] = result<destsize-1:0>;}
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MUL

Multiply

\[ \text{Rd} = \text{Rn} \times \text{Rm} \]

This is an alias of \texttt{MADD}. This means:

- The encodings in this description are named to match the encodings of \texttt{MADD}.
- The description of \texttt{MADD} gives the operational pseudocode for this instruction.

\end{array}
\]

\[ 00 \quad \text{Ra} \]

32-bit (sf == 0)

MUL \(<Wd>, \<Wn>, \<Wm>\)

is equivalent to

MADD \(<Wd>, \<Wn>, \<Wm>, \text{WZR}\)

and is always the preferred disassembly.

64-bit (sf == 1)

MUL \(<Xd>, \<Xn>, \< Xm>\)

is equivalent to

MADD \(<Xd>, \<Xn>, \< Xm>, \text{XZR}\)

and is always the preferred disassembly.

**Assembler Symbols**

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

The description of \texttt{MADD} gives the operational pseudocode for this instruction.
MVN

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

<table>

32-bit (sf == 0)

MVN <Wd>, <Wm>{, <shift> #<amount>}

is equivalent to

ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

64-bit (sf == 1)

MVN <Xd>, <Xm>{, <shift> #<amount>}

is equivalent to

ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### Assembler Symbols

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<shift>` is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>

<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

```
<table>

<xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

// do nothing

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias `MVN`.

<table>
<thead>
<tr>

32-bit (sf == 0)

ORN `<Wd>, <Wn>, <Wm>{,<shift> #<amount>}`

64-bit (sf == 1)

ORN `<Xd>, <Xn>, <Xm>{,<shift> #<amount>}`

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Alias Conditions

<table>
<thead>
<tr>

</tbody>
</table>
Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 OR operand2;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**ORR (immediate)**

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias **MOV (bitmask immediate)**.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>0</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0 && N == 0)**

ORR <Wd|WSP>, <Wn>, #<imm>

**64-bit (sf == 1)**

ORR <Xd|SP>, <Xn>, #<imm>

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

**Assembler Symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<imm>` For the 32-bit variant: is the bitmask immediate, encoded in “imms:immr”.
- For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr”.

**Alias Conditions**

<table>
<thead>
<tr>
<th>Alias</th>

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

if HavePACExt() then
  if source_is_sp then
    X[d] = AddPACIB(X[d], SP());
  else
    X[d] = AddPACIB(X[d], X[n]);

PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

For information about memory accesses, see Load/Store addressing modes.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.<type> is one of:

 PLD  Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

 PLI  Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

 PST  Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

 L1  Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

 L2  Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

 L3  Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

 KEEP  Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

 STRM  Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory. For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
Operation

bits(64) address;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);
endif

if n == 31 then
    address = SP[ ];
else
    address = X[n];
endif

address = address + offset;

Prefetch(address, t<4:0>);

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.
	<type> is one of:
	PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
	PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

**Shared Decode**

```plaintext```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

---

**PRFUM**
Operation

bits(64) address;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(FALSE);

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

### System

*(FEAT_SPE)*

```assembly
if !HaveStatisticalProfiling() then EndOfInstruction();
```

### Operation

```assembly
ProfilingSynchronizationBarrier();
```

Internal version only: isa v33.16decrel, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.
- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode for this instruction.

\[
\begin{array}{ccccccccccccccccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

PSSBB is equivalent to DSB #4

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.
Reverse Bits reverses the bit order in a register.

### 32-bit (sf == 0)

\[ \text{RBIT} \langle W_d \rangle, \langle W_n \rangle \]

### 64-bit (sf == 1)

\[ \text{RBIT} \langle X_d \rangle, \langle X_n \rangle \]

integer \( d = \text{UInt}(Rd); \)
integer \( n = \text{UInt}(Rn); \)
integer datasize = if sf == '1' then 64 else 32;

#### Assembler Symbols

- \( <W_d> \) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <W_n> \) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( <X_d> \) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <X_n> \) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

#### Operation

\[
\begin{align*}
\text{bits(datasize) operand} &= X[n]; \\
\text{bits(datasize) result}; \\
\text{for } i = 0 \text{ to } \text{datasize-1} & \text{ result<((datasize-1)\cdot i) = operand<i>; } \\
X[d] &= \text{result}; 
\end{align*}
\]

#### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RET

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.

```
0 0 0 0 0 0 0 0 | Rn | 0 0 0 0 0 0 0
1 1 0 1 0 1 1 1 | Z  | 1 1 1 1 1 1 0 1
0 1 0 1 1 1 1 1 | op | A  M
```

RET `{<Xn>}`

```
integer n = UInt(Rn);
```

**Assembler Symbols**

`<Xn>` Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

**Operation**

```
bits(64) target = X[n];

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';
BranchTo(target, BranchType_RET, FALSE);
```

Internal version only: isa v33.16decr, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

Copyright © 2010-2021 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**RETA, RETAB**

Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for RETAA, and key B is used for RETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
**REV64**

Reverse Bytes reverses the byte order in a 64-bit general-purpose register. When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is optional whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of **REV**. This means:

- The encodings in this description are named to match the encodings of **REV**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **REV** gives the operational pseudocode for this instruction.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

RMIF <Xn>, <shift>, <mask>

if !HaveFlagManipulateExt() then UNDEFINED;
integer lsb = UInt(imm6);
integer n = UInt(Rn);

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift> Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<mask> Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

Operation

bits(4) tmp;
bets(64) tmpreg = X[n];
tmp = (tmpreg:tmpreg)<lsb+3:lsb>;
if mask<3> == '1' then PSTATE.N = tmp<3>;
if mask<2> == '1' then PSTATE.Z = tmp<2>;
if mask<1> == '1' then PSTATE.C = tmp<1>;
if mask<0> == '1' then PSTATE.V = tmp<0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.

### 32-bit (sf == 0 && N == 0 && imms == 0xxxx)

ROR <Wd>, <Ws>, #<shift>

is equivalent to

EXTR <Wd>, <Ws>, <Ws>, #<shift>

and is the preferred disassembly when Rn == Rm.

### 64-bit (sf == 1 && N == 1)

ROR <Xd>, <Xs>, #<shift>

is equivalent to

EXTR <Xd>, <Xs>, <Xs>, #<shift>

and is the preferred disassembly when Rn == Rm.

**Assembler Symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Ws> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xs> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <shift> For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.
  
  For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

**Operation**

The description of EXTR gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.

- <Xm> is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;

**Operational Information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Speculation Barrier is a barrier that controls speculation. The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

```
if !HaveSBExt() then UNDEFINED;
```

**Operation**

```
SpeculationBarrier();
```

SBFIZ

Signed Bitfield Insert in Zeros copies a bitfield of \( \langle \text{width} \rangle \) bits from the least significant bits of the source register to bit position \( \langle \text{lsb} \rangle \) of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of \text{SBFM}. This means:

- The encodings in this description are named to match the encodings of \text{SBFM}.
- The description of \text{SBFM} gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

\text{SBFIZ} \ <Wd>, \ <Wn>, \ #\langle \text{lsb} \rangle, \ #\langle \text{width} \rangle

is equivalent to

\text{SBFM} \ <Wd>, \ <Wn>, \ #(-\langle \text{lsb} \rangle \mod 32), \ #(\langle \text{width} \rangle-1)

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

64-bit (sf == 1 && N == 1)

\text{SBFIZ} \ <Xd>, \ <Xn>, \ #\langle \text{lsb} \rangle, \ #\langle \text{width} \rangle

is equivalent to

\text{SBFM} \ <Xd>, \ <Xn>, \ #(-\langle \text{lsb} \rangle \mod 64), \ #(\langle \text{width} \rangle-1)

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

Assembler Symbols

- \( \langle Wd \rangle \): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle Wn \rangle \): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( \langle Xd \rangle \): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle Xn \rangle \): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \( \langle \text{lsb} \rangle \): For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \( \langle \text{width} \rangle \): For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-\( \langle \text{lsb} \rangle \).
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-\( \langle \text{lsb} \rangle \).

Operation

The description of \text{SBFM} gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SBFM

Signed Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.
If \( \text{immr} \) is greater than or equal to \( \text{imms} \), this copies a bitfield of \((\text{imms} - \text{immr}) + 1\) bits starting from bit position \( \text{immr} \) in the source register to the least significant bits of the destination register.
If \( \text{immr} \) is less than \( \text{imms} \), this copies a bitfield of \((\text{imms} + 1)\) bits from the least significant bits of the source register to bit position \((\text{regsize} - \text{immr})\) of the destination register, where \text{regsize} is the destination register size of 32 or 64 bits.
In both cases the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.

// determine extension bits (sign, zero or dest register)
bits(datasize) top = Replicate(src<S>);

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SBFX

Signed Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

<table>

32-bit (sf == 0 && N == 0)

SBFX <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

SBFM <Wd>, <Wn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

64-bit (sf == 1 && N == 1)

SBFX <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

SBFM <Xd>, <Xn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SDIV

Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit (sf == 0)

SDIV <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

SDIV <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;
if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero(Real(Int(operand1, FALSE)) / Real(Int(operand2, FALSE)));
X[d] = result<datasize-1:0>;
**SETF8, SETF16**

Set the PSTATE.NZV flags based on the value in the specified general-purpose register. SETF8 treats the value as an 8 bit value, and SETF16 treats the value as an 16 bit value. The PSTATE.C flag is not affected by these instructions.

### Integer

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SETGP, SETGM, SETGE**

Memory Set with tag setting. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGP, then SETGM, and then SETGE.

SETGP performs some preconditioning of the arguments suitable for using the SETGM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGM performs an IMPLEMENTATION DEFINED amount of the memory set. SETGE performs the last part of the memory set.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGP, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGP, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGM, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGM, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGE, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGE, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.
Epilogue (op2 == 1000)

**SETGPN, SETGMN, SETGEN**

Memory Set with tag setting, non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPN, then SETGMN, and then SETGEN.

SETGPN performs some preconditioning of the arguments suitable for using the SETGMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETGEN performs the last part of the memory set.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPN, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPN, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

SETGPT, SETGMT, SETGET

Memory Set with tag setting, unprivileged. These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPT, then SETGMT, and then SETGET.

SETGPT performs some preconditioning of the arguments suitable for using the SETGMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMT performs an IMPLEMENTATION DEFINED amount of the memory set. SETGET performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPT, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.(N,Z,V) are set to {0,0,0}.

After execution of SETGPT, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.(N,Z,V) are set to {0,0,0}.

For SETGMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGET, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

**SETP, SETM, SETE**

Memory Set. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETP, then SETM, and then SETE.

SETP performs some preconditioning of the arguments suitable for using the SETM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETM performs an IMPLEMENTATION DEFINED amount of the memory set. SETE performs the last part of the memory set.

**Note**

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

**Note**

Portable software should not assume that the choice of algorithm is constant.

After execution of SETP, option A (which results in encoding PSTATE.C = 0):
- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETP, option B (which results in encoding PSTATE.C = 1):
- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETM, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETM, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

For SETE, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETE, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

SETPN, SETMN, SETEN

Memory Set, non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPN, then SETMN, and then SETEN.

SETPN performs some preconditioning of the arguments suitable for using the SETMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETEN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPN, option A (which results in encoding PSTATE.C = 0):
- If \( X_n<63> == 1 \), the set size is saturated to \( 0x7FFFFFFFFFFFFFFF \).
- \( X_d \) holds the original \( X_d \) + saturated \( X_n \).
- \( X_n \) holds \(-1^*\) saturated \( X_n \) + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

After execution of SETPN, option B (which results in encoding PSTATE.C = 1):
- If \( X_n<63> == 1 \), the copy size is saturated to \( 0x7FFFFFFFFFFFFFFF \).
- \( X_d \) holds the original \( X_d \) + an IMPLEMENTATION DEFINED number of bytes set.
- \( X_n \) holds the saturated \( X_n \) - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

For SETMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- \( X_n \) is treated as a signed 64-bit number.
- \( X_n \) holds \(-1^*\) number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to - \( X_n \).
- At the end of the instruction, the value of \( X_n \) is written back with \(-1^*\) the number of bytes remaining to be set in the memory set in total.

For SETMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- \( X_n \) holds the number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of \( X_n \) is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of \( X_d \) is written back with the lowest address that has not been set.

For SETEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
- \( X_n \) is treated as a signed 64-bit number.
- \( X_n \) holds \(-1^*\) number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to - \( X_n \).
- At the end of the instruction, the value of \( X_n \) is written back with \(0\).

For SETEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
- \( X_n \) holds the number of bytes remaining to be set in the memory set in total.
- \( X_d \) holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of \( X_n \) is written back with \(0\).
  - the value of \( X_d \) is written back with the lowest address that has not been set.

SETPT, SETMT, SETET

Memory Set, unprivileged. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPT, then SETMT, and then SETET.

SETPT performs some preconditioning of the arguments suitable for using the SETMT instruction, and performs an implementation defined amount of the memory set. SETMT performs an implementation defined amount of the memory set. SETET performs the last part of the memory set.

Note

The inclusion of implementation defined amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is implementation defined.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPT, option A (which results in encoding PSTATE.C = 0):
• If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an implementation defined number of bytes set.
• PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

After execution of SETPT, option B (which results in encoding PSTATE.C = 1):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xd holds the original Xd + an implementation defined number of bytes set.
• Xn holds the saturated Xn - an implementation defined number of bytes set.
• PSTATE.\{N,Z,V\} are set to \{0,0,0\}.

For SETMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• Xn holds -1* number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
  ◦ the value of Xd is written back with the lowest address that has not been set.

For SETET, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• Xn holds -1* the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For SETET, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
  ◦ the value of Xd is written back with the lowest address that has not been set.

SETPTN, SETMTN, SETETN

Memory Set, unprivileged and non-temporal. These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPTN, then SETMTN, and then SETETN.

SETPTN performs some preconditioning of the arguments suitable for using the SETMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMTN performs an IMPLEMENTATION DEFINED amount of the memory set. SETETN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPTN, option A (which results in encoding PSTATE.C = 0):
• If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xd holds the original Xd + saturated Xn.
• Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
• PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPTN, option B (which results in encoding PSTATE.C = 1):
• If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
• Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
• Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
• PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• Xn holds -1* number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  ◦ the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  ◦ the value of Xd is written back with the lowest address that has not been set.

For SETETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:
• Xn is treated as a signed 64-bit number.
• Xn holds -1* the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to -Xn.
• At the end of the instruction, the value of Xn is written back with 0.

For SETETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:
• Xn holds the number of bytes remaining to be set in the memory set in total.
• Xd holds the lowest address that the set is made to.
• At the end of the instruction:
  ◦ the value of Xn is written back with 0.
  ◦ the value of Xd is written back with the lowest address that has not been set.

result = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));

X[d] = result<63:0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Secure Monitor Call causes an exception to EL3. SMC is available only for software executing at EL1 or higher. It is **UNDEFINED** in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value 0x17, that is taken to EL3.

If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is **UNDEFINED**.

**SMNEGL** \(<Xd>, <Wn>, <Wm>\)

is equivalent to

**SMSUBL** \(<Xd>, <Wn>, <Wm>, XZR\)

and is always the preferred disassembly.

**Assembler Symbols**

- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

The description of **SMSUBL** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v33.16decrel, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

• When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  ◦ The store is to the same location as the load.
  ◦ The store uses the same virtual address as the load.
  ◦ The store appears in program order before the SSBB.

• When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  ◦ The store is to the same location as the load.
  ◦ The store uses the same virtual address as the load.
  ◦ The store appears in program order after the SSBB.

This is an alias of DSB. This means:

• The encodings in this description are named to match the encodings of DSB.
• The description of DSB gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>CRm</th>

**No memory ordering (R == 0)**

STADDB <Ws>, [<Xn|SP>]

is equivalent to

LDADDB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**Release (R == 1)**

STADDLB <Ws>, [<Xn|SP>]

is equivalent to

LDADDB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

### Assembler Symbols

- <Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDH does not have release semantics.
- STADDLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH. This means:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in *Load-Acquire, Store-Release*. For information about memory accesses, see *Load/Store addressing modes*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    bits(datasize DIV 2) el1 = X[t];
    bits(datasize DIV 2) el2 = X[t2];
    data = if BigEndian(AccType_ORDEREDATOMIC) then el1:el2 else el2:el1;
    bit status = '1';
    // Check whether the Exclusives monitors are set to include the
    // physical memory locations corresponding to virtual address
    // range [address, address+dbytes-1].
    if AArch64.ExclusiveMonitorsPass(address, dbytes) then
        // This atomic write will be rejected if it does not refer
        // to the same physical locations after address translation.
        Mem[address, dbytes, AccType_ORDEREDATOMIC] = data;
        status = ExclusiveMonitorsStatus();
        X[s] = ZeroExtend(status, 32);
```
**STLXR**

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

### 32-bit (size == 10)

STLXR <Ws>, <Wt>, [<Xn|SP>{,,#0}]

### 64-bit (size == 11)

STLXR <Ws>, <Xt>, [<Xn|SP>{,,#0}]

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);  // ignored by all loads and store-release

integer elsize = 8 << UInt(size);
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt unknown = TRUE;  // store UNKNOWN value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
    if s == n && n != 31 then
        Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
        assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
        case c of
            when Constraint_UNKNOWN rn unknown = TRUE;  // address is UNKNOWN
            when Constraint_UNDEF UNDEFINED;
            when Constraint_NOP EndOfInstruction();
```

For information about the CONstrained UNpredictable behavior of this instruction, see *Architectural Constraints on UNpredictable behaviors*, and particularly *STLXR*.

**Assembler Symbols**

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:
- Memory is not updated.
Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize \div 8;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STRB (immediate)

Store Register Byte (immediate) stores the least significant byte of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes*.

It has encodings from 3 classes: *Post-index*, *Pre-index* and *Unsigned offset*.

Post-index

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------|-----------------|-----------------|
| size                | opc             |
```

```java
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------|-----------------|-----------------|
| size                | opc             |
```

```java
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------|-----------------|-----------------|
| size                | opc             |
```

```java
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

For information about the CONstrained unPREDITABLE behavior of this instruction, see *Architectural Constraints on UNPREDITABLE behaviors*, and particularly STRB (immediate).

Assembler Symbols

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSET, STSETL

Atomic bit set on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- **STSET** does not have release semantics.
- **STSETL** stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

This is an alias of **LDSET, LDSETA, LDSETAL, LDSETL**. This means:

**32-bit LDSET alias (size == 10 && R == 0)**

STSET <Ws>, [<Xn|SP>]

is equivalent to

LDSET <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**32-bit LDSETL alias (size == 10 && R == 1)**

STSETL <Ws>, [<Xn|SP>]

is equivalent to

LDSETL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDSET alias (size == 11 && R == 0)**

STSET <Xs>, [<Xn|SP>]

is equivalent to

LDSET <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDSETL alias (size == 11 && R == 1)**

STSETL <Xs>, [<Xn|SP>]

is equivalent to

LDSETL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSETB, STSETLB

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETB does not have release semantics.
- STSETLB stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB. This means:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

32-bit (size == 10)

STTR <Wt>, [<Xn|SP>, {, #simm}]

64-bit (size == 11)

STTR <Xt>, [<Xn|SP>, {, #simm}]

```
integer scale = UInt(size);
bias(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.
- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.
- `<simm>` Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Shared Decode

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype;
unpriv_at_el1 = PSTATE.EL == EL1 & & !(EL2Enabled() & & HaveNVExt() & & HCR_EL2.<NV,NV1> == '1');
unpriv_at_el2 = PSTATE.EL == EL2 & & HaveVirtHostExt() & & HCR_EL2.<E2H,TGE> == '1';

user_access_override = HaveUAOExt() & & PSTATE.UAO == '1';
if !user_access_override & & (unpriv_at_el1 || unpriv_at_el2) then
   acctype = AccType_UNPRIV;
else
   acctype = AccType_NORMAL;

integer datasize = 8 << scale;
boolean tag_checked = n != 31;
```
Operation

bits(64) address;
bets(datasize) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
address = address + offset;
data = X[t];
Mem[address, datasize DIV 8, acctype] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/Store addressing modes.

**Assembler Symbols**

- `<Wt>` is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared Decode**

```java
integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;
```

**Operation**

```java
bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, AccType_NORMAL] = data;
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Store Register Halfword (unscaled) calculates an address from a base register value and an immediate offset, and
stores a halfword to the calculated address, from a 32-bit register. For information about memory accesses, see Load/
Store addressing modes.

### Assembler Symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in
  the "imm9" field.

### Shared Decode

```
integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;
```

### Operation

```
bits(64) address;
bites(16) data;

if HaveMTEx2Ext() then
  SetTagCheckedInstruction(tag_checked);
if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n];

address = address + offset;
data = X[t];
Mem[address, 2, AccType_NORMAL] = data;
```

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses, see Load/Store addressing modes.

### 32-bit (sz == 0)

STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,,#0}]

### 64-bit (sz == 1)

STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,,#0}]

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);  // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release
integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;  // store UNKNOWN value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
    if s == n & n != 31 then
        Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
        assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
        case c of
            when Constraint_UNKNOWN rn_unknown = TRUE;  // address is UNKNOWN
            when Constraint_UNDEF UNDEFINED;
            when Constraint_NOP EndOfInstruction();
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXP.

### Assembler Symbols

- `<Ws>` is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.

- `<Xt1>` is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt2>` is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Wt1>` is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:
  - Memory is not updated.
  - <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
  - If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
  - Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsiif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
if rt_unknown then
    data = bits(datasize) UNKNOWN;
elsielse
    bits(datasize DIV 2) el1 = X[t];
    bits(datasize DIV 2) el2 = X[t2];
    data = if BigEndian(AccType_ATOMIC) then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the physical memory locations corresponding to virtual address range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information about memory accesses see *Load/Store addressing modes*.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly STXR.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.
Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Store Exclusive Register Byte stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic.

For information about memory accesses see Load/Store addressing modes.

For information about memory accesses see Load/Store addressing modes.

### Assembler Symbols

**<Ws>**

Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- **0** If the operation updates memory.
- **1** If the operation fails to update memory.

**<Wt>**

Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

**<Xn|SP>**

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- **<Ws>** is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly **STXRB**.
Operation

bits(64) address;
bits(8) data;

if HaveMTE2Ext() then
    SetTagCheckedInstruction(tag_checked);
endif

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
endif

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t];
endif

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 1) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**STXRH**

Store Exclusive Register Halfword stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See [Synchronization and semaphores](#). The memory access is atomic.

For information about memory accesses see [Load/Store addressing modes](#).

    Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
```

**Assembler Symbols**

- `<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:
- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

```c
bits(64) address;
bites(16) data;

if HaveMTEx2Ext() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STZ2G

Store Allocation Tags, Zeroing stores an Allocation Tag to two Tag granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset

Post-index
(Feat_MTE)

\[
\begin{array}{cccccccccccccccccccc}
1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & \text{imm9} & 0 & 1 & Xn & Xt \\
\end{array}
\]

Store Allocation Tag, Zeroing stores an Allocation Tag to memory, zeroing the associated data location. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset

### Post-index (FEAT_MTE)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 0  | 1  | Xn | Xt |

STZG `<Xt|SP>, [<Xn|SP>], #<simm>

if !HaveMTEExt() then UNDEFINED;
integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = TRUE;

### Pre-index (FEAT_MTE)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 1  | 1  | Xn | Xt |

STZG `<Xt|SP>, [<Xn|SP>, #<simm>]

if !HaveMTEExt() then UNDEFINED;
integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = FALSE;

### Signed offset (FEAT_MTE)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 1  | 0  | Xn | Xt |

STZG `<Xt|SP>, [<Xn|SP], #<simm>

if !HaveMTEExt() then UNDEFINED;
integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = FALSE;
boolean postindex = FALSE;

### Assembler Symbols

- `<Xt|SP>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Xt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Xn" field.
- `<simm>` Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.
Operation

bits(64) address;

\texttt{SetTagCheckedInstruction}(FALSE);

if \( n == 31 \) then
  \texttt{CheckSPAlignment}();
  address = \texttt{SP}[];
else
  address = \texttt{X}[n];

if !postindex then
  address = address + offset;

if address != \texttt{Align}(address, \texttt{TAG\_GRANULE}) then
  \texttt{AArch64.Abort}(address, \texttt{AlignmentFault}(\texttt{AccType\_NORMAL}, \texttt{TRUE}, \texttt{FALSE}));

\texttt{Mem}[address, \texttt{TAG\_GRANULE}, \texttt{AccType\_NORMAL}] = \texttt{Zeros}(\texttt{TAG\_GRANULE} * 8);

bits(64) data = if \( t == 31 \) then \texttt{SP}[] else \texttt{X}[t];
bits(4) tag = \texttt{AArch64.AllocationTagFromAddress}(data);
\texttt{AArch64.MemTag}[address, \texttt{AccType\_NORMAL}] = tag;

if writeback then
  if postindex then
    address = address + offset;
  if \( n == 31 \) then
    \texttt{SP}[] = address;
  else
    \texttt{X}[n] = address;
STZGM

Store Tag and Zero Multiple writes a naturally aligned block of N Allocation Tags and stores zero to the associated data locations, where the size of N is identified in DCZID_EL0.BS, and the Allocation Tag written to address A is taken from the source register bits<3:0>. This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

**Integer**

**(FEAT_MTE2)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

**SUB (extended register)**

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| sf | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 1 | Rm | option | imm3 | Rn | Rd |

**32-bit (sf == 0)**

\[
\text{SUB } \langle \text{Wd}\,|\,\text{WSP} \rangle, \langle \text{Wn}\,|\,\text{WSP} \rangle, \langle \text{Wm} \rangle, \langle \text{extend} \rangle \{\langle \text{#amount} \rangle \}
\]

**64-bit (sf == 1)**

\[
\text{SUB } \langle \text{Xd}\,|\,\text{SP} \rangle, \langle \text{Xn}\,|\,\text{SP} \rangle, \langle \text{R} \rangle \langle \text{m} \rangle, \langle \text{extend} \rangle \{\langle \text{#amount} \rangle \}
\]

integer \( d = \text{UInt}(\text{Rd}) \);
integer \( n = \text{UInt}(\text{Rn}) \);
integer \( m = \text{UInt}(\text{Rm}) \);
integer datasize = if sf == '1' then 64 else 32;
\[
\text{ExtendType extend_type = DecodeRegExtend(option)};
\]
integer shift = \( \text{UInt}(\text{imm3}) \);
if shift > 4 then UNDEFINED;

**Assembler Symbols**

- \( \langle \text{Wd}\,|\,\text{WSP} \rangle \): Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( \langle \text{Wn}\,|\,\text{WSP} \rangle \): Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \( \langle \text{Wm} \rangle \): Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \( \langle \text{Xd}\,|\,\text{SP} \rangle \): Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \( \langle \text{Xn}\,|\,\text{SP} \rangle \): Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \( \langle \text{R} \rangle \): Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>( \langle \text{R} \rangle )</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

\( \langle m \rangle \): Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

\( \langle \text{extend} \rangle \): For the 32-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>( \langle \text{extend} \rangle )</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>
If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SUB (immediate)**

Subtract (immediate) subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.

32-bit (sf == 0)

```
SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit (sf == 1)

```
SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case sh of
    when '0' imm = ZeroExtend(imm12, datasize);
    when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);

**Assembler Symbols**

- `<Wd|WSP>` is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.
- `<Wn|WSP>` is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.
- `<Xn|SP>` is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- `<imm>` is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.
- `<shift>` is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;
operand2 = NOT(imm);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
• The values of the data supplied in any of its registers.
• The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  • The values of the data supplied in any of its registers.
  • The values of the NZCV flags.
### SUB (shifted register)

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias **NEG (shifted register)**.

#### 32-bit (sf == 0)

Subtract \( <Wd> \), \( <Wn> \), \( <Wm> \)}, \( <\text{shift}> \) \(#<\text{amount}>\)

#### 64-bit (sf == 1)

Subtract \( <Xd> \), \( <Xn> \), \( <Xm> \)}, \( <\text{shift}> \) \(#<\text{amount}>\)

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

#### Assembler Symbols

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Xm>** Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<shift>** Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- **<amount>** For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

#### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>( Rn == '11111' )</td>
</tr>
</tbody>
</table>
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Subtract with Tag subtracts an immediate value scaled by the Tag granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

**Assembler Symbols**

- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Xd” field.
- `<Xn|SP>` is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Xn” field.
- `<uimm6>` is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the “uimm6” field.
- `<uimm4>` is an unsigned immediate, in the range 0 to 15, encoded in the “uimm4” field.

**Operation**

```plaintext
bits(64) operand1 = if n == 31 then SP[] else X[n];
bits(4) start_tag = AArch64.AllocationTagFromAddress(operand1);
bits(16) exclude = GCR_EL1.Exclude;
bits(64) result;
bits(4) rtag;
if AArch64.AllocationTagAccessIsEnabled(AccType_NORMAL) then
    rtag = AArch64.ChooseNonExcludedTag(start_tag, uimm4, exclude);
else
    rtag = '0000';
(result, -) = AddWithCarry(operand1, NOT(offset), '1');
result = AArch64.AddressWithAllocationTag(result, AccType_NORMAL, rtag);
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```
SUBP

Subtract Pointer subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64-bits, and writes the result to the destination register.

Integer

\[ \text{SUBP} \; <Xd>, \; <Xn|SP>, \; <Xm|SP> \]

if \(!\text{HaveMTEExt}()\) then UNDEFINED;
integer \(d = \text{UInt}(Xd);\)
integer \(n = \text{UInt}(Xn);\)
integer \(m = \text{UInt}(Xm);\)

Assembler Symbols

\(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Xd" field.
\(<Xn|SP>\) is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
\(<Xm|SP>\) is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

Operation

bits(64) \(\text{operand1} = \text{if } n == 31 \text{ then } SP[] \text{ else } X[n];\)
bites(64) \(\text{operand2} = \text{if } m == 31 \text{ then } SP[] \text{ else } X[m];\)
\(\text{operand1} = \text{SignExtend}(\text{operand1}<55:0>, 64);\)
\(\text{operand2} = \text{SignExtend}(\text{operand2}<55:0>, 64);\)
bites(64) \(\text{result};\)
\(\text{operand2} = \text{NOT}(\text{operand2});\)
\((\text{result}, \text{ -}) = \text{AddWithCarry}(\text{operand1}, \text{operand2}, '1');\)
\(X[d] = \text{result};\)
**SUBPS**

Subtract Pointer, setting Flags subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64-bits, and writes the result to the destination register. It updates the condition flags based on the result of the subtraction.

This instruction is used by the alias **CMPP**.

**SUBPS** `<Xd>`, `<Xn|SP>`, `<Xm|SP>`

```
if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
integer m = UInt(Xm);
```

### Assembler Symbols

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Xd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<Xm|SP>` Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMPP</td>
<td>$ S == '1' &amp;&amp; Xd == '11111'$</td>
</tr>
</tbody>
</table>

### Operation

```
bits(64) operand1 = if n == 31 then SP[] else X[n];
bits(64) operand2 = if m == 31 then SP[] else X[m];
operand1 = SignExtend(operand1<55:0>, 64);
operand2 = SignExtend(operand2<55:0>, 64);
bits(64) result;
bits(4) nzcv;
operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```
**SUBS (extended register)**

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias **CMP (extended register)**.

### 32-bit (sf == 0)

```plaintext
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

### 64-bit (sf == 1)

```plaintext
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>
If “Rn” is ‘11111’ (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when “imm3” is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

### Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

### Operational information

- If PSTATE.DIT is 1:
  - The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias **CMP (immediate)**.

### 32-bit (sf == 0)

**SUBS**<sup>Wd>, <Wn|WSP>, #<imm>{, <shift>}

### 64-bit (sf == 1)

**SUBS**<sup>Xd>, <Xn|SP>, #<imm>{, <shift>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

```plaintext
case sh of
    when '0' imm = ZeroExtend(imm12, datasize);
    when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

**Assembler Symbols**

SVC

Supervisor Call causes an exception to be taken to EL1. On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in `ESR_ELx`, using the EC value 0x15, and the value of the immediate argument.

```
  1 1 0 1 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1
```

SVC `#<imm>`

// Empty.

Assembler Symbols

`<imm>` Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.CheckForSVCTrap(imm16);
AArch64.CallSupervisor(imm16);
```
SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, SWPA and SWPAL load from memory with acquire semantics.
- SWPL and SWPAL store to memory with release semantics.
- SWP has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Aquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

SXTB <Wd>, <Wn>

is equivalent to

SBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

64-bit (sf == 1 & N == 1)

SXTB <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #7

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit (sf == 0 & N == 0)

SXTH \(<Wd>, <Wn>\)

is equivalent to

SBFM \(<Wd>, <Wn>, \#0, \#15\)

and is always the preferred disassembly.

### 64-bit (sf == 1 & N == 1)

SXTH \(<Xd>, <Wn>\)

is equivalent to

SBFM \(<Xd>, <Xn>, \#0, \#15\)

and is always the preferred disassembly.

**Assembler Symbols**

\(<Wd>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\)  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<Wn>\)  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:

Assembler Symbols

- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SYS

System instruction. For more information, see Op0 equals 0b01, cache maintenance, TLB maintenance, and address translation instructions for the encodings of System instructions.

This instruction is used by the aliases AT, CFP, CPP, DC, DVP, IC, and TLBI.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}

integer t = UInt(Rt);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Assembler Symbols

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

AArch64.SysInstr(1, sys_op1, sys_crn, sys.crm, sys_op2, t);
### Assembler Symbols

- `<Xt>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
- `<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cn>` Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

### Operation

```c
// No architecturally defined instructions here.
AArch64.SysInstrWithResult(1, sys_op1, sys_crn, sys_crm, sys_op2, t);
```
TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

<table>
<thead>
<tr>
<th>b5</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>b40</th>
<th>imm14</th>
<th>Rt</th>
</tr>
</thead>
</table>

\[ \text{op} \]

TBNZ <R><t>, #<imm>, <label>

integer \( t = \text{UInt}(\text{Rt}) \);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler Symbols

<\text{R}> \quad \text{Is a width specifier, encoded in “b5”:}

\begin{array}{c|c}
\text{b5} & \text{<R>} \\
0 & W \\
1 & X \\
\end{array}

In assembler source code an ‘X’ specifier is always permitted, but a ‘W’ specifier is only permitted when the bit number is less than 32.

<\text{t}> \quad \text{Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.}

<\text{imm}> \quad \text{Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.}

<\text{label}> \quad \text{Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.}

Operation

\begin{align*}
\text{bits(datasize) operand} &= \text{X}[t]; \\
\text{if operand<bit pos> == op then} \\
\quad \text{BranchTo}(\text{PC}[\] + offset, \text{BranchType_DIR}, \text{TRUE});
\end{align*}
TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

<table>
<thead>
<tr>
<th>b5</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>0</th>
<th>b40</th>
<th>imm14</th>
<th>Rt</th>
</tr>
</thead>
</table>

**Assembler Symbols**

- **<R>** Is a width specifier, encoded in “b5”:
  - b5 <R>
    - 0: W
    - 1: X
  In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

- **<t>** Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.

- **<imm>** Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

- **<label>** Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

**Operation**

```plaintext
integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

bits(datasize) operand = X[t];
if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_DIR, TRUE);
```

TLBI

TLB Invalidate operation. For more information, see \texttt{op0==0b01, cache maintenance, TLB maintenance, and address translation instructions}.

This is an alias of \texttt{SYS}. This means:

- The encodings in this description are named to match the encodings of \texttt{SYS}.
- The description of \texttt{SYS} gives the operational pseudocode for this instruction.

\begin{verbatim}
1 1 0 1 0 1 0 0 0 1 0 0 0 0 0 1
\end{verbatim}

\texttt{TLBI <tlbi_op>{, <Xt>}}

is equivalent to

\texttt{SYS #<op1>, C8, <Cm>, #<op2>{, <Xt>}}

and is the preferred disassembly when \texttt{SysOp(op1,'1000',CRm,op2) == Sys_TLBI}.

**Assembler Symbols**

- \texttt{<op1>} is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- \texttt{<Cm>} is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- \texttt{<op2>} is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- \texttt{<tlbi_op>} is a TLBI instruction name, as listed for the TLBI system instruction group, encoded in "op1:CRm:op2":

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to ‘11111’, encoded in the “Rt” field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If \textit{FEAT\_TRF} is not implemented, this instruction executes as a \textit{NOP}.

System
\textit{(FEAT\_TRF)}

\begin{verbatim}
    31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9   8   7   6   5   4   3   2   1   0
    1  1  0  1  0  1  0  0  0  0  0  1  1  0  0  1  0  0  0  1  0  0  1  0  1  1  1  1  1  1
\end{verbatim}

\textit{TSB CSYNC}

if !\texttt{HaveSelfHostedTrace}() then \texttt{EndOfInstruction}();

\textbf{Operation}

\texttt{TraceSynchronizationBarrier}();

TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result

: Rn AND imm.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

```
| sf | 1 | 1 | 1 | 1 | 0 | 0 | 0 | N | immr | imms | Rn | 1 | 1 | 1 | 1 | Rd |
```

**32-bit (sf == 0 && N == 0)**

TST <Wn>, #<imm>

is equivalent to

ANDS WZR, <Wn>, #<imm>

and is always the preferred disassembly.

**64-bit (sf == 1)**

TST <Xn>, #<imm>

is equivalent to

ANDS XZR, <Xn>, #<imm>

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<imm>` For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

32-bit \( (sf == 0) \)

TST \(<Wn>, <Wm>{, <shift> #<amount>}\)

is equivalent to

ANDS WZR, \(<Wn>, <Wm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

64-bit \( (sf == 1) \)

TST \(<Xn>, <Xm>{, <shift> #<amount>}\)

is equivalent to

ANDS XZR, \(<Xn>, <Xm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

Assembler Symbols

\(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<shift>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**UBFIZ**

Unsigned Bitfield Insert in Zeros copies a bitfield of \(<width>\) bits from the least significant bits of the source register to bit position \(<lsb>\) of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of **UBFM**. This means:

- The encodings in this description are named to match the encodings of **UBFM**.
- The description of **UBFM** gives the operational pseudocode for this instruction.

![Register Encoding](image)

**32-bit (sf == 0 & N == 0)**

**UBFIZ <Wd>, <Wn>, #<lsb>, #<width>**

is equivalent to

**UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)**

and is the preferred disassembly when \(\text{UInt(imms)} < \text{UInt(immr)}\).

**64-bit (sf == 1 & N == 1)**

**UBFIZ <Xd>, <Xn>, #<lsb>, #<width>**

is equivalent to

**UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)**

and is the preferred disassembly when \(\text{UInt(imms)} < \text{UInt(immr)}\).

**Assembler Symbols**

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<lsb>\): For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<width>\): For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of **UBFM** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**UBFM**

Unsigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If `<imms>` is greater than or equal to `<immr>`, this copies a bitfield of `(imms-<immr>+1)` bits starting from bit position `<immr>` in the source register to the least significant bits of the destination register.

If `<imms>` is less than `<immr>`, this copies a bitfield of `(imms+1)` bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH.

bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// combine extension bits and result bits
X[d] = bot AND tmask;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
UBFX

Unsigned Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This is an alias of UBFM. This means:

• The encodings in this description are named to match the encodings of UBFM.
• The description of UBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

UBFX <Wd>, <Wn>, <lsb>, <width>

is equivalent to

UBFM <Wd>, <Wn>, <lsb>, (<lsb>+(<width>-1))

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

64-bit (sf == 1 && N == 1)

UBFX <Xd>, <Xn>, <lsb>, <width>

is equivalent to

UBFM <Xd>, <Xn>, <lsb>, (<lsb>+(<width>-1))

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32.<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64.<lsb>.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED.

```

**32-bit**

UXTH `<Wd>, <Wn>`

is equivalent to

UBFM `<Wd>, <Wn>, #0, #15`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of UBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 0 1 1 0 0 1 0 0 0 0 0 0 1 0 1 1 1 1
```

WFE

// Empty.

Operation

```
Hint_WFE(1, WFxType_WFE);
```

Wait For Event with Timeout is a hint instruction that indicates that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see Wait For Event mechanism and Send event.

As described in Wait For Event mechanism and Send event, the execution of a WFET instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

XAFLAG

Convert floating-point condition flags from external format to Arm format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from an alternative representation required by some software to a form representing the result of an Arm floating-point scalar compare instruction.

System
(FEAT_FlagM2)

if !HaveFlagFormatExt() then UNDEFINED;

Operation

bit N = NOT(PSTATE.C) AND NOT(PSTATE.Z);
bz Z = PSTATE.Z AND PSTATE.C;
bz C = PSTATE.C OR PSTATE.Z;
bz V = NOT(PSTATE.C) AND PSTATE.Z;

PSTATE.N = N;
PSTATE.Z = Z;
PSTATE.C = C;
PSTATE.V = V;
XPACD, XPACI, XPACLRI

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPACI and XPACD, and is in LR for XPACLRI. The XPACD instruction is used for data addresses, and XPACI and XPACLRI are used for instruction addresses. It has encodings from 2 classes: Integer and System.

Integer
(FEAT_PAuth)

```
0 0 0 0 0 0 0 1 0 0 1 1 0 1 0 1 1 1 1 1 1 1
```

XPACD (D == 1)

```
XPACD <Xd>
```

XPACI (D == 0)

```
XPACI <Xd>
```

```java
boolean data = (D == '1');
integer d = UInt(Rd);
if !HavePACExt() then
    UNDEFINED;
```

System
(FEAT_PAuth)

```
0 0 0 0 0 0 0 1 0 0 1 1 0 1 0 1 1 1 1 1 1 1
```

XPACLRI

```
integer d = 30;
boolean data = FALSE;
```

Assembler Symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

```
if HavePACExt() then
    X[d] = Strip(X[d], data);
```

Internal version only: isa v33.16decrel, AdvSIMD v29.05, pseudocode v2021-12_rel, sve v2021-12 ; Build timestamp: 2021-12-15T12:33

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability. For more information about the recommended use of this instruction, see The YIELD instruction.

Operation

```
// Empty.

Hint_Yield();
```

A64 -- SIMD and Floating-point Instructions (alphabetic order)

**ABS**: Absolute value (vector).

**ADD (vector)**: Add (vector).

**ADDHN, ADDHN2**: Add returning High Narrow.

**ADDP (scalar)**: Add Pair of elements (scalar).

**ADDP (vector)**: Add Pairwise (vector).

**ADDV**: Add across Vector.

**AESD**: AES single round decryption.

**AESE**: AES single round encryption.

**AESIMC**: AES inverse mix columns.

**AESMC**: AES mix columns.

**AND (vector)**: Bitwise AND (vector).

**BCAX**: Bit Clear and XOR.

**BFCVT**: Floating-point convert from single-precision to BFloat16 format (scalar).

**BFCVTN, BFCVTN2**: Floating-point convert from single-precision to BFloat16 format (vector).

**BFDOT (by element)**: BFloat16 floating-point dot product (vector, by element).

**BFDOT (vector)**: BFloat16 floating-point dot product (vector).

**BFMLALB, BFMLALT (by element)**: BFloat16 floating-point widening multiply-add long (by element).

**BFMLALB, BFMLALT (vector)**: BFloat16 floating-point widening multiply-add long (vector).

**BFMMLA**: BFloat16 floating-point matrix multiply-accumulate into 2x2 matrix.

**BIC (vector, immediate)**: Bitwise bit Clear (vector, immediate).

**BIC (vector, register)**: Bitwise bit Clear (vector, register).

**BIF**: Bitwise Insert if False.

**BIT**: Bitwise Insert if True.

**BSL**: Bitwise Select.

**CLS (vector)**: Count Leading Sign bits (vector).

**CLZ (vector)**: Count Leading Zero bits (vector).

**CMEQ (register)**: Compare bitwise Equal (vector).

**CMEQ (zero)**: Compare bitwise Equal to zero (vector).

**CMGE (register)**: Compare signed Greater than or Equal (vector).

**CMGE (zero)**: Compare signed Greater than or Equal to zero (vector).

**CMGT (register)**: Compare signed Greater than (vector).

**CMGT (zero)**: Compare signed Greater than zero (vector).

**CMHI (register)**: Compare unsigned Higher (vector).

**CMHS (register)**: Compare unsigned Higher or Same (vector).
CMLE (zero): Compare signed Less than or Equal to zero (vector).
CMLT (zero): Compare signed Less than zero (vector).
CMTST: Compare bitwise Test bits nonzero (vector).
CNT: Population Count per byte.
DUP (element): Duplicate vector element to vector or scalar.
DUP (general): Duplicate general-purpose register to vector.
EOR (vector): Bitwise Exclusive OR (vector).
EOR3: Three-way Exclusive OR.
EXT: Extract vector from pair of vectors.
FABD: Floating-point Absolute Difference (vector).
FABS (scalar): Floating-point Absolute value (scalar).
FABS (vector): Floating-point Absolute value (vector).
FACGE: Floating-point Absolute Compare Greater than or Equal (vector).
FACGT: Floating-point Absolute Compare Greater than (vector).
FADD (scalar): Floating-point Add (scalar).
FADD (vector): Floating-point Add (vector).
FADDP (scalar): Floating-point Add Pair of elements (scalar).
FADDP (vector): Floating-point Add Pairwise (vector).
FCADD: Floating-point Complex Add.
FCCMP: Floating-point Conditional quiet Compare (scalar).
FCCMPE: Floating-point Conditional signaling Compare (scalar).
FCMEQ (register): Floating-point Compare Equal (vector).
FCMEQ (zero): Floating-point Compare Equal to zero (vector).
FCMGE (register): Floating-point Compare Greater than or Equal (vector).
FCMGE (zero): Floating-point Compare Greater than or Equal to zero (vector).
FCMGT (register): Floating-point Compare Greater than (vector).
FCMGT (zero): Floating-point Compare Greater than zero (vector).
FCMLA: Floating-point Complex Multiply Accumulate.
FCMLA (by element): Floating-point Complex Multiply Accumulate (by element).
FCMLE (zero): Floating-point Compare Less than or Equal to zero (vector).
FCMLT (zero): Floating-point Compare Less than zero (vector).
FCMP: Floating-point quiet Compare (scalar).
FCMPE: Floating-point signaling Compare (scalar).
FCSEL: Floating-point Conditional Select (scalar).
FCVT: Floating-point Convert precision (scalar).
FCVTAS (scalar): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar).
FCVTAS (vector): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector).
FCVTAU (scalar): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar).
FCVTAU (vector): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (vector).
FCVTLL, FCVTLL2: Floating-point Convert to higher precision Long (vector).
FCVTMS (scalar): Floating-point Convert to Signed integer, rounding toward Minus infinity (scalar).
FCVTMS (vector): Floating-point Convert to Signed integer, rounding toward Minus infinity (vector).
FCVTMU (scalar): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar).
FCVTMU (vector): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (vector).
FCVTNL, FCVTNL2: Floating-point Convert to lower precision Narrow (vector).
FCVTPS (scalar): Floating-point Convert to Signed integer, rounding toward Plus infinity (scalar).
FCVTPS (vector): Floating-point Convert to Signed integer, rounding toward Plus infinity (vector).
FCVTPU (scalar): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (scalar).
FCVTPU (vector): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (vector).
FCVTNXN, FCVTNXN2: Floating-point Convert to lower precision Narrow, rounding to odd (vector).
FCVTZS (scalar, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar).
FCVTZS (scalar, integer): Floating-point Convert to Signed integer, rounding toward Zero (scalar).
FCVTZS (vector, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (vector).
FCVTZS (vector, integer): Floating-point Convert to Signed integer, rounding toward Zero (vector).
FCVTZU (scalar, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (scalar).
FCVTZU (scalar, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (scalar).
FCVTZU (vector, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (vector).
FCVTZU (vector, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (vector).
FDIV (scalar): Floating-point Divide (scalar).
FDIV (vector): Floating-point Divide (vector).
FJCVTZS: Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero.
FMADD: Floating-point fused Multiply-Add (scalar).
FMAX (scalar): Floating-point Maximum (scalar).
FMAX (vector): Floating-point Maximum (vector).
FMAXNM (scalar): Floating-point Maximum Number (scalar).
FMAXNM (vector): Floating-point Maximum Number (vector).
FMAXNMP (scalar): Floating-point Maximum Number of Pair of elements (scalar).
FMAXNMP (vector): Floating-point Maximum Number Pairwise (vector).

LD4 (single structure): Load single 4-element structure to one lane of four registers.
LD4R: Load single 4-element structure and Replicate to all lanes of four registers.
LDNP (SIMD&FP): Load Pair of SIMD&FP registers, with Non-temporal hint.
LDP (SIMD&FP): Load Pair of SIMD&FP registers.
LDR (immediate, SIMD&FP): Load SIMD&FP Register (immediate offset).
LDR (literal, SIMD&FP): Load SIMD&FP Register (PC-relative literal).
LDR (register, SIMD&FP): Load SIMD&FP Register (register offset).
LDUR (SIMD&FP): Load SIMD&FP Register (unscaled offset).
MLA (by element): Multiply-Add to accumulator (vector, by element).
MLA (vector): Multiply-Add to accumulator (vector).
MLS (by element): Multiply-Subtract from accumulator (vector, by element).
MLS (vector): Multiply-Subtract from accumulator (vector).
MOV (element): Move vector element to another vector element: an alias of INS (element).
MOV (from general): Move general-purpose register to a vector element: an alias of INS (general).
MOV (scalar): Move vector element to scalar: an alias of DUP (element).
MOV (to general): Move vector element to general-purpose register: an alias of UMOV.
MOVI: Move Immediate (vector).
MUL (by element): Multiply (vector, by element).
MUL (vector): Multiply (vector).
MVN: Bitwise NOT (vector): an alias of NOT.
MVNI: Move inverted Immediate (vector).
NEG (vector): Negate (vector).
NOT: Bitwise NOT (vector).
ORN (vector): Bitwise inclusive OR NOT (vector).
ORR (vector, immediate): Bitwise inclusive OR (vector, immediate).
ORR (vector, register): Bitwise inclusive OR (vector, register).
PMUL: Polynomial Multiply.
PMULL, PMULL2: Polynomial Multiply Long.
RADDHN, RADDHN2: Rounding Add returning High Narrow.
RAX1: Rotate and Exclusive OR.
RBIT (vector): Reverse Bit order (vector).
REV16 (vector): Reverse elements in 16-bit halfwords (vector).
REV32 (vector): Reverse elements in 32-bit words (vector).
REV64: Reverse elements in 64-bit doublewords (vector).
RSHRN, RSHRN2: Rounding Shift Right Narrow (immediate).
RSUBHN, RSUBHN2: Rounding Subtract returning High Narrow.
SABA: Signed Absolute difference and Accumulate.
SABAL, SABAL2: Signed Absolute difference and Accumulate Long.
SABD: Signed Absolute Difference.
SABDL, SABDL2: Signed Absolute Difference Long.
SADALP: Signed Add and Accumulate Long Pairwise.
SADDL, SADDL2: Signed Add Long (vector).
SADDP: Signed Add Long Pairwise.
SADDLV: Signed Add Long across Vector.
SADDW, SADDW2: Signed Add Wide.
SCVTF (scalar, fixed-point): Signed fixed-point Convert to Floating-point (scalar).
SCVTF (scalar, integer): Signed integer Convert to Floating-point (scalar).
SCVTF (vector, fixed-point): Signed fixed-point Convert to Floating-point (vector).
SCVTF (vector, integer): Signed integer Convert to Floating-point (vector).
SDOT (by element): Dot Product signed arithmetic (vector, by element).
SDOT (vector): Dot Product signed arithmetic (vector).
SHA1C: SHA1 hash update (choose).
SHA1H: SHA1 fixed rotate.
SHA1M: SHA1 hash update (majority).
SHA1P: SHA1 hash update (parity).
SHA1SU0: SHA1 schedule update 0.
SHA1SU1: SHA1 schedule update 1.
SHA256H: SHA256 hash update (part 1).
SHA256H2: SHA256 hash update (part 2).
SHA256SU0: SHA256 schedule update 0.
SHA256SU1: SHA256 schedule update 1.
SHA512H: SHA512 Hash update part 1.
SHA512H2: SHA512 Hash update part 2.
SHA512SU0: SHA512 Schedule Update 0.
SHA512SU1: SHA512 Schedule Update 1.
SHADD: Signed Halving Add.
SHL: Shift Left (immediate).
SHLL, SHLL2: Shift Left Long (by element size).
SHRN, SHRN2: Shift Right Narrow (immediate).
SHSUB: Signed Halving Subtract.
SII: Shift Left and Insert (immediate).
SM3PARTW1: SM3PARTW1.
SM3PARTW2: SM3PARTW2.
SM3SS1: SM3SS1.
SM3TT1A: SM3TT1A.
SM3TT1B: SM3TT1B.
SM3TT2A: SM3TT2A.
SM3TT2B: SM3TT2B.
SM4E: SM4 Encode.
SM4EKEY: SM4 Key.
SMAX: Signed Maximum (vector).
SMAXP: Signed Maximum Pairwise.
SMAXV: Signed Maximum across Vector.
SMIN: Signed Minimum (vector).
SMINP: Signed Minimum Pairwise.
SMINV: Signed Minimum across Vector.
SMLSL, SMLSL2 (by element): Signed Multiply-Subtract Long (vector, by element).
SMMLA (vector): Signed 8-bit integer matrix multiply-accumulate (vector).
SMOV: Signed Move vector element to general-purpose register.
SQABS: Signed saturating Absolute value.
SQADD: Signed saturating Add.
SQDMLSL, SQDMLSL2 (by element): Signed saturating Doubling Multiply-Subtract Long (by element).

SQDMLUH (by element): Signed saturating Doubling Multiply returning High half (by element).

SQDMLUH (vector): Signed saturating Doubling Multiply returning High half.

SQDMULL, SQDMULL2 (by element): Signed saturating Doubling Multiply Long (by element).

SQNEG: Signed saturating Negate.

SQRDMLAH (by element): Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element).

SQRDMLAH (vector): Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (vector).

SQRDMLSH (by element): Signed Saturating Rounding Doubling Multiply Subtract returning High Half (by element).

SQRDMLSH (vector): Signed Saturating Rounding Doubling Multiply Subtract returning High Half.

SQRSHL: Signed saturating Rounding Shift Left (register).

SQRSHRN, SQRSHRN2: Signed saturating Rounded Shift Right Narrow (immediate).

SQRSHRUN, SQRSHRUN2: Signed saturating Rounded Shift Right Unsigned Narrow (immediate).

SQRSHL (immediate): Signed saturating Shift Left (immediate).

SQRSHL (register): Signed saturating Shift Left (register).

SQRSHLU: Signed saturating Shift Left Unsigned (immediate).

SQRSHRN, SQRSHRN2: Signed saturating Shift Right Narrow (immediate).

SQRSHRUN, SQRSHRUN2: Signed saturating Shift Right Unsigned Narrow (immediate).

SQRSUB: Signed saturating Subtract.

SQXTN, SQXTN2: Signed saturating extract Narrow.

SOXTUN, SOXTUN2: Signed saturating extract Unsigned Narrow.

SRHADD: Signed Rounding Halving Add.

SRI: Shift Right and Insert (immediate).

SRSRL: Signed Rounding Shift Left (register).

SRSRH: Signed Rounding Shift Right (immediate).

SRSRA: Signed Rounding Shift Right and Accumulate (immediate).

SSHLL, SSHLL2: Signed Shift Left Long (immediate).

SSHR: Signed Shift Right (immediate).

SSRA: Signed Shift Right and Accumulate (immediate).

SSUBL, SSUBL2: Signed Subtract Long.

SSUBW, SSUBW2: Signed Subtract Wide.

ST1 (multiple structures): Store multiple single-element structures from one, two, three, or four registers.

ST1 (single structure): Store a single-element structure from one lane of one register.
**ST2 (multiple structures)**: Store multiple 2-element structures from two registers.

**ST2 (single structure)**: Store single 2-element structure from one lane of two registers.

**ST3 (multiple structures)**: Store multiple 3-element structures from three registers.

**ST3 (single structure)**: Store single 3-element structure from one lane of three registers.

**ST4 (multiple structures)**: Store multiple 4-element structures from four registers.

**ST4 (single structure)**: Store single 4-element structure from one lane of four registers.

**STNP (SIMD&FP)**: Store Pair of SIMD&FP registers, with Non-temporal hint.

**STP (SIMD&FP)**: Store Pair of SIMD&FP registers.

**STR (immediate, SIMD&FP)**: Store SIMD&FP register (immediate offset).

**STR (register, SIMD&FP)**: Store SIMD&FP register (register offset).

**STUR (SIMD&FP)**: Store SIMD&FP register (unscaled offset).

**SUB (vector)**: Subtract (vector).

**SUBHN, SUBHN2**: Subtract returning High Narrow.

**SUDOT (by element)**: Dot product with signed and unsigned integers (vector, by element).

**SUQADD**: Signed saturating Accumulate of Unsigned value.

**SXTL, SXTL2**: Signed extend Long: an alias of SSHLL, SSHLL2.

**TBL**: Table vector Lookup.

**TBX**: Table vector lookup extension.

**TRN1**: Transpose vectors (primary).

**TRN2**: Transpose vectors (secondary).

**UABA**: Unsigned Absolute difference and Accumulate.

**UABAL, UABAL2**: Unsigned Absolute difference and Accumulate Long.

**UABD**: Unsigned Absolute Difference (vector).

**UABDL, UABDL2**: Unsigned Absolute Difference Long.

**UADALP**: Unsigned Add and Accumulate Long Pairwise.

**UADDL, UADDL2**: Unsigned Add Long (vector).

**UADLP**: Unsigned Add Long Pairwise.

**UADLV**: Unsigned sum Long across Vector.

**UADDW, UADDW2**: Unsigned Add Wide.

**UCVT (scalar, fixed-point)**: Unsigned fixed-point Convert to Floating-point (scalar).

**UCVT (scalar, integer)**: Unsigned integer Convert to Floating-point (scalar).

**UCVT (vector, fixed-point)**: Unsigned fixed-point Convert to Floating-point (vector).

**UCVT (vector, integer)**: Unsigned integer Convert to Floating-point (vector).

**UDOT (by element)**: Dot Product unsigned arithmetic (vector, by element).

**UDOT (vector)**: Dot Product unsigned arithmetic (vector).

**UHADD**: Unsigned Halving Add.
**UHSUB**: Unsigned Halving Subtract.

**UMAX**: Unsigned Maximum (vector).

**UMAXP**: Unsigned Maximum Pairwise.

**UMAXV**: Unsigned Maximum across Vector.

**UMIN**: Unsigned Minimum (vector).

**UMINP**: Unsigned Minimum Pairwise.

**UMINV**: Unsigned Minimum across Vector.

**UMLAL, UMLAL2 (by element)**: Unsigned Multiply-Add Long (vector, by element).

**UMLAL, UMLAL2 (vector)**: Unsigned Multiply-Add Long (vector).

**UMLSL, UMLSL2 (by element)**: Unsigned Multiply-Subtract Long (vector, by element).

**UMLSL, UMLSL2 (vector)**: Unsigned Multiply-Subtract Long (vector).

**UMMLA (vector)**: Unsigned 8-bit integer matrix multiply-accumulate (vector).

**UMOV**: Unsigned Move vector element to general-purpose register.

**UMULL, UMULL2 (by element)**: Unsigned Multiply Long (vector, by element).

**UMULL, UMULL2 (vector)**: Unsigned Multiply long (vector).

**UQADD**: Unsigned saturating Add.

**UQRSHL**: Unsigned saturating Rounding Shift Left (register).

**UQRSHRN, UQRSHRN2**: Unsigned saturating Rounded Shift Right Narrow (immediate).

**UQSHL (immediate)**: Unsigned saturating Shift Left (immediate).

**UQSHL (register)**: Unsigned saturating Shift Left (register).

**UQSHRN, UQSHRN2**: Unsigned saturating Shift Right Narrow (immediate).

**UQSUB**: Unsigned saturating Subtract.

**UQXTN, UQXTN2**: Unsigned saturating extract Narrow.

**URECPE**: Unsigned Reciprocal Estimate.

**URHADD**: Unsigned Rounding Halving Add.

**URSHL**: Unsigned Rounding Shift Left (register).

**URSHR**: Unsigned Rounding Shift Right (immediate).

**URSORTE**: Unsigned Reciprocal Square Root Estimate.

**URSRA**: Unsigned Rounding Shift Right and Accumulate (immediate).

**USDOT (by element)**: Dot Product with unsigned and signed integers (vector, by element).

**USDOT (vector)**: Dot Product with unsigned and signed integers (vector).

**USHL**: Unsigned Shift Left (register).

**USHLL, USHLL2**: Unsigned Shift Left Long (immediate).

**USHR**: Unsigned Shift Right (immediate).

**USMMLA (vector)**: Unsigned and signed 8-bit integer matrix multiply-accumulate (vector).

**USQADD**: Unsigned saturating Accumulate of Signed value.
**USRA**: Unsigned Shift Right and Accumulate (immediate).

**USUBL, USUBL2**: Unsigned Subtract Long.

**USUBW, USUBW2**: Unsigned Subtract Wide.

**UXTL, UXTL2**: Unsigned extend Long: an alias of USHLL, USHLL2.

**UZP1**: Unzip vectors (primary).

**UZP2**: Unzip vectors (secondary).

**XAR**: Exclusive OR and Rotate.

**XTN, XTN2**: Extract Narrow.

**ZIP1**: Zip vectors (primary).

**ZIP2**: Zip vectors (secondary).
**ABS**

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped. It has encodings from 2 classes: Scalar and Vector.

**Scalar**

        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

```
0 1 0 1 1 1 1 0 | size 1 | Rm 1 0 0 0 0 1 | Rn 1 0 0 0 0 1 | Rd
```

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see \textit{RADDHN}.

The \textit{ADDHN} instruction writes the vector to the lower half of the destination register and clears the upper half, while the \textit{ADDHN2} instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the \textit{CPACR_EL1}, \textit{CPTR_EL2}, and \textit{CPTR_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\begin{verbatim}
ADDHN(2) <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
\end{verbatim}

\begin{verbatim}
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean round = (U == '1');
\end{verbatim}

\textbf{Assembler Symbols}

2 \hspace{1cm} Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

\begin{verbatim}
Q 0 1
\end{verbatim}

\begin{verbatim}
[absent] [present]
\end{verbatim}

\textbf{<Vd>} \hspace{1cm} Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\textbf{<Tb>} \hspace{1cm} Is an arrangement specifier, encoded in "size:Q":

\begin{verbatim}
size Q <Tb>
00 0  8B
00 1  16B
01 0  4H
01 1  8H
10 0  2S
10 1  4S
11 x  RESERVED
\end{verbatim}

\textbf{<Vn>} \hspace{1cm} Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\textbf{<Ta>} \hspace{1cm} Is an arrangement specifier, encoded in "size":

\begin{verbatim}
size <Ta>
00  8H
01  4S
10  2D
11  RESERVED
\end{verbatim}

\textbf{<Vm>} \hspace{1cm} Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;
for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembly Symbols

<ADDP> <V>d>, <Vn>..<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize * 2;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDP (vector)

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BCAX

Bit Clear and Exclusive OR performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register. This instruction is implemented only when FEAT_SHA3 is implemented.

Advanced SIMD (FEAT_SHA3)

BFCVT

Floating-point convert from single-precision to BFloat16 format (scalar) converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

ID AA64ISARI_EL1.BF16 indicates whether this instruction is supported.

Single-precision to BFloat16

(Feat_BF16)

<table>
<thead>
<tr>

</table>

BFCVT <Hd>, <Sn>

if !HaveBF16Ext() then UNDEFINED;
integer n = UInt(Rn);
integer d = UInt(Rd);

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(32) operand = V[n];
FPCRTYPE fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

Elem[result, 0, 16] = FPConvertBF(operand, fpcr);

V[d] = result;
BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector) reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The BFCVTN instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero, while the BFCVTN2 instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

Vector single-precision to BFloat16

BFDOT (by element)

BFloat16 floating-point dot product (vector, by element). This instruction delimits the source vectors into pairs of BFloat16 elements.

Irrespective of the control bits in the FPCR, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.

The BFloat16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

    Elem[result, e, 32] = sum;
V[d] = result;
BFMLALB, BFMLALT (by element)

BFLOAT16 floating-point widening multiply-add long (by element) widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and the indexed element in the second source vector from BFLOAT16 to single-precision format. The instruction then multiplies and adds these values without intermediate rounding to single-precision elements of the destination vector that overlap with the corresponding BFLOAT16 elements in the first source vector.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

BFMMLA

BFLOAT16 floating-point matrix multiply-accumulate into 2x2 matrix.
Irrespective of the control bits in the FPCR, this instruction:

- Performs two unfused sums-of-products within each two pairs of adjacent BFLOAT16 elements while multiplying the 2x4 matrix of BFLOAT16 values in the first source vector with the 4x2 matrix of BFLOAT16 values in the second source vector. The intermediate single-precision products are rounded before they are summed and the intermediate sum is rounded before accumulation into the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating two 2-way unfused dot products per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Generates only the default NaN, as if FPCR.DN is 1.

Note

Arm expects that the BFMMLA instruction will deliver a peak BFLOAT16 multiply throughput that is at least as high as can be achieved using two BFDOT instructions, with a goal that it should have significantly higher throughput.

  \item The values of the NZCV flags.
  \end{itemize}
\end{itemize}
**CLS (vector)**

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
The values of the data supplied in any of its registers.

The values of the NZCV flags.
CLZ (vector)

Count Leading Zero bits (vector). This instruction counts the number of consecutive zeros, starting from the most significant bit, in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
CMEQ (register)

Compare bitwise Equal (vector). This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector.

        Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Compare signed Greater than (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

CMLE (zero)

Compare signed Less than or Equal to zero (vector). This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**Scalar**

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**CMTST**

Compare bitwise Test bits nonzero (vector). This instruction reads each vector element in the first source SIMD&FP register, performs an AND with the corresponding vector element in the second source SIMD&FP register, and if the result is not zero, sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CNT

Population Count per byte. This instruction counts the number of bits that have a value of one in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|------------------------------------------|----------|----------|
| 0 0 0 1 1 1 0 0 0 0 0 0 0 1 0 1 1 0     |
| size | Rd | Rn |
```

CNT <Vd>.<T>, <Vn>.<T>

```
integer d = UInt(Rd);
integer n = UInt(Rn);

DUP (element)

Duplicate vector element to vector or scalar. This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias \texttt{MOV (scalar)}.

It has encodings from 2 classes: \texttt{Scalar} and \texttt{Vector}.

\textbf{Scalar}

\begin{verbatim}
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
DUP (general)

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
// imm5<4:size+1> is IGNORED
if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in “imm5:Q”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>x</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>xxxx1</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>
<td>xxx10</td>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>xxx10</td>
<td>1</td>
<td>8H</td>
</tr>
<tr>
<td>xx100</td>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>xx100</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>x1000</td>
<td>0</td>
<td>RESERVED</td>
</tr>
<tr>
<td>x1000</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

<R> Is the width specifier for the general-purpose source register, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>W</td>
</tr>
<tr>
<td>xxx10</td>
<td>W</td>
</tr>
<tr>
<td>xx100</td>
<td>W</td>
</tr>
<tr>
<td>x1000</td>
<td>X</td>
</tr>
</tbody>
</table>

Unspecified bits in “imm5” are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**EOR (vector)**

Bitwise Exclusive OR (vector). This instruction performs a bitwise Exclusive OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 1 1 0 0 0 1 1 1 0 0 0 1 1 1 1 0 0 0 0 0 0 0 1 1 1 0
```

EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

**Assembler Symbols**

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<T>** Is an arrangement specifier, encoded in “Q”:

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

- **<Vn>** Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- **<Vm>** Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];
operand1 = V[m];
operand2 = Zeros();
operand3 = Ones();
V[d] = operand1 EOR ((operand2 EOR operand4) AND operand3);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when \textit{FEAT\_SHA3} is implemented.

### Advanced SIMD
\textbf{(FEAT\_SHA3)}

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

integer a = \text{UInt}(Ra);

### Assembler Symbols

\(<V_d>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
\(<V_n>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
\(<V_m>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
\(<V_a>\) Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

### Operation

\texttt{AArch64.CheckFPAvSIMDEnabled();}

\texttt{bits(128) \ V_m = V[m];}
\texttt{bits(128) \ V_n = V[n];}
\texttt{bits(128) \ V_a = V[a];}
\texttt{V[d] = V_n \ EOR \ V_m \ EOR \ V_a;}

### Operational information

If \texttt{PSTATE.DIT} is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows an example of the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “Q”:

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<index> Is the lowest numbered byte element to be extracted, encoded in “Q:imm4”:

<table>
<thead>
<tr>
<th>Q</th>
<th>imm4&lt;3&gt;</th>
<th>&lt;index&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>imm4&lt;2:0&gt;</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>RESERVED</td>
</tr>
<tr>
<td>1</td>
<td>x</td>
<td>imm4</td>
</tr>
</tbody>
</table>

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
bits(datasize) lo = V[n];
bits(datasize*2) concat = hi:lo;
V[d] = concat<position+datasize-1:position>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision.

### Scalar half precision

\[ \text{<Vn>} \] Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;

V[d] = result;
```

FACGE

Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision, and Vector single-precision and double-precision

Scalar half precision

V[d] = result;
```
**FADD (vector)**

Floating-point Add (vector). This instruction adds corresponding vector elements in the two source SIMD&FP registers, writes the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR** or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

FADDP (scalar)

Floating-point Add Pair of elements (scalar). This instruction adds two floating-point vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FCADD

Floating-point Complex Add.
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on the
corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is
  rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in
either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point
exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

\( V[d] = \text{result} \);
FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the \textit{PSTATE}.\{N, Z, C, V\} flags. If the condition does not pass then the \textit{PSTATE}.\{N, Z, C, V\} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR}, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.
\end{verbatim}
Operation

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];

if ConditionHolds(cond) then
    flags = FPCmpare(operand1, operand2, FALSE, FPCR[]);
PSTATE.<N,Z,C,V> = flags;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the `PSTATE` condition flags to N=0, Z=0, C=1, and V=1.
FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.\{N, Z, C, V\} flags. If the condition does not pass then the PSTATE.\{N, Z, C, V\} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.
**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];

if ConditionHolds(cond) then
  flags = FPCompare(operand1, operand2, TRUE, FPCR[]);
PSTATE.<N,Z,C,V> = flags;
```

**Operational information**

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the `PSTATE` condition flags to N=0, Z=0, C=1, and V=1.
FCMEQ (register)

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

FCMGE (zero)

Floating-point Compare Greater than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

Floating-point Complex Multiply Accumulate.
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCMLA (by element)**

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding. This instruction can generate a floating-point exception. Depending on the settings in `FPCR`, the exception results in either a flag being set in `FPSR` or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCMLE (zero)

Floating-point Compare Less than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in \texttt{FPCR}, the exception results in either a flag being set in \texttt{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: \texttt{Scalar half precision}, \texttt{Scalar single-precision and double-precision}, \texttt{Vector half precision} and \texttt{Vector single-precision and double-precision}

**Scalar half precision**

FCMP

Floating-point quiet Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.\{N, Z, C, V\} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<\(S_m\)> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = \(V[n]\);
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else \(V[m]\);
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR[]);
```

**Operational information**

The IEEE 754 standard specifies that the result of a comparison is precisely one of \(<, ==, >\) or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the `PSTATE` condition flags to `N=0, Z=0, C=1, and V=1`.

    For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR[]);
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.
FCSEL

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operation

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) result;

result = if ConditionHolds(cond) then V[n] else V[m];

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCVTAU (scalar)**

Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in `FPCR`, the exception results in either a flag being set in `FPSR`, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPToFixed(element, 0, unsigned, fpcr, rounding);
V[d] = result;
**FCVTL, FCVTL2**

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCVTMU (scalar)**

Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(dataSize) operand = V[n];

bits(eSize) element;
FPCRTYPE fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, fpcr, rounding);

V[d] = result;
**FCVTN, FCVTN2**

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

FCVTNU (vector)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (vector). This instruction converts a scalar or each element in a vector from a floating-point value to an unsigned integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

FCVTXN, FCVTXN2

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Note

This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

</tr>
</tbody>
</table>

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(2*datasize) operand = V[n];
FPCRType fpcr = FPCR[];
boolean merge = elements == 1 &\& IsMerging(fpcr);
bv128 result = if merge then V[d] else Zeros();

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], fpcr, FPRounding_ODD);

if merge then
    V[d] = result;
else
    Vpart[d, part] = Elem[result, 0, datasize];
FCVTZS (scalar, fixed-point)

Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

FCVTZU (scalar, fixed-point)

Floating-point Convert to Unsigned fixed-point, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

  Elem[result, e, esize] = FPToFixed(element, 0, unsigned, fpcr, rounding);

V[d] = result;
**FDIV (scalar)**

Floating-point Divide (scalar). This instruction divides the floating-point value of the first source SIMD&FP register by the floating-point value of the second source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in **FPSCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(128) result = if merge then V[n] else Zeros();

Elem[ result, 0, esize] = FDIV(operand1, operand2, FPCR[]);

V[d] = result;
FDIV (vector)

Floating-point Divide (vector). This instruction divides the floating-point values in the elements in the first source SIMD&FP register, by the floating-point values in the corresponding elements in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FJCVTZS

Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be represented as a signed 32-bit integer, then the result is the integer modulo $2^{32}$, as held in a 32-bit signed integer. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMAXNM (scalar)

Floating-point Maximum Number (scalar). This instruction compares the first and second source SIMD&FP register values, and writes the larger of the two floating-point values to the destination SIMD&FP register. NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result that is placed in the vector is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMAXNMP (vector)

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMAXP (vector)

Floating-point Maximum Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the larger of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**FMINNM (scalar)**

Floating-point Minimum Number (scalar). This instruction compares the first and second source SIMD&FP register values, and writes the smaller of the two floating-point values to the destination SIMD&FP register. NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result that is placed in the vector is the numerical value, otherwise the result is identical to FMIN (scalar). This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMINNMP (scalar)

Floating-point Minimum Number of Pair of elements (scalar). This instruction compares two vector elements in the source SIMD&FP register and writes the smallest of the floating-point values as a scalar to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**Half-precision (FEAT_FP16)**

FMINNMP (vector)

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPSCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped. It has encodings from 2 classes: Half-precision and Single-precision and double-precision.

FMLA (by element)

Floating-point fused Multiply-Add to accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results in the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR} or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision and Vector, single-precision and double-precision

\begin{verbatim}

FMLS (by element)

Floating-point fused Multiply-Subtract from accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision, and Vector, single-precision and double-precision

Scalar, half-precision

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<V>  Is a width specifier, encoded in “sz”:

<table>
<thead>
<tr>
<th>sz</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>S</td>
</tr>
<tr>
<td>1</td>
<td>D</td>
</tr>
</tbody>
</table>
<d>  Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n>  Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
For the half-precision variant: is an arrangement specifier, encoded in “Q”:

\[
\begin{array}{c|c}
Q & \text{T} \\
\hline
0 & 4H \\
1 & 8H \\
\end{array}
\]

For the single-precision and double-precision variant: is an arrangement specifier, encoded in "Q:sz":

\[
\begin{array}{c|c}
Q & \text{sz} \\
\hline
0 & 0 \\
0 & 1 \\
1 & 0 \\
1 & 1 \\
\end{array}
\]

<\text{n}>
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<\text{m}>
For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.

For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<\text{s}>
Is an element size specifier, encoded in “sz”:

\[
\begin{array}{c|c}
sz & \text{s} \\
\hline
0 & 5 \\
1 & 0 \\
\end{array}
\]

<\text{i}>
For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.

For the single-precision and double-precision variant: is the element index, encoded in “sz:L:H”:

\[
\begin{array}{c|c|c}
sz & L & \text{i} \\
\hline
0 & x & \text{H:L} \\
1 & 0 & \text{H} \\
1 & 1 & \text{RESERVED} \\
\end{array}
\]

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(esize) element1;
bits(esize) element2 = Elem[operand2, index, esize];
FPCRTYPE fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    if sub_op then element1 = FPNeg(element1);
    Elem[result, e, esize] = FPMulAdd(Elem[operand3, e, esize], element1, element2, fpcr);
V[d] = result;
```

**FMLS (vector)**

Floating-point fused Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see **Floating-point exception traps**.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

### Half-precision (FEAT_FP16)

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

FMLSL, FMLSL2 (by element)

Floating-point fused Multiply-Subtract Long from accumulator (by element). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLSL and FMLSL2

FMOV (register)

Floating-point Move register without conversion. This instruction copies the floating-point value in the SIMD&FP source register to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 0 0 1 1 1 1 0 0 0 0 0 0 0 1 0 0 0 0 | Rd
| opc
```

Half-precision (ftype == 11) (FEAT_FP16)

FMOV <Hd>, <Hn>

Single-precision (ftype == 00)

FMOV <Sd>, <Sn>

Double-precision (ftype == 01)

FMOV <Dd>, <Dn>

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize;
case ftype of
    when '00' esize = 32;
    when '01' esize = 64;
    when '10' UNDEFINED;
    when '11'
        if HaveFP16Ext() then
            esize = 16;
        else
            UNDEFINED;
```

Assembler Symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FMUL (by element)**

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in **FPSCR**, the exception results in either a flag being set in **FPSR** or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped. It has encodings from 4 classes: **Scalar, half-precision**, **Scalar, single-precision and double-precision**, **Vector, half-precision** and **Vector, single-precision and double-precision**

**Scalar, half-precision**

FNMADD

Floating-point Negated fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, subtracts the value of the third SIMD&FP source register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler Symbols

- **<Hd>** Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Hn>** Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- **<V>** Is a width specifier, encoded in "sz":

<table>
<thead>
<tr>
<th>sz</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>S</td>
</tr>
<tr>
<td>1</td>
<td>D</td>
</tr>
</tbody>
</table>

- **<d>** Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- **<n>** Is the number of the SIMD&FP source register, encoded in the "Rn" field.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(esize) operand = V[n];

FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

Elem[result, 0, esize] = FPREcpX(operand, fpcr);
V[d] = result;
```
**FRINT32X (scalar)**

Floating-point Round to 32-bit Integer, using current rounding mode (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value that fits into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When the result value is not numerically equal to the input value, an Inexact exception is raised. When the input is infinite, NaN or out-of-range, the instruction returns {for the corresponding result value} the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FRINT64Z (vector)

Floating-point Round to 64-bit Integer toward Zero (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 64-bit integer size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in $FPCR$, the exception results in either a flag being set in $FPSR$, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the $CPACR_EL1$, $CPTR_EL2$, and $CPTR_EL3$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR[], rounding, exact);
V[d] = result;
FRINTN (scalar)

Floating-point Round to Integral, to nearest with ties to even (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR[], rounding, exact);
V[d] = result;
FRINTX (scalar)

Floating-point Round to Integral exact, using current rounding mode (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

When the result value is not numerically equal to the input value, an Inexact exception is raised. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 1 1 1 0 ftype 1 0 0 1 1 1 0 1 0 0 0 0  Rn  Rd
```

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.
